ABSTRACT

The proliferation of social media, especially platforms like X (formerly Twitter), has made available a large volume of real-time data valuable across diverse fields. During natural disasters, such data aids humanitarian efforts by providing crucial insights. However, processing this vast amount of data necessitates automated systems, often relying on annotated datasets for training. While supervised learning dominates this area, multilingual and multimodal annotated datasets are scarce. The present study addresses this gap by introducing M-CATNAT, a multimodal dataset of French tweets about natural disasters. Unlike previous datasets, M-CATNAT integrates annotations for texts, images, and their multimodal combination. Leveraging CrisisMMD guidelines, this work in progress aims to annotate 1,430 tweets, generating over 4,500 labels. The M-CATNAT dataset not only expands resources to non-English languages but also enhances multimodal analysis by furnishing three levels of annotation for each tweet (one per modality plus one for the whole tweet).

Keywords

Deep learning, French multimodal data, Crisis management, CrisisMMD Datatset

INTRODUCTION

The spread of social media use in this last decade has made available massive real time data. Particularly in platforms such as X (previously Twitter) where user-generated content has real value that can be used in a variety of applications including public health, economics and politics (Wu & Mebane Jr, 2022). When a natural disaster

*corresponding author

occurs, tweets can help humanitarian organizations to gather essential information in order to understand the scope of the disaster and prioritize actions to reduce suffering and rebuild communities (Alam et al., 2018). Nevertheless, the need to process the large amount of data available on social media requires the development of automated systems and methods that need annotated data to be trained.

The automation of social media information processing has recently become a hot research topic, with a majority of existing approaches relying heavily on supervised learning methods. Their primary objective is to categorize each post into a specific class based on the targeted task, such as informativeness (Alam et al., 2018) or relatedness (Kozlowski et al., 2020). Annotated datasets being the core element in supervised learning, considerable efforts have been made to manually construct such datasets. While most resources are text-based and predominantly in English, it's worth noting that resources in other languages also exist (Alharbi & Lee, 2019; Cobo et al., 2015; Cresci et al., 2015; Gru¨nder-Fahrer et al., 2018; Kozlowski et al., 2020) (see the following section for more details).

Despite numerous studies indicating that multimodality (e.g. text, images, video) can significantly enhance the performance of these methods (Abavisani et al., 2020; Ofli et al., 2020), there is currently only one extensively studied dataset – CrisisMMD (Alam et al., 2018), which focuses on multimodal English tweets related to crisis (natural disasters). Such a resource in English can be used to fined-tune a multilingual pre-training model (Conneau & Lample, 2019) and thus process French tweets. Although the preliminary results we have obtained with this process are not sufficiently satisfactory, they give reason to hope that the introduction of even a limited number of tweets in French during training would improve performance. Aligning the annotations of this new data (in French) with the annotations of the CrisisMMD dataset is, however, a prerequisite for success.

In this context, this work (in progress) aims to create the M-CATNAT dataset : a multimodal dataset of 1,430 French tweets about various natural disasters with annotations aligned with CrisisMMD tasks. However, the CrisisMMD dataset has the following limitation : it contains annotations for each of the two modalities of a tweet (text and image), but does not propose gold (i.e. manually annotated) annotations for the multimodal tweet as a whole (text+image). Since learning a multimodal model requires such a global label, tweets whose annotations for the two modalities do not match are generally filtered out (Ofli et al., 2020). Unlike CrisisMMD, the M-CATNAT dataset we are preparing includes not only gold annotations for the image modality and the text modality but also the gold label of the tweet as a whole, i.e the multimodal instance (text+image). Interestingly, the full annotation model proposed makes it possible to offer a greater representativeness of tweets in terms of the diversity of relationships between modalities (e.g. redundancy, complementary or contradiction in the information).

In this article, we present the framework defined for the multimodal annotation process of the 1,430 French tweets that will make up the M-CATNAT dataset[1].

So far, seven annotators from the research team have fully annotated 837 tweets, out of the 1,430 planned. This ongoing process has resulted in the creation of more than 3,000 manual annotations, as each instance entails three labels (one for the image, one for the text, and one for the multimodal instance with some tweets having multiple images). The CrisisMMD humanitarian classes definition guided our annotation process, ensuring consistency and reliability in the labeled data. In addition, the annotation process was regularly evaluated to check both its consistency (inter-annotator agreement) and its alignment with the CrisisMMD dataset.

RELATED WORKS

The surge in the use of social media has led to an increased interest in processing their content with numerous studies focusing, in particular, on crisis-related tweets. As reported in Table 1, a lot of emphasis has been placed on text-based analysis, given that the majority of annotated datasets primarily feature labels on text alone. These datasets have introduced various tasks, such as assessing the *relatedness* of tweets to a specific disaster (Kozlowski et al., 2020), determining the *informativeness* of tweets (Alam et al., 2021; Olteanu et al., 2015), classifying *crisis types*, and detecting *eyewitnesses* (Zahra et al., 2020). In the domain of image processing for tweets, tasks include estimating the *damage severity* (Alam et al., 2018; Nguyen et al., 2017) and *damage type* (Mouzannar et al., 2018), evaluating *informativeness* (Alam et al., 2018). Most resources are in English, although resources also exist in other languages like Spanish (Cobo et al., 2015), Italian (Cresci et al., 2015), German (Gru¨nder-Fahrer et al., 2018) and Arabic (Alharbi & Lee, 2019). For the French language, (Kozlowski et al., 2020) proposed a text only disaster tweet dataset with three classification levels including *relatedness*, *urgency* and *intent to act*. One should note that the various tasks addressed lead the community to produce datasets more or less compatible with the central resource that is CrisisMMD. Each dataset whose task mentions *humanitarian* is either an implementation of the CriseMMD guidelines or a mapping to a simplified set of classes, keeping it compatible with CrisisMMD[2].

1The dataset is available here : https://github.com/badreddineFarah/M-CATNAT

2For a substantial survey of existing datasets for English, see (Feng et al., 2022).

Table 1. Crisis related published resources.

	Modal. labels	Tasks	Platform	Size	Language
(Olteanu et al., 2015)	Text	informativeness, humanitarian, source	Twitter	28,000	English
(Alam et al., 2021)	Text	informativeness, humanitarian	Twitter	166,098 (inf.), 141,533 (hum.)	English (94%)

Despite recent studies highlighting the effectiveness of multimodal datasets in improving the performance of machine learning models through multimodal training (Abavisani et al., 2020; Liang et al., 2022; Long & McCreadie, 2022; Ofli et al., 2020), limited attention has been given to the creation of new multimodal crisis-related datasets and CrisisMMD remains the most widely used dataset despite its inherent limitations. A first notable limitation is that CrisisMMD independently annotates images and text, necessitating practitioners to filter instances with discordant labels (different labels for image and text) and retain instances with consistent labels for training. This approach does not take into account the various relationships between modalities in social media data (Vempala & Preo¸tiuc-Pietro, 2019). In response to this gap, (Sosea et al., 2021) introduced Disrel, a dataset for classifying the relationship between image and text. Their work demonstrated that incorporating such tasks can enhance the performance of models trained on CrisisMMD.

This study aims to enhance CrisisMMD in two dimensions. Firstly, we augment the corpus by incorporating French tweets, enabling multilingual and multimodal training. Secondly, we provide three annotations for each instance, hypothesizing that this enriched dataset will enable models to better capture the relationships between images and texts, thereby improving overall system performance. Importantly, we adhered to the CrisisMMD guidelines to ensure alignment between our annotations and the original annotation guide.

DATA COLLECTION

To initiate the annotation process, it is essential to gather data. For this purpose, we used datasets collected as part of the Re´SoCIO project by the French Geological Survey (BRGM) via its SURICATE-Nat platform (Auclair et al., 2019). The data collection process relies on the interrogation of Twitter's "academic" API on the basis of a carefully chosen keyword search, exploring French-speaking lexical fields related to floods on the one hand, and earthquakes on the other. Below are the specific queries used for each type of disaster, with the aim of retrieving a maximum number of posts describing the effects of the phenomena, as well as a minimum number of off-topic posts.

Flood key-words The keywords used are the following (taking spelling errors into account) : "*inondation*" (flood), "*inonde´*" (flooded / inundated), "*sous l'eau*" (under water), "*rivie`re en crue*" (swollen river), "*crue*" (flood upward trend / freshet), "*de´crue*" (flood downward trend), "*onde de crue*" (flood wave), "*sort de son lit*" (rise above the banks), "*torrentiel*" (torrential), "*emporte´ par les eaux*" (washed away). The query excludes retweets and tweets with flood lexical fields related to politics, sex or migration, while focusing only on French language tweets by specifying "lang:fr".

Earthquake key-words "*Se´isme*" or "*tremblement de terre*" (earthquake), "*magnitude*" (magnitude), and "*terre tremble*" (ground shaking) are the keywords used to retrieve the tweets (taking spelling errors into account as well). The query excludes retweets and tweets with earthquake lexical fields related to sex, migration or politics, while focusing only on French language tweets by specifying "lang:fr".

DATA SAMPLING

As illustrated in Table 2, we sampled tweets from various events of natural disaster, taking one-third from earthquake events and two-thirds from flood events, in order to respect the representativeness of each disaster while keeping the number of tweets sufficient for each disaster. The earthquakes and flash floods selected correspond to significant

events for mainland France, from a phenomenological and/or a crisis management point of view. To maintain data quality and relevance, we applied additional criteria, exclusively selecting tweets with text lengths between 5 to 40 words to ensure sufficient textual content for comprehensive analysis. Additionally, we selectively included tweets with at least one associated image, as the presence of visual content is pivotal for preserving the multimodal nature of the dataset.

The goal is to annotate a total of 1,430 multimodal tweets, with each tweet divided into three instances: text alone, image alone, and the combination of text and image, resulting in approximately 4,775 instances for annotation (because some tweets contain several images). For tweets with multiple images, we annotate the text, each image, and multiple text-image combination instances are created by merging the tweet's text with each associated image.

It is worth noting that since the beginning of the annotation process, around 5% of the data have been deleted from X, leading us to revise the dataset size from 1,500 to 1,430 tweets. In addition, it is still possible that between now and the end of the annotation process, new tweets will be deleted, reducing the total number of tweets available for annotation.

TASKS DESCRIPTIONS

As said before, we use the *humanitarian* and *informative* tasks (from CrisisMMD) to annotate the dataset[3]. However, we also adapt the task to the practises in the community, as its was already done within several works (Abavisani et al., 2020; Liang et al., 2022; Long & McCreadie, 2022; Ofli et al., 2020) which have merged classes relative to damages ("infrastructure_and_utility_damage" and "vehicle_damage") into "infrastructure_and_utility_damage" and classes relative to human casualties ("affected_individuals","injured_or_dead_people","missing_or_found_people") into "affected_individuals", resulting in a five classes task described bellow:

Affected individuals If the tweet/image reports or shows individuals affected by the disaster event, such as people sitting outdoors, individuals standing in lines for assistance, people in need of shelter facilities, missing or found individuals, or deceased individuals.

Infrastructure and utility damage If the tweet/image reports or shows a damaged structure or one whose use is affected by an earthquake, fire, heavy rains, floods, strong winds, gusts, etc., such as damaged houses, roads, buildings; flooded houses, streets, highways; blocked roads, bridges, paths; collapsed bridges, power lines, cars, boats, communication poles, etc.

Rescue volunteering or donation effort If the tweet/image reports or shows any type of rescue, volunteering, or donation effort, such as transporting people to safe locations, evacuating people from the hazardous area, individuals receiving medical or food aid, people in shelter facilities, monetary donations, blood donations, or services, etc.

Other relevant information If the tweet/image does not fit into any of the three categories above but still contains important information useful for humanitarian aid.

Not related or not relevant information If the tweet/image is not useful for humanitarian aid.

As described in the CrisisMMD paper, only informative tweets have been annotated into one of the *humanitarian* classes. Thus, considering other tweets as not informative (not related or not relevant) the annotated dataset can also be used to train models on the task *informativeness*.

ANNOTATION METHODOLOGY

In the annotation methodology, we implemented a four-phase process to ensure high-quality annotation of the dataset. At the end of each phase, an assessment of the annotations was made according to different indicators, followed by a consultation meeting focusing on examples with substantial disagreement occurred. A clarification, accompanied by illustrative examples was then incorporated into the annotation guide. Also, to mitigate the bias in labelling the modalities from each (multimodal) tweet, the order of presentation of the instances to be annotated needs to be carefully considered. An annotator who is first presented with a complete multimodal tweet (text +

[3]The annotation guide is delivered with the resource (https://anonymous.4open.science/r/M-CATNAT-5692/README.md).

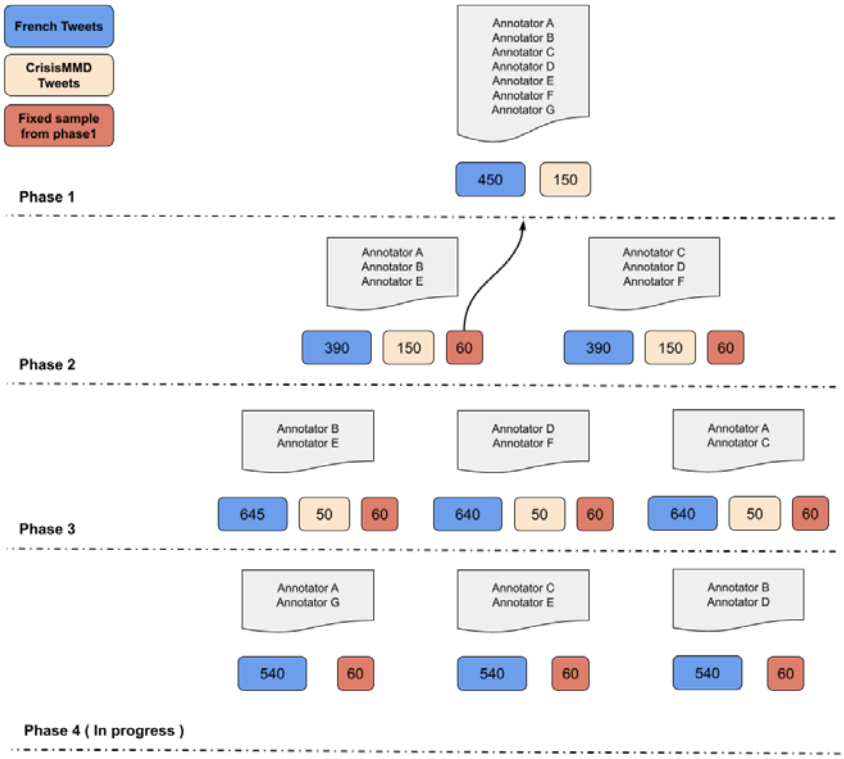

Figure 1. Overview of the annotation protocol. This diagram illustrates our multi-phase annotation methodology. In each phase, we annotate a specific number of new instances (image, text and multimodal instances), highlighted in blue. To maintain alignment with the CrisisMMD, a small portion of this dataset is also annotated. Lastly, to ensure the self-consistency of each annotator, some instances are selected for re-annotation.

image) will undoubtedly be influenced in his annotation (a posteriori) of each of the modalities. We have therefore ensured that the text and image modalities are presented first and in a separate slot (groups of annotators) or phases from the multimodal tweet (text+image).

This sequential presentation aimed to ensure independent labeling decisions for both unimodal and multimodal instances, minimizing potential bias in annotations.

As presented in Figure 1, Phase 1 involved seven annotators collectively annotating one shared dataset of 600 instances constituted of 150 instances from CrisisMMD and 450 instances from new French tweets ($\frac{1}{3}$images, $\frac{1}{3}$ texts and $\frac{1}{3}$ multimodal instances). In this phase, when an instance is annotated identically by at least 5 annotators (out of 7), this annotation is definitively used as a label. The other instances (for which the annotation is not consensual) are discussed and collectively labelled at the end of the phase during the consultation meeting. This process allowed us to clarify and adjust the annotation guide. This first phase is an agreement (or training) phase for the annotators. Subsequent phases gradually "industrialise" the annotation process, with annotators organised into parallel pools.

Phase 2 comprised two pools, each pool was made up of 3 annotators responsible for annotating 600 instances. Among the 600 instances, we maintained a set of 150 CrisisMMD instances and introduced 60 instances from phase 1 in order to compute the consistency of annotations through the phases for each annotator involved in the process. At the end of this phase, the instances with two identical annotations are definitively labelled, while we proceed to a correction phase during which each disagreement is resolved by an annotator from the other pool.

In phase 3, we decomposed our team into three annotation pairs, for each annotation pool we reduced the number of CrisisMMD instances to 50 while keeping the 60 instances from phase 1. The disagreement is resolved by a third annotator from another pool.

Currently ongoing, Phase 4 involves three new pairs of annotators, each annotating 540 instances, along with the 60 instances from Phase 1. The ultimate goal is to annotate the full set of 1,430 tweets, amounting to approximately 4,775 manual annotations at the conclusion of the process.

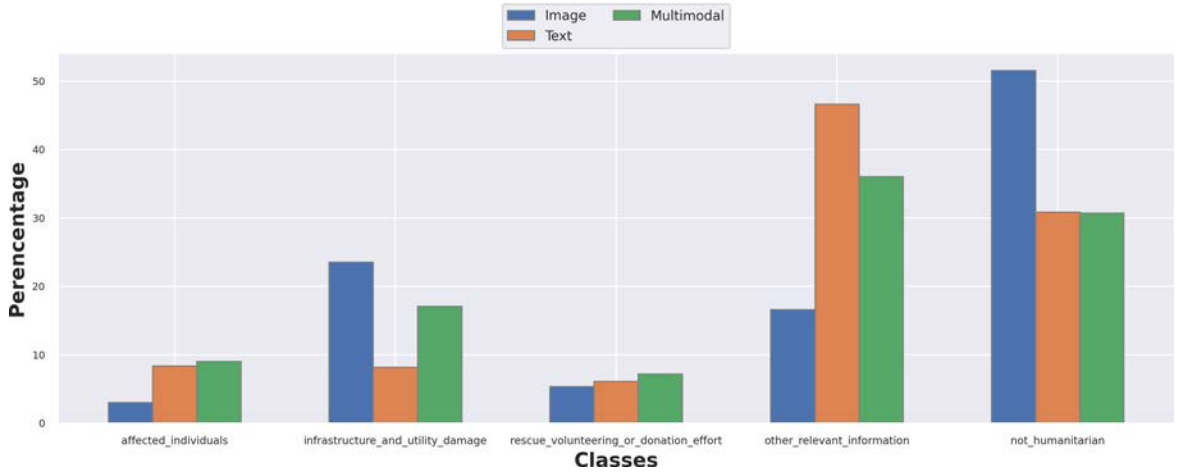

Figure 2. Comparison of label distribution for each modality, the distributions are calculated on a 1,032 fully annotated instances.

RESOURCE ANALYSIS

In this section, we provide a comprehensive analysis of the M-CATNAT resource at the time of writing (837 unique tweets fully labelled corresponding to 1,032 multimodal pairs since some tweets have multiple images). Firstly, we outline the distribution of labels for each modality and for each type of disaster (earthquakes and floods). Secondly, we present the results of annotation scores, including the Fleiss Kappa score (Fleiss et al., 2013) and the CrisisMMD alignment score. Finally, we show the distribution of class concordance/discordance according to modalities.

LABEL DISTRIBUTION

Figure 2 illustrates the label distribution across different classes. Notably, the class "Affected Individuals" exhibits the lowest representation. The "Not Humanitarian" class, equivalent to "Not informative" in the *informativeness* task

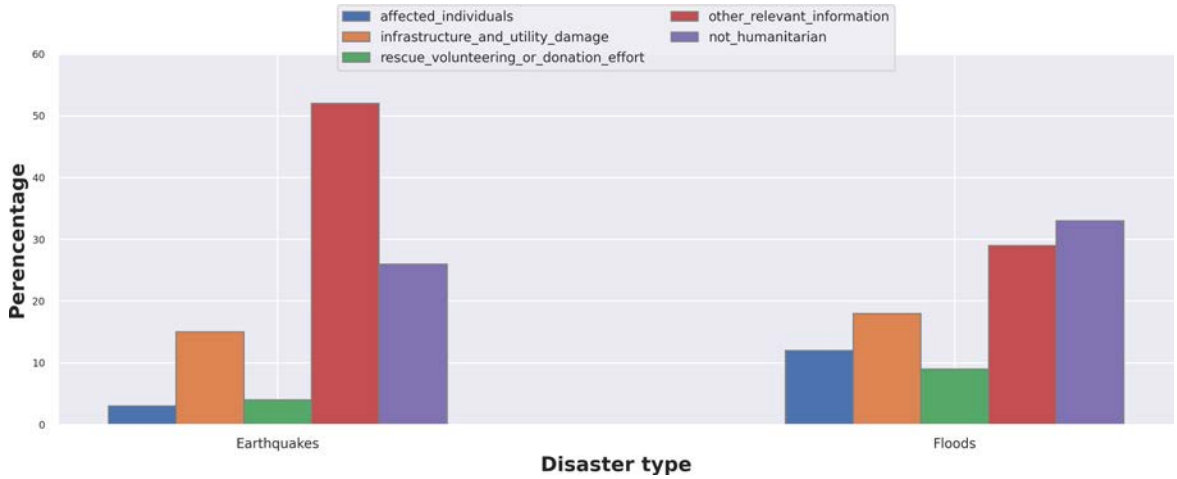

Figure 3. Comparaison of label distribution for earthquakes and floods, the result are on 307 earthquake related tweets and 725 floods related tweets.

Table 3. Fleiss kappa scores on each phase.

Phase	1	2	3
Mean (over pools)	0.64	0.70	0.61
Common examples	0.64	0.68	0.66

Table 4. CrisisMMD alignment scores on each phase.

Phase	1	2	3
CrisisMMD alignment	79%	74%	77%

of CrisisMMD, constitutes 30% in text and multimodal instances but rises to approximately 50% in image labels. Conversely, "Other Relevant Information" represents 46% in texts and 36% in multimodal instances, contrasting with its lower representation at 16% in images. This difference is attributed to the enriching role of textual information in multimodal instances, aiding in disaster characterization regarding intensity and location. The distribution of multimodal labels closely aligns with the text distribution, highlighting the importance of textual information in crisis datasets in general and in the M-CATNAT dataset in particular. The emphasis on textual information stems from its reflective of tweet intentions and provision of more precise details. Classes such as "Rescue Volunteering and Donation Efforts" are more prominent in CrisisMMD (14.5%), indicating that the disasters in our data are comparatively less severe.

Figure 3 reports the distribution of multimodal annotations according to the type of disaster in our dataset. "Other Relevant Information" exhibits higher representation in earthquake-related tweets, due to the lower magnitude of these earthquakes where tweets often provide basic information about the incident, such as location and magnitude. Conversely, "Affected Individuals" and "Rescue volunteering or donation effort" are more represented in flood-related tweets, reflecting the extensive damage caused by such events.

ANNOTATOR SCORES

In accordance with the annotation methodology outlined in the "Annotation Methodology" section, our process involves four phases, each subdivided into annotator pools. In consequence we propose to measure inter-annotator agreement on each phase using the Fleiss Kappa (Fleiss et al., 2013)[4]. Table 3 reports the results obtained: first row shows the mean Fleiss Kappa score overs pools for each phase, while in the second row Fleiss Kappa scores were calculated specifically for the 60 common examples (highlighted as red samples in Figure 1). The variations observed are mainly due to the changes made to the annotation guide over the phases; it is also significant to note that the inter-annotator agreements remained above 0.60 in each of the three phases. To be complete, we noticed the agreement between annotators varied across modalities. A higher agreement is observed for images (up to 0.85) compared to texts which exhibited a poorer annotator agreement, particularly in Phase 1 (0.56).

4In addition, at every phase we made annotations for a sample of 60 fixed instances (in red in Figure 1) in order to monitor the intra-annotator agreement along the whole process. The percentage scores obtained vary between 67% and 78% for the transition from phase 1 to phase 2 and between 82% and 89% for the transition from phase 2 to phase 3.

CRISISMMD ALIGNMENT

Moreover, we assessed alignment with the CrisisMMD dataset (see Table 4). In Phase 1, alignment was computed on 150 examples after disagreement resolution, yielding a score of 79% (with a notable increase to 90% for multimodal instances). In Phase 2, the alignment score was computed on 150 examples for each pool and the mean score obtained is 74%, while it reached 77% in phase 3 on 50 examples for each pool (mean score of the three pools is reported). These results are encouraging given our will to use the proposed resource in addition to CrisisMMD in a multilingual configuration.

MODALITY LABEL ANALYSIS

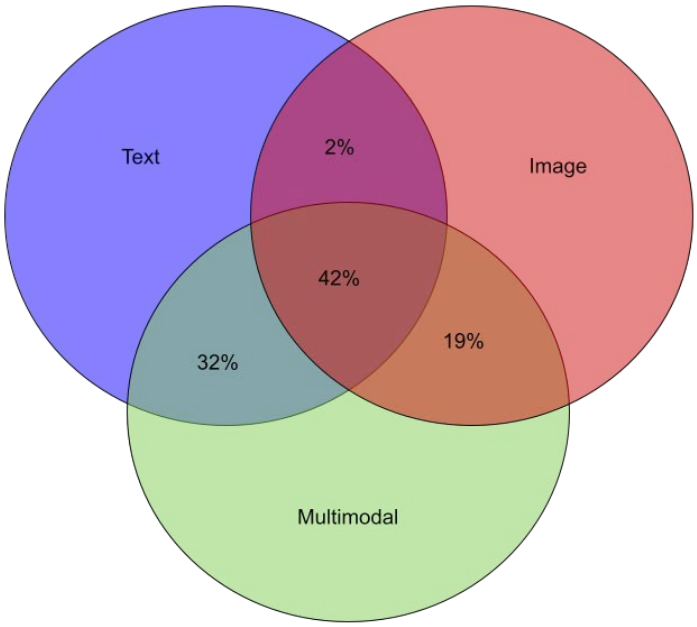

Figure 4. Label Combinations for Image, Text, and Multimodal on 1,032 fully annotated instances.

Figure 4 shows an analysis of the labelling of the 1,032 5 examples in the current M-CATNAT dataset. It reveals the relation in the distribution of labels across the three labels assigned to one Tweet : the *image* label, the *text* label and the *multimodal* label. A significant portion, accounting for 42% of the examples, demonstrates consistency across all three labels ; this suggests a strong correlation among the different types of data and their respective labels. In 32% of cases, although the text label differs from the image label, it aligns with the multimodal label ; this implies that the textual content plays a crucial role in shaping the combined interpretation. Conversely, 19% of the examples have an image label distinct from the text label but aligning with the multimodal one, highlighting the influence of visual elements in these instances. Following these results, one may consider the need to train models to spot instances where the information looked for may be found in a specific modality. Lastly in a small proportion, just 2%, the image and text labels match but differ from the multimodal label, and lastly, 5% of cases shows complete disparity across all three labels. These findings underscore the variety of relations between different modalities and emphasize the importance of considering multimodal annotation rather than an independent annotation of the text and the image.

It's worth noting that crisisMMD use cases typically focus only on instances with identical labels across modalities. However, our study overlooks more than 50% of the data, disregarding the diverse relationships between images and text present in the multimodal tweets dataset.

CONCLUSION

Leveraging social media information during natural disasters can significantly help humanitarian aid organizations. Deep learning models play a crucial role in filtering and classifying this data efficiently. However, the effectiveness of such models relies heavily on labeled data for training. Research has highlighted the potential of multimodal

5We can get 1,032 image-text instances from the 837 annotated tweets as a tweet can have multiple images.

data in enhancing performance, yet available datasets are predominantly unimodal and in English. Although one multimodal dataset exists, its separate labeling for images and text poses limitations. This work addresses this gap by introducing M-CATNAT, a French multimodal dataset aligned with CrisisMMD, featuring three labels for each instance. This alignment facilitates multilingual training, thereby broadening the applicability of deep learning techniques. We provide annotator scores and other analyses to support deep learning practitioners in utilizing the dataset effectively. In future work, our aim is to further expand the annotated data and train models on this dataset.

ACKNOWLEDGEMENT

This work was supported by the French national research agency (ANR) under the program IA.iO (ANR-20-THIA-0017-01), as well as within the Re´SoCIO project (ANR-20-CE39-001). ABSTRACT

This paper introduces the results of a survey that was conducted among German firefighters in 2023 to investigate the current situation of knowledge management. We want to examine which systems and techniques are in use, what the end users' expectations towards knowledge management are, and which requirements a system should fulfill. We focus on all stages of the crisis management circle, from prevention and preparation to the response to an incident as well as recovery.

The goal of this survey is to evaluate firefighters' needs in order to be able to define requirements for a knowledge management system that will be accepted by the users. The exchange of information items between entities (emergency units, authorities, and enterprises) and other IT systems is one important aspect. We identify existing information and knowledge management systems, and means to improve user satisfaction by leveraging users to maintain a system with relevant and up-to-date information and knowledge.

Keywords

Knowledge management, firefighter, emergency management, survey, Germany

INTRODUCTION

During the past decades, crisis management has experienced many changes regarding exterior circumstances and interior preconditions. New and changing legal and administrative regulations hamper the performance of emergency management organizations, digitization puts new requirements on the practitioners' skills (cf. (Sauerland et al., 2020)) and the technical and procedural understanding has to grow constantly. It is challenging to find new (voluntary) personnel as their expectations shift towards work- and family-friendly conditions and the level of skills and knowledge required continues to increase. Since the amount of necessary time is constantly increasing, measurements have to be taken into account to cope with it. There are few publications related to the combination of knowledge management and crisis management, as stated by Anand et al. in their survey study related to knowledge management in contexts of crisis (Anand et al., 2022). They identified 59 publications focusing on knowledge management and disaster management, but factors supporting the development of knowledge management for crisis preparedness is scant. Oktari et al. showcase the positive effects of knowledge management that improves both the effectiveness and performance of operations as well as innovation among users (Oktari et al., 2020). Only few literature can be found that deals with the actual implementation of a knowledge management system for emergency

*corresponding author

services. One older article from Pickles describes the development of a knowledge management infrastructure in Australia but hardly more information about the system can be found (Pickles, 2004). Another description comes from Timm et al. who describe the comparison of different open-source systems to be used as a knowledge and collaboration platform (Timm et al., 2013). Some German fire brigades make use of the Einsatzleiterwiki, which is a software solution that stores incident-relevant information in a wiki. A public instance exists that is accessible on the internet[1]. The usage as a closed system by the Berlin fire department is described in (Ziehr et al., 2017). This shortage in knowledge management research led the authors to perform a survey among German firefighters to find out what their attitudes towards knowledge and knowledge management are.

This survey is one of the first steps in a holistic process of examining knowledge management among firefighters, surveying the current status and needs of emergency personnel regarding knowledge management, and finally developing a system that incorporates the findings. It aims to bridge the gap between research and practice by laying the foundation to develop a system according to the needs of end users. The focus is on the German firefighters, where each federal state (Bundesland) has to govern the emergency management and issue laws and regulations (except civil protection for which the Federal State (Bund) is responsible for) on its own. The vast majority are voluntary firefighters, and in general, the bigger the city, the more professional firefighters are on duty, mostly 24/7. See (Deutscher Feuerwehrverband, 2021) and Figure 6 for details. The results of the survey should be independent of the specific organisation of the participants. Of course, some organisations either have more personal capacities like professional personal who are employed or have motivated voluntary members who are already involved in maintaining a knowledge management systems (KMS). In general, the prerequisites should be similar between fire services, relief organisations or other emergency organisations and a comparability of the survey results is given. In contrast to KMS in a corporate environment, KMS for emergency services can profit from an absent competitive situation which would impede the exchange of information between organisations.

In this evaluation, a methodical approach was followed, guided by the methods recommended in *Umfragen erstellen und auswerten* (Creating and Evaluating Surveys) (Ortmanns & Sonntag, 2023). The central research question is: To what extent is knowledge management bruited in German fire departments, particularly outside of emergency situations, and what are the end users' expectations towards a KMS. The extent of the dissemination and intensity of the use of KMS were examined. The hypothesis was formulated that the spread and use of such systems in German fire departments is currently limited and confined to a few projects. Emergency personnel, although not stated explicitly in literature, wishes for a system to manage their knowledge.

The survey plan was developed in line with the methods suggested by (Ortmanns & Sonntag, 2023). The investigation employed a quantitative survey method, supplemented by the inclusion of some open questions to allow for a broader range of responses. The survey was tested before dissemination internally several times and by few senior firefighters known to the authors. Particular care was taken to reach as many firefighters as possible. To this end, fire department associations in Germany were contacted, and the survey was distributed via social media. The data collection was conducted online with the EU Survey system[2] to make use of a flexible and proven system to ensure maximum reach and user friendliness.

Terms and concepts related to knowledge management often do not have a universally valid definition. Therefore, we provide a disambiguation and distinguish between the terms data, information, and knowledge in the following way, according to (North, 2016; Mozgova et al., 2020) and depicted in Figure 1:

- Symbols are the basic set of available characters (letters, numbers) that, when combined in a syntactical way, form data.
- Data are uninterpreted sets of symbols that do not have a specific meaning until a sense is added.
- Information is data with a context of meaning and an added relationship.
- Knowledge is the result of connected information. Information forms the basis and needs to be interpreted by a human being.

The remaining stairs in 1 refer to a more business-oriented view on knowledge management, which is only partly applicable for emergency management (Duscher, 2010). At least the last step, competitiveness, does not make sense for emergency personnel since there is no need to compete rather than to collaborate.

This paper is structured as follows: At first, we will give an overview of the survey and present our methodology as well as demographic data about our respondents. Then we will examine the knowledge management-related

1https://einsatzleiterwiki.de/
2https://ec.europa.eu/eusurvey/

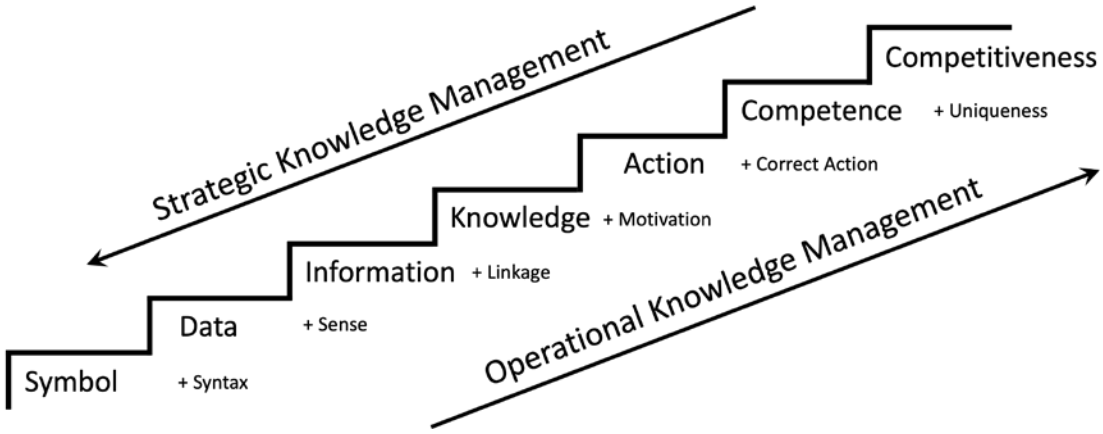

Figure 1. Knowledge staircase according to (North, 2016)

aspects of our survey, where we elaborated on the current status of German fire brigades as well as respondents' requirements and wishes. Next, we present the findings of our survey and deduce aspects that have to be taken into account when developing a KMS for emergency personnel. Finally, a conclusion summarizes our presentation and shows further areas that need to be examined.

SURVEY

The survey was designed to get an overview of current aspects related to knowledge and knowledge management among firefighters, from the beginner to senior experts with decades of experience. The procedure for the whole survey is shown in Figure 2. During creation, the questionnaire was divided into the blocks *statistical data* (8 questions), *information management* (19 questions plus free text fields to clarify answers), *information exchange* (5 questions plus free text fields to clarify answers), and *data maintenance* (21 questions plus free text fields to clarify answers). The survey period was from August 2023 until October 2023. We distributed the survey among both, federal and state fire organizations and via personal contacts with the request to forward it to them, and we posted calls to encourage participation online via Facebook posts and groups. We received a total of 577 responses from firefighters across Germany. Only 5 submissions were empty and excluded beforehand. Since some questions were only shown based on certain previous answers and other questions have multiple answers possible, the number of responses per question might vary. The evaluation is carried out in this paper.

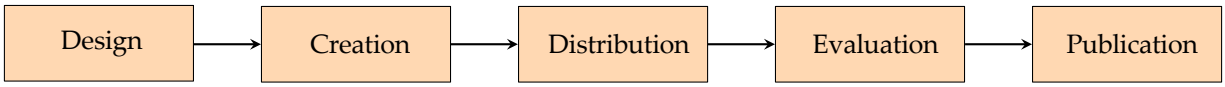

Figure 2. Survey process

We contacted each state fire association (Landesfeuerwehrverband) in Germany but only two replied positively; one declined our request, and the rest did not answer at all. The distribution via Facebook by the DFV[3] is likely location-independent, other invitations to participate via Facebook groups might be filtered more restrictively by Facebook's algorithms. The participants and results of our survey roughly align both with the population's distribution in Germany, as indicated in Figure 3, as well as the distributions of education and expertise among the firefighters. But we do not consider our study fully representative for Germany since the emergency domain differs in each state and we do not have sufficient answers from every state.

Overview

Beginning with demographic data for the subsequent analysis, we asked the participants questions to get an idea of their type and location of engagement, experience in the emergency domain, their IT and leadership skills, and their age and duration of membership. In the following, we considered the current state of information and knowledge

[3] https://www.facebook.com/112willkommen/posts/pfbid02kjfzQVu9T5UNjajxDo9qQ7zQiaheFCE8nAYgqzvMfgBJimWRhp7GAxVc5qmFX5Qjl retrieved August 2, 2023

management in their units. We were interested in exploring how information and knowledge are currently being exchanged among firefighters and the tools they utilize for this purpose. We aligned our survey with information from the DIN ISO 30401 norm, which deals with requirements for KMS in business contexts (Deutsches Institut fu¨r Normung, 2022). Another important step in managing knowledge is the exchange of already-available information via Information Management Systems (IMS), respectively KMS. Therefore, we examined the distribution of means to share data between entities (emergency units, authorities, and enterprises) or IT systems. In the last section, we examined the current status and willingness to maintain KMS. We wanted to see whether our participants are already involved in creating knowledge, instructions, or sharing information and how they do it. We asked them to rate several statements regarding the upkeep of knowledge in a KMS, focusing on the amount of time they devote or would devote to maintenance tasks and their preferred tools for these activities.

Detailed Insights

We received a total of 577 valid answers that were taken into account for our validation. Only one answer is not based within Germany; five did not provide their origin. The federal states of North Rhine-Westphalia and Lower Saxony are particularly well represented. City states like Berlin, Hamburg, or Bremen have the lowest numbers of responses. The distribution of responses by state, as shown in Figure 3, does not perfectly match the distribution of the German population across federal states. However, our results are generally in line with the population distribution. A comparison between the actual numbers of firefighters per state with the submitted surveys would have been preferable, but it is difficult to obtain comparable recent numbers for all federal states.

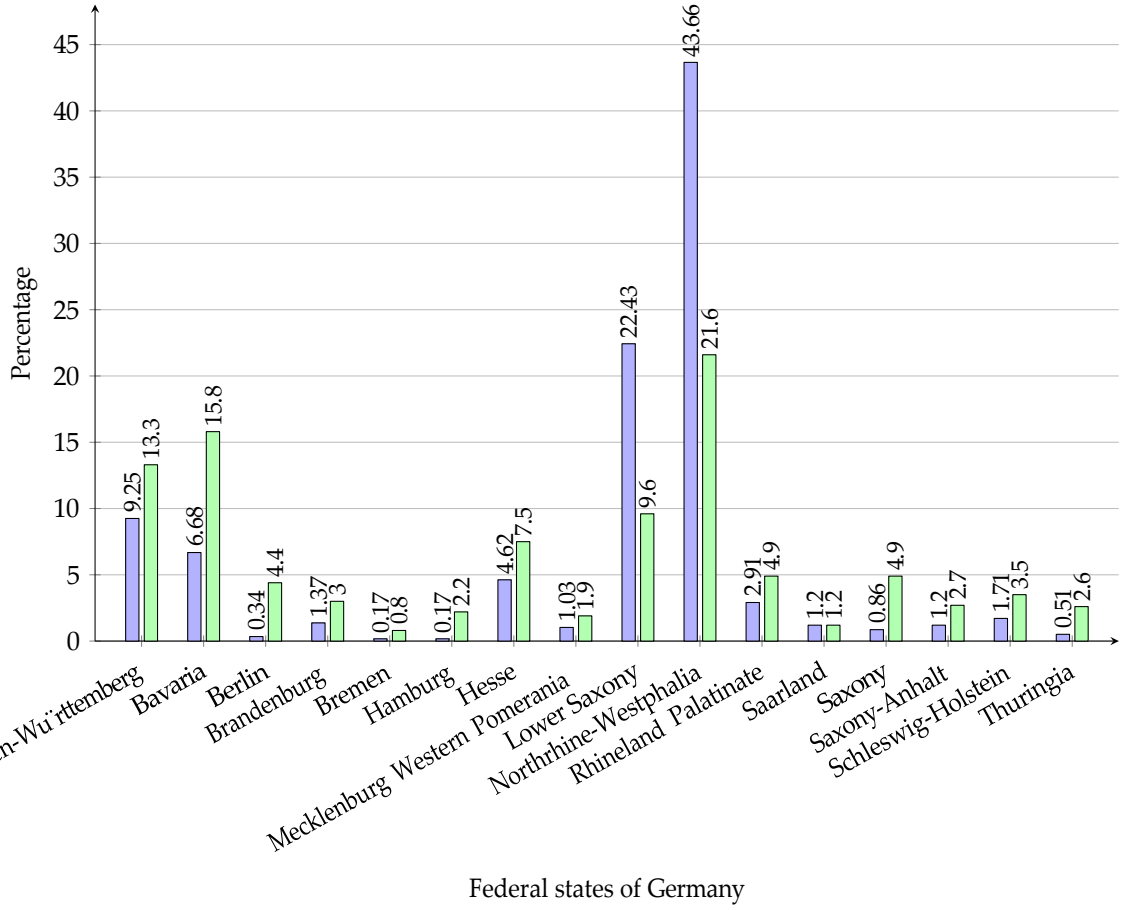

Figure 3. Distribution of survey answers (in blue) compared to inhabitants (in green), data from (Bundeszentrale fu¨r politische Bildung, 2023)

The age structure of our participants shows a relatively even distribution across all ages, ranging from 18 to the age at which emergency personnel typically retire. According to the German fire brigade association (Deutscher Feuerwehrverband), the age limit for active duty in emergency services varies from state to state. For instance, in some states, young people can participate with limitations beginning at 16 years old, while in other states, the minimum age is 17 or 18 years old. The upper age limit also shows variation, ranging between 60 and 67 years across different regions (Deutscher Feuerwehrverband, 2017).

The duration of membership of our respondents appears to be evenly distributed across the 10-year categories. Significantly, a number of participants with decades of experience contributed to our survey, providing valuable insights into their extensive knowledge, as depicted in Figure 4.

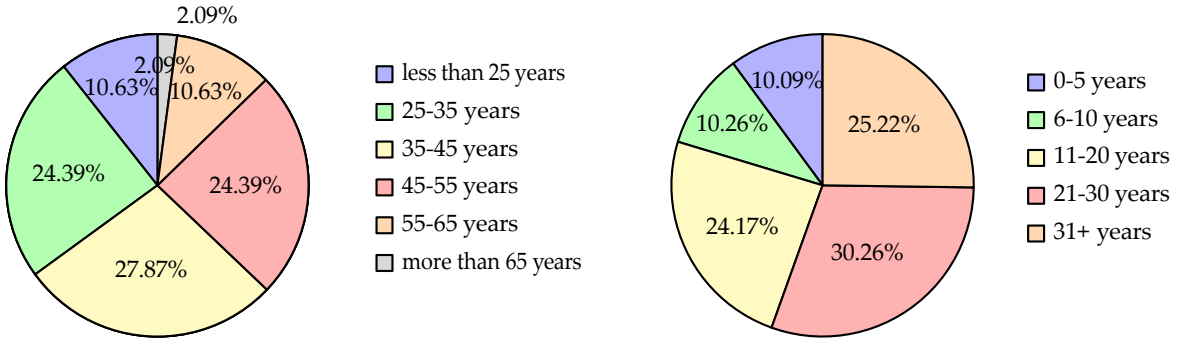

Figure 4. Age (left) and years of membership (right)

The management education of our participants is rather high, and a particular emphasis is on group, platoon, and formation leaders (Gruppen-, Zug- und Verbandsfu¨ hrer), who usually take responsibility for their units and lead operations and organizations (cf. left chart of Figure 5).

We further asked our participants to rate their perceived IT knowledge to get an idea of their skills and to be able to rate their answers in an IT-related context. Although this rating is not objective, it helps us rate comments and attitudes (cf. the right chart of Figure 5).

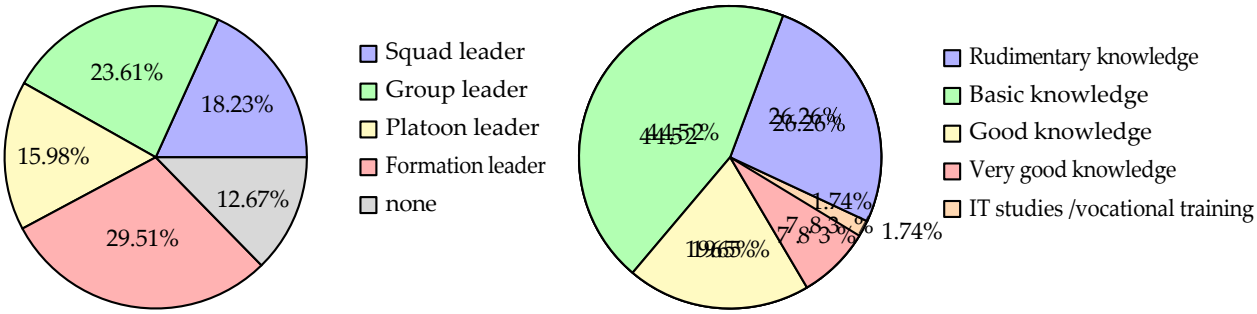

Figure 5. Level of fire department management training (left) and IT knowledge (right)

The vast majority of our participants are doing firefighting on a voluntary basis. This is not a surprise, since of the 1.385 million firefighters in Germany, 1.014 million belong to a voluntary fire brigade. Only 35 thousand firefighters are professional firefighters at governmental institutions, plus another 34 thousand firefighters work for companies. The remaining 301 thousand are members of youth fire departments. Some people also belong to both types of organizations (Deutscher Feuerwehrverband, 2021). The shares can be seen in Figure 6.

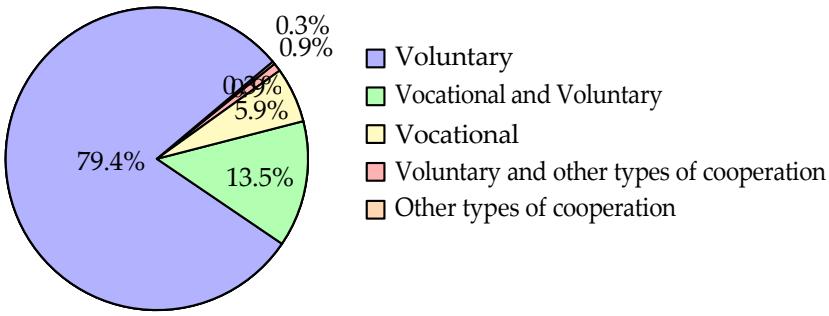

Figure 6. Types of engagement in the fire department

SURVEY EVALUATION

In the following section, we will present the knowledge-management-related aspects. We will begin with a survey of the current status of knowledge management. This includes, according to (Nonaka & Takeuchi, 1995), the acquisition, administration, and dissemination of *information* (cf. Figure 1). This is followed by questions about knowledge management and its distribution, as well as requirements from our respondents.

Information Acquisition, Administration, and Dissemination

Regarding the systems that are in use for information dissemination and the perceived availability of information, we asked the following questions:

How is new information, such as instructions (e.g., service instructions, emergency plans), processes, contact persons, etc., currently distributed in your fire department? (multiple answers possible)

The prevalent means of information management are e-mail, text messaging (such as WhatsApp and Telegram), verbal communication, and notices on a board (see Figure 7). Other platforms, such as a cloud, wiki, or forum, are barely used currently. The participants indicated the following software in the free text field: DIVERA 24/7 (10), Spond (9), Internal area of the homepage / intranet (8), APager (6), Teams (5), Alamos (4), as well as other products with less than three answers per product. The products are presented in detail in the Findings section.

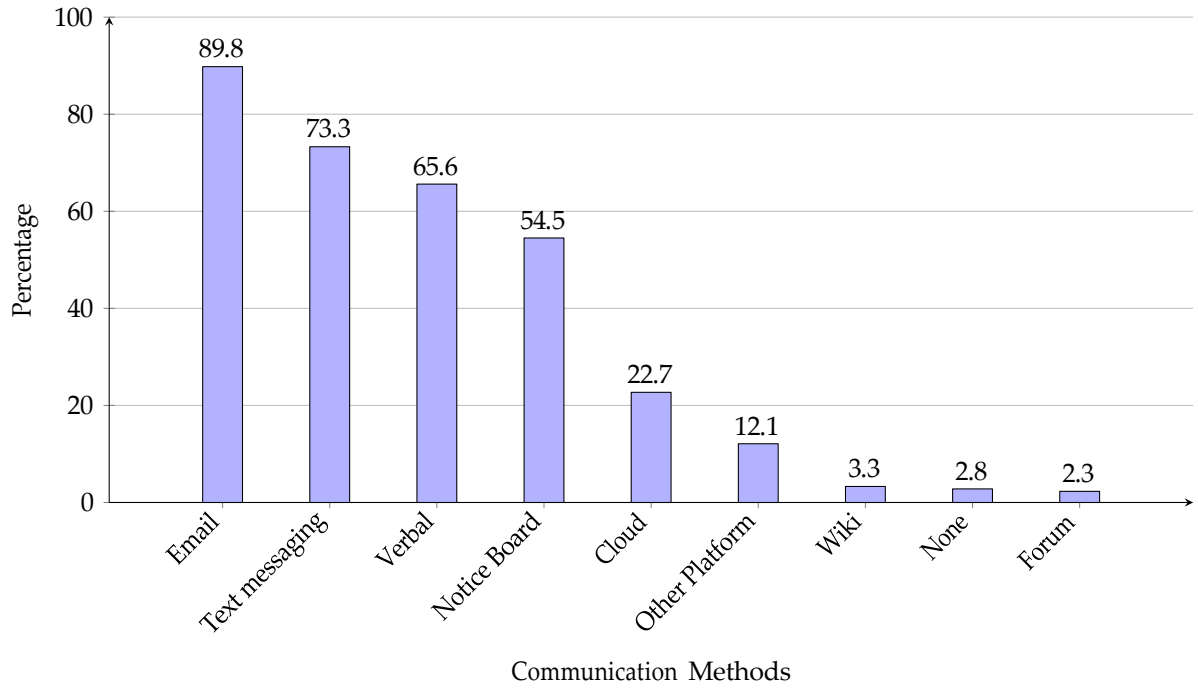

Figure 7. Distribution of communication methods in fire departments (multiple answers possible)

Rating statements towards the current situation of information and knowledge management.

We asked the following questions, the answers to which are shown in Figure 8.

- Question 1: I have the feeling that all current and new information is available to me.
- Question 2: I find it important that information and knowledge are stored in an organized way in my unit.
- Question 3: It is important to me that as much knowledge as possible is available to as many people as possible.
- Question 4: A knowledge management system should provide answers to recurring questions.
- Question 5: A knowledge management system should help to keep the content up-to-date.
- Question 6: The same information must be communicated frequently (e.g., answers to recurring questions).

Remarkably, only 53 percent of the participants stated that they agree, or rather agree, with the claim in Question 1. On the other hand, 32 percent said that they disagree, or rather disagree, with this claim. So, a significant share of the participants perceive a lack of information.

Questions 2 and 3 (cf. Figure 8) relate to the organization and dissemination of information among firefighters. The participants find it important that information is stored in an organized way and, thus, ideally, retrievable with no extra effort. Also, the transparency of information is important to keep personnel informed about everything relevant.

Questions 4 and 5 deal with the features that knowledge management should provide. Here are only two preliminary questions to get a first overview. More requirements and expectations are raised in the course of the survey.

Question 6 revealed other results than expected. Our assumption was that management personnel have to constantly answer similar questions. The response behavior is not as clear as expected but still displays the need to communicate similar information.

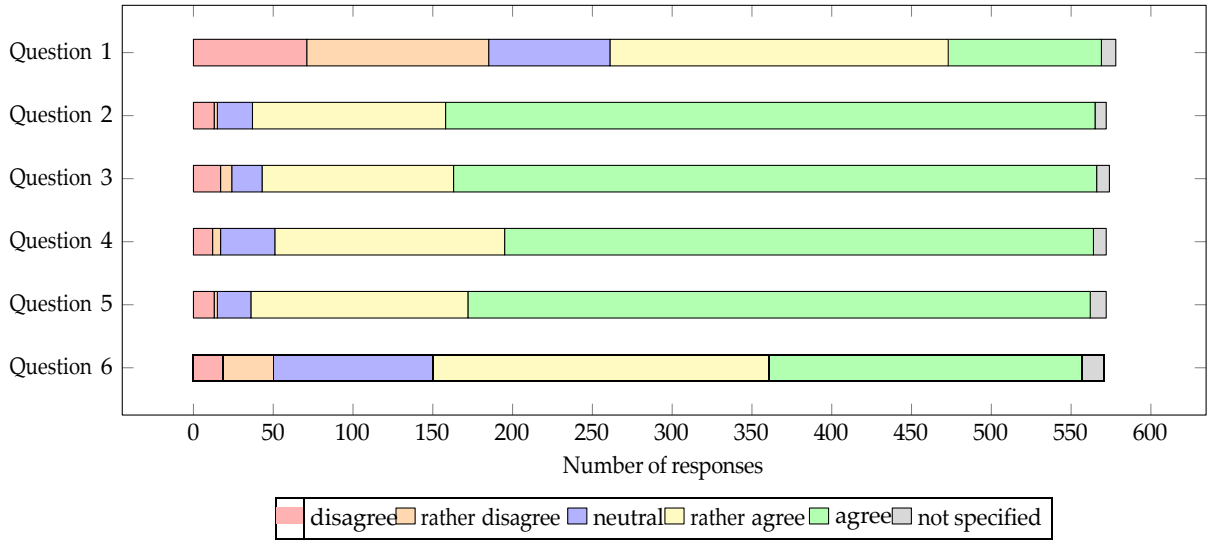

Figure 8. Statements towards information and knowledge management

Knowledge Management

Next, we surveyed the current status of knowledge management. 117 respondents (20.03 %) use a KMS, 343 (58.73 %) do not use a KMS, and 118 (20.21 %) are unsure whether their unit has a KMS in use. All respondents stating 'yes' were then asked which system they use exactly. This gives an overview of many systems that have practical applications. The whole set of software products mentioned throughout the survey is listed in Table 1.

Knowledge management systems in use

We grouped the answers with at least three mentions into the following categories:

- Information management systems / Databases: MP-Feuer (23), FeuerON (19), fireplan (8), Wasserkarte.info (3), 'database' (3) (not further specified)
- Knowledge management systems: Fireboard (19), Alamos (11), Wiki (5) (unclear about the actual usage), DIVERA 24/7 (4), L2R (3)
- Other software (depends on the usage, thus not categorised in one category above): Cloud solutions (18), Teams (3), self-development (3)

Features of knowledge management systems

We asked the participants without a KMS in their unit which features they personally would make use of. 414 would use the KMS for saving data for operations (e.g., hydrant plans or checklists), 411 would use it for providing content for basic and advanced training (e.g., training scripts), and 392 would use the system for saving instructions

for procedures (e.g., clothing exchanges or service directives). With a certain distance, 301 answered "Storing task descriptions (e.g., tasks as a manager)", 286 answered "Saving information about operations (e.g., operation reports)", and 280 answered "Managing base data (for promotions, addresses, or equipment maintenance)".

Subsequently, we asked which functions or contents should be added to or provided by an existing KMS. The answers are partially very generic; others are very specific. We tried to categorize the answers into different, throughout the process evolving, categories that match the meanings of the respondents best.

Many respondents (46) ask for a feature to provide teaching material from existing courses to either have a look at it prior to training or afterwards to refresh the knowledge of an attended course. Another 20 respondents want a KMS to help them harmonize existing teaching material to align and adjust courses' contents to have similar training for all personnel. 9 respondents request a lessons-learned approach to be able to gain knowledge from incidents or risk situations and to inform others about this issues.

Also a regular request is the storage of instructions (29) to have a central position where all applicable instructions can be found. 15 people requested an update mechanism to receive information upon changes in whatever information is stored in the KMS. Another 9 respondents want to record responsibilities and organization charts in a KMS, together with 9 answers that seek to display processes. 5 people want to have an frequently asked questions (FAQ) section, together with another 5 respondents demanding an on-boarding procedure in the KMS. 5 people requested a database of forms.

20 people requested mission-related standardized rules, emergency plans (22) and other maps relevant to an incident.

12 respondents want to store user manuals in a KMS, together with duty roster / appointments (11), equipment and material management (9), personnel administration (8), and training administration (7).

Give an example in which the knowledge management system has contributed or could contribute to solving a problem within the fire department

One respondent reports the necessity of training about 86 fire brigades and their members in their rural district according to a state-wide regulation for vegetation firefighting. The training has to be both theoretical and practical, which requires an enormous amount of effort. The respondent suggests a KMS that helps convey the training content by providing an eLearning course that adapts to the participant's prior knowledge. The course concludes with a test that certifies the theoretical knowledge, which is then applied practically in a second part. Updated material on this topic can be posted in a KMS for former attendees of the course. Likewise, 28 other respondents stated their wish to have standardized implementation of training in a KMS that adapts to the respective management level. The possibility of recovering previously attended courses is demanded, too. Besides, respondents required the standardization of knowledge bases (11) and processes (6), as well as maintaining a set of FAQs (6).

The process of onboarding new personnel is important for 14 respondents who wish to have a place where they can both store information for the people introducing new colleagues to their job as well as a possibility for new people to read up on things about their new place of duty. 4 respondents want to have a place for descriptions of their tasks to facilitate the handover of responsibilities if people in positions change.

11 respondents want to use a KMS to organize their material and knowledge, which was substantiated by others in terms of storing instructions in a sorted way (15), saving information about locations of fire hydrants and other building-related firefighting plans (14) as well as standard operating rules (9). 6 participants requested a facility to store the latest versions of forms in one central place. 13 answers indicated that an important use case would be the management of shift plans and other means to plan events with personnel. 7 people demand a way of centrally informing and being informed of news and updates.

A respondent emphasized the central aspect of a KMS that helps the users avoid unnecessary work. The respondent described that they had to maintain their data every time the program was updated and suggested a central programmer who would take care of this issue instead of dealing with it in every single unit.

Information sharing among different legal bodies

We asked the participants whether they would make use of a KMS that is run by a fire brigade from another municipality. About 83 % answered yes, while only 13 % would not use such a system. 4 % did not answer this question. As mentioned by Duscher, there is no need to compete between different fire brigades (Duscher, 2010), which might be a reason why the exact same percentage of respondents would be in favor of opening their system for members of another fire brigade (83 %), while about 13 % would not, and 4 % did not answer this question.

Sharing of information and knowledge in the line of command

Next, we wanted to know if and how our participants make their knowledge available for others (480), issue instructions (326), and forward information in the line of command (482). We were also interested in the means they use for this, which is plotted in Figure 9. It is apparent that email is the predominant system in all three scenarios of knowledge sharing, issuing instructions, and forwarding information. Verbal communication and text messaging via WhatsApp and Co. are in second and third place, respectively. The notice board is still used by half of our respondents who issue instructions. More digitally advanced systems like clouds, wikis, and forum systems are barely used. The means are complemented by the free text answers where the user referred to Teams (7), Divera 24/7 (7), eLearning like L2R (3), and paper-based notes (3).

We also asked the respondents which digital systems they would like to use to provide knowledge, which is depicted in Figure 9 in the color red. Here, emails are the prevalent means as well, followed by text messaging. The share of people who want to use a cloud is notably higher (58 %) than the current usage of cloud platforms, and the same holds for wikis (30 %) and forums (20 %) as well. We deliberately asked only for digital means of information sharing, which is why verbal and notice boards do not have a value in red. Many free text answers support this hypothesis since only two answers stated that they would like to use analogous means like a notice board.

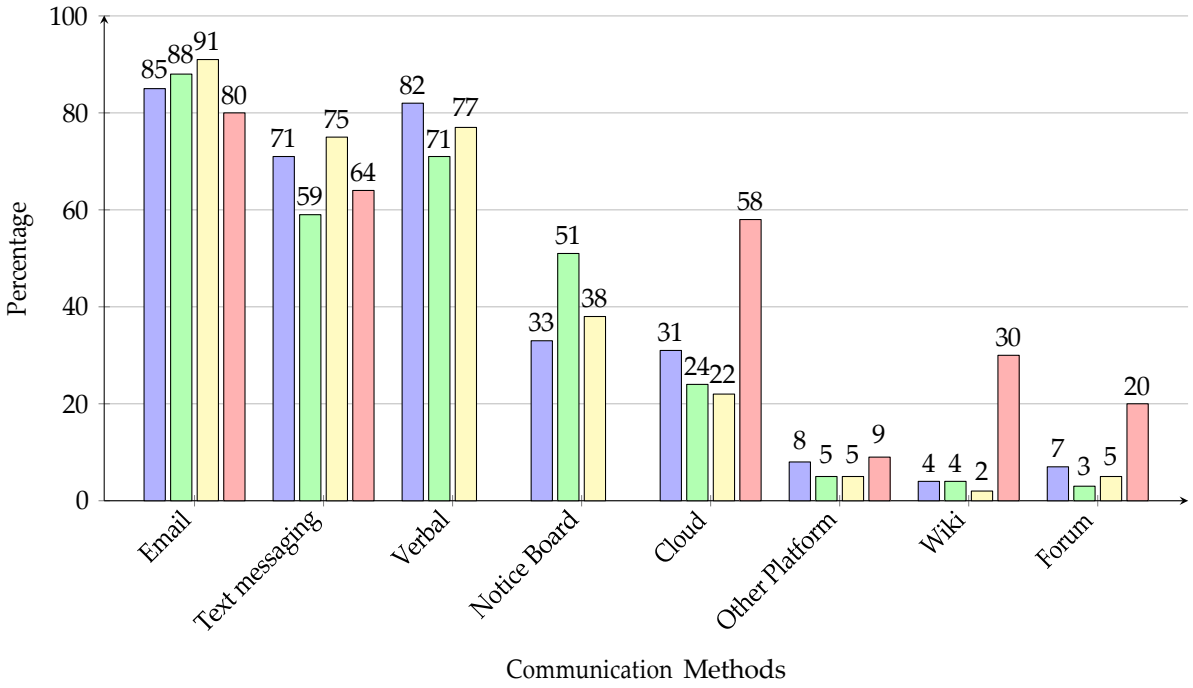

Figure 9. Distribution of means in use for knowledge sharing (blue), instruction issuing (green), information forwarding (yellow), and digital means respondents would like to use (red) (multiple answers possible)

Maintenance of knowledge in knowledge management systems

In the last section of the survey, we covered the aspect of maintaining the KMS. Therefore, we asked the respondents the following six different questions, for which the answers are shown in Figure 10.

- Question 1: It is important to me to be able to access older versions of entries.
- Question 2: It is important to me to be able to integrate / reference / transfer content from external systems.
- Question 3: It is important to me to be able to integrate content from the knowledge management system into other systems.
- Question 4: I would enter information into a knowledge management system myself.
- Question 5: I would have time to keep the knowledge I have entered up-to-date.
- Question 6: The knowledge, information, and instructions I provide are also taken into account in the long term.

Question 1 refers to the possibility for the user to access older versions of a record to keep track of changes and be able to understand its evolution and current status. Questions 2 and 3 deal with the integration of information items from external systems into the unit's KMS as well as referring to information items from other systems to avoid redundancies. Questions 4 and 5 cover the personal perception of both entering information into a KMS and keeping the provided information up-to-date. Question 6 is a more estimating question that refers to information and instruction in general that are issued and distributed by our respondents.

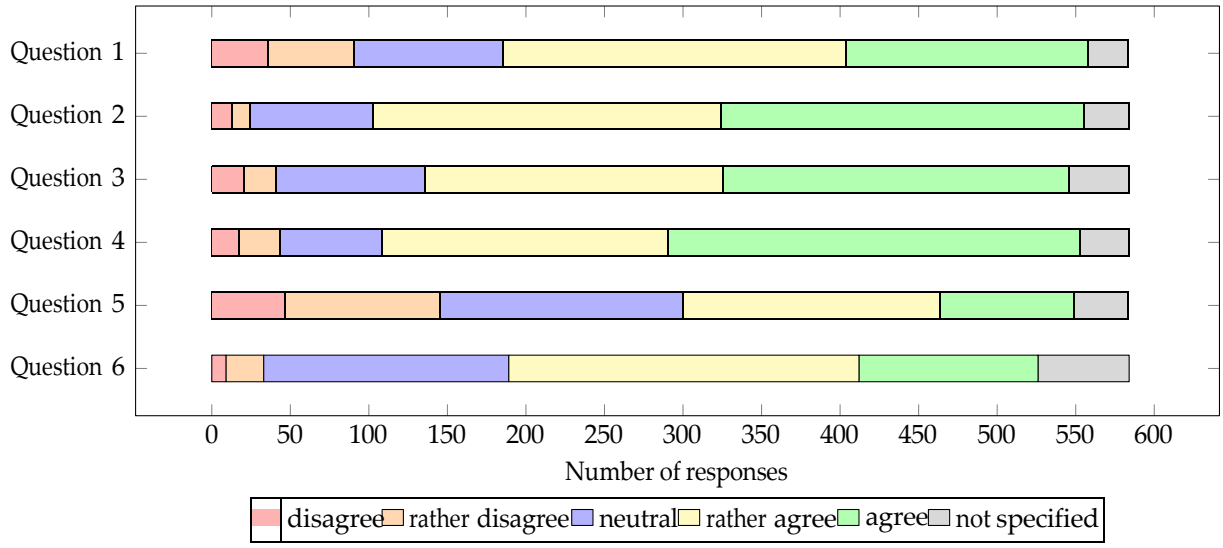

Figure 10. Statements towards information and knowledge maintenance

Final remarks on the topic of knowledge management in fire brigades in general

As the closing question, we asked the participants to write whatever they think they need to communicate to us regarding the survey's realm, which has not been addressed yet.

The most mentioned aspect is the need and requirement to have a KMS that is not only managed and maintained by a central authority (mostly state-wide) but also filled with general content (15). This is supported by the claims that the necessary efforts to run a KMS are quite high (6), as well as interfaces to other systems that are needed (4). 5 respondents explicitly stated user friendliness as an important point.

14 respondents thanked for the survey and expressed their opinion that this topic is important in modern firefighting. 4 also deliberately said that digitization in general is an important topic for the fire brigades, while 3 respondents stressed the need to have a positive balance between effort and effect. 3 respondents stated that current and existing solutions are not used enough, although they exist.

10 respondents reported that the introduction of a KMS in their unit may also be hampered by their current leadership. Some of them might object to a KMS (as something not needed) or refuse to use one because sharing information could endanger their high position (if knowledge is shared more widely). Others might only be reluctant to use digital systems in an environment that has a long tradition and well-established processes. Respondents are also rejecting a KMS because of the high demand to keep it up-to-date (5) and the costs it imposes (5). 3 respondents stated that there is no willingness to share information because others might have unwanted advantages of one's information.

Validity

The results of the survey represent the attitude of the participants towards knowledge management in fire brigades. The participants' distribution is spread across all ages and leadership levels with a tendency towards higher educated leadership levels. Since the call to participate in the survey was only distributed through digital means, this might have impacted our results as we were not able to reach people who do not use any of these means. But on the other hand, these technologies are used by a vast majority of people in Germany (Pokorny & Roose, 2020), and our intention was not to have a representative survey with exact values but to have a first estimation of this extensive topic.

FINDINGS

Although we provided a short description of what we deem an *information* management system and what a *knowledge* management system, many responses expected a KMS to be an all-in-one solution of IMS (master data about persons, equipment, and histories of trainings or incidents), a command support system (used during an emergency to provide plans, files, and procedures), and an actual KMS (dealing with training curricula, maintaining instruction and procedures, lessons learned, and best practices). Especially in the training sector, many respondents seek a system that supports their knowledge management (acquisition, administration, and dissemination).

The answers often focus on incident-related topics and the management of crises like fire hydrant maps, means to store evacuation plans, and standard operating rules for incidents. In addition, the inclusion of non-incident-related topics such as training or the management of administrative knowledge and processes indicates a more holistic view.

As seen in the red bars in Figure 9, the willingness to use digital solutions in the firefighting domain is existent. The users know these systems from other applications and want to transfer them to the fire brigades as well.

It is noteworthy that most respondents want to enter their knowledge into a KMS at first but then do not think that they have enough time to keep it up-to-date (cf. Questions 4 and 5 in Figure 10).

Next, we give a short overview of the most frequently mentioned software products throughout our survey to have a single place where we can relate to them during the presentation of the results. A summary of the software products that have been mentioned throughout our survey and are presented below can be found in Table 1.

- DIVERA 24/7[4] represents a web-based database solution primarily aimed at enhancing efficiency and precision in personnel deployment within the civil protection and disaster relief sectors. This system records, analyzes, and visually presents the availability of emergency service personnel, including firefighters and rescue services, thereby facilitating more effective resource management in emergency situations.
- Spond[5] is a digital solution focused on the administrative management of teams, primarily in sporting environments. Its functionality includes the creation of events and facilitates the exchange of a variety of data forms, such as text, images, and files, within a team setting. It is used to organize groups of several people.
- APager PRO[6], developed by Alamos GmbH[7], represents a mobile solution engineered for the enhancement of emergency alerting, response feedback, and availability planning mechanisms. Utilizing established Google and Apple transmission channels, the system ensures prompt and secure dissemination of alerts and informational messages through push notification technology. This capability is maintained even in scenarios of limited or no internet connectivity. The application further incorporates advanced geospatial features, allowing for precise display and navigation to incident sites. In addition to APager PRO, Alamos GmbH has other software and hardware solutions for alarm systems, visualization tools, and deployment tablets.
- Microsoft Teams[8] is an office application for organizational use, providing a workspace for real-time collaboration and communication. This platform integrates functionalities for meetings, file and app sharing, and allows for a more engaged and effective team environment.
- Fireboard[9], a comprehensive incident command software, is engineered to streamline the management of emergency responses. Integrating a suite of functionalities, it facilitates detailed documentation, resource allocation, and real-time situational analysis. Its modular design allows customization for specific operational needs, encompassing incident command, mapping, communication, and patient management.
- Wasserkarte.info[10] serves as a software tool for maintenance, documentation, and planning. The application offers various features like maintenance planning and automatic data transfer, enhancing the operational efficiency of water supply management.
- L2R[11] is an eLearning platform tailored to the specific needs of personnel in emergency services, including rescue, emergency medicine, and firefighting. Courses can be purchased as well as entered individually.

- MP-Feuer[12] is an administration software for the fire department, rescue service, and preventive fire protection in Germany. It is established in Germany and has over 7,000 customers. MP-Fire consolidates relevant information into one, easy-to-navigate system, enabling rapid deployment across multiple operational areas.
- FeuerON[13] is a web-based software solution designed for the streamlined and transparent management of critical fire department data. It facilitates the organization of personnel, equipment, reports / incidents, and training registrations. The system offers comprehensive access to relevant data from any location with internet connectivity, enhancing operational efficiency in various areas such as personal data management, equipment and material tracking, report generation, and appointment monitoring. It features an individual rights management system, allowing administrators to control access based on user relevance.
- Fireplan[14] streamlines emergency response through its auto-dispatch and object information features, providing crucial data en route to incidents. It enhances incident management with capabilities like automatic documentation, integrated review and approval processes, and intelligent billing. The software also includes comprehensive modules for reporting, personnel, and equipment management, supporting efficient organization and analysis. Additionally, Fireplan integrates various management aspects such as training, awards, maintenance logs, and scheduling, all within a user-friendly platform.
- MediaWiki[15] is the most prominent example of a wiki system. It is the technical basis for wikis and is therefore an indispensable tool for the community-based collection and dissemination of knowledge. MediaWiki is known for its customizability and is supported by a variety of extensions and skins. It is used in a variety of projects, from large knowledge bases such as Wikipedia to small community initiatives, and features robust syntax, comprehensive user management, and detailed revision histories. MediaWiki is open source, while other wiki systems might be commercial.

CONCLUSION

We have conducted a survey with 577 responses from firefighters from all over Germany and were able to extract new findings from the data, which we will then use to elaborate on the requirements for a KMS. We can conclude that our initial hypothesis, which postulated that the spread and use of *knowledge* management systems in German fire departments is currently limited and confined to a few projects, is true. There are only very few systems in use that can be considered a KMS. This also highly depends on the individual usage of a system like a cloud or Microsoft Teams. *Information* management systems are widely used by fire brigades, as indicated by our respondents, and some examples of these systems are listed above. This survey also revealed aspects that have to be considered when designing and developing a KMS for fire brigades. The need for a system that makes use of an information sharing infrastructure is supported by the answers from our respondents, who seek an easy-to-use system where information is added only once by a superior authority and then all subsequent units can import this information items. Nevertheless, local adjustments and characteristics have to be considered since not everything can be described globally. An integrated solution that also enables the import of information from external systems would be useful to keep the maintenance of the KMS simple and automated. In addition to the insights mentioned above, our survey underscores the importance of a KMS that is applicable in both routine and exceptional operational scenarios. Our findings indicate that firefighters' familiarity with the KMS during regular duties and activities contributes to their ability to use the system effectively, even in stressful situations.

When taking the next steps in designing, developing, and implementing a KMS for emergency organisations, there are many more aspects to be taken into account. One is the rejection by end users who are not familiar with IT or deem it to be unhelpful in their daily tasks. Especially IT systems in use during the response to an emergency pose high requirements to their developers and multiple reasons for rejection (Elmasllari, 2018; Kapalo et al., 2019). Therefore, we focus at the beginning on non-incident scenarios where a KMS can have large effects like time savings, information distribution, and training as well. Nevertheless, the gained knowledge should always contribute to the cirsis management which is the core task of every emergency organisation.

Another aspect that has to be taken into account is data protection, together with data safety and security. In the EU, the General Data Protection Regulation (GDPR) poses high requirements when dealing with personal data (or data that refers to a human person) that have to be respected when developing and operating a KMS (Hu¨ttelmaier et al.,

CoRe Paper – Impact-driven Emergency and Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

2021). But also, the security aspect has to be taken into account (Walker, 2012) since many of the data stored is confidential, leading to the need for certain restriction policies.

A broader literature review on KMS in disaster management was performed by Dorasamy et al. Their results state that the terminology related to emergency and disaster management should be standardized to ensure the comparability of different approaches. Also, the differences and similarities between KMS and emergency management information systems should be elaborated upon (Dorasamy et al., 2013). Using standardized procedures as well as interfaces between KMS and third-party systems is an important factor when it comes to implementation. Many fire brigades already use one or another software tool, and interoperability should be possible. As indicated by Wesendrup et al., the six challenges for data management for firefighting in Germany are "cartographic data harmonization, information system (IS) standardization, information gathering from unstructured data, canonical bodies of knowledge, and data-driven firefighting support" (Wesendrup et al., 2019).

Open-source software itself is not required by many respondents in our survey, maybe due to their lack of IT knowledge. But having software that is free to use is important if it is supposed to be used by many, especially smaller fire brigades who cannot afford personnel to run the system for them (Timm et al., 2013).

All together, knowledge management offers great possibilities for modern firefighting to make use of the vast amount of knowledge and high technology. It can speed up actions, keep people informed as well as motivated, and help organizations in transition phases while preventing a loss of knowledge. To be successful, many requirements by end users have to be considered, and satisfaction and acceptance are key success factors for the helpful development and implementation of a KMS.

ABSTRACT

The impact of COVID-19 on the lives of people and businesses across the globe was devastating. While governments across the world had undertaken a slew of measures to control the spread of the COVID-19 virus within their geography, many of these measures had long and unintended consequences. The restrictions imposed by the governments on the movement of people and goods across the world brought supply chains to a grinding halt. This study identifies the cascading effects of supply chain disruptions on the water sector. Since these systems are closely integrated and the impact of COVID-19 needs to be analysed at a much broader level, this study uses a systems-thinking approach to study the effect of supply chain disruptions on water services. The study develops a causal loop model to gain further insight into how supply chain disruptions caused by COVID-19 affected the coping capabilities of society and how critical services were affected.

Keywords

Qualitative systems model, COVID-19, water sector, supply chain disruptions, disaster management

INTRODUCTION

Supply chain disruption (SCD) is an unexpected event that stops or slows the normal flow of material with potentially negative consequences to supply chain members (Chopra and Sodhi, 2004). At a broad level, SCDs are usually classified based on their causes, such as acts of nature (e.g. flooding, earthquakes, hurricanes and pandemics). While this cause-based classification identifies the underlying reasons for these disruptions, it is often much more useful to gain further insights into the effects and stage of disruption and this has led to other classifications of SCDs. For instance, Ivanov et al. (2017) classified SCD based on the level or echelon at which the disruption has occurred. Chopra and Sodhi (2014) classified SCD based on the causes other than n atural or manmade disasters and identified that SCDs can be caused by delays in commerce systems, forecasts, intellectual property, etc. Other classifications for SCDs are based on frequency of occurrence (Tang et al., 2014), nature and their source of origin (Christopher et al., 2011) and who they affect, from broad to specific (Dolgui and Ivanov, 2021). The impact of SCDs on businesses can be operational, marketing and financial (Katsaliaki et al., 2021). Operational impacts can be product unavailability, partially fulfilled orders, late deliveries, logistic challenges, etc. (Jabbarzadeh et al., 2018; Wagner and Neshat, 2012). While marketing impact can be increase in customer

WiP Paper – Impact-driven Emergency and Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

complaints, damage to brand reputation, loss of customers, breach of supplier contracts, penalties etc. (Ponomarov and Holcomb, 2009). And finally, financial impacts are, loss of sales and revenue, reduced market share, complaints, damage to brand reputation, loss of customers, breach of supplier contracts, penalties etc. (Ponomarov and Holcomb, 2009).

However, what has been lacking in studies related to SCDs is their impact on the security of the supply of critical services, such as quality of water for daily use including drinking and bathing. The revised Drinking water directive (2020) by the EU parliament defines essential quality standards for water intended for human consumption. It requires Member States to regularly monitor the quality of water by using a 'sampling points' method. The revised directive updates existing safety standards and improves access to safe drinking water along the lines of the latest recommendations of the World Health Organization (Curmei and Kurrer, 2023). Furthermore, the directive also focuses on building more resilient drinking water system and designates the water infrastructure as a "critical entity" (European Commission, 2020). This has led to the creation of a waster security plan for prompt response and recovery from intentional or unintentional contaminations affecting the drinking water supply system, reducing the impact severity such as the potential escalation to service disruption and disease outbreaks which could have catastrophic consequences (Teixeira et al. 2019).

During the peak COVID-19, the focus on personal hygiene and cleanliness has been at the peak. This had led to rapid increase in the domestic water consumption. However, the lockdown also had a negative impact on the businesses, and this led to a rapid drop in the industrial water consumption. Overall, this mismatch in the demand profile had affected the revenues of the water companies and further affected the operations of many water companies. World bank (2020) estimated that there was a drop of about 40% where many countries had suspended the water charges to give some financial relief to their citizens during the economic slowdown during COVID-19. Furthermore, there were widespread interruption of operations due to absenteeism, labor cost and procurement of adequate personal protective equipment for staffs and limited supply of essential chemicals for water treatment during the COVID-19 pandemic were other challenges COVID-19 posed to the water sector (Joo and Trindade, 2023). This was further complicated with SCDs owing to the internal restriction set by multiple countries affecting both capacity and transportation of necessary chemicals and spare parts used by the water management companies to ensure safe water services. Thus, in this study, we explore the impact of the SCD caused by COVID-19 on the water industry and how it can contribute to the conversation of security of supply (water) of daily operations of a water utility's system and help to detect other safety issues as well as supply chain disruptions (e.g. shortage of key workers; shortage of key chemical supplies).

BRIEF LITERATURE REVIEW

Supply Chain Disruption

In decades, supply chains have moved towards efficiency and cost reduction. To improve the efficiency, economies of scale, reduction in safety stock and focus on the sole source of suppliers has been leveraged by many supply chain managers (Parmigiani et al., 2011). However, the major side effect of these activities was that the supply chains became extremely fragile and would break down even at the slightest disruption since it lacked enough cushion (Ivanov et al., 2016). This was most evident during the COVID-19 pandemic, when supply chains were under severe stress owing to supply and demand shocks (Atkinson et al., 2020).

SCD severity is influenced by design characteristics and mitigation capabilities, highlighting the need for resilience planning and business continuity planning (Craighead et al., 2007). Furthermore, it is seldom that SCD effects remain localized and often they propagate along the supply chain. They severity and intensity of SCD propagation depends on the nature of disruption, structure of supply chains, and managerial decision-making (Scheibe and Blackhurst, 2018). SCDs often has a cascading effect across the entire supply chain network (SCN). The propagation of a disruption across the SCN and its associated impact is called the ripple effect and is distinct from the well-known bullwhip effect (Dolgui et al., 2018). In more severe cases, the ripple effect can cause some nodes and arcs in the SCN to become temporarily dysfunctional (e.g. due to a material shortage and capacity loss) (Dolgui et al., 2018).

To understand the supply chain ripple effect, it is imperative to understand risk propagation in the SCN. In practice, a disruption to an SCN often begins locally, with a trigger event affecting any one or a group of nodes in the network usually located within the same vicinity. This impact spreads to other firms (or nodes) through their relationships. Consequently, the impact might propagate to parts of the network through a set of cascading effects and affect nodes that are far from the origin of the impact (Scala et al., 2021). The extent to which the

impact propagates in the supply network is also a testament to the resilience of the network (Li and Zobel, 2020). Dolgui et al. (2018) discussed the main reasons for the systemic vulnerabilities that make SCNs more prone to the ripple effect when presented with a disruption in any or multiple nodes within the SCN. These reasons can be broadly classified into four main categories: sourcing strategy risks, production planning risks, inventory management risk and control risk.

COVID-19 and Water Sector

Prior to COVID-19, the water industry across the globe were impacted by five major trends. These included, (a) global warming led increase in extreme floods and droughts, challenging the resilience of water and sanitation systems, (b) increasing number of people living in areas facing water stress (currently 2 billion), which increases water supply vulnerabilities, (c) rapid urbaniza tion, which strains existing water resources and ecosystems, (d) the emergence of megacities, which adds the challenge of extending water and sanitation services to about 1 billio n people living in informal settlements not served by water grids, (e) aging infrastructure, which has increased pressure to accelerate investments in more advanced markets, following decades of underinvestment (Butler et al., 2020). Along with the pre-existing challenges, some of the major impact of COVID-19 on water services are summarized below.

With the nationwide lockdowns, there was a marked increase in the household consumption of water and a significant decrease in the non-household or industrial consumption. With the increase in the household consumption, thereby increasing the cost of water production (Ong and Nielsen, 2020). However, revenue from metered household customers has increased because of increased demand and companies with comparatively more metered customers saw a greater increase in household revenue in the short -term, while the ones with industrial consumers saw a significant drop in their revenues (Ong and Nielsen, 2020).

On the other hand, the Health and Safety Executive (HSE) in the UK advised business including water sector to prioritize becoming "COVID-secure" by adapting to current guidance and implementing measures to control the risk of COVID-19 to protect workers and others. These steps included carrying out COVID-19 risk assessments adhering to HSE guidance, enhancing cleaning, hand washing, and hygiene procedures, taking all reasonable steps to help people work from home, etc. To comply with these mandates, water companies have had to adapt various measures, including regulatory inspections, limited site visits, phone calls (remote working), and collection of visual evidence (photos and video footage), etc. (Frontier, 2020; HSE, 2020). The pandemic had disrupted the water sector's revenue and growth projections. Hence there was a need for readjustment for the rest of the Asset Management Period (AMP) to reprioritize projects supported by Ofwat (England and Wales agency that Promotes competition, sets price limits, ensures that water companies can finance and carry out their functions, promotes economy and efficiency) (Horton and Laikin, 2020). This further affected the capital investments both in term so of maintenance and upgrading the water systems. The cost structures and lack of funding sources in the post pandemic environment put halt on the new capital expenditures for both maintenance and modernization of the water system. The tariffs were insufficient to recover operating costs and the water utilities require support from other sources, usually the government budget had also reduced during peak COVID-19 (Butler, et al., 2020). A decline in demand from large industrial and commercial users due to lockdowns and travel restrictions significantly reduced revenues to water utilities. Specific measures adopted by the governments like (a) deferments on or exemptions from utility bill payments for vulnerable groups, (b) moratoriums on cutting off the water supply, and (c) suspensions of meter reading and invoicing also a ffected the revenues of the water industry (Butler, et al., 2020).

WASH and COVID-19

The water supply and sanitation services must be considered within a larger framework of integrated water management, water quality, ecosystem health and governance and is crucial for public health and human development (Gaddis et al., 2019). Mukhtarov et al., (2022) argued that COVID-19 and water management will have long term mutual impact on each other. The direct impact includes prioritizing WASH at the expense of other crucial challenges such as climate change adaptation, land use patterns, ecosystem h ealth and energy. Furthermore, lesser public funds will be made available for water infrastructure and management and the danger of oversized influence of private financial capital in the water sector might cause lower quality of water related infrastructure. On the other hand, the long-term indirect impact will be securitisation of WASH that may lead to day-to-day and fragmented management. With private financial take-over of water infrastructure and services, the attention to techno-fixes with a relative neglect of social and political aspects of water management and governance may be affected in long term and might as well take a back seat in long run .

SYSTEMS THINKING AND METHODOLOGICAL FRAMEWORK

Systems thinking has been used as a tool to study complex interactions in supply chain research. The "system" is defined as 'a whole consisting of two or more parts, where each of which can affect the performance or properties of the whole, none of which can have an independent effect overall, and no subgroup of which can have an independent effect on the "whole". In brief, a system is a whole that cannot be divided into independent parts or subgroups of parts' (Ackoff, 2010). In the same vein, Ackoff (2010) defined systems thinking as looking at relationships (rather than unrelated objects), connectedness, process (rather than structure), the whole (rather than just its parts), the patterns (rather than the contents) of a system and context (Ackoff, 2010). This view of systems thinking aligns with the supply chain function, in which various aspects of the supply chain need to relate to an established process to communicate with various parts of the supply chain to fulfil consumers' demands (Wilden et al., 2022). According to Wieland et al. (2023), supply chains are not only complex adaptive systems but a lso have close connections with social, economic, ecological and political contexts within which they are embedded. While not referring to systems thinking directly, Sarkis et al. (2020) took systems view to critique the weaknesses in the supply chain and promote resilience measures, in addition to detailed lessons learned from a post -COVID perspective (Sarkis, 2020). Elias et al. (2021) used systems thinking to holistically analyze the complexities involved in the adoption of a sustainable wood supply chain in Amazon and to develop strategic interventions to improve the system.

System dynamics, a research approach based on systems thinking, often uses group model building (GMB) to identify complex relationships between various entities and subsystems (Vennix et al., 1999). GMB has been the favored approach for the system dynamist for three main reasons: first, to capture the required knowledge in the mental models through the various stakeholders; second, to increase the chances of implementation of model results; and third, to enhance the stakeholder learning process (Vennix et a l., 1997). GMB exercises allow stakeholders to voice their individual perceptions of reality and help them develop a shared mental model of their perceptions as a group (Elias, 2016).

For this study, an exploratory approach using the GMB method was adopted to gain an understanding of the complex nature of SCDs due to COVID-19 and its impact on the water sector (Rouwette et al., 2002). Due to the exploratory nature of the research, the discussions were semi-structured to enable the researchers to discover the varying causal influences that the participants perceived to occur in practice (Graham et al., 199 2). The subsequent sections broadly explain the main parts of the research process. The research process was divided into four ma in steps, as described below (Hovmand et al., 2021).

- The first step included an initial literature review and identification of the main impact on the water sector due to SCDs caused by COVID-19
- The second stage involved initial data collection based on a questionnaire developed by the gatekeepers, which was shared with the sCience and human factOr for Resilient sociEty (CORE) consortium members to gather insights into the impacts of supply chain disruption on the water sector due to COVID-19.
- The third stage involved a GMB workshop in Helsinki, in which the participants developed an initial set of relationships between the variables and helped identify an initial set of relationships. As part of initiating GMB, experts in HUMLOG were contacted and invited to be part of GMB.
- The fourth stage involved final model building and validation, where the model was shared with members of the CORE consortium project.

CAUSAL LOOP MODEL FOR WATER SECTOR

The impact of COVID-19 on water sector has not received much attention. However, it is not to say that the impact has been any less. This section discusses the main impacts COVID-19 had on water sector through a causal loop model developed through GMB.

The lockdowns had a significant impact on the water industry. Due to the lockdowns and increase in the remote working, a lot more people have spent significant amount of time indoors. Therefore, the domestic water consumption had increased significantly. While, on the other hand, the industrial water consumption had reduced. this had significant impact on the revenues generated by the water companies. However, the lockdown induced domestic consumption had a lot more impact than merely an increase in the domestic water consumption. With a significant amount of time spent indoors, people started using more water at home for water intensive activities such as gardening, swimming, etc. This is represented by the RW1 is a positively reinforcing loop which captures the impact of household water consumption for WASH demand which has a positive impact on reducing the risk of infection.

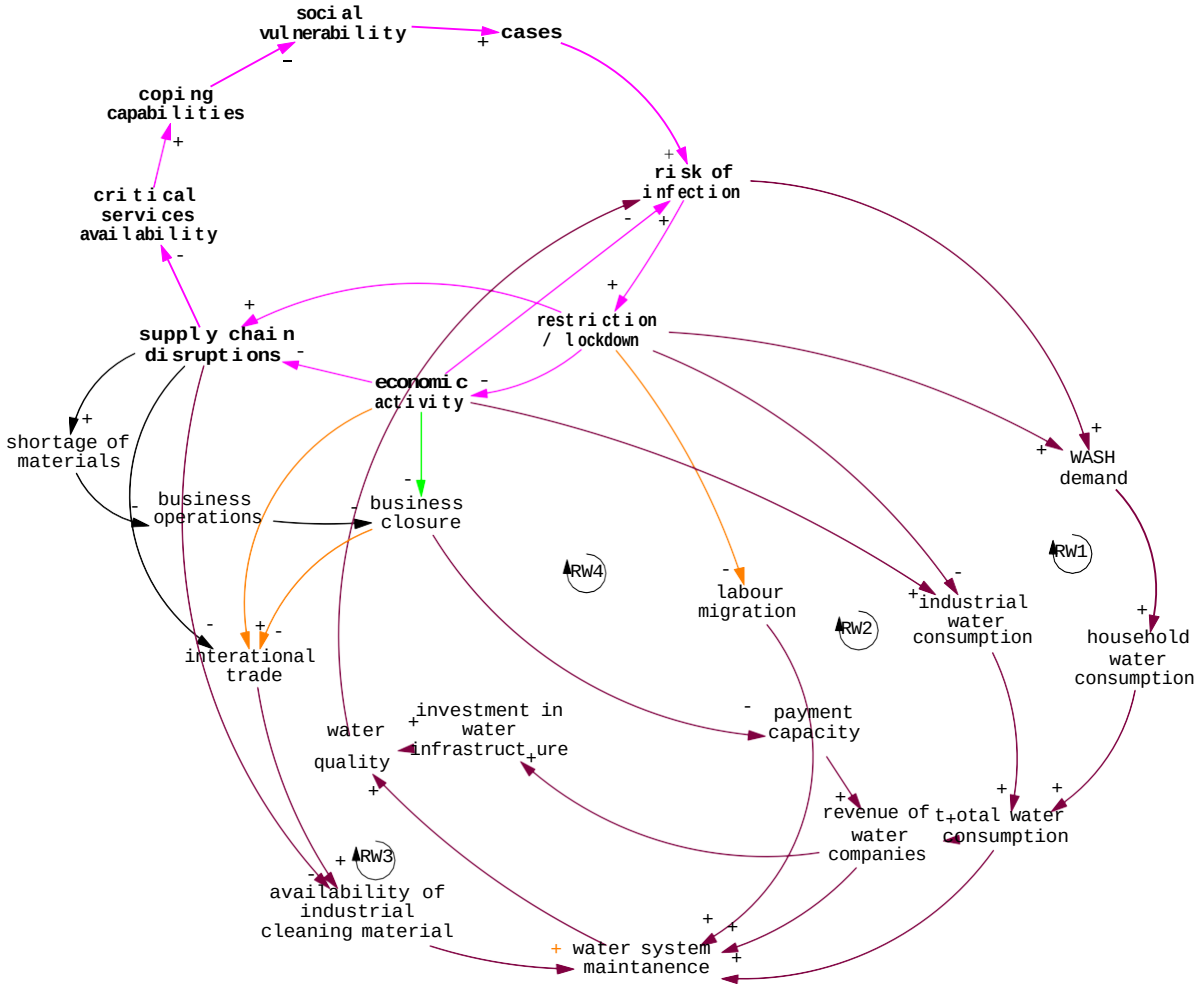

Figure 1. Causal Loop Model

However, this increase in the domestic water consumption had other unexpected impact on the water systems as well. It was observed that people were flushing down and putting things that were not supposed to be put into the drains. For instance, due to the shortages in the toilet paper (owing to international lockdowns and supply cha in disruptions), many were forced to use alternatives which were not supposed to be flushed in the drains. These kinds of behaviours had cost significant blockages along the drains and sewers, which had put additional pressure on the water companies in terms of maintenance. Thus, it became significantly more expensive for water and water systems management. Furthermore, the household demand offset the reduction in the non-household demand and as a result the water production cost for the companies had increased significantly during this time . This is represented by the negative reinforcing loops RW2 in the figure 1. RW2 captures the impact of reduction in the revenues of water companies due to that restrictions and lockdowns and thereby the substantial reduction in the industrial water consumption along with the increased expense to maintain the water systems from collapsing due to the excess stress on the already aging water filtration systems due the increase in the domestic water consumption.

The supply chain disruption due to COVID-19 had significant impact on the quality of water itself. While multiple transmission modes of COVID-19 were being closely evaluated, it was identified that COVID-19 virus could be transmitted through water as well, especially through the sewage systems from residentia l (toilet, shower, washing, etc.) and through medical centres. Thus is became the priority of the both local and national governments to ensure that water treatment was carried out properly and the water companies had been mandated to ensure that there is no lax in the water treatment protocols. However, frequent water quality checks revealed that there were increased viral levels even in the treated wastewater which indicated that the wastewater treatment was not carried out with adequate efficiency to remove COVID-19 viruses. One of the main reasons cited by the water companies for this lack of efficiency in filtration systems was due to the age-old equipment that had not received proper maintenance or in many cases were passed their due life. Secondly, it was also identified that in many cases the water companies were not able to source the chemicals and components for the filtration systems due to the supply chain disruptions. Since many are of the chemicals used in the water filtration systems are not manufactured within

Europe and is usually imported from Asia , the disruption of the international trade had led to a severe shortage of chemicals required for the water filtration. These challenges to water is represented by the reinforcing loop RW3. However, RW3 is a negatively reinforcing loop representing the impact of supply chain disruptions due to the restrictions and lockdowns on the availability of industrial cleaning material which had an impact on the water maintenance system and thereby the quality of water increasing the risk of infection through the water systems.

Finally, COVID-19 severely affected the modernization and capacity expansion plans of the water sector. Due to the reduced revenues and supply chain disruptions, many water companies decided to halt or slow down engineering investments in improving the water and sanitation systems. For instance, Ofwat, the water management authority in the UK had given clear instructions to the water companies to meet core service obligations which is, to provide water and wastewater services and not to prioritise engineering projects in the meanwhile. This was also affected due to the lack of temporary and seasonal labourers who are critical in large scale engineering projects. As mentioned earlier, the availability of these labourers was affected due to the border closures and lockdowns. The supply chain disruptions also had an impact on procuring raw materials and parts which would have been used in these engineering projects. Furthermore, the COVID-19 pandemic had further disrupted the sectors demand and growth projections. With an increase in the domestic water consumption, many were wary about the long term shift in the water consumption pattern. Another major impact on the revenues of the water companies was the non-payment of dues by the existing businesses. Due to the lockdown, both industrial and non-industrial small-scale businesses had to be shut down temporarily. This had affected the revenue streams of these small businesses and many of them did not have the capability to pay for the outstanding bills of the water companies. This this led to an increase in the accounts receivable for the water companies which further affected the revenues and financial outlay for large scale engineering projects. This is shown by the reinforcing loop RW 4 in figure 1.

As shown in figure 1, the water quality has a direct impact on the risk of infection , which further effects water for WASH. while the risk of infection leads to further restrictions or lockdown, it has a direct impact on the industrial water consumption. The reduction in the economic activities lead to business closures and the payment capability of both individuals and businesses thereby further reducing the revenue for water companies. Furthermore, the supply chain disruptions Leeds shortage of materials and availability of industrial cleaning items. All these factors affect the maintenance of water systems which further negatively affects quality of the water and the loop continues.

CONCLUSION

Global supply chains and connectivity make it possible for us to source, produce, and consume goods from all over the world through the integrated network of supply chains that run continually throughout. And thus, business have realized the importance of keeping the supply operational and spend billions to ensure that there are no disruptions to this SC operations. The effects of SCDs on enterprises have been thoroughly investigated in the past. Nevertheless, little focus has been placed on how they affect people's lives on day-to-day basis and, consequently, the vulnerability of society. Business owners and policy makers have become aware of this due to the recent global SCDs due to COVID-19. Previous studies, while having studied exogenous risks from SCDs, usually do not consider both supply-and demand-side risks caused by SCDs. This study offers a novel outlook into the role of exogenous risks from SCDs, especially in the water sector, which can have both supply and demand implications. Furthermore, the study uses a system thinking approach to develop a holistic view of how SCDs produce ripple effects on the water sector. While this study offers a holistic perspective using systems thinking, more empirical research needs to be conducted to quantify the real impact of SCDs across the water value chain.

This study was carried out as part of Work Package 4, Task 4.3, under the CORE project, to study the impact of SCDs due to COVID-19 on creating social vulnerabilities. This was explored through the impact of SCDs on the water sector. Since this sector is critical to the functioning of society, it is imperative to ensure that it functions without disruption. The study also explores how SCDs affected the operational capabilities of the water sector and how they influenced both short-term and long-term operational capabilities.

ACKNOWLEDGMENTS

ABSTRACT

Small islands face unique challenges when it comes to increasing the resilience of their infrastructure systems, especially against climate-related disruptions. This proposal outlines a resilience-focused methodology for assessing critical infrastructure in such environments, integrating four interrelated phases: (1) literature review and documentary analysis to understand the context and existing knowledge, (2) conducting participatory workshops for local insights, (3) semi-structured interviews for in-depth perspectives, and (4) data analysis to integrate findings. This methodology, centered on participatory approaches, seeks to explore the dynamics of the impacts of disasters on the infrastructure of small islands. Developed as part of doctoral research at the German Aerospace Center and the University of Wuppertal, this methodology will be tested on Germany's East Frisian Islands from 2023 to 2026. Its emphasis on stakeholder involvement aims to bridge gaps in existing research and provide practical strategies to enhance the long-term disaster resilience of small islands communities.

Keywords

Infrastructure resilience, small islands, participatory approach, critical infrastructure, disaster impacts.

INTRODUCTION

Recent years have witnessed significant changes in global climate patterns, resulting in increased risks of adverse weather events and environmental change (Mycoo et al., 2022). These changes have profound implications, affecting various facets of society, from local livelihoods to infrastructure (Moser et al., 2012; Roy et al., 2023).

Among the most susceptible to these impacts are small islands, which face distinct challenges due to their physical exposure and limited space and resources (Kelman, 2010; Pörtner et al., 2022; Rampengan et al., 2014). Environmental changes also pose significant threats to the stability and operability of critical infrastructure (CI), such as public water services, energy supply, communication networks and transport, which are crucial to the functioning and security of island communities.

Disruptions caused by disasters can manifest themselves in various ways, including physical damage to infrastructure assets, disruptions to essential services such as transport and utilities, and socio-economic consequences such as loss of livelihoods and population displacement. In addition, the interconnected nature of infrastructure systems exacerbates the cascading effects of disaster disruptions, amplifying their overall impact on community well-being (Labaka et al., 2014; Pal et al., 2023).

As these disasters are often unforeseen in terms of time, magnitude and location, managing the resilience of CI becomes crucially important. Within this context, resilience refers to the capacity of a system to recover from

WiP Paper – Impact-driven Emergency and Crisis Management

challenges or disruptive events (Cantelmi et al., 2021).

Managing the resilience of critical infrastructure involves considering available risk management methods to integrate different perspectives and address complexity and uncertainty (Kröger & Zio, 2011). However, small islands encounter additional obstacles when increasing infrastructure resilience due to factors such as financial constraints, geographical limitations and dependence on external aid for disaster response and recovery (Pörtner et al., 2022; Rampengan et al., 2014).

Numerous studies have explored the resilience of CIs, but only a few have focused on small islands as a distinct system. In addition, studies addressing these impacts often take a mono sectoral approach, focusing only on specific sectors and neglecting the cascading effects, dependencies, and wider social impacts of disruptions (Bruijn et al., 2019).

These issues highlight the need for innovative methodologies that not only understand the intricate dynamics of disaster disruptions to infrastructure systems but also facilitate the formulation of context-specific resilience strategies for small islands.

In addressing such challenges, participatory engagement emerges as a key function in building resilience in small island communities. By actively involving stakeholders in decision-making processes, participatory approaches benefit from local knowledge and insights, thus facilitating the development of context-specific resilience strategies (Jamero et al., 2018).

In this study, a resilience-focused methodology will be developed and proposed to analyze the impacts disaster events on CIs and societal well-being in small island contexts. By examining the impacts, duration, severity, and dependencies, the aim is to propose a methodology to measure and/or enhance resilience and safeguard the sustainability of small islands. Through a participatory approach, stakeholders are involved in developing strategies to strengthen infrastructure resilience and mitigate disaster disruptions.

CURRENT STATE OF THE ART

Disaster Impacts in the Context of Small Islands

Although there is no clear definition in the literature in terms of population or size, small islands can be broadly classified into three types (Petzold & Magnan, 2019): Small Island Developing States (SIDS), Dependent Islands, and Semi-Autonomous Subnational Island Jurisdictions (SNIJs). SIDS are recognized for their vulnerability to climate change and have been prominent in international discussions and research on this topic. Dependent islands are territories that, while not independent, are part of larger continental states and often have limited access to international aid, relying instead on national development strategies and funds. SNIJs possess a degree of autonomous government and are involved in a formal political partnership with a larger state, but they may face challenges such as limited regional cooperation and internal migration.

Despite socio-political differences, these island types share common issues related to climate change and general vulnerability due to their unique geographical and socio-economic characteristics. These impacts encompass shifts in atmospheric and oceanic conditions, leading to phenomena like sea level rise, ocean warming, ocean acidification, and alterations in extreme weather patterns such tropical cyclones and hurricanes (Nurse et al., 2014).

Extreme weather events, like hurricanes and cyclones, can inflict severe damage on small island infrastructure, including critical systems like energy, water, and sanitation (Nurse et al., 2014). Coastal infrastructure is especially vulnerable, with storm surges and high winds threatening seawalls, roads, and buildings near the shore. Limited resources for emergency response and reconstruction further exacerbate the challenges faced by these islands.

The primary effects of climate change also trigger secondary impacts, such as saltwater intrusion into groundwater and soils, marine flooding, and shifts in species distribution due to temperature and precipitation changes (Holding et al., 2016). Intrusion of saltwater can degrade water infrastructure and agricultural land, posing threats to food and water security.

From a social aspect, common challenges across small islands include limited regional-scale climate information, governance complexities, and economic vulnerabilities. These islands often rely heavily on natural resources like fisheries and tourism, making them particularly susceptible to climate-induced disruptions (Hiwasaki et al. 2014). Population dynamics, ranging from urbanization to depopulation, further strain their capacity to adapt to climate and environmental change. Moreover, small islands often depend on external financial resources and aid for development and climate change adaptation, with governance structures and historical legacies shaping their

adaptation capabilities.

Despite their vulnerabilities, small islands possess characteristics that could enhance their resilience to climate-related challenges, such as dense social networks, experience in coping with environmental adversity, and traditional knowledge (Ratter & Ratter, 2018).

CI and CI Resilience

Critical Infrastructure (CI) encompasses the essential facilities and systems crucial for the functioning of urban and rural areas, such as railways, roads, tunnels, bridges, power grids, energy sources, electricity networks, telecommunications, water supplies, sewers, etc. (Feofilovs & Romagnoli, 2017). They play a central role in society, especially when facing both technological and natural disasters.

The definition of CI is not universally standardized, as different entities and regions have varying perspectives on what constitutes CI. For instance, the U.S. Department of Homeland Security considers infrastructures critical if their incapacity would significantly impact defense and economic security (U.S Department of Homeland and Security, 2022), while the European Commission identifies CIs as those whose disruption would seriously affect the health, safety, security, or economic well-being of citizens or the functioning of governments in the European Union (EU) (EUR-Lex, 2010).

Despite the lack of a universally accepted definition, all conceptions of CI emphasize its vital role and the potentially severe societal consequences in the event of its disruption. Similarly, the term “resilience” is multidisciplinary and poses challenges in its definition. Originating in mechanics, it initially described an object's capacity to revert to its original form after undergoing external forces without fracturing (Holling, 1973). Over time, it has found broad application across various disciplines including ecology, sociology, psychology, etc. (Bruneau et al., 2003).

When applied to CIs, the concept of resilience emphasizes the ability capacity of a system to widely recover following disasters, even when infrastructure systems experience localized damage due to severe natural or human-induced disruptive occurrences (Ouyang et al., 2019). The concept is also applied to the interdependencies between CIs, recognizing that the failure of one infrastructure can have cascading effects on others (Pal et al., 2023).

CI Assessments and Participatory Approaches

Resilience is often assessed through indicators and variables that affect CIs’ organizational functionalities. They provide a means to assess baseline conditions, measure the effectiveness of interventions, and track resilience progress over time (Bruijn et al., 2019).

An indicator is factual data that can be measured, and its assessment can adopt quantitative, semi-quantitative or qualitative formats. Quantitative approaches offer standardized measures to quantify value across applications and frameworks tailored to specific domains. Semi-quantitative approaches provide numerical descriptions without complex formulas or models, while qualitative methods rely on subjective analyses and judgments, often incorporating insights from surveyed experts or operators (Cantelmi et al., 2021).

Evaluating the current resilience of a system can be accomplished through two main approaches. Firstly, by analyzing how the system responds to an event and measuring the extent of disruption or recovery across various scenarios. For example, Barabadi et al. (2020) examined the resilience of health infrastructure before and after the COVID-19 pandemic, assessing its ability to withstand and recover from the crisis.

Alternatively, resilience can be assessed by identifying the inherent characteristics of the system that promote resilience. This involves pinpointing societal factors and infrastructure qualities that contribute to resilience, such as the 100 Resilience City Framework developed by ARUP (2018). By evaluating the presence of these characteristics, analysts can gauge the system's capacity to adapt and recover from disruptive events.

Participatory processes are particularly valuable in capturing indicators in small island settings, as they facilitate the inclusion of perspectives from potentially marginalized groups into resilience planning and implementation (Bedsted and Gram, 2013). A participatory approach involves actively engaging community members in decision-making processes, ensuring that their perspectives are incorporated into the development of resilience strategies and actions (Jamero et al., 2018).

However, it's essential to recognize that labeling an approach as "participatory" does not guarantee its inclusivity at all scales, as cautioned by Cunningham (2019). This process must be accompanied by accountability and transparency to ensure that responsibility for critical infrastructure (CI) resilience is translated into practice. It

goes beyond mere consultation, emphasizing collaboration and partnership between researchers, policymakers, and local stakeholders.

This approach has been applied across various settings, as demonstrated in Talubo et al. (2022), where a combination of participatory methods was used to identify composite indicators for assessing disaster resilience in an island community.

PROPOSED METHODOLOGY

The approach proposed in this methodology involves examining the system's response to an event, quantifying both the disturbances, impacts, and dependencies, and the subsequent recovery across a specific scenario. The methodology will be employed as part of a 2023-2026 doctoral study program conducted at the University of Wuppertal and the German Aerospace Center, focusing on the East Frisian Islands in Lower Saxony-Germany as a case study. The East Frisian Islands present a pertinent context for this research due to their small island setting, vulnerability to climate change-induced hazards, and reliance on CI for socio-economic activities and community well-being.

Utilizing case studies as a research method are valuable in comprehending how individuals and communities respond to contemporary events and issues (Robson & McCartan, 2016; Yin, 2018). An exploratory approach guides the investigation of these case studies, allowing for a deeper understanding of the factors influencing priorities in the face of climate-related hazards. This approach is particularly suitable when exploring issues beyond the researcher's control, such as the unpredictable nature of climate impacts (Yin, 2018).

The study advocates a stakeholder-led approach, emphasizing the central role of participatory approaches in data collection. These methods are structured to develop in four distinct but interrelated phases, which may at times take place simultaneously:

- On Phase 1, thorough examination of existing literature, documents, reports, and academic publications an initial literature review and documentary analysis are conducted to gain a comprehensive understanding of the contextual factors and distinctive challenges encountered by small island communities, with a specific focus on the case study area.
- Phase 2 brings together stakeholders in participatory workshop(s) conducted in collaboration with local authorities, community representatives, and infrastructure managers. These will serve as interactive platforms for assessing the impacts of disaster disruptions on infrastructure systems, taking into account dependencies and cascade effects.
- On Phase 3 semi-structured interviews are conducted as a complementary approach to further enrich the insights gained from other phases, particularly regarding stakeholders' perceptions and experiences.
- Phase 4 employs an integrated qualitative and/or quantitative analysis based on the findings from the scenario-based impact assessments in order to refine strategies for mitigating disruptions and enhancing CI resilience.

Phase One: Literature Review and Documentary Analysis

The methodology employed in this study encompasses an extensive review of existing literature on disaster impacts, infrastructure resilience assessments, and participatory approaches in small island contexts. This review aims to identify gaps and relevant concepts pertinent to the subject matter, focusing on the specific context and requirements of the small island(s) to be assessed.

To conduct the literature review, a systematic approach is adopted, involving keyword searches, content analysis, and the examination of titles and abstracts to identify relevant literature. This approach ensures a comprehensive understanding of the current state of knowledge in the field, allowing for the identification of key themes, trends, and areas requiring further investigation. The review encompasses a range of sources, including scientific studies, case reports, and institutional documents, focusing on climate change vulnerability and resilience in small island contexts.

In addition to the literature review, a documentary analysis method is employed for the study case(s). This qualitative technique involves the analysis of content within various documents, such as official reports, meeting minutes, newspaper articles, social media posts, and other written or recorded content. Documentary analysis is valuable for gaining deeper insights into the research topic, complementing research efforts (Robson & McCartan, 2016).

The records produced during documentary analysis provide a deeper understanding of the case studies as real-world communities, serving as a vital step before fieldwork begins. Specific key questions addressed include which scenarios, key stakeholders, and elements of infrastructure should be included in the assessment process. An example of potential CI sectors to be considered is presented in Table 1 (Petrakos & Kotzanikolaou, 2019).

Table 1: Example of CI sectors and their respective service/organizations.

CI Sector	Service/Organizations
Transport	- Air/road/train/maritime transport
	- Services and network
Water (supply and disposal)	- Storage, distribution, quality
	- Collection and treatment
Energy (electricity, petroleum, gas, etc.)	- Production, transport and distribution
Health	- Emergency healthcare
	- Hospital care
	- Medical supplies
	- Nursing care
Food	- Agriculture/fishery production
	- Food supply and distribution
Information technologies & media	- Web/cloud services
	- Internet, voice/data communication
	- Media press and broadcasting
Administration	- Government functions (economy, engineering, etc.)
Defense and civil protection	- Crisis management, emergency and rescue services
Tourism	- Touristic infrastructure (property, visitors' sites, recreational services)
	- Sector employment
Housing and land use	- Village urban planning zone
	- Private and public properties
Community and social organizations	

Phase Two: Participatory Workshops

Participatory workshops are conducted on the selected small islands to engage communities in assessing potential impacts and cascading effects on infrastructure using developed scenarios.

Scenarios serve as a crucial tool to address uncertainty, particularly concerning poorly understood, difficult-to-quantify, or unidentified risks. They provide a systematic method for assessing how diverse and complex risks could impact society, essentially evaluating the resilience of systems to potential disruptions (Strong et al., 2020).

During the workshops, collaboration between various stakeholder groups, including community members, municipal representatives, critical infrastructure operators, authorities and organizations with security tasks, is encouraged to address concrete indicators of functionality in crisis events and dependencies on other organizations. This participatory approach promotes dialogue, knowledge exchange, and collective problem-solving (Bizikova et al., 2011; Sheppard et al., 2011), and has also been recorded in the particular context of coastal communities (Simpson et al., 2012). Peer learning is also promoted, as workshops lead to a facilitated exchange of best practices and experiences between participants.

The workshops are structured to commence with an explanation of the workshop's purpose and an introductory keynote addressing key issues faced by small islands during disasters, emphasizing the significance of evaluating their impacts on infrastructure and population.

Then, participants are presented with a range of potential scenarios, covering sudden-onset hazards ranging from

natural occurrences such as floods, coastal erosion, droughts or storms, to human-induced events such as blackouts, disease epidemics or civil conflicts (Strong et al., 2020). These scenarios are discussed among the participants and ranked based on their potential impacts and occurrence probability in their small island context.

In the second part, one scenario is selected for further analysis. Stakeholders identify emerging issues from the selected scenario for their respective facilities and interests, explore mutual dependencies, and support potentials between different organizations. Questions to stakeholders revolve around indicators: variables that affect their organization's functionalities (e.g. number of accommodation facilities or access sea routes into the island at a given time). Questions are exemplified below:

- What indicators are necessary in your organization to ensure its functionality? Give examples in measurable and comprehensive units.
- How can those indicators be impacted in each disaster scenario?
- What dependencies exist with other organizations? What possible impact does the non-conformity of these dependencies have on the infrastructure system and population?
- What challenges do you foresee arising in your organization from each scenario?

The results are collectively discussed, and the points raised by the participants can be listed and placed in diagrams for better visualization of the CIs and their dependencies. After the discussion, a feedback session takes place to gather additional insights and perspectives.

Phase Three: Semi-Structured Interviews

Building upon workshop insights, interviews are conducted with identified actors from the study area(s) to gather valuable insights into various aspects of the island's infrastructure and also to complement the data and results of the other phases.

The semi-structured interview provides consistency in conversations through predefined prompts, while also allowing for unexpected topics of interest to be explored and for clarifications/follow-up questions from participants' answers (Paine, 2015).

These interviews are conducted with experts who possess relevant knowledge or access to such knowledge within their organizational units. The insights provided by these experts offer valuable perspectives on different facets of the island's infrastructure, contributing to a comprehensive understanding of its strengths, weaknesses, and resilience.

Considering the scenario chosen during the workshops, a second part of the interview focuses on what kind of mitigating actions could be implemented by the organization or sector itself or in collaboration with others.

Interview questions and dynamics are flexibly structured to ensure alignment with the research objectives and methodology. This flexibility allows for the exploration of diverse topics related to infrastructure resilience, climate change impacts, and disaster preparedness. It also facilitates the first hand transmission of participant knowledge and expertise, enabling researchers to glean nuanced insights into the challenges and opportunities facing the island's infrastructure.

Phase Four: Data Analysis

Data obtained from phases 1, 2 and 3 can be examined using quantitative or qualitative approaches. The debate over which method to use when studying complex issues is tenuous, as each approach has its own strengths and weaknesses (Matsika et al., 2016).

Decision makers often favor quantitative data for their decision-making processes, especially in analyses like cost-benefit assessments that require numerical values (Matsika et al., 2016). However, qualitative assessments offer valuable context and understanding, complementing quantitative data (Bernroider et al., 2016).

For instance, Van Laere et al. (2017) investigated challenges encountered during disruptions in the payment system using inductive qualitative research methods. Through document analysis, interviews with key sector representatives, and workshops with local and national stakeholders, they developed scenarios and identified resilience challenges for CIs. Their analysis underscored the importance of addressing communicative challenges such as maintaining trust and preventing panic among the public, alongside technical solutions.

However, Fekete & Fiedrich (2018) expressed skepticism about measuring resilience quantitatively due to the complexity of CIs but also cautioned against relying solely on qualitative assessments. They advocated for a

mixed-methods approach, combining quantitative and qualitative dimensions to provide a broader perspective and cater to diverse end users. Münzberg et al. (2017), exemplifies this approach on supporting community resilience through a spatial-temporal vulnerability assessment. By integrating various indicators using the Delphi method and Monte Carlo simulation, they provided decision-makers with a comprehensive understanding of power outage impacts, aiding in resilience-building efforts.

In the context of disaster resilience and CI, the data analysis techniques may involve utilizing quantitative methods to analyze numerical data collected during impact assessments or participatory workshops. This could include statistical analysis to identify patterns or trends in the data.

Qualitative data analysis techniques, on the other hand, may involve thematic analysis of interview transcripts or documentary analysis findings. This qualitative approach allows researchers to explore the nuanced perspectives and experiences of stakeholders, providing rich insights into their perceptions and behaviors.

CONCLUSION

The resilience-focused methodology proposed in this study offers a comprehensive structure for assessing infrastructure resilience in small island environments. By synthesizing findings from literature reviews, documentary analyses, interviews and participatory workshops the methodology aims to capture the complex dynamics of disaster impacts and cascading effects within these vulnerable contexts.

One key feature of the proposed methodology is its emphasis on scenario-based participatory approaches, which enable stakeholders to actively engage in the assessment process and explore various resilience strategies. Through this collaborative approach, the methodology seeks to provide a nuanced understanding of how disasters disrupt infrastructure systems and the subsequent consequences on communities.

Moreover, the discussion surrounding the choice between quantitative and qualitative approaches to analyze the data highlights the flexibility inherent in the proposed methodology. By acknowledging the advantages and drawbacks of each approach, the methodology offers researchers and organizations a practical guide for tailoring their assessment strategies to the unique characteristics of small island settings. Overall, the application of this methodology may generate contributing results for advancing knowledge on infrastructure resilience and supporting efforts for mitigating the impacts of disasters and safeguarding the sustainability of small islands globally.

ABSTRACT

Coastal regions in China have long been plagued by tropical cyclone (TC) disasters, and TC vulnerability function for disaster-bearing bodies is a widely used quantitative vulnerability assessment method in face of TCs. TC vulnerability functions may vary across different regions due to geographical heterogeneity, hindering this method from universal use. This study systematically collects a 15-year-long dataset from 12 provinces in China. Six alternative TC vulnerability functions are comprehensively investigated by province, and a library of the optimal TC vulnerability functions for three kinds of disaster-bearing bodies, that is, economic, population, and crop in different provinces is developed. The heterogeneity of TC vulnerability in different provinces along the coastal areas in China is then thoroughly analyzed. This paper provides a deeper understanding of the spatial heterogeneity characteristics of disasters and disaster-bearing bodies, and provides good references for local departments to carry out more targeted disaster prevention and reduction work.

Keywords

Tropical cyclone, vulnerability functions, coastal areas in China, disaster loss assessment.

INTRODUCTION

Tropical cyclones (TCs) are low-pressure vortices that occur over tropical or subtropical oceans. A TC with a central sustained wind speed of 32.7 to 41.4 meters per second is named as a typhoon (located in the western North Pacific) or a hurricane (located in other typhoon-prone regions) (WMO, 2022; National Meteorological

WiP Paper – Impact-driven Emergency and Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

Information Center, 2023). It is reported that TCs are natural disasters that have a wide range of impacts and are extremely destructive. Over the past twenty years, there have been a total of about two thousand tropical storms globally with a wide distribution in Asia, North America and Europe. The number of people affected by TCs accounted for 19.52%; the number of deaths and missing persons accounted for 19.17%; and the direct economic losses accounted for 48.57% of the total global natural disasters (Academy of Disaster Reduction and Emergency Management et al., 2023). Relevant data show that the TC disaster is one kind of the main natural disasters faced by human beings, which needs great and urgent attention.

The area of China's coastal provinces and provinces adjacent to coastal provinces is a typical region most severely hit by typhoons (Xu et al., 2015; Wan et al., 2023). Every year, a large number of typhoons make landfall in the southeastern coastal areas of China, causing huge losses. In August 14th, 2019, typhoon "Likima" affected a total of 14.02 million people in China with 2.10 million people urgently relocated, and caused 57 deaths, as well as a direct economic loss of 53.72 billion yuan. In September 5th, 2023, typhoon "Haikui" had caused record-breaking extreme rain in Fujian, Guangdong, and other places. Many findings also suggest that typhoon disasters in coastal areas in China will become increasingly severe in the future (Lee et al., 2020; Wang et al., 2021). Therefore, it is of great significance to study typhoon disasters in China's coastal areas.

In this study, the classic method of typhoon vulnerability functions is utilized to depict the current typhoon risk in China's coastal area. It is widely recognized that typhoon vulnerability functions have significant spatial heterogeneity. This paper currently focuses on the heterogeneity of typhoon vulnerability functions in different provinces along the coastal areas in China. Considering that the loss of typhoon disasters not only depends on the typhoon intensity itself, but also depends on the resilience characteristics of disaster-bearing bodies and the scientific nature of disaster prevention measures, the authors believe that the results provided by this paper have an important reference value for improving emergency management capabilities and strategies in future emergency work in face of typhoons.

The remainder of the paper is organized as follows. Section 2 is the literature review, which reviews the application areas of vulnerability curve methods and their specific applications in typhoon loss assessment. Section 3 outlines the writing approach of the article. Section 4 introduces the research area and data sources used in the paper. Section 5 presents the form of vulnerability curves selected for this study. Section 6 analyzes the heterogeneity of vulnerability curves in the study area. Section 7 discusses the limitations of the research and future directions. Finally, Section 8 summarizes the main findings and their significance.

LITERATURE REVIEW

Vulnerability and Vulnerability Curve

With the concept of "vulnerability" being widely used in multiple fields during the past decades, such as politics (White at al., 2018), economic (Barnett, 2020), ecosystem (Xu et al., 2023), infectious disease (Shifa et al., 2022), and disasters (Colombi et al., 2008; Godfrey et al., 2015), etc., more and more scholars in the field of disaster studies began to pay attention to the technology of vulnerability functions, which could be rapidly assessed the risk. The vulnerability function, also known as the vulnerability curve, is a quantitative assessment method depicting the relationship between the intensity of hazard factors and the loss degree of the disaster-bearing bodies. The vulnerability function (curve) is usually represented in a two-dimensional coordinate system, where the horizontal axis represents the hazard intensity, such as rainfall intensity or wind speed, etc., and the vertical axis represents the loss degree of the disaster-bearing bodies, such as the loss rate of crops, buildings, or economic, etc. (Zhang et al., 2016).

The Application of Vulnerability Curves/Functions in the Field of Disasters

The vulnerability curve has been widely applied across various fields in recent years. It has become a crucial component in disaster assessment, quantitative risk analysis, and the creation of risk maps. Zhou et al. summarized the research progress of vulnerability curves for various disasters, including floods, earthquakes, landslides, droughts, typhoons (hurricanes) (Zhou et al., 2012). Monteleone et al. reviewed 52 articles on vulnerability curves of different crops under extreme weather events and climate change, outlining the vulnerability curve forms of different crops under conditions such as droughts, floods, and cold weather (Monteleone et al., 2023). Papathoma-Köhle et al. summarized the three analysis methods and advantages and disadvantages of physical vulnerability analysis for buildings based on debris flow disaster, including vulnerability matrices, curves, and indicators (Papathoma-Köhle et al., 2017). Vamvatsikos et al. reviewed existing concepts and methods for assessing structural vulnerability to natural disasters (earthquakes, landslides, tsunamis, and wind disasters) from a structural

and engineering perspective (Vamvatsikos et al., 2010). This indicates that the application scope of vulnerability curves in the disaster domain is wide, with diverse forms and a rich variety of vulnerability assessment targets covered.

The Current Status of Vulnerability Curves in TC Risk Assessment and Loss Analysis

Nowadays, TC vulnerability function/curve method has been a widely recognized and effective method in TC risk assessment and loss analysis. There are usually two methods to establish the typhoon vulnerability function/curve - one is the engineering experiment (simulation) method, and the other is the field investigation (data inversion) method. As to the engineering experiment (simulation) method, the techniques like wind tunnel test and computer simulation are usually used to detect under what TC intensity a whole building or structural parts will fail; then, based on the original value or the reconstruction cost of the structure, the loss rate of the structure can be calculated (Zhong et al., 2017). For example, the Hazus model and the Florida hurricane model applied by the U.S. government used the structural engineering simulation to build the building vulnerability (Pinelli et al., 2011; Vickery et al., 2006a, 2006b). Compared with the engineering experiment (simulation) method, the field investigation (data inversion) method, which is based on real historical data record, is usually able to obtain data closer to the real result. Acosta et al. assessed typhoon damage in Philippine schools using empirical vulnerability curves, based on damage quantification against maximum local wind speeds (Acosta et al., 2018). Zhu et al. developed a road vulnerability model against TCs in Hainan Province, using historical road damage data and historical TC intensity measures like precipitation and wind speed (Zhu et al., 2022).

Despite numerous studies on TC vulnerability functions, it should be noted that TC vulnerability functions often differ across regions due to the geographical spatiotemporal heterogeneity. Limited by the availability of research data, many studies only focus on a specific province or city without comparing differences between different regions. In some practical applications, there have been cases where the typhoon vulnerability curve of a certain province has been used to assess losses in another province when the historical data records of the latter is inaccessible, introducing significant human error into typhoon damage assessments. Therefore, developing a library of typhoon vulnerability functions suitable for different regions has become a worthwhile hotspot in this field.

THE OVERALL STRUCTURE

The overall structure of this study is shown in Figure 1. The region studied comprises twelve coastal provinces and provinces adjacent to coastal provinces in China, having a characteristic of being vulnerable to typhoons. The basic data by province and a 15-year-long typhoon dataset in all provinces, including disaster intensity and losses caused by TCs, are collected. Based on the basic dataset, six alternative vulnerability functions are calibrated to fit the loss rates of the economic, population, and farmland in each province, respectively, and finally, the optimal vulnerability functions are selected to profile the losses caused by typhoons. The heterogeneity of the losses of different disaster-bearing bodies in different provinces along the coastal areas in China are analyzed. The results provided by this paper could provide a profound understanding of typhoon disasters in coastal areas in China, and also the reference and technological support for the government emergency management to cope with typhoon disasters.

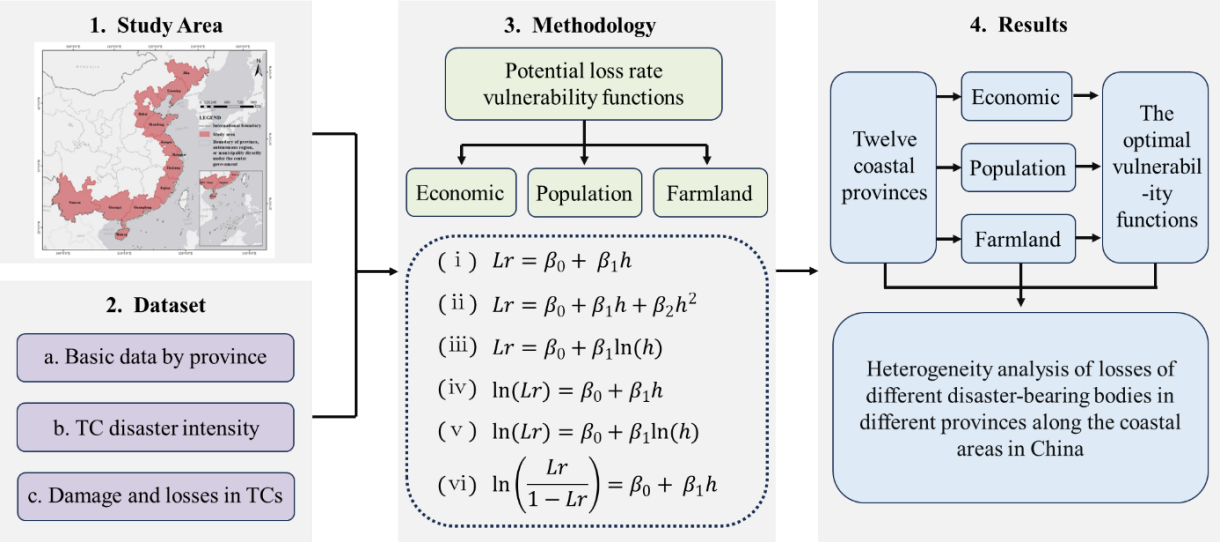

Figure 1. The Overall Structure of This Study

STUDY AREA AND DATASETS

Study Area

"China Marine Statistical Yearbook" defines coastal areas as regions with coastlines, including both categories of mainland coastlines and island coastlines (Ministry of Natural Resources of the People's Republic of China, 2017). According to this definition, ten coastal provinces in China are considered in this paper, including Liaoning, Hebei, Shandong, Jiangsu, Shanghai, Zhejiang, Fujian, Guangdong, Guangxi, and Hainan. According to the historical records of typhoon-related disasters and the impact of typhoons, Jilin Province and Yunnan Province are also tagged as provinces prone to typhoons, so these two provinces are also included in the scope of this study. Due to the data availability issue, Tianjin Province, Taiwan Province, Hong Kong Special Administrative Region (SAR) and Macao SAR are temporarily not taken into account in this paper. Summarily, this study includes 12 provinces in total. Figure 2 illustrates the study area in this study.

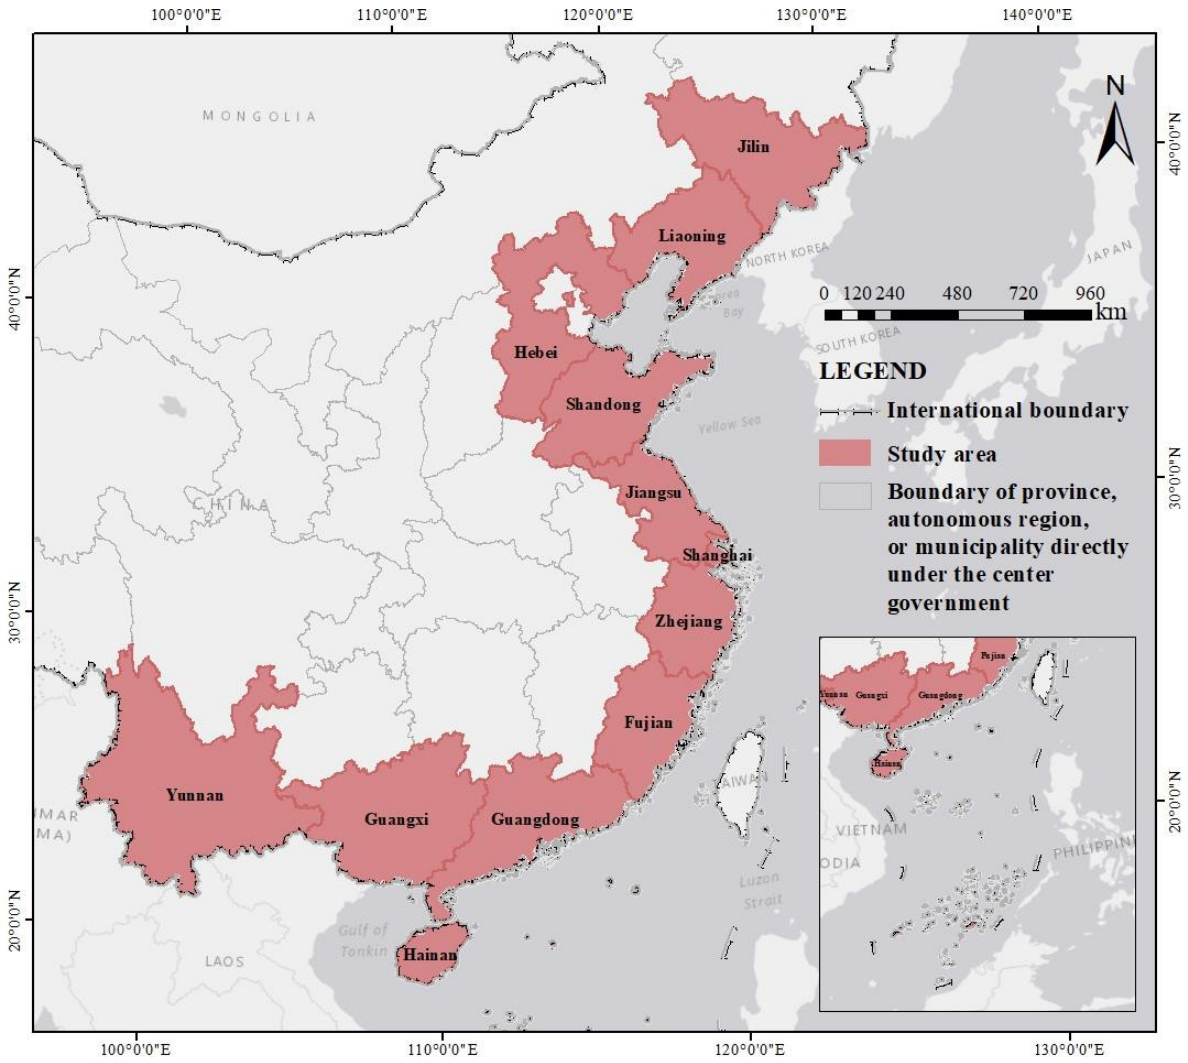

Figure 2. The Study Area in This Study

The basic situations of all the provinces involved in this study are shown in Table 1. It should be noted that the number of meteorological stations in Table 1 refers to the number of the stations which have ever reported the total cumulative rainfall during the typhoons. Stations that do not give records are not counted. The precipitation data from multiple meteorological stations consider the spatial heterogeneity of total rainfall in each province. A total of 451 typhoons with recorded disasters occurred in 22 provinces in China from 2003 to 2018. Among them, the 12 provinces selected for this study experienced a total of 357 typhoon events, indicating that this region is under serious threat of typhoon disasters.

Table 1. Basic Overview of The Study Area (Using Data in 2018)

Province	Gross Regional Product (100 million yuan)	Population (10000 persons)	Total Sown Area (1000 hectares)	Number of meteorological stations	Number of typhoons from 2003 to 2018
Jilin	15074.6	2704	6080.9	6	5
Liaoning	25315.4	4359	4207.1	5	12
Hebei	36010.3	7556	8197.1	5	9
Shandong	76469.7	10047	11076.8	6	16
Jiangsu	92595.4	8051	7520.2	7	21
Shanghai	32679.9	2424	282.3	1	17
Zhejiang	56197.2	5737	1978.7	5	44
Fujian	35804	3941	1577.3	3	59

Guangdong	97277.8	11346	4279.4	7	69
Guangxi	20352.5	4926	5972.4	6	45
Hainan	4832.05	934	712.9	2	45
Yunnan	17881.1	4830	6890.8	8	15

Datasets

Since the precipitation data for each typhoon is only available until 2018, this study covers a period of 15 years from 2003 to 2018. The basic data by province, such as gross regional product (GRP), population, and sown area are obtained from the "China Statistical Yearbook" (National Bureau of Statistics of China, 2004-2019). The total precipitation caused by individual typhoons, a factor contributing to disasters, is extracted from the Tropical Cyclone Data Center of the China Meteorological Administration (Ying et al., 2014; Lu et al., 2021). The typhoon disaster loss data, including direct economic losses, affected population, and affected crop area, are sourced from the "Yearbook of Meteorological Disasters in China" (China Meteorological Administration, 2004-2019). All the involved data is publicly available, and the authors have placed download links of all the data in References section.

METHODOLOGY

The alternative forms of the TC vulnerability functions considered in this paper are inspired by the work by Jiang et al. (Jiang et al., 2023). The general form of the vulnerability regression model with the loss rate as the dependent variable is as follows:

$$g(Lr) = f(h) + \varepsilon, \varepsilon \sim N(0, \sigma^2) \quad (1)$$

Where Lr denotes the loss rate; $g(Lr)$ denotes the transformation function of the dependent variable Lr ; h denotes the hazard intensity that serves as the independent variable; $f(h)$ denotes the regression function of the independent variable h. The function $f(h)$ may depend on several parameters, denoted by β_0, β_1, etc., which remain to be estimated. ε denotes the random error term, usually conforming to the normal distribution.

Vulnerability regression models can be categorized into three main types: linear models, logarithmic models and probability curve model.

Linear Models

The linear model does not transform the dependent variable (the loss rate) to other mathematical forms. That is, $g(Lr) = Lr$. The linear models comprise three forms, namely simple linear model, polynomial model, linear-logarithmic model. The formulas are as follows, respectively.

$$Lr = \beta_0 + \beta_1 h \quad (2)$$

$$Lr = \beta_0 + \beta_1 h + \beta_2 h^2 \quad (3)$$

$$Lr = \beta_0 + \beta_1 \ln(h) \quad (4)$$

where: β_1 denotes the slope parameter, indicating the degree and trend of the change in the loss rate with change in hazard intensity. β_0 denotes the intercept parameter, representing the baseline loss rate when the hazard indicator is zero. In formula (3) β_2 denotes quadratic term. It should be noted that, although a non-zero intercept term is challenging to interpret, β_0 is not forced to be zero in this study. The main reason for this is that the cumulative rainfall intensity during a typhoon, which is selected as an indicator for hazard intensity, may not paint the full picture of that typhoon. Therefore, setting the parameter β_0 artificially to zero may not make sense.

Logarithmic Models

Logarithmic models involve the operation of taking the logarithm of the dependent variable Lr, that is, $g(Lr) = \ln(Lr)$. The logarithmic models comprise two forms, namely logarithmic-linear model and logarithmic-logarithmic model. The formulas are as follows, respectively.

$$\ln(Lr) = \beta_0 + \beta_1 h \quad (5)$$

$$\ln(Lr) = \beta_0 + \beta_1 \ln(h) \quad (6)$$

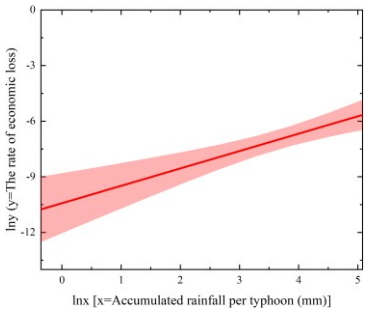
where: the slope parameter β_1 in Formula (5) and Formula (6) represents the absolute change and the relative

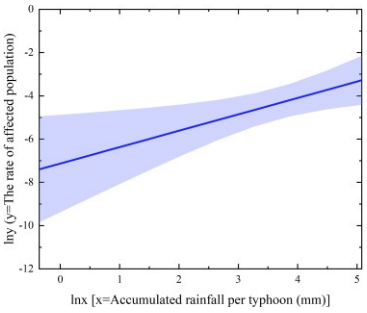
change in hazard intensity, respectively.

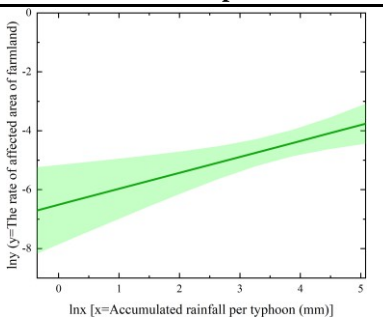
Probability Curve Model

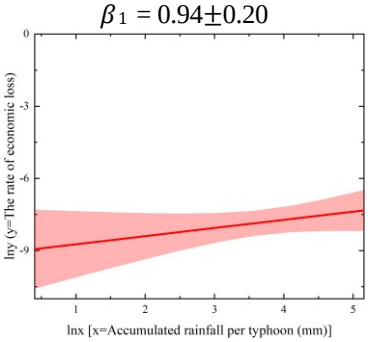
Linear models and logarithmic models cannot guarantee that the predicted values of the loss rate will fall entirely within the interval of [0, 1]. In order to overcome this shortcoming, another function form is introduced here which takes the logarithm of the ratio of the loss rate Lr to $(1 - Lr)$. This model is named as logistic curve model. The formula is as follows.

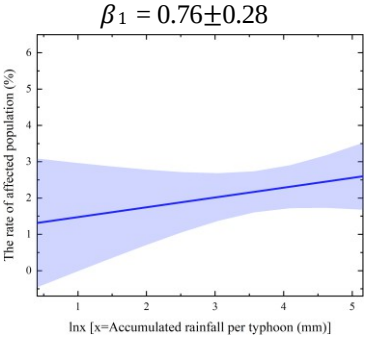
$$\ln\left(\frac{Lr}{1 - Lr}\right) = \beta_0 + \beta_1 h \tag{7}$$

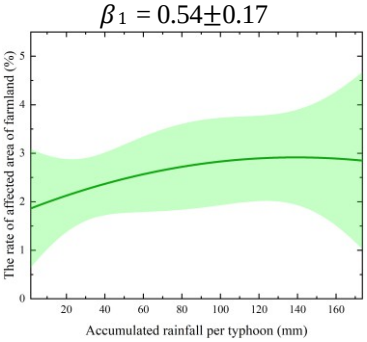




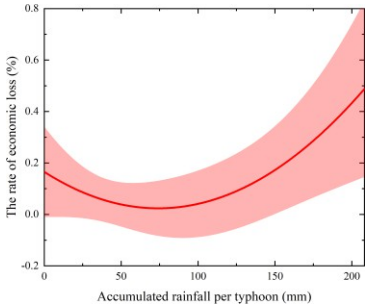


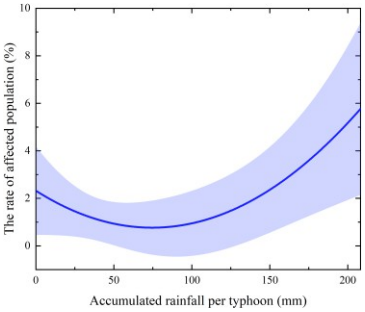


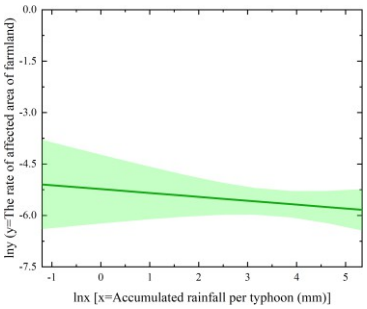


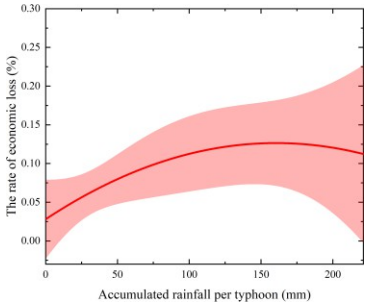


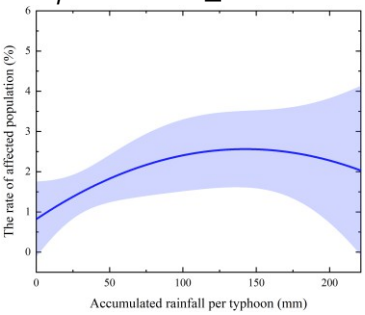
RESULTS

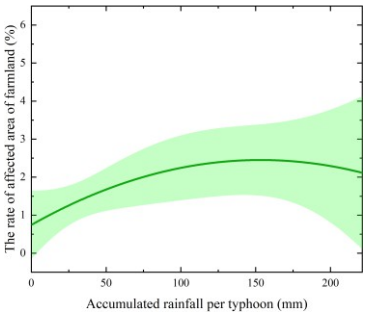


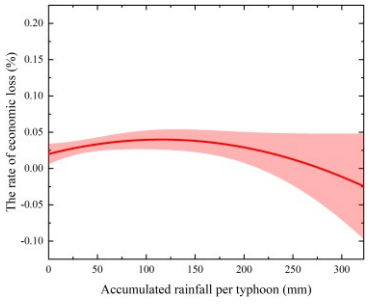


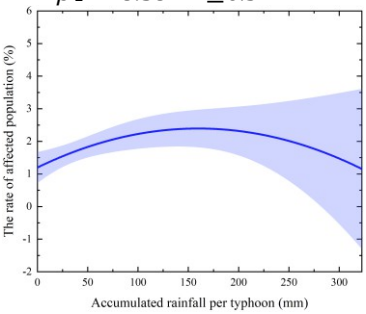


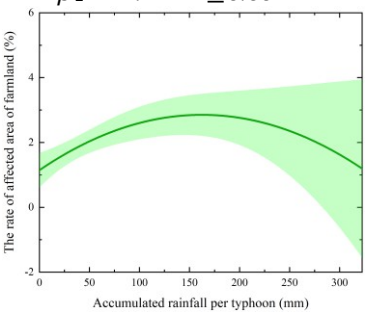


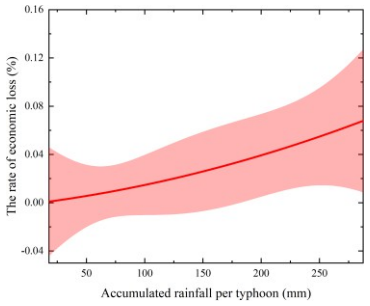


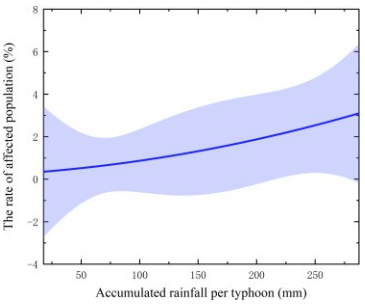


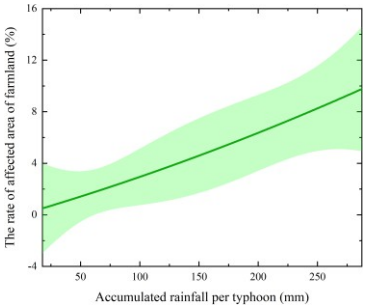






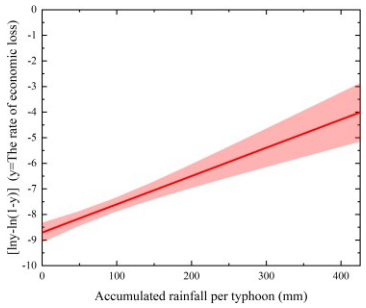


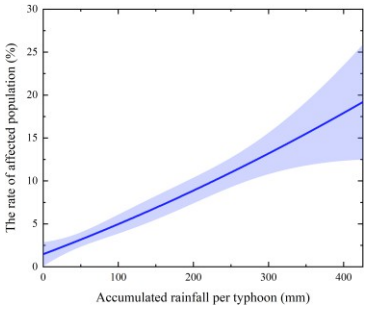


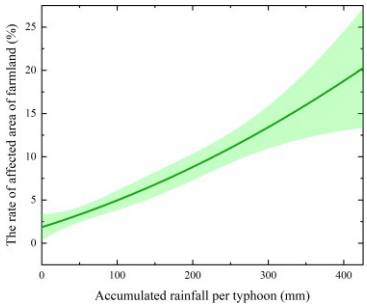


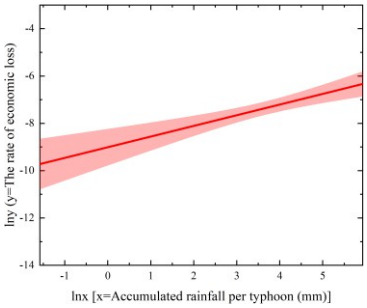
The Optimal Vulnerability Functions of Economic, Population, and Crop in Different Provinces

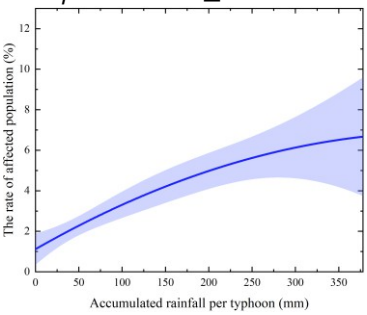
The refined data of all single typhoons transiting the study area from 2003 to 2018 were collected in this study. The accumulated rainfall during the typhoons at various meteorological stations were compiled as the independent variable. For all the 12 provinces, three kinds of disaster-bearing bodies are considered, including economic, population, and crops. The data of the disaster-bearing bodies were normalized by dividing the loss values by the total amount, that is, the area of affected crop is divided by the sown area; the affected population is divided by the year-end population; and the economic loss is divided by the year-end GDP, respectively. Finally, the economic loss rate, the affected population rate, and the affected crop rate were obtained and then considered as the dependent variables in this study.

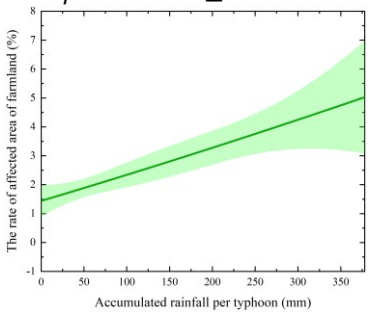


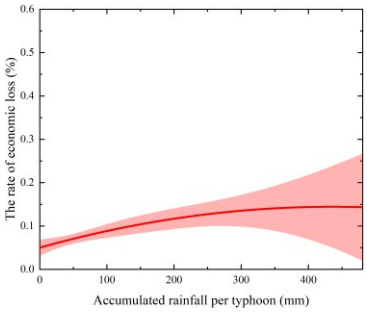


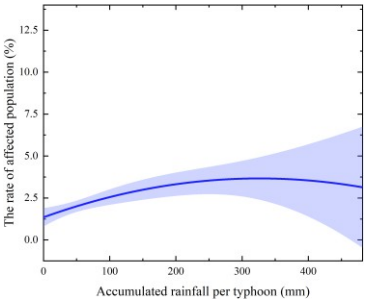


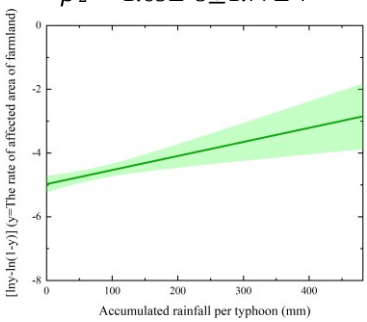


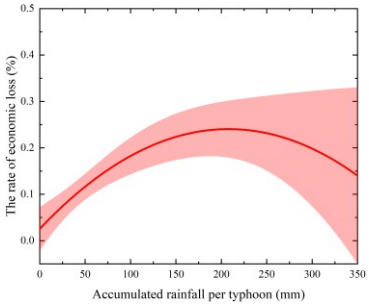


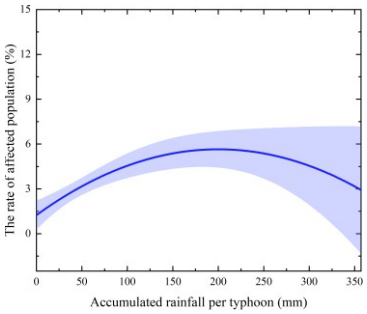


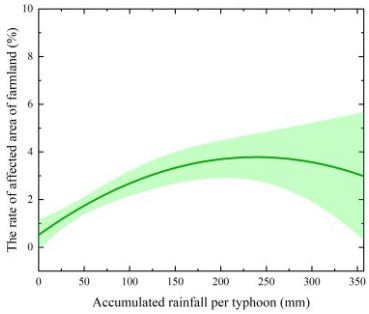












The provincial data were fitted to alternative vulnerability models introduced in Methodology section and the optimal vulnerability function was finally selected by comparing the *R*-squared values of different curves. A 95% confidence interval was plotted for each optimal vulnerability curve to depict the potential range of $f(h)$ at a 95% confidence level. The aggregated results of all the optimal vulnerability functions are presented in Table 2 below.

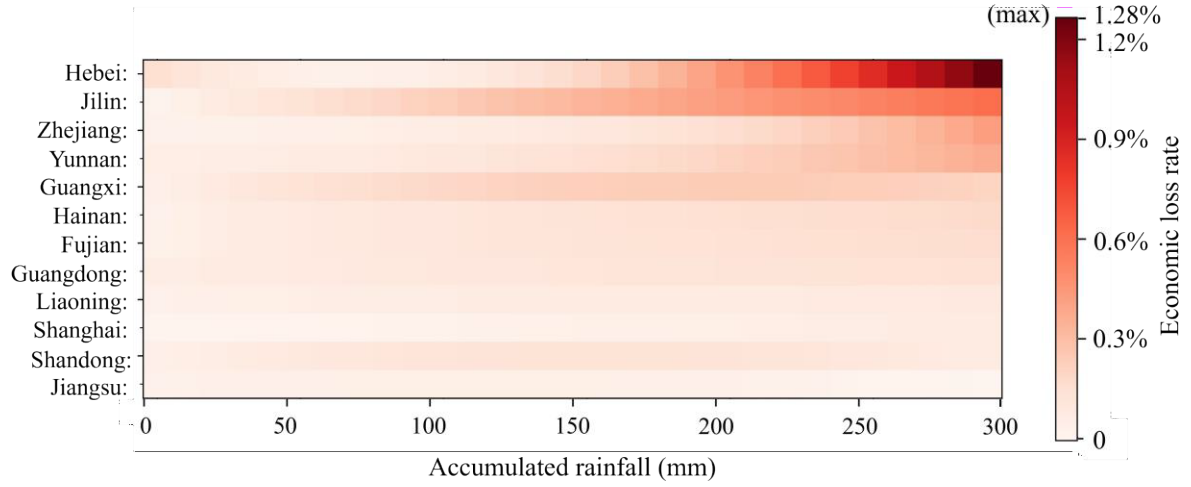
It can be seen from Table 2 that the optimal vulnerability functions for all the three disaster-bearing bodies mainly concentrate on two categories: polynomial model and logarithmic-logarithmic model, accounting for 64% and 25% of the total, respectively. It means that the polynomial model and logarithmic-logarithmic model can more effectively capture the nonlinear relationship between the disaster intensity and the loss rate of the disaster-bearing bodies, thereby showing better fitting performance.

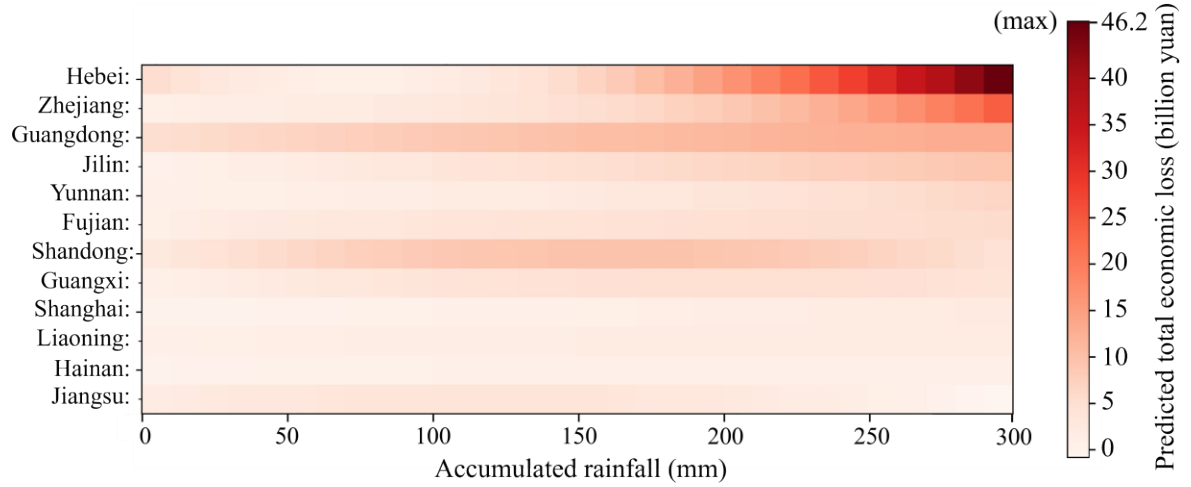
It is found that the optimal vulnerability function forms for the three disaster-bearing bodies may vary even in the same province. For instance, the vulnerability function types for the three disaster-bearing bodies are the same in Jilin, Shandong, Jiangsu, Shanghai, Guangxi, and Hainan, while differ from one another in all the other provinces. Therefore, when studying vulnerability of different disaster-bearing bodies in a specific region, the optimal vulnerability function type should be chosen based on the actual fitting performance, and it is not advisable to simply use a single type of vulnerability function for analysis.

For the provinces of Jilin, Shandong, Jiangsu, Shanghai, Guangxi, and Hainan, despite that all the three vulnerability functions have the consistent form, the parameters from the curve fitting are not the same, indicating that the loss rate variabilities of different disaster-bearing bodies are not the same. Taking Hainan Province as an example, the vulnerability function forms of economic, population, and crop conform to logarithmic-logarithmic model while the parameter β_1 in the models are different, showing the following rules: β_1 of the economic loss rate model > β_1 of the affected crop rate model > β_1 of the affected population rate model. The results suggest that changes in the typhoon intensity have different impact mode and degree on different disaster-bearing bodies.



Comparative analysis of the vulnerability functions of the same disaster-bearing body in different provinces reveals that the styles of vulnerability functions usually vary for different regions, even when the optimal fitting vulnerability function types are consistent. For example, Jilin, Liaoning, Fujian, and Hainan share the same form of vulnerability function while the key parameters in the functions are diverse from each other, with β_1 in the model in Jilin > β_1 in the model in Hainan > β_1 in the model in Fujian > β_1 in the model in Liaoning. This reflects that the resilience of different provinces to typhoon disasters could be different.

The Vulnerability Heterogeneity of Economic, Population, and Crop in Different Provinces

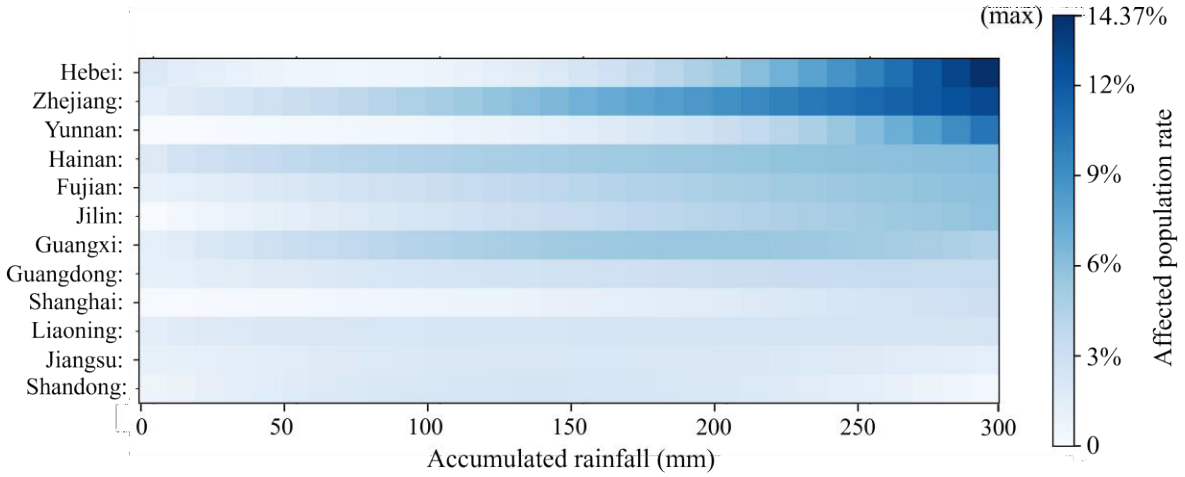


Preliminary conclusions can be drawn by comparing the size of key parameters when the same vulnerability

function form is applied in different disaster-bearing bodies in different provinces, but it is difficult to carry out comparative studies intuitively for different vulnerability function forms. To solve this problem, further visual analysis of the loss rates and predicted loss values (based on the 2018 data) of the three disaster-bearing bodies in 12 provinces under the same disaster intensity is conducted (Figure 3), so as to see the vulnerability heterogeneity of economic, population, and crop in different provinces more directly. It can be seen from Figure 3 that the loss rates and predicted loss values of all the three disaster-bearing bodies generally increase with the increase of the accumulated rainfall during the typhoon, suggesting that more severe disasters can bring greater losses, which is consistent with people's perception. More specifically, there are the following important findings.

As to the heterogeneity of economic loss rate in extreme typhoon-rainfall scenarios in different provinces, it can be seen from Figure 3(a) that Hebei, Jilin, Zhejiang, and Yunnan top the list. It can be seen from Table 1 above that among these provinces, Hebei, Jilin, and Yunnan have the fewest typhoons per year on average. It can be reasonable to speculate that these provinces may be less prepared for typhoons since typhoons are not frequent in history, resulting in greater impacts when typhoons occur. It reminds us that relevant departments should deal with extreme disasters such as typhoons that occur infrequently. Figure 3(b) shows that Hebei, Zhejiang, Guangdong, Jilin, and Yunnan top the list of the predicted total economic loss in extreme typhoon-rainfall scenarios. The ranking of the predicted total economic loss does not change much in general, while of course the ranking of provinces with large Gross Regional Product, such as Guangdong, will rise.

(a) Economic loss rate under the same scenario of typhoon-induced rainfall



(b) Predicted total economic loss under the same scenario of typhoon-induced rainfall

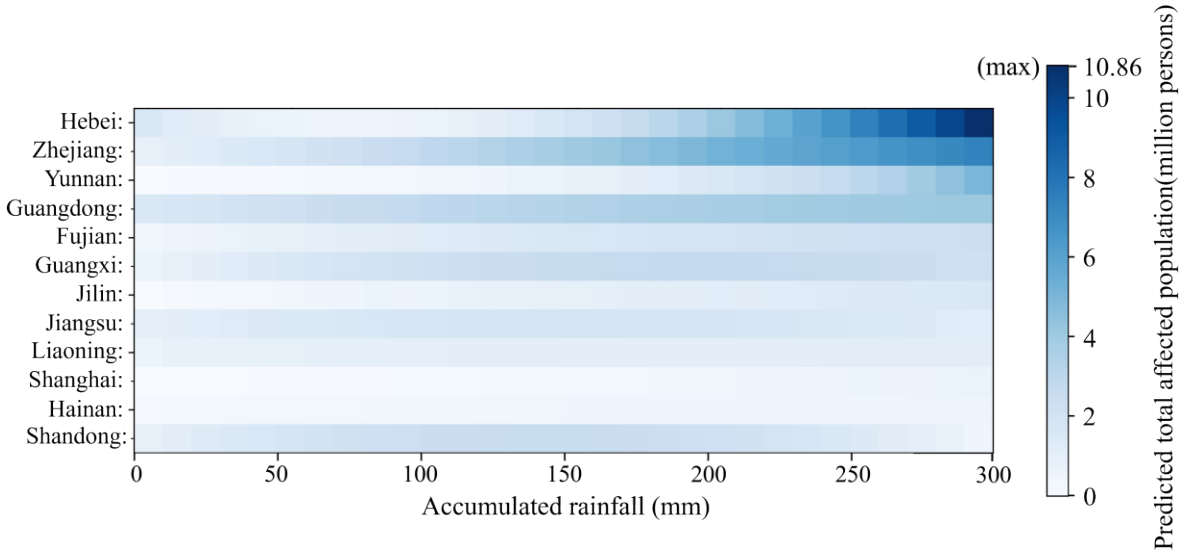


Figure 3. Heterogeneity of Economic Loss in Different Provinces

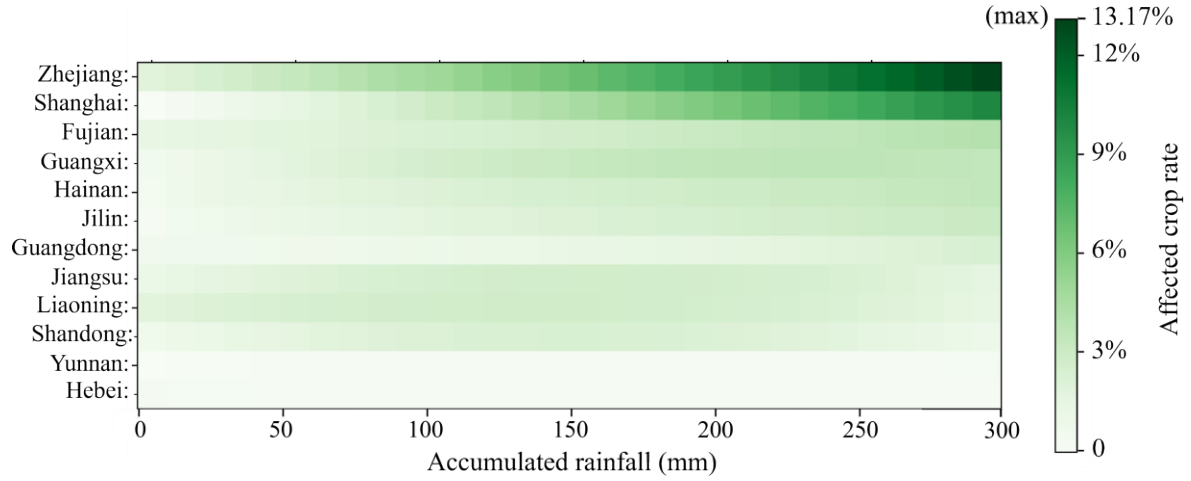
As to the heterogeneity of affected population rate in extreme typhoon-rainfall scenarios in different provinces, it can be seen from Figure 4(a) that Hebei, Zhejiang, Yunnan, Hainan, and Jilin top the list. This finding is highly

consistent with the finding related to economic loss, suggesting a high similarity degree between the vulnerability of the affected population and the vulnerability of the economic system in these provinces, most of which have experienced less typhoon damage in the history. It can be seen from Figure 4(b) that Hebei, Zhejiang, Yunnan, Guangdong, Fujian top the list of predicted total affected population in extreme typhoon-rainfall scenarios in different provinces. Considering that Guangdong has 113.46 million population and Fujian has 39.41 million population, which are significantly larger than the population in Hainan (9.34 million population) and Jilin (27.04 million population), this result is not difficult to understand.

(a) Affected population rate under the same scenario of typhoon-induced rainfall



(b) Predicted total affected population under the same scenario of typhoon-induced rainfall

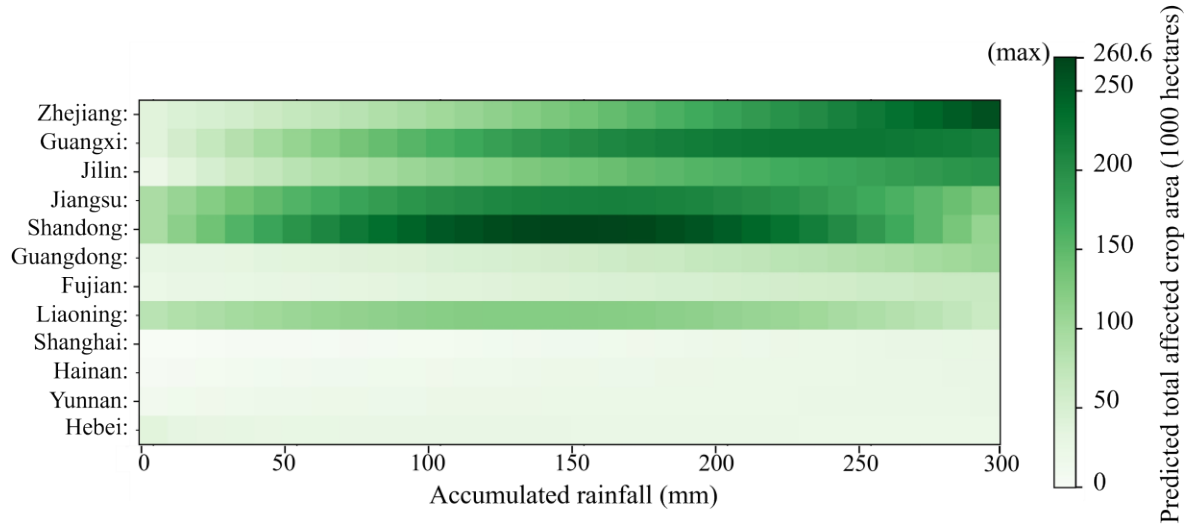


Figure 4. Heterogeneity of Affected Population in Different Provinces

As to the heterogeneity of affected crop rate in extreme typhoon-rainfall scenarios in different provinces, it can be seen from Figure 5(a) that Zhejiang and Shanghai top the list, with obviously larger value of affected crop rate. However, the pattern in Figure 5(b) is a little more complex. Firstly, the predicted total affected crop area in Shanghai is very small, only ranking the fourth from bottom. The main reason for this phenomenon is that Shanghai, as a modern metropolis, has almost no agricultural production. The total sown area in Shanghai is only 282.3×10^3 hectares, and the sown area is even less than 1/10 of that of some provinces. Despite that the affected crop rate in extreme typhoon-rainfall scenarios in Shanghai is huge, the overall crop loss is small. Secondly, due to the regional differences in the crop area, many provinces, although the crop loss rate is small, the total crop loss under extreme typhoon-rainfall scenarios could be large. These provinces include Guangxi (4th in loss rate; 2nd in loss), Jilin (6th in loss rate; 3rd in loss), Jiangsu (8th in loss rate; 4th in loss), and Shandong (10th in loss rate; 5th in loss). These provinces have a common feature that they are traditionally large agricultural provinces, with

a large area of cultivation. Therefore, only the affected crop rate cannot accurately reflect the overall situation of agricultural damage while total affected crop area could be a more accurate indicator. Thirdly, it is found that Zhejiang Province is a typical province with severe agricultural damage under typhoon disasters. Not only the crop loss rate is high in Zhejiang, but also the total crop loss value is extremely large.

LIMITATIONS AND FUTURE WORK

Limitation in The Selection of Disaster Indicator

When a typhoon passes through, there are often multiple dimensions of disaster indicators. As a preliminary study, only cumulative rainfall during the typhoon transit was selected as the indicator of disaster intensity due to the accessibility of the data in this study, and other indicators were not considered temporarily. In the further study, we plan to furtherly investigate the applicability of other disaster indicators as the independent variable in TC vulnerability function construction for a more accurate and comprehensive typhoon risk assessment.

Limitation in The Selection of Potential TC Vulnerability Functions

Appropriate choice of the potential vulnerability curve forms is the basis for developing effective vulnerability curves. In this study, the six potential vulnerability functions suggested by the work by Jiang et al. (2023) were

mainly referred to. The authors plan to test more forms of vulnerability functions, and hope that more regionally applicable vulnerability curves might be found in near future.

Limitation in Limited Number of Data Samples in Domain of High Disaster Intensity

Higher disaster intensity typically results in greater losses. However, fewer data points from infrequent high-intensity typhoons can disrupt curve accuracy, which causes the problem that the vulnerability curve does not increase monotonously. The authors plan to accumulate typhoon data over a longer period of time, thereby increasing the number of high-intensity-value points to obtain more accurate fitting results.

CONCLUSIONS

Tropical cyclones are one of the natural disasters with high frequency, strong destructive power, and widespread global impact. The southeast coastal area of China is the most economically developed and densely populated area in China, and is also a typhoon-prone area. Therefore, conducting a disaster-bearing body vulnerability assessment in the coastal areas of China is imperative. Based on the collected disaster data in 12 provincial-level coastal regions in China from 2003 to 2018, this study selected accumulated rainfall during the typhoons as the causative factor. The direct economic loss rate, affected population rate, and affected crop rate were selected as the indexes of the disaster outcome. Through the construction, fitting, and comparation of six alternative regression-based vulnerability functions, the optimal vulnerability functions for three disaster-bearing bodies in 12 provinces in were identified.

It was found in this study that the optimal vulnerability curves for all the disaster-bearing bodies are mainly concentrated in polynomial model and logarithmic-logarithmic model, accounting for 64% and 25% of the total, respectively, which shows that these two models could be the most suitable choice for the application of vulnerability assessment in the study area. It was also found that the constructed vulnerability curves generally exhibit a monotonically increasing trend, indicating that losses continuously increase with the increase of cumulative typhoon rainfall. As to the heterogeneity in different provinces, it was found that Hebei, Jilin, Zhejiang, Yunnan, and Hainan top the list of economic loss rate and affected population rate, while most of them have the fewest typhoons per year on average. It indicates that the economic loss and the population suffering condition may be severer in the provinces where typhoons are not common relatively, probably since these provinces were less well prepared for typhoons. Also, it was found that the provincial differences in crop loss rates and crop loss values are very large. The loss rate in large agricultural provinces is not high, but the absolute loss value could be very large, reflecting that crop losses are very dependent on the size of agricultural acreage, rather than solely determined by the loss rates.

As a preliminary study, there are still some limitations in this paper. To the best of the authors' knowledge, this paper gives a first attempt in exploring the optimal vulnerability functions for coastal provinces in China. The relevant results from this paper are of great significance for understanding the spatial heterogeneity of typhoon disasters and disaster victims. This paper could also provide valuable references for government departments in implementing accurate typhoon risk assessment, and improving disaster prevention and response capabilities.

ABSTRACT

Crises and disasters have become omnipresent worldwide in recent years. But thinking of managing those critical situations the focus of the public and scientific research in recent years was primarily on blue light organizations, i.e., classic emergency response organizations. This changed with the refugee situation in 2015/2016 and the COVID-19 pandemic, when public administrations and local authorities in particular took on a central role in crisis management. They became the central players in those situations, played an important role at the interface with the local population and were the first point of contact and information for them. This article sheds light on municipal administrations in Germany which have often be overlooked in various stages of crisis management. Drawing on empirical evidence from a German research project, it delves into the extent to which municipalities may have been overlooked or disregarded in certain aspects.

Keywords

Public administrations, Crisis management, Refugee movements, COVID-19, Empirical research

INTRODUCTION

Crises and disasters have become omnipresent worldwide in recent years. Authorities and organizations with safety and security tasks (AOS) implement measures to deal with these events on the basis of their (organizational) structures and processes, and developed and tested operational plans. Thinking of crises and disasters, the focus of the public, but also of scientific research in the last few years, was primarily on blue light organizations, i.e., classic emergency response organizations like the German Federal Agency for Technical Relief or fire brigades. On the basis of an ongoing research project, we would like to draw attention to an actor apart from the classic “blue light organizations” who, in our view, plays an important role in all phases of crisis management: local administrative authorities or municipalities. While "usual" crises such as extreme weather events are particularly challenging for established emergency organizations, the refugee situation 2015/16 and the COVID-19 pandemic are examples of how important crisis-proof and crisis-tested structures are, not only in established emergency management organizations, but also in public administrations. These situations are characterized by the range of tasks that arise for public administrations (on different levels) in the context of crisis management, which makes them the central players in those situations. They played an important role at the interface with the local population and were the first point of contact and information for them. During the refugee situation in 2015/16,

WiP Paper – Impact-driven Emergency and Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

administrations took on tasks in the area of health protection, registration and accommodation of refugees. During the COVID-19 pandemic, administrations had to compensate for staff shortages, while at the same time the number of personnel-intensive tasks, such as contact tracing and vaccine prioritization and distribution, increased. This clearly shows that administrations play a key role in crisis situations. Therefore, it is necessary for them to establish processes for the preparation, management and also recovery phase. Personnel in public administrations needs the necessary training and flexibility for effective crisis management, for which sufficient resources and skills are required even before the crisis situation arises in order to be able to react quickly and flexibly.

This article sheds light on municipal administrations in Germany which have often be overlooked in various stages of crisis management. It will be discussed to which extent local administrations or local authorities may have been forgotten or neglected in some respects in an integrated perspective on crisis management. Based on empirical interview material on the handling of the COVID-19 pandemic and the analysis of media and administrative documents in Germany, we look at how local authorities have positioned themselves in the area of crisis management in this long-lasting situation. We also examine how cooperation between local authorities and other crisis management stakeholders has developed and evolved and why the preparation and follow-up phase of the crisis management lifecycle play an important role in integrated crisis management.

RESEARCH PROJECTS: DATA COLLECTION AND METHODS

The project " *Local governments in crisis mode (KoViK)*", which is funded by the German Research Foundation between 2022 and 2024, deals with the management of the COVID-19 pandemic from a municipal perspective. The project builds on previous research on dealing with the refugee situation in 2015/2016 from the perspective of various actors, including various public administrations. The resulting findings revealed the following:

(1) that administrations had little practice in crisis management at that time, that administration representatives did not see themselves or their organizations as central authorities in crisis management and that crisis management was not a central, but merely an "additional task" alongside the actual administrative work;
(2) that they were not perceived by third parties such as AOS as professional representatives of crisis management;
(3) that administrations lacked suitable structures for the adequate management of an acute crisis, but were instead rather inhibited due to bureaucratic principles and a so-called "iron cage" inherent in bureaucracy, and
(4) that in some places they were preoccupied with addressing their internal organizational challenges rather than effectively managing the situation at hand (Schütte et al., 2022; Schulte et al., 2022).

The KoViK project builds on these findings and pursues three objectives: Firstly, using the SARS-CoV-2 situation as an example, insights are to be gained into practiced approaches to crisis management and crisis communication by municipal administrations. Secondly, those are reflected with regard to established forms and, thirdly, the consequences of pluralistic approaches for the population and other actors are anticipated. The project focuses on cases in North Rhine-Westphalia (NRW).

In order to take as comprehensive a look as possible at the crisis management of local authorities, the study uses a multi-method approach, which can be seen in the following figure (see Figure 1).

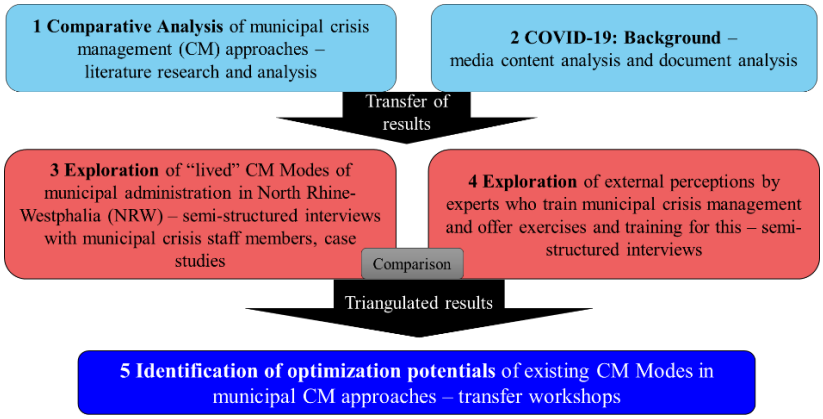

Figure 1. Work structure of the KoViK research project on municipal crisis management (Source: own illustration based on Schönefeld et al. (2023)).

The aim of the first work package (WP) (1) was a comparative analysis of scientific studies that deal with the topic of municipal crisis management. Here, a state of research and the approaches to be derived from it were developed. Parallel to this, a media content analysis on the development of the pandemic in municipalities in NRW was carried out in WP 2. In addition, legal texts in the field of disaster and crises law were analyzed to see how they deal with the concept of crisis management (WP 2). Based on the results of WP 2, 25 semi-structured interviews were conducted: (a) 19 interviews with administrative staff of independent cities and rural districts in NRW who were involved in crisis management activities during COVID-19 pandemic at least, i.e., in crisis teams (self-perception) (WP 3) as well as (b) 6 interviews with experts who provide training in municipal crisis management, design and conduct training, exercises for this purpose and are therefore able to provide an external assessment of municipal crisis management and crisis team work (external perception) (WP 4). The empirical results of WP 1, 2, 3 and 4 will be triangulated and documented in five case studies. In these, the results for the 19 cities and districts are summarized at the level of administrative districts (there are five administrative districts in NRW) in order to ensure a certain degree of anonymity. All of the results will be triangulated and prepared for practice transfer workshops in which practitioners will collaborate to identify opportunities for improvement explore feasible implementation strategies (WP 5). The following sections present the (not yet conclusive) results of WP 1 to 3.

(LOCAL) PUBLIC ADMINISTRATIONS IN CRISIS MANAGEMENT: BRIEF STATE OF THE ART

Global critical situations also affect the local level. This was the case for the COVID-19 pandemic as well. For more than two years, public administrations at all federal levels in Germany operated in a continuous crisis mode. Municipalities, as the "lowest main administrative level(s) responsible for the entire local administration" (Ehl & Wendekamm, 2013, p. 133, own translation) were facing major challenges, because it was their mission to implement decisions made at federal and state level. Municipal governments took over a central part of coping with consequences of the COVID-19 pandemic within their frameworks of local crisis management, while their daily tasks had to be continued. Before that, local and intermediary (here: *Landkreise/Regierungsbezirke*) actors typically gained relatively low attention by the public, media, research, etc. in crises and disasters, compared to “blue light organizations” or the administrative counterparts on the national and federal level (Benton, 2002; Schneider & Park, 1989), although it does not match with the high importance of local and regional emergency management. Major exceptions are events such as the storm surge in Hamburg in 1962, when Helmut Schmidt (then Hamburg's police senator and later German Chancellor) implemented a rapid but legally difficult rescue operation.

At least until 2020, it can be assumed that the state of the art in (administrative) science – especially in the German-language literature – was deficient. Research revealed only a few studies on the crisis management of public administrations in relation to social crises, as the following quote makes clear:

"From an administrative science perspective, disasters and manifest crises are rarely studied. This is particularly surprising because public authorities play a central role in coping with disasters" (Hustedt, 2019, p. 183, own translation).

In recent years, overviews of administrative science on administration in Germany have focused on crises, the associated challenges for German administrations, and the resulting (potential) changes and reforms (e.g., digitalization of administrations) have been discussed, but no mention has been made of specific crisis management approaches by administrations for such social crises, forms of handling such as administrative staff or aspects of crisis communication (e.g., Bauer & Grande, 2018; Bogumil et al., 2016; Bogumil & Jann, 2020; Kuhlmann & Schwab, 2017; Möltgen-Sicking & Winter, 2018; Ziekow, 2018 cited after Schönefeld et al., 2023). One possible reason for this could be that public administrations were less likely to appear as "the" central crisis managers in earlier times. Usually, various public safety and emergency response organizations such as the police and fire department were the focus of social and media attention when it came to dealing with critical situations (Schönefeld et al., 2023). However, this changed with the refugee movements in 2015/2016 and the COVID-19 pandemic. During the pandemic, studies on public administrations – especially local administrations – focused primarily on, e.g., the assessment of measures (by administrative staff and citizens) and the satisfaction of the population with municipal crisis management (e.g. Eckhard & Lenz, 2020; Otto, 2021; Pöhler et al., 2020). In addition, approaches to learning from critical phases were also examined (e.g. Aden, 2023; C. Bauer & Egger, 2023; Bauer et al., 2022). Nevertheless, there were mostly rather superficial considerations of the crisis management of public administrations (Neumann, 2020). Studies examining the distinctions and interconnections among crisis management at various governmental levels – federal, state, district, and local – have only begun to emerge gradually, roughly coinciding with the progression of the pandemic (e.g., Kuhlmann & Franzke, 2022; Lenz, 2023).

When the KoViK was applied for in 2021, the scientific literature on crisis management in (German) local authorities was comparatively "thin" and pointed to more research gaps and associated questions than findings and answers. Against this background, corresponding media content and document analyses (of legal texts and other legal foundations) were carried out in order to create the basis for an understanding of the image of crisis management in local government that is conveyed. The following passages take a closer look at the findings.

(LOCAL) PUBLIC ADMINISTRATIONS: FORGOTTEN TALES IN DOCUMENTS AND MEDIA

Media Content Analysis

As already mentioned, (local) public administrations are an important stakeholder in crisis management. During COVID-19, they were a key player when it came to developing or implementing rules in relation to pandemic management. They were and are an important link between the population (as those affected by the pandemic and the chosen crisis management measures) and the higher crisis management levels on district, state and federal levels. Based on this, the question arises as to whether the role those local administrations have taken on in crisis management has also been reflected in media coverage. This analysis was predicated on the assumption that experiences in complex societies are predominantly mediated through media channels (Sackmann, 2020, p. 354). As the project focuses on one region in Germany, regional newspapers were chosen accordingly. A total of seven newspapers were scrutinized by using a search strategy incorporating terms related to the pandemic, municipal administrations and crisis management (actors) as shown here and translated from German by the authors ((Corona OR COVID-19 OR SARS-CoV-2 OR pandemic) AND (municipality OR public health department OR administration) AND (crisis*)). This strategy was designed to capture articles published from the onset of 2020 through the early stages of 2023, specifically selecting the first complete week of each quarter as sampling points. This temporal delineation was chosen to ensure a comprehensive overview of the media landscape over the specified period. For initial screening of the articles four inclusion and 19 exclusion criteria were formulated, grounded in qualitative theses on crisis management and municipal administration. Two of the 23 criteria are listed here as examples. The inclusion criteria primarily comprised the relevant actors, as well as the organization and processes for crisis management, e.g. “The report is neutral/positive/negative about pandemic management / crisis management (in particular organization/structure/processes of the stakeholders)”. Reports on multiple crises, such as a flood occurring at the same time as the pandemic, were also included. In contrast, articles of less than 300 words were excluded, as were articles that merely reported on the course of the pandemic (e.g., in the form of indices) or, for example, on progress in vaccinating the population. The included articles should explicitly focus on crisis management.

The first search identified a corpus of 674 articles. 128 articles then were removed due to duplicates. From the remaining 546 articles 108 were selected on the basis of the in- and exclusion criteria (see Figure 2).

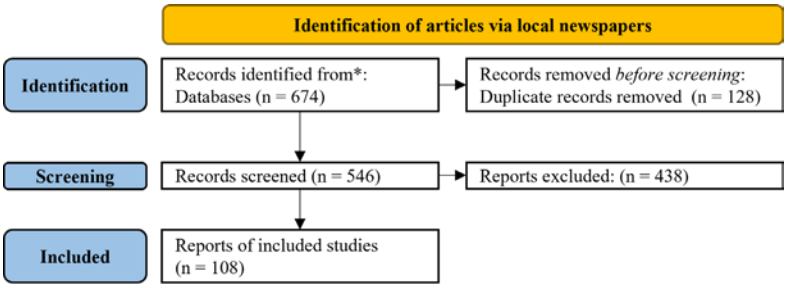

Figure 2. Retrieval of local newspaper articles; own illustration based on Page et al., 2021.

The analysis of the media content has not yet been fully completed. Only initial highlights can be presented here. Using a qualitative thematic synthesis (Thomas et al., 2017) for the analysis illuminates several predominant themes in relation to crisis management. These included the (differences in) municipal handling of the COVID-19 pandemic and the development of case numbers and vaccine availability, challenges for the local citizens like closing of schools, and financial measures implemented by local governments, e.g., for small businesses. A significant emphasis was placed on challenges such as staffing shortages and the imperative for digitalization within municipal crisis management operations. Conversely, less attention was afforded to the structures and processes underpinning crisis management efforts. In summary, explicit references to crisis management were infrequently encountered within the titles or texts of the analyzed articles, suggesting a more implicit engagement with the topic within media discourses. The emphasis in the analyzed media content predominantly lays on the immediate visible aspects and impacts of the crisis, the reactive measures undertaken and the challenges faced, rather than on a detailed examination of strategic or procedural aspects of crisis management. The complexities

of crisis management and more comprehensive public understanding of the roles of municipal administrations in such critical situations remain in the background.

Document analysis of legal background of CM in Germany

A further step in the project presented is the analysis of documents relating to public administrations and their crisis management. The document analysis was intended to examine how the actor and its crisis management is anchored and structured in terms of administrative law. For this purpose, the 16 disaster control laws on state level – because there are no "crisis management laws" or anything comparable – in Germany were analyzed using a qualitative content analysis (Kuckartz & Rädiker, 2022) and compiled in a synopsis. It focused on the statutory frameworks across the federal states of Germany, specifically examining their references to municipal crisis management. This investigation looked into the legal texts to identify the regulations regarding the requirements, structures, processes, and the provisions for personnel and technical equipment outlined therein. Furthermore, the analysis sought to understand how these statutes address the various phases of crisis management in these legislative texts. The primary aim was to identify how these laws articulate the roles and responsibilities at the municipal level, alongside the mechanisms and resources allocated for crisis management and disaster response. The content analysis of the legal documents revealed a few interesting points: A notable observation is that only a few states offer a general definition of crisis management, and even fewer distinguish clearly between the concepts of disaster management and crisis management. This lack of differentiation suggests a conceptual overlap that may affect the clarity and effectiveness of crisis response strategies. Civil protection departments are predominantly designated as the lead actors in these frameworks, a consistent topic across the legislative texts. However, the depth of description regarding the operational teams or staffs for disaster management or crisis management varies significantly, often described in broad terms without delving into the specifics of their formation, roles, or operational guidelines. The general approach to detailing the structure of crisis management efforts underscores a potential gap in providing clear guidance for the execution of these crucial functions at the municipal level. The way in which crisis management work is organized is therefore the responsibility of the actors involved and is therefore left to each local authority. Another critical finding of this analysis is the sporadic mention of the crisis management cycle phases within these laws. Notably, the follow-up phase, essential for learning and improvement post-crisis, is almost never explicitly addressed. This points to a potential oversight in ensuring comprehensive crisis management planning that includes not only immediate response but also the long-term embedding and improvement of the crisis management process. These insights result from the 16 analyzed disaster control laws of the federal states in Germany. The findings highlight the need for clearer definitions, differentiated roles, and detailed procedural guidelines within Germany's disaster management and crisis response statutes. Addressing those gaps through legislative refinement and the incorporation of comprehensive crisis management cycle considerations could significantly enhance the effectiveness and efficiency of municipal crisis management efforts.

However, the document analysis has not yet been completed. Further documents will be included. The authors see the need to look at regulations and decrees at the local level, which can provide additional detail and concrete examples of crisis management practices. For example, the crisis management directive in NRW represents a more detailed formulation of local crisis management, which could provide insights into the operationalization of local crisis management frameworks.

(LOCAL) PUBLIC ADMINISTRATIONS: FORGOTTEN TALES IN EMPIRICS/PRACTICE

This section is about forgotten tales and our findings in the empirical data in terms of interviews that we collected in the KoViK research project. The interviews were semi-structured, i.e., they combined pre-determined questions with the opportunity for the interviewer to explore deeper insights or follow up on responses through additional, impromptu questions. This approach allowed for a flexible conversation while ensuring that specific topics of interest were covered, facilitating both comparability across interviews and in-depth exploration of individual perspectives. The interviews were then transcribed and subsequently coded. Coding of interview content is a systematic process used in qualitative research to organize and categorize the data collected from interviews. This involves identifying patterns, themes, or concepts within the interview transcripts and assigning codes (labels or tags) to segments of text that represent these ideas. Coding serves as a crucial step in interpreting and drawing meaningful conclusions from qualitative data. For this interview material, a deductive-inductive approach was chosen for coding the interviews (Kuckartz & Rädiker, 2022).

We concentrate on four main topics that we consider as particularly relevant.

(1) *The myth of follow-up (respectively evaluation) of actual crisis management practices in municipal administrations*: Follow-up practices are regularly been considered as important in a holistic approach to crisis

management. However, it regularly falls by the wayside or is carried out subordinately. It can be noted that a debriefing is universally desired, but often there is a lack of personnel resources, as one crisis follows another, or the return to day-to-day business leaves no more capacity for in-depth follow-up. Moreover, employees leave the administration faster than expected, taking the relevant knowledge with them:
"What we would like is truly a debriefing of all participants […] Besides the fact that so much has changed, the memories fade. And it's not just me; next year, our department head, who played a major role in handling the pandemic, will no longer be here. And who are you going to work with to process things when the key players involved are no longer around?" (PublicAdministrationInterview(PAI)_15)
In addition to the content, however, the importance of a ceremonial follow-up in the form of thank-you celebrations and small tokens of appreciation was repeatedly mentioned, which are seen as important from an emotional point of view in order to return to normal mode, but also to maintain the willingness to actively support crisis management in future situations. It is the explicit aim of the KoViK research project to gather and systematize the available crisis knowledge in order to be better prepared in the future and to support the often-limited follow-up resources of municipalities.

(2) *Learning on the job and missing exercises*: Exercises play a pivotal role in any civil protection curriculum. In the case of municipal administrations, the relevant training content is how to work in an administrative (not an operational) crisis management staff. Various public institutions in Germany offer these courses (e.g., Federal Office for Civil Protection and Disaster Assistance, Fire Brigade Institute of North Rhine-Westphalia), but resources are limited. On the other hand, interest of municipalities has so far been limited. The size and length of the crisis meant that untrained personnel also had to be deployed in crisis management (and therefore *was learning on the job*).
The task "crisis management" had to be re-learned: *"After the fall of the Cold War wall, I believe, no one thought anymore about disasters, crises, wars. The change has definitely been there for the last two years"* (PAI_3). This departure from the task of crisis management also meant that hardly any resources were available for it: *"The mechanisms that used to exist, and the resources that had been dismantled, are only now slowly being rebuilt."* (PAI_7). This also includes that untrained personnel had to be trained on the job, in the crisis: *"not everyone who was involved there was fully trained. Instead, they had to grow into the task through the crisis"* (PAI_1).

(3) *Empowerment of public servants during crises*: The extent of the COVID-19 pandemic required a large part of the municipal workforce to actively participate in crisis management – in addition to or instead of their actual tasks. Especially in the particularly intense initial phase of the pandemic, municipal staff were occupied with crisis management tasks in multiple shifts over several months. A cliché of working in administration is that of routine and sometimes even boring-monotonous work. The crisis provided staff with the "opportunity" for a different kind of work, across established hierarchical and professional boundaries, and possibly also with a different sense of self-efficacy: *"this mixing of levels was incredibly good for the self-perception of a district administration. Because suddenly people were important whom one might have foolishly thought before were not so important. And they were very important for certain things"* (PAI_1). The fast-paced environment was felt as an attractive alternative to the usual tasks: *"it wasn't as slow as the administration usually operates, but it was fast-paced. Suddenly, you could be active. So, for the first time in a while, I really enjoyed my job again because there was real momentum"* (PAI_15).

(4) *Collaboration with stakeholders*: Crisis management is often associated more with emergency services, i.e., the operational aspect, rather than with the administrative part, which is less illustrative. On the contrary, the image of administration is pretty much the opposite of what one associates with crisis management organizations. This also affects the perception that AOS have of administrations. In Germany, this seems to have started to change only in recent years. Various prolonged situations (migration situation in 2015/2016 and again since 2022, COVID-19, energy crisis) were not classic emergency services situations but primarily required leadership through the administrative strand of crisis management.
On the one hand, administrations were very active but not immediately visible. One could rather see the classic relief organizations instead: *"Many others, of course, see on-site, (...) Red Cross, fire department, and don't even know (...) that we organized it"* (PAI_1). However, municipal administrations were key network facilitators on the local level and this corresponds with their self-perception: *"we always function as a network organization, always"* (PAI_12). Despite the health focus of the crisis, collaboration with medical professionals are not reflected as a good practice: *"the worst, (…) and I say this very critically, were the doctors. The doctors were not the pioneers. (...) They didn't want to test, they didn't want to vaccinate afterwards. They were afraid of Corona."* (PAI_15)

CONCLUSION

Drawing upon an integrated perspective on crisis management, this article emphasizes the central role of local administrations during the COVID-19 pandemic. We shed light on the significance of local administrations, which are often overlooked in both research and practice.

In the past, public administrations have been part of "forgotten tales" in crisis management research, where the focus was instead on blue light organizations and their crisis management. This is gradually being addressed as these public administrations as well as their crisis management are increasingly being included in the academic discourse. Additionally, their crucial contribution to crisis management is being recognized through crisis situations such as the 2015/16 refugee situation, the COVID-19 pandemic, or the energy crisis in Germany. The roles of local administrations are now slowly being more and more recognized and integrated into broader narratives of crisis management.

The underlying legal framework also reflects the “forgotten tales”. The pandemic has stressed the need for "new chapters and layers" within the legal paradigms to adequately capture, define and delineate crisis management. The permanent crisis mode during the pandemic provides a favorable opportunity for the adaptation and refinement of legislation, as it is currently happening in NRW. At the same time, the forgotten perspective of local governments as crisis actors was also not highlighted in the local media landscape even during COVID-19. It became apparent that local administrations were not really portrayed as crisis managers in the media and that the visible aspects or the consequences of measures tended to be described or that individual, specialized experts or important political decision-makers had their say in some articles.

In practice, the pandemic has served as a catalyst for awareness-raising and change in perception of and in local administrations. The pandemic has highlighted the shortcomings and unexplored potential of current crisis management practices and highlighted areas for improvement and innovation in public administrations. Despite this progress, experience from previous crises shows that certain lessons are not being addressed. Issues such as the follow-up and sustainability of crisis management often fall by the wayside and are overlooked after the crisis has been managed. Conversely, certain practices, such as conducting exercises, have become much more common, although this may be more of a passing trend than a permanent part of crisis preparation.

In summary, the COVID-19 pandemic has highlighted the key role of local administrations in crisis management. It has drawn attention to the legal, scientific and practical framework for crisis management and made it clear that an integrated perspective on crisis management is necessary in various crisis situations. However, not all lessons have been learned from the pandemic. With the research project and further research work, we would like to contribute to ensuring that not only immediate adjustments are made in crisis mode, but also that the sustainability of these measures is guaranteed. The experiences and adjustments made by local administrations during the pandemic provide a valuable basis for this.

ABSTRACT

The importance of extreme weather situations is increasing due to their number and, above all, their impact on stakeholders in emergency response. They are characterized by cascading effects with global and local interdependencies. Extreme data must be included as a basis for decision-making. The impact in emergency response depends on diverse, multidisciplinary competencies required to interpret information. Scenarios are used in various forms of preparation: in exercises, but also for the design of information systems and validation. Based on literature, this article brings together different types of scenarios and related work in the field of Model-Based Systems Engineering. Using an exemplary case relating to possible pluvial urban floods, the added value resulting from a focus on the impact of innovative solutions is discussed. It is shown that the use of scenarios helps to make the desired impact assessable for decision-makers in all phases of research and development projects.

Keywords

systems, scenarios, engineering, models, innovation

INTRODUCTION

Extreme weather situations are increasing due to climate change (Lee et al., 2023). Weather-induced emergencies are characterized by cascading effects with global and local interdependencies (Schauwecker et al., 2019). In hazard analysis and response, it is therefore necessary to deal with extreme data that is obtained from heterogeneous data sources and evaluated using various methods, including machine learning (cf. (Abily et al., 2020)). Examples include global data such as geodata, traffic information, satellite images and weather forecasts on the one hand, and local data from sensor systems such as weather stations, ground-based or flying robots (UAV/UGV) on the other (Kruijff-Korbayova et al., 2021). Extreme weather therefore places extreme demands on information and communication technologies (ICT) (Terti et al., 2019) and self-protection of the population (Gräßler et al., 2018). Effective support for all stakeholders requires the provision of weather forecasts and, above all, constantly updated impact forecasts as the emergency progresses, in order to prepare for such an emergency and its development over time (e.g., (Sutanto et al., 2019)). This becomes even more important the less specialist expertise is available in a command and control post in areas such as meteorology, geology or sensor technology.

WiP Paper – Impact-driven Emergency and Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

The management of critical situations in real time with extreme and complex data must therefore be based on an assessment of the information quality of extreme data. Different fields of view and sampling frequencies of sensor technology, latencies in communication, gaps in data collection, differences in data formats, etc. characterize "extreme data" - the term "big data" is therefore avoided due to the too narrow reference to volume. In the decision-making process, an awareness must be created that uncertainty is always inherent here. Indicators of data and information quality offer a possible approach (Eppler, 2006). The achievable effect depends on the application context in different command and assistance centers as well as the available infrastructure with devices for visualization, interfaces of weather services, sensor systems and rescue robotics. This article is therefore based on the assumption that the consistent use of scenarios is crucial for the successful impact of innovative solutions in the application. This can be based on the approaches of Model-Based Systems Engineering (MBSE) (Gräßler et al., 2023). While requirements can be represented in previous system models, there is no explication of narrative knowledge. In scenarios, these can be discussed and referenced (cf. (Friberg et al., 2010)).

The article summarizes different types of scenarios based on the literature in the following chapter. Related work in the field of MBSE is adopted for application in emergency management. The concept for the conceptualization and abstraction of different types of scenarios covers the entire chain from domain exploration to the evaluation of the impact of a technology in this domain. Using a case study relating to possible pluvial urban flooding situations, the added value that arises along the chain from actual practice scenarios to target application scenarios and validation scenarios is discussed. In the conclusion, it is shown that the use of scenarios can help to make the desired effect of innovations explicit early on in development and research projects and thus make them assessable for decision-makers.

STATE-OF-THE-ART IN SCENARIO REPRESENTATION

The aim of scenarios is to transform statements into descriptive, intuitively usable auxiliary artifacts. They thus combine the illustrative perspective with a purpose-related, constructive view. The challenge is the qualitative description based on subjective descriptions and perceptions. These can be related to the problem and solution space. With regard to the problem space in particular, it becomes clear that the need for information extends well beyond the domain of product development. Accordingly, information from different domains is integrated here. Distortions as a result of the scenario form must be taken into account (Sabatucci et al., 2015).

Scenarios in Research on ICT in Impact-Oriented Emergency Management

Systematically researching the ISCRAM library following the principles of the PRISMA statement (Page et al., 2021), several notions of “scenarios” become obvious. This is supported by cross-checking with Web of Science and Scopus databases. Amongst others, there is a variety of work that applies scenarios in (virtual) simulations resp. exercises. Further references are available that make use of scenarios to model and understand a certain domain of interest or type of hazard, like people evacuation, food supply or humanitarian assistance. When searching for an exact match of scenarios and systems engineering or related terms, there are not direct matches. Extending the scope, some papers can be identified that support the relevance of scenarios along design and engineering activities for ICT systems in emergency and crisis management. Intending an advanced User Experience, TOULOUM et al. propose to incorporate service touchpoints explicitly in scenarios (Touloum et al., 2013). Based on structured scenarios from overall scenarios to activity diagrams and interaction models (cf. (Friberg et al., 2010)), touchpoints are extracted representing those system elements that require UX design interventions. GARCIA-ARISTIZABAL et al. introduce their work on Cascading Effects Scenarios with several case studies (Garcia-Aristizabal et al., 2015). Their work combines analytical elements when describing past emergencies through scenarios (as-is scenarios) with prescriptive use cases when targeting supportive measures like ICT systems. RAMIREZ et al. focus on risk analysis based on scenarios (Ramirez de la Huerga, Miguel et al., 2015). Even though this is not directly linked to Systems Engineering, the presented approach can help to prioritize scenarios targeting risks of cascading events. This could be coupled with Systems Engineering approaches targeting similar risk-oriented objectives (Gräßler et al., 2022). On a different layer, POLIPARKUS et al. research on collaboration in (virtual) scenario generation (Poliparkus et al., 2018). Understanding Systems Engineering as a set of tasks that needs to be fulfilled in a collaborative manner, especially the findings regarding feedback loops and finetuning of scenarios to ensure realistic settings are considered in the paper at hand.

Criteria to Categorize Scenario Types

Process-related scenarios usually include events and/or activities in narrative form. One example is the description of an actual process within which problems are to be identified. Situation-related scenarios, on the other hand, describe states as intended or anticipated situations. One example is future scenarios that anticipate possible

futures. They can also include a temporal dimension that describes the achievement of this situation or a further development. Selection scenarios are used to support decision-making and therefore have a reference to a decision-making situation. In the application perspective, the use of a product is assumed, which must be available accordingly. ROLLAND et al. recommend a classification of scenarios based on form, content, purpose and life cycle (Rolland et al., 1998, p. 45; Weidenhaupt et al., 1998, p. 35). FILIPPIDOU identifies form- and content-related comparison criteria for the classification of scenarios based on a literature analysis (Filippidou, 1998, p. 5) (extended based on (Jarke et al., 1998; Pohl, 2010, p. 148; Rolland et al., 1998; Weidenhaupt et al., 1998, p. 37)).

Table 1. Criteria to categorize scenario types

Layer 1	Layer 2	Values
form	degree of formalization	informal to formal
	form of presentation	statistical to animation/simulation
	stakeholder input	purely synthetic to intense (workshops etc.)
	abstraction hierarchy	existing (e.g., use case models) to not existing (unstructured, without underlying schema)
	complexity hierarchy	Existing or non-existing classification with regard to a combination of generalization and specialization
	method of generation	automated (e.g., (Bagschik et al., 2018, p. 1816)), reference models, …
	method of analysis	observatory, argumentative, automated
	intention	descriptive, explorative or explanatory (Pohl, 2010, p. 148)
content	concreteness	„3ague“ (e.g., future scenarios) to detailed (e.g., test scenarios)
	boundedness	specific situation to “big picture” (overarching, generic view), system-related differentiation into system-internal, interaction and environment/context scenarios (Jarke et al., 1998; Pohl, 2010, p. 148)
	plausibility	differentiation between desired/positive scenarios and scenarios to be avoided/negative scenarios or scenarios that contribute to or jeopardize objectives (incl. misuse scenarios) (Pohl, 2010, p. 148)
	visualization	current/actual/indicative vs. planned/optional scenarios (cf. (Jarke et al., 1998, p. 157)), also differentiation between instance and type scenarios (Pohl, 2010, p. 148); supplements are anticipated scenarios
life cycle	criticism	not done – testable/possible – tested/iterated
	evolution	temporary scenarios with dynamics vs. persistent scenarios
	alternatives	alternatives: main, alternative and exceptional scenarios (Pohl, 2010, p. 148)

Requirements Engineering: Practice und Interaction Scenarios

Requirements engineering is a cooperative, iterative and incremental process (Pohl, 2010). It includes eliciting, analyzing and structuring, documenting, negotiating and specifying as well as managing and validating requirements (Pohl, 2010, 41ff; Rupp, 2014). The use of scenarios as auxiliary artifacts is taken up in Scenario-Based Requirements Engineering (A. G. Sutcliffe et al., 1998). Scenario types in the development of e.g. requirements and prototypes require a concrete, possibly simulatable and at least semi-formal form of representation. They are used a) to represent a current state or a current situation or b) to describe a desired state or a desired situation (Pohl, 2010, 149ff). ROSSON and CARROLL emphasize problem scenarios in the first case (Rosson & Carroll, 2008, p. 26). In the future-oriented case, the focus can be on interaction with the technical system to be developed (interaction scenario, e.g. in the form of user stories or use cases). Anticipated errors in product use (misuse scenario), deliberately incorrect use (abuse scenario) and even threat scenarios can be modeled here (see, e.g., (Gräßler et al., 2020; Tuma et al., 2018)).

RELATED WORK IN MODEL-BASED SYSTEMS ENGINEERING

The largest group of related work deals with metadata modeling for scenarios in requirements development. ARRUDA et al. develop the BD-REAM in the form of an entity-relationship model (Arruda, 2020; Arruda & Madhavji, 2017). Big data requirements are placed in the context of software, system and quality requirements, test and business cases. In a software implementation (QualiBD), for instance the completeness of a requirements set is checked (Arruda, 2020, p. 157). BERKOVICH et al. develop a domain mapping matrix (DMM) for mapping relations of different requirement types (Berkovich et al., 2014). Even though "needs" are explicitly addressed, a formal mapping seems to start later at the level of customer requirements. The Scenario-based Requirement Model (SBRM) from Xi et al. models scenarios from the perspective of requirements: A requirement is visualized by scenarios, processes and rules contained therein (Xi et al., 2019). This perspective is deepened by the ontology development in this domain (see, e.g., literature studies (Castañeda et al., 2010; Dermeval et al., 2016)). ReqIF, as mentioned above, contains a data schema for "SpecObjects" (requirements) and "Specification" (requirement set) (Object Management Group [OMG], 2016). There is no abstraction to the semantic level here, only recommendations for the exchange of requirements artifacts. TUDORACHE models dependencies between development artifacts including requirements. It uses the semantic level to check consistency, conformity and compliance with the specification by means of "design models" (Tudorache, 2006). The SoftWiki Ontology for Requirements Engineering (SWORE) is a central work in terms of metadata modeling (Riechert & Berger, 2009; Riechert et al., 2007). SIEGEMUND is more specific in the area of the representation of metrics (also in the form of qualitative SoftMetric), test cases and obstacles (Siegemund, 2014, p. 60). He maps the response to uncertainty with reference to risks, without modeling the uncertainty directly. Individual works focus on requirements change management. ALSANAD et al. present an ontology that declares the requirements, parts of requirements and requirements sets for the Aspect_of_Change as reference objects for changes (Alsanad et al., 2019, p. 49357). Uncertainty is part of the motivation in some works (e.g. (Heling et al., 2018)), but only in a few approaches explicitly part of the solution approach. FEHLMANN et al. do not focus on the representation of uncertainties, but describe the propagation of "customer needs" to use cases or test cases (measurable e.g. via the number of bugs) (Fehlmann & Santillo, 2007, p. 204). The solution approaches mentioned are presented in Figure 1 in a comparative overall context. Work that focuses on the work processes for creating these scenario artifacts without explicit modeling is not considered here (see, e.g., (Georg et al., 2015)).

CLASSIFICATION AND ABSTRACTION OF SCENARIOS

Along Systems Engineering phases, different scenario types are relevant (Anggreeni & Voort, 2007), which are incorporated in Figure 2 based on criteria in Table 1: Illustrative scenarios in the form of explorative scenarios (e.g. (potential) stakeholder stories) and actual or intended practical scenarios serve to reduce ignorance in early phases of the V model. Interaction, detailed scenarios and validation/test scenarios are used in later phases, also closing feedback loops across engineering iterations.

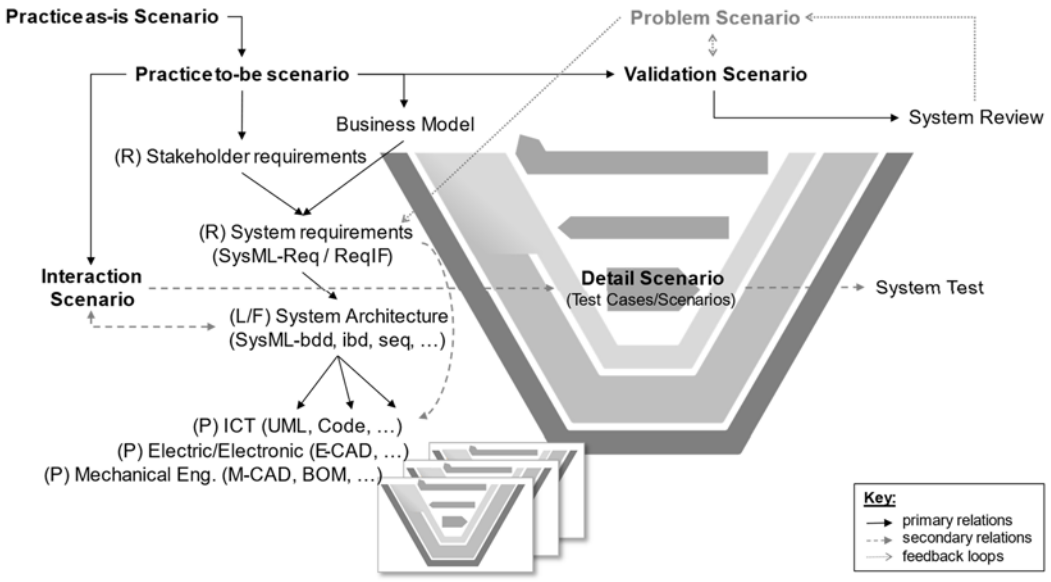

Figure 2. Utilization of scenarios along (Model-Based) Systems Engineering tasks

Classification of Scenarios

Based on the classification scenarios, basic assumptions can be made with regard to the dependence on information quality (Figure 3). Modeling and representation in the form of information resources is usually carried out using standard software as an authoring tool (e.g. Microsoft Office). Special tools can be used in scenario management, but are rarely in productive use (see as an example (Anggreeni & Voort, 2009)).

Figure 3. Classification of scenarios with corresponding interrelations

Abstraction of Scenarios

The definition of scenarios is initially based on the definition of a scenario type and an associated scenario form. Figure 4 shows a corresponding procedure with reference to data sources. These include free text, structured text, images, animations or simulations, state charts, process models, activity and interaction diagrams (Weidenhaupt et al., 1998, p. 37). For these types of scenarios, formalized and standardized forms are defined to varying degrees. Depending on the type of scenario, priorities are set: For example, while state machines (standardized as part of UML and SysML, among others) emphasize the relationship between events and states and activities are secondary, the latter are the focus of process models (e.g. UML/SysML, eEPK and BPMN) with only implicitly recognizable state changes. In line with this focus, data and information are collected and processed in order to design scenarios. These are purpose-related. Validation is recommended as a prerequisite for reuse (A. G. Sutcliffe et al., 1998, p. 1074). One example is the use for requirements elicitation and later for the derivation of test cases.

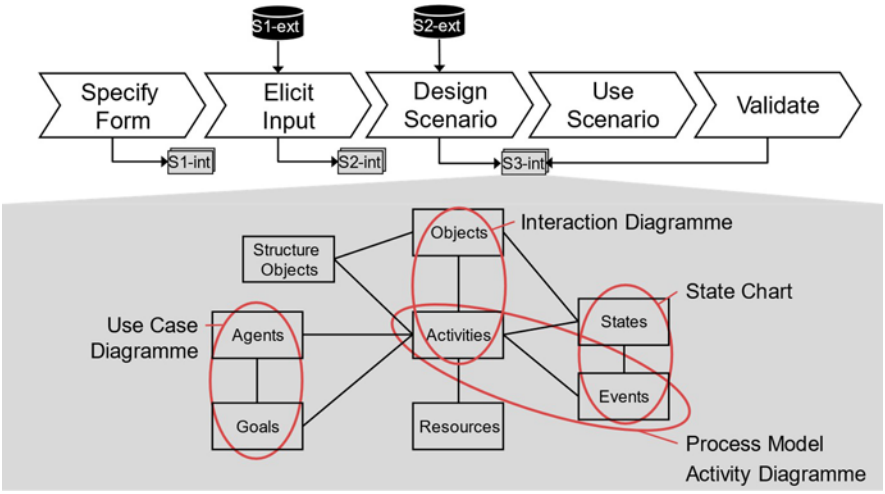

Figure 4. Scenario definition, elements and types (based on (A. Sutcliffe, 1998, p. 51; A. G. Sutcliffe et al., 1998, p. 1074))

The input (S1-ext) is collected, for example, through observation or questioning, content analysis on the basis of specifications including underlying regulations or the interpretation of experiences from previous product generations. As a result of this step (S2-int), ignorance with regard to the initial data must be taken into account as well as ignorance with regard to the relevance for the product to be developed. When designing scenarios, (partial) scenarios that have been defined for comparable products and product types can be reused (S2-ext). The indeterminacy in the design of scenarios as an active, decision-making activity results from the selected form (S1-int) and the content depicted therein (S3-int). Both forms of uncertainty must be examined in the validation.

Conceptualization of Practice and Interaction Scenarios

A metadata model to support scenario-based requirements engineering must support the use of scenarios in the activities from elicitation to analysis and validation of requirements. Accordingly, the differentiated integration of scenarios in requirements engineering must be realized on the one hand, and integration into the higher-level system model on the other. In addition, the projections of future requirements and the risk of change to requirements are challenges in requirements analysis (Graessler et al., 2020).

Requirements should be modeled in a (semi-)structured way. Templates prepare the formalization of metadata and can be used as a basis for conceptualization. Natural language is used for the representation of requirement descriptions. Requirement attributes are defined in the SysML requirement artifact specification, among others. (INCOSE, 2014). Templates are available in the form of the Volere template for requirements (Robertson & Robertson, 2013) and the SOPHIST schemas for requirement descriptions (Rupp, 2014). Its use ensures both a high degree of structuring and flexibility for intuitive descriptions. The semantic model is extended by an ontology for requirements engineering, which is based on the „SWORE – SoftWiki Ontology for Requirements Engineering“ (Dermeval et al., 2016; Riechert & Berger, 2009; Riechert et al., 2007). According to ReqIF (OMG, 2016, p. 12) and the concept introduced by BEVAN et al. (Bevan et al., 2018, p. 8), a distinction between stakeholder requirements and system requirements is recommended. Requirements are logically bundled into sets, which in turn are documented in specifications at defined points in time or events.

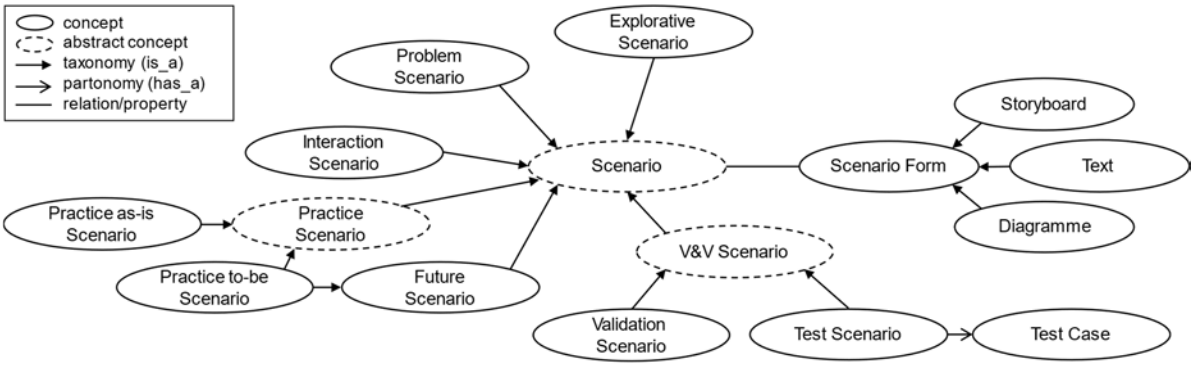

Figure 5. Representation of scenario types and their interrelations

The basis of the conceptual model presented in Figure 5 is attributed by the above-mentioned properties. As special scenario form, practice scenarios are derived as indicative actual or optative target scenarios. Future scenarios depict needs or serve to illustrate business cases. They have an explanatory effect or are used for exploratory analysis (Anggreeni & Voort, 2007). This prepares the ground for both market-oriented and order-related use. Interaction scenarios are derived in a solution-oriented manner, which can also be expressed in the negative form of problem or even misuse scenarios (Pohl, 2010, p. 148). Validation scenarios in the broader sense mentioned above are concretized in terms of Verification and Validation (V&V). Such V&V scenarios are understood as an abstract concept which is detailed by validation scenarios (involving end users or representatives) and test scenarios. Test scenarios are either created based on test cases (e.g., when field trials are scheduled from scratch), or test cases are incorporated into existing test scenarios (e.g., when an exercise is already scheduled).

ADOPTION FOR INNOVATION IN WEATHER-INDUCED EMERGENCIES

The value of traceable scenario utilization of discussed based on two successive exemplary projects. They focus on the algorithms and technical capabilities indicated by the layers in Figure 5. In general, data needs to be integrated including both the current situation (data collected until t_0) and a projected situation (anticipating situation at t_{+m}). Challenges subsume spatial and temporal domains. All layers are based on efficient data acquisition. They include the entire chain from processing close to the sensor, extraction of information and its visualization. It is crucial to ensure explainability in the user interface. Instead of technical explainability, which is understood as technical measures to explain the underlying model, solutions are required to provide decision-makers with information that they perceive as "sufficiently explained". In this case example, rescue robotics (Kruijff-Korbayova et al., 2021) are combined with a Geo Information System (GIS) which was built on the basis of results from the ANYWHERE project (see Figure 6, cf. (Abily et al., 2020; Van Lanen et al., 2019)). Users include civil protection, but also public or private institutions such as water management or the management of flood evacuation plans in campsites. This functional basis is available to implement and discuss the chain of interdependent scenarios. Figure 6 shows the processing levels from data at the bottom to visualized information on top of the stack. The vision of CREXDATA is to develop a generic platform for real-time critical situation management including flexible action planning and agile decision making over data of extreme scale and complexity. Temperatures, videos, forest fire index and wind conditions are indicated as examples of data at the bottom. All of these data types are processed using methods such as trained classifiers or Complex Event Forecasting (cf. (Pottebaum et al., 2012)). An 'explainability layer' in the sense of eXplainable AI (XAI) complements content with additional information that is understandable to humans. This creates the basis for applying visualization approaches.

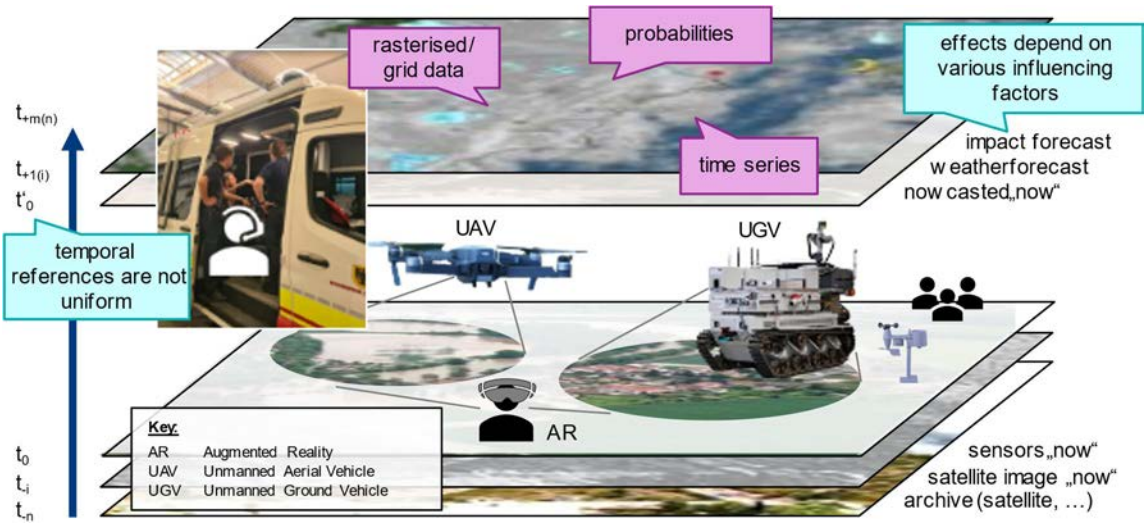

Figure 6. Exemplary case of an ICT solution to support multi-level decision-making in extreme weather scenarios considering global data, for example provided by UAV/UGVs and meteorological services (Pottebaum et al., 2023).

The design of the system is extremely challenging due to several reasons. In addition to the general challenge that there is a large gap between technical opportunities and technologies actually deployed, such reasons include:

- complexity of stakeholder landscape and use cases across functions/institutions (breadth of use cases) and along hierarchy of command (depth of use cases)
- sparsity of extreme weather events, implying that only few experienced stakeholders can be acquired
- variety of domains, often requiring deep knowledge up to scientific competences (like meteorology)
- intellectual Property across data sources, with heterogenous users and their licenses
- variety of technical interfaces
- uncertainty of data along the data processing pipeline

Therefore, the concept of scenarios was applied from early explorative phases through requirements engineering to planning of evaluation with laboratory settings and field trials. Figure 7 presents an overview of the approach incorporating different types and forms of scenarios utilized in impact-oriented research.

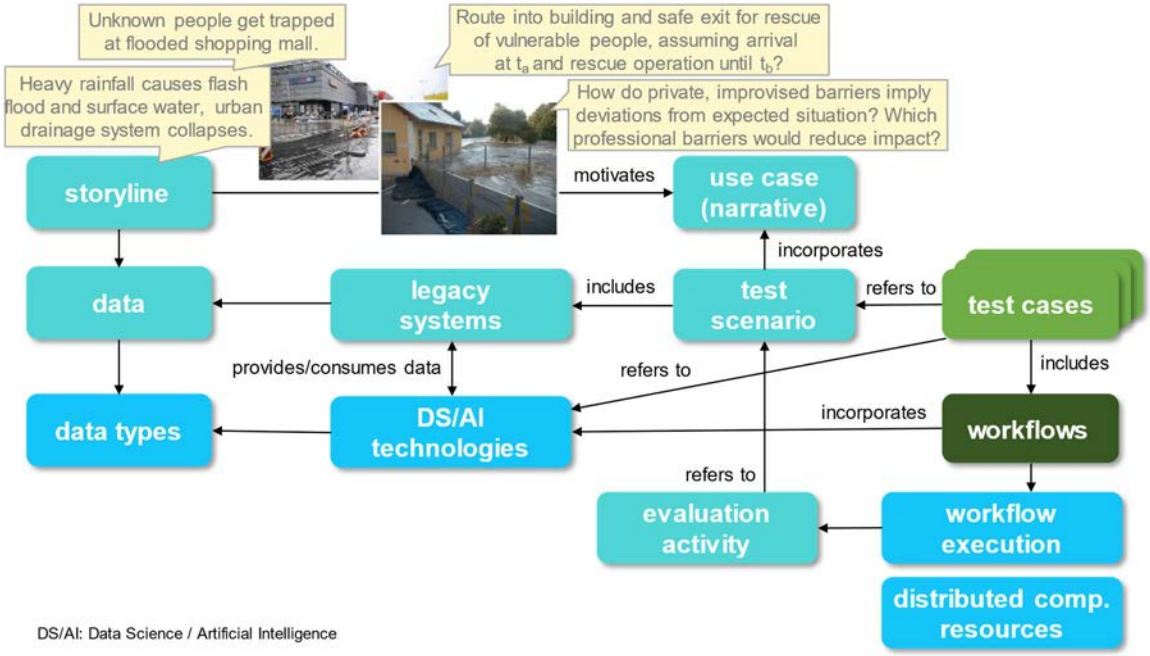

Figure 7. Adoption of various types of scenarios in research on utilizing extreme data with high uncertainties for precise decision support in weather-induced emergencies

The explorative phase of the CREXDATA project was supported by informal "storylines", established in the form of storyboards. Two storylines are created in intense stakeholder meetings to detail the general "pluvial urban flooding" scenarios. In the first storyline, the evacuation of a shopping mall in Dortmund (Germany) with heterogenous visitors is required. In the second storyline, water management with barriers is needed to assess and to avoid threats to traffic and buildings in Innsbruck (Austria). Individual steps within these storyboards become referrable by linking them to simple activity diagrams. Process modelling with Business Process Model and Notation (BPMN) simplifies uptake of existing process models wherever possible. From such storylines, an early exploration is possible regarding relevant data (cf. distinction of global and local data introduced above) and corresponding data types. This is essential in projects that envisage uptake of Data Science (DS) and Artificial Intelligence (AI) technologies. For instance, for technologies like Complex Event Forecasting (CEF), time series data is required in combination with logical modelling of relevant event types to be recognized resp. forecasted. The initial indication on potential data sources enables a two-sided approach: Potential event types can be prescribed by users parsing storylines stepwise, and data sets can be analyzed by CEF partners to identify patterns in data without in-depth domain knowledge. Problem-oriented storylines as explorative scenarios and practice as-is scenarios are transformed into practice to-be scenarios and use case narratives. Such narratives still subsume sketches and natural language bodies but described in a solution-oriented way. These artefacts incorporate knowledge about the technologies to be integrated into the system under development. Bridging system design and system Verification & Validation (V&V), test scenarios are derived. Each test scenario subsumes specific test cases. In research on DS/AI data processing, test cases refer to specific data processing workflows designed using Altair RapidMiner Studio. Test scenarios are utilized with respect to evaluation activities in a two-fold approach: On the one hand, scheduled exercises of stakeholders are identified and checked for applicability in the CREXDATA project. Often, exercises conducted by stakeholders like civil protection authorities, technical relief agencies or fire departments anyhow are most realistic measures for gathering feedback. Researchers need to map exercise objectives and evaluation objectives. On the other hand, field trials are scheduled with the dedicated purpose of evaluation. Practicing procedures is a side-effect for stakeholders then. For the CREXDATA project itself, the mapping of evaluation activities to workflows through test scenarios and test cases ensures traceability of results, enables actual conclusions from application to data processing foundations, and simplifies communication among all partners.

CONCLUSIONS

The article summarizes different types of scenarios based on the literature. A focus is set to scenario types utilized in Requirements Engineering, as there is a variety of background available to gather feedback from stakeholders. Related work in the field of MBSE is adopted for application in emergency management. Scenario types subsume problem-oriented types like exploratory and practice as-is scenarios, as well as solution- and, as such, impact-oriented types like practice to-be and interaction scenarios. The concept for the conceptualization and abstraction of different types of scenarios covers the entire chain from domain exploration to the evaluation of the impact of a technology in this domain. It is based on the V model of Systems Engineering. Using a case study relating to possible pluvial urban flooding situations, the added value that arises along the chain from actual practice scenarios to target application scenarios and validation scenarios is discussed based on two successive exemplary projects. As a conclusion, the mapping along the entire chain from explorative storylines through practice scenarios to evaluation activities ensures traceability of results. The linkage of these scenarios to workflows through test scenarios and test cases enables actual conclusions from application to data processing foundations and simplifies communication among all partners.

ABSTRACT

Systemic risk is ubiquitous in our increasingly globalised world owing to the interconnections within and across sectors. However, a review of National Risk Assessments performed in OECD member countries reveals that systemic risk is rarely mentioned, and it is never accounted for in those assessments.

A powerful method accounts for systemic risk and identifies mitigating strategies using participatory modelling with stakeholders: strategy mapping with *Strategyfinder*. The risk model is represented as a directed graph consisting of risk nodes and directed edges (arrows) expressing causal influences. The method originated in the management of large, complex projects, and it has been applied to systemic risks in critical infrastructures and pandemics.

We demonstrate the *Strategyfinder* method using a scenario describing a cyberattack on electronic communication infrastructure leading to serious consequences for health and lives. The scenario is borrowed from the report Analysis of Risk Scenarios by the Norwegian Directorate for Civil Protection.

Keywords

National Risk Assessments, Risk scenarios, Disaster risk reduction, Vicious cycles, Cascading effects.

INTRODUCTION

A Wider Perspective of Systemic Risk

Systemic risk has been increasingly recognised during the last 2-3 decades as ubiquitous. While the disaster risk reduction community is aware of systemic risk in financial systems (Kim et al., 2022, p2; Schweizer, 2021, p90), the community is less conscious of the role of systemic risk in disruption and delays in complex projects (Gonzalez & Eden, 2023). Not being sufficiently aware of the literature on systemic risk in complex projects (e.g., Ackermann et al. 2007; Ackermann et al. 2011; Williams et al., 1997), the disaster risk reduction community has not yet adopted a validated approach of strategy mapping for disaster risk management using participatory modelling with a team of stakeholders (practitioners, and power-brokers). Using this approach, the team develops risk mitigations strategies deemed effective and practical. Recent evidence of the approach's applicability in disaster risk management has emerged (Abildsnes 2023; Bryson et al., 2023; Eden & Gonzalez, 2023).

Feedback Loops as Result of Interconnected risks

While there are many definitions of systemic risk, all mention feedback (a.k.a. circular causality) among its characteristics (Centeno et al, 2015; Flood et al., 2022; Gonzalez & Eden, 2023; Kaufmann & Scott, 2003; Kim et al, 2022; Reichstein et al., 2021; Renn et al., 2019; Schwarcz, 2008; Schweizer, 2021; UNDRR & UNU-EHS, 2022).

Systemic risk occurs because of the interconnections between risks. When risks give rise to further risks, as is the case in financial systems, in complex projects, and in many disasters, the consequences become very complicated. In all of them, a risk can cause a plethora of other risks, and significantly that risks reinforce themselves through feedback loops (a.k.a., vicious cycles).

Major disasters, like the COVID pandemic, trigger many vicious cycles across the critical infrastructures of nations (in fact, across the whole world). Cascading effects happen both within sectors and across sectors. The mitigation of systemic risks cannot proceed by mitigating separately single vicious cycles. Rather, the identification of the potency of risks – those risks with the most vicious cycles – is a must, to make those most potent risks the priority for risk mitigation measures (Gonzalez et al., 2021).

UNDRR Report on Systemic Risk Mitigation

Systemic risk has got prominent attention from the United Nations Office for Disaster Risk Reduction (UNDRR) in its two last reports on disaster risk reduction – counting together 730 pages. The Global Assessment Report on Disaster Risk Reduction 2019 (UNDRR, 2019), and the Global Assessment Report on Disaster Risk Reduction 2022 (UNDRR, 2022), are extensive reviews of the emergent science of systemic risk and of the challenges posed by systemic risk. In the following we refer to those reports as GAR2019 and GAR2022 for brevity.

GAR2019 states that systemic risks are triggered by the complexity and the interconnections of our increasingly globalised world, whereby the resulting networks determine the exposure and vulnerability shaping the dynamic interactions among the Sendai Framework, the 2030 Agenda, the Paris Agreement, New Urban Agenda, and the Agenda for Humanity (UNDRR, 2019, p32). Assessment and management methodologies for systemic risks are not yet part of the current operations of the twenty-first century risk management institutions; however, there is a growing sense of urgency for a paradigm shift (ibid, p44). The science of systemic risk and systemic risk management is still in "primordial state" (ibid, p146). GAR2022 asserts that little progress has happened in the three years since the previous global assessment report (UNDRR, 2022, p146).

However, the GAR2022 report fails to capture recent advancements utilising strategy mapping. Several publications (Abildsnes et al., 2023; Gonzalez et al., 2021; Gonzalez & Eden, 2022; Eden & Gonzalez, 2023; Gonzalez & Eden, 2023) and a recent report (Bryson et al., 2023, p24-30) describe the extension and application of the approach which emerged in complex project management to systemic risk in the COVID pandemic.

National Risk Assessments – A Fertile Ground for Systemic Risk Management?

The national civil protection agencies are tasked with maintaining a general overview of risk and vulnerability within society. Systemic risk became a hot topic for disaster risk reduction about 2 -3 decades ago. Thus, it is natural to ask: do the national civil protection agencies account for systemic risk in their national risk assessments? If the answer is 'not yet', is there a fertile ground in future national risk assessments for using the recent advancements in strategy mapping (ibid)?

Our method to answer the question consists of two steps:

1. Check if a representative report on national risks assessments proves that systemic risk is being accounted for.
2. If the answer to #1 is 'no', apply strategy mapping to an existing national risk assessment to account for systemic risk.

We proceed to these steps in the following two sections.

IS SYSTEMIC RISK ACCOUNTED FOR IN NATIONAL RISK ASSESSMENTS?

For the first step, we examine the report on disaster risk analysis procedures by the Organisation for Economic Co-operation and Development (OECD). The OECD report presents a cross country perspective of national risk assessments including governance practices for National Risk Assessments and the assessment results in the 20 OECD countries including Australia, Austria, Canada, Denmark, Estonia, Finland, Germa ny, Hungary, Korea, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Spain, Sweden, Switzerland,

United Kingdom, and the United States (OECD, 2018).

The OECD report states: "National Risk Assessments are used to support risk management decisions in a rapidly changing global risk landscape characterized by increasingly complex, interconnected societies and highly mobile people, information and goods." In increasingly complex and interconnected societies the risks become increasingly systemic.

Among the countries reviewed in the OECD report, New Zealand is the only country that included systemic risk in its key definitions, stating that systemic risks are those that "arise from the interactions between interdependent elements of the economy and society". One of the criteria used in New Zealand to characterise risks requiring a national response relates to have "multiple or inter-related problems which when taken together constitute a national or systemic risk".

However, none of the national risk assessments reviewed in (OECD, 2018) report systemic risks.

APPLYING STRATEGY MAPPING TO AN EXISTING NATIONAL RISK ASSESSMENT

For the second step, we examine if a 'promising' risk scenario implicitly accounts for systemic risk. By a 'promising' risk scenario we mean a very detailed scenario where risks cause cascading effects across several critical infrastructures.

The Norwegian Directorate for Civil Protection has been conducting national analyses of risk scenarios since 2011. The risk analyses take a social science approach and are based on qualitative data, expert assessments, and broad participation in the analysis processes. The analyses, which are updated regularly, are very detailed.

Among the 25 risk scenarios described by the Norwegian Directorate for Civil Protection in their last issue of Analysis of Crisis Scenarios (Norwegian Directorate for Civil Protection, 2020), we select a scenario which *a priori* could be expected to contain many interconnected risks, viz. scenario 18.2 "Cyber attack on electronic communications infrastructure" (Norwegian Directorate for Civil Protection, 2020, p204 -207). The scenario describes a cyber attack against the central nodes in the transport network of the Norwegian telecommunications company Telenor. According to the national risk analysis, the attack would cause all electronic communication devices in Norway to fail completely for five days, with massive consequences on critical infrastructures, particularly on life and health.

In the scenario, Telenor's transport network for electronic communications is described as the only nationwide in Norway. The situation has changed since. But although two additional networks, Broadnet and Telia, increased its coverage since the report was produced, Telenor is still the largest transport network in Norway, with more than 200,000 kilometres of fibre and copper cables, and more than 10,000 base stations.

Therefore, the scenario 18.2 "Cyber attack on electronic communications infrastructure" described in the report by the Norwegian Directorate for Civil Protection (ibid, p204-207) is still suitable for answering the question whether the social science-based scenario analysis employed by the Norwegian Directorate for Civil Protection considers systemic risk.

Method

Reinforcing feedback loops of risks (a.k.a. vicious cycles) are the cause of escalating cascading effects. They must be expected in a massive cyber attack to the electronic communication infrastructure. Accordingly, we check whether the risk analysis of scenario 18.2 in (Norwegian Directorate for Civil Protection, 2020, p204 -207) contains feedback loops. To be able to check whether the risk analysis of scenario 18.2 contains feedback loops we must first express the scenario as a formal model capable of being analysed for the existence of feedback loops.

Such formal model can be created with *Strategyfinder*™. *Strategyfinder* is a browser-based professional version of methods and tools developed at the University of Strathclyde since the 1990'ies. With *Strategyfinder* teams collaboratively work in person or virtually on messy problems, to develop strategies, and manage risks. However, in this paper we use *Strategyfinder* to create a formal risk model by reverse engineering scenario 18.2.

A *Strategyfinder* model of risks is a mathematical object known as a directed graph. In a directed graph there are nodes and directed edges ('arrows') expressing causality (i.e., that a node impacts causally on another node).

The nodes in a *Strategyfinder* risk model are risk statements: sentences of typically around 6-12 words describing risks. We adopt Lupton's (2013) definition of a risk: "a phenomenon that has the potential to deliver substantial harm, whether or not the probability of this harm eventuating is estimable".

The first step to create a *Strategyfinder* version of the scenario is parsingthe description of scenario 18.2 to identify

the risks. Since *Strategyfinder* assigns a reference number to each statement, we number the risks in the order in which they are parsed in the subsections below.

The risks are listed in the subsections of the scenario 18.2 "Assessment of vulnerability", "Assessment of likelihood", "Assessment of consequences – Life and health", "Assessment of consequences – Economy", "Assessment of consequences – Social stability", and "Democratic values and capacity to govern". There is some redundancy in the scenario description: some risks are mentioned several times in different subsections. Hence, some statements which are obvious risks appear below without reference number (meaning that they are present in the *Strategyfinder* version using a slightly different wording).

In the following subsections we parse the text from scenario 18.2 (ibid, 204-207), labelling the risks with numbers in the same order as they appear in the scenario. In other words, we proceed by copy/pasting from scenario 18.2 and adding sequent numbers to each risk.

Parsed Risks from Scenario 18.2, Subsection "Assessment of Vulnerability"

[1] Telenor's transport network for electronic communications is the only nationwide one in Norway. [2] Broadnet has a transport network that covers 90 Norwegian towns and cities. However, [3] some of the infrastructure is shared with Telenor, and a [4] failure in Telenor's network would therefore also [5] knock out Broadnet's network. [6] Other electronic communications operators such as Telia, Ice, the emergency services' network (Nødnett) and others, mainly use Telenor's transmission infrastructure, and to some extent Broadnet's. [7] National radio and television companies rely on Telenor's transport network to get signals to transmitters. [8] Telenor's transport network is robust and well protected. However, in the event of [9] any network outage there are no alternatives. [10] Satellite telephony and radio communications do not have nearly enough capacity to meet the need for communication.

The most serious consequences are: [11] Management of the crisis at a political and administrative level becomes difficult, with [12] reduced opportunities for communication and coordination. The [13] disappearance of radio, television and the Internet means that [14] important information channels for the public would be unavailable. [15] Rescue efforts become more difficult in the [16] absence of telephony and when the [17] functionality of emergency numbers and the emergency services' network (Nødnett) is severely hampered. [18] Railway and air traffic would stop. [19] Road and maritime traffic would also experience problems. [20] Failures in payment services would cause [21] major challenges for the commercial sector and the public.

Parsed Risks from Scenario 18.2, Subsection "Assessment of Likelihood"

In this subsection of scenario 18.2 some of the statements are risk attributes, rather than risks themselves. We opt for considering them in the model, since the attributes have causal implications on the risks.

[22] Conducting a successful cyber attack as outlined in this scenario [23] requires a very high level of expertise and capacity – also with regard to intelligence. It is believed that only a [24] few actors have such capabilities. The likelihood would depend on the [25] international threat picture. The Norwegian Police Security Service's open threat assessment for 2018 states that "[26] enterprises within the Norwegian defence and public security sector, public administration, research and development and critical infrastructure are assessed to be particularly at risk of becoming intelligence targets." This applies with respect to [27] both network operations and more traditional intelligence gathering. [28] Several countries' intelligence services have interests within these areas.

Parsed Risks from Scenario 18.2, Subsection "Assessment of Consequences – Life and Health"

[29] Reduced opportunity to notify the emergency services in the event of acute events, [30] no possibility to call an ambulance in the normal manner, [31] inadequate communication and coordination between the emergency services, as well as [32] reduced efficiency and delayed treatment of patients in the health and care sector will have [33] consequences for life and health.

The analysis is based on an assumption that around 5% of acutely sick or injured people (who would otherwise have survived) would die. This means that, overall, the scenario would result in around 10 more deaths per day, or approximately 50 deaths in a five-day period, which represents [34] an increase of around 10% in relation to the normal daily mortality rate. [35] A number of planned treatments would be cancelled due to reduced efficiency. [36] During a five-day period, we estimate that 200–300 people would become significantly more ill due to reductions in the provision of treatment.

Parsed Risks from Scenario 18.2, Subsection "Assessment of Consequences – Economy"

It is assumed that the [37] direct economic losses will be NOK 2 to 10 billion and that they will mainly be associated with [38] the necessary repair and replacement of physical components and infrastructure.

The indirect economic losses will be associated with [39] loss of income, production losses and a decline in consumption, orders, and deliveries. A functioning payment system is a prerequisite for being able to pay for the delivery of goods and services, as well as the trading of financial instruments. Around a third of the normal production, or approximately NOK 13 billion, will be lost as a result of the loss of electronic communications. Even if some of the lost revenue can be recouped, it is assumed that [40] the net loss will exceed NOK 10 billion.

Parsed Risks from Scenario 18.2, Subsection "Assessment of Consequences – Social Stability"

The scenario would result in [41] significant reactions among the public in the form of anxiety, insecurity, fear and a feeling of powerlessness. The incident would be experienced as sudden and unfamiliar. A lack of information would significantly contribute to the level of anxiety. The reactions would be reinforced by [42] people involved in emergency situations being unable to get through on emergency numbers.

Parsed Risks from Scenario 18.2, Subsection "Democratic Values and Capacity to Govern"

The outage of electronic communications would cause [43] major challenges for governance and crisis management. The event would be perceived as a significant violation of shared cultural and democratic values, as well as basic individual rights and personal safety.

STRATEGYFINDER MODEL OF SCENARIO 18.2

The *Strategyfinder* modelin this section sticks to the description of the risk scenario 18.2 provided in (Norwegian Directorate for Civil Protection, 2020, p204 -207). Accordingly, from now on we will refer to the corresponding *Strategyfinder* model as the 'basic risk model'.

Fig. 2 on p7 displays the *Strategyfinder* basic risk model of the scenario 18.2. Explaining all the risk nodes and causal relations (represented by directed links, i.e., arrows) would be extensive. Hence, we use *pars pro toto* a restricted view produced with the *Strategyfinder* analysis tool 'dependency range' applied to #11 'management of the crisis at a political and administrative level becomes difficult' (Fig. 1 on p6). Fig. 1 shows only the risks and issues that directly or indirectly impact on #11.

First, notice that all the risks and issues shown in Fig. 1 are taken from the list of risks and issues parsed from scenario 18.2, cf. p4-5. Then, notice that some items, e.g., #9, #11, and #22, are formatted differently from the others. The reason for the different formatting will be explained below.

The arrow #12→#11 expresses that reduced opportunities for communication and coordination causes that the management of the crisis at a political and administrative level becomes difficult. The arrow #15 →#12 expresses that absence of telephony causes reduced opportunities of communication and coordination. Hence, #15 impacts indirectly on #11. In addition to absence of telephony, the fact that in the event of an outage to the transport network there would be no alternatives means that #9 impacts directly causally on #11 in addition to doing it indirectly via #15. Thus, one has a direct causal impact on #11 expressed by the arrow #9 →#11, and an indirect causal impact on #11 expressed by the series of arrows #9 →#15→12→#11.

If there is an outage, risk #9 (no alternatives for electronic transport in case of an outage) causes #13 , disappearance of radio, television, and the internet, hence the arrow #9 →#13; crucial for that is the impact #7→#13, viz., that radio and television companies rely on Telenor's transport network to get signals to transmitters.

Multiple causes impact risk #9 ('no alternatives for electronic transport in case of an outage'):

- #4→#9, since failure in the Telenor's transport network directly impacts on #9, and because of #1→#9, that Telenor's transport network is the only nationwide one in Norway;
- #5→#9, since Broadnet, who could provide part of the electronic transport, is impacted #4→#5 from the failure in Telenor's transport network;
- #6→#9 expresses that other alternatives depend on Telenor or on Broadnet. Thus, no alternative operates in the case of the outage that knocks out Telenor and Broadnet.

The arrow #8→#4 is labelled with a red minus sign. Arrows with a red minus sign express *negative polarity*, viz., that *increasing* the cause *reduces* the causal impact. Here it means that the high robustness and degree of protection

of Telenor' network decreases the probability that a network failure happens. Arrows with positive polarity are in *Strategyfinder* not labelled with a + sign. I.e., no polarity sign means positive polarity by default.

Consider now #22 'conducting a successful cyber attack'. Risk #22 represents the desired outcome of the malicious agent. Hence, #22 has been formatted using the predefined *Strategyfinder* category 'STRATEGY'.

Conducting a successful cyber attack leads to failure of Telenor's network, hence the causal link #22 →#4.

Conducting a successful attack requires network operations and intelligence gathering by the malicious agent, expressed by #27→#22.

We skip explaining more arrows, since at this stage they should be self-explanatory.

The outcome #11 (the management of the crisis becomes difficult) is a goal for the agents behind the cyber attack. Hence, it has been formatted using the predefined *Strategyfinder* category 'GOAL'. Goals are outcomes desired on their own right. Goals have mostly only incoming arrows. Nevertheless, one can have goals (desired outcomes on their own right) one or two levels below a final goal. E.g., #12 ('reduced opportunities for communication and coordination in Norway') is arguably also a goal for the malicious agent. However, it is also a very busy node, with many ingoing and outgoing arrows, in the risk model. Hence #12 was rather formatted with the FOCUS category (red font), as were #9 and #32 for the same token (very busy nodes).

Strategyfinder has analysis tools to detect the busiest elements in the risk model (e.g., using the analysis submenu 'counting ingoing and outgoing links') and to detect 'heads' (elements with only ingoing arrows). The nodes #11, #34, #37, #40 and #41 are all 'heads' and have been formatted with the *Strategyfinder* category GOAL. Note that they are **negative** goals, i.e., intended outcomes of the cyber attack, which need mitigation strategies and actions on the side of the defenders (Eden, 2004; Eden & Gonzalez, 2023).

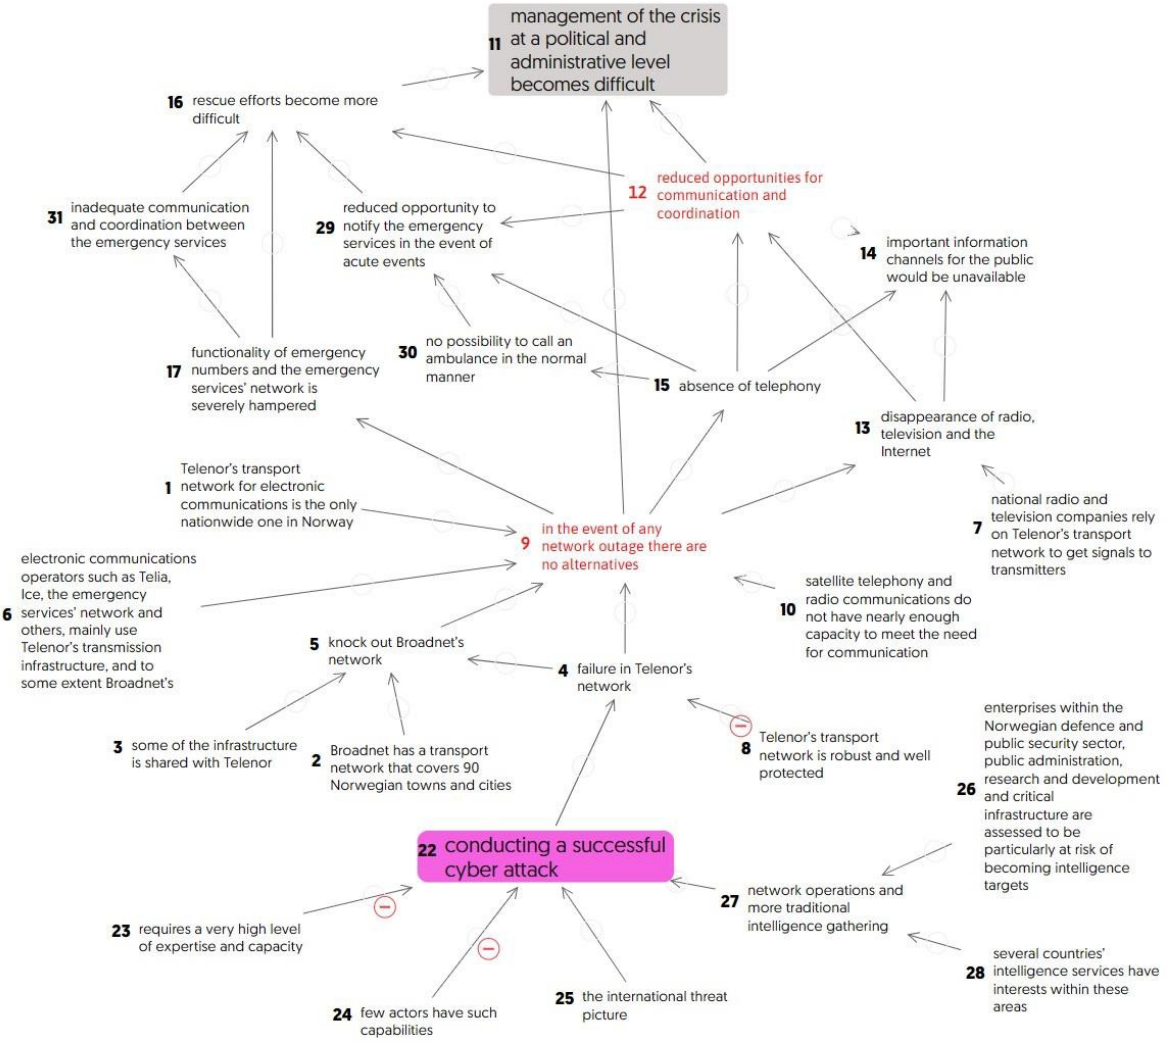

Figure 1 A restricted view of the basic risk model (shown in full on Figure 2) with the risks and issues that directly or indirectly impact on #11 'management of the crisis at a political and administrative level becomes difficult'.

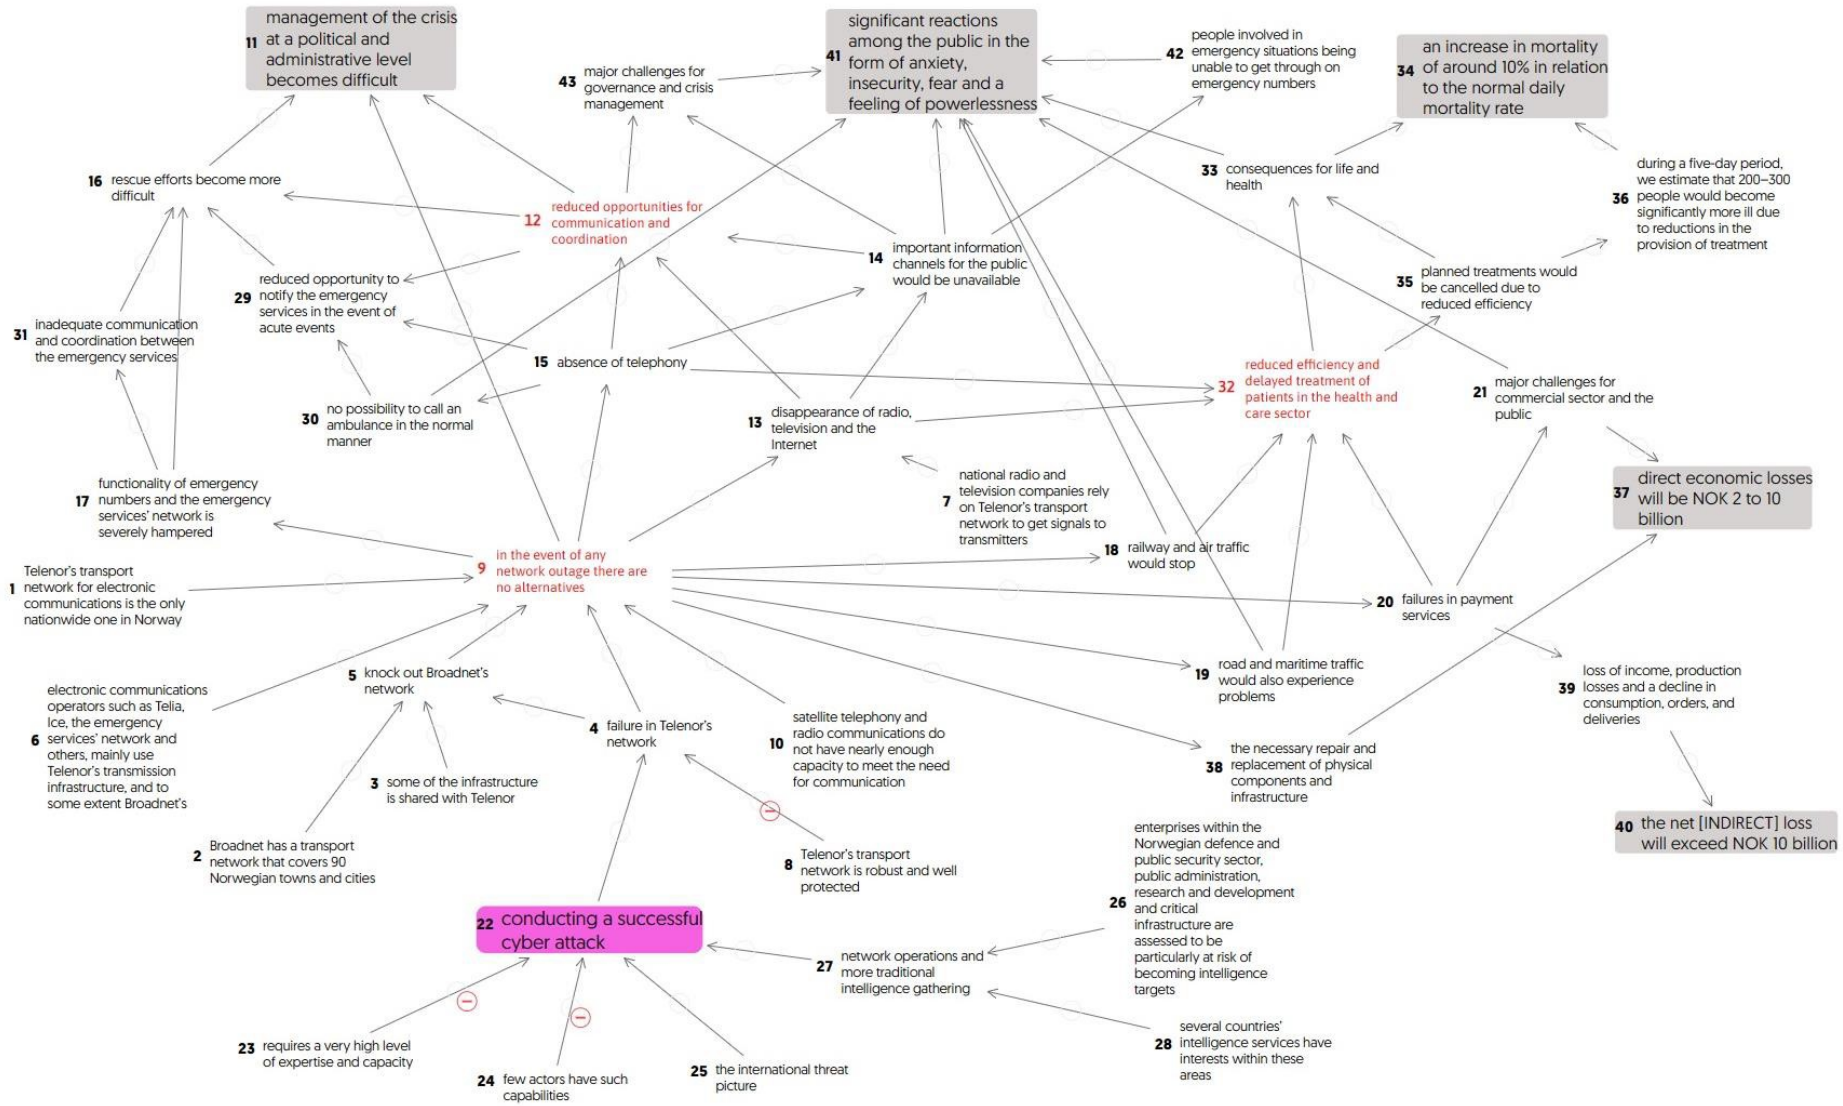

Figure 2 The complete risk model corresponding to Scenario 18.2.

Does the Basic Risk Model Exhibit Systemic Risk?

Systemic risk has a particular kind of complexity, viz., *dynamic complexity*. Dynamic complexity arises if there is causal feedback in a system (Sterman, 2000 , p12-13, 138-141). In the case of disasters, one has reinforcing feedback of risks (vicious cycles of risks). Systems with vicious cycles have dynamic complexity, which makes them very difficult to manage (Eden & Gonzalez, 2003; Gonzalez & Eden, 2023).

A powerful feature of *Strategyfinder* is its ability to detect and identify feedback loops using analysis algorithms applied to the directed graph representing the risk model. Using this feature on the basic risk scenario model, *Strategyfinder* reported 'no loops detected'. Accordingly, the model of risks and their causal interconnections matching the description provided in (Norwegian Directorate for Civil Protection, 2020, p204 -207) must be incomplete, since it does not have feedback loops and, hence, lacks major cascading effects. A massive cyber attack leading to a full failure of the electronic communication devices for five days in Norway must be expected to escalate the risks over time, i.e., to generate vicious cycles of risks (i.e., reinforcing feedback loops of risks and risk outcomes).

ACCOUNTING FOR SYSTEMIC RISK USING THE *STRATEGYFINDER* METHOD

We recall from the previous section, that scenario 18.2 described in (Norwegian Directorate for Civil Protection, 2020, p204-207) does not account for all the causal links among the listed risks, since the basic risk model does not have feedback loops. Without feedback loops the dynamic behaviour of the basic risk model appears to be far too simple. There is no escalation of risks over time. Such escalation must be expected as consequence of a massive cyber attack with cascading effects on several critical infrastructures.

In addition to the missing causal links, which must be expected within the critical infrastructures mentioned in (ibid, p204-207), viz. electronic communication, life and health, transport and finances, the description also seems to be incomplete regarding risks content. For instance, a massive cyber attack disrupting all electronic communication networks for five days would also knock out energy production, in particular hydroelectric energy production (Norway's main source of energy for the public, for much of its industry and for hospitals). Among the consequences of energy disruption, a major one would be the impact on livestock (cattle, pigs, etc), and fish farming (one of the main sources of Norway's prosperity), as well as the impact on refrigerators (household, commerce, and industry).

Extending the risk model to consider all aspects of a massive cyber attack is beyond the scope of this paper. (We mention in passing that such a full risk model would be needed in order to develop adequate mitigating strategies of the risks.) For the purpose of this paper, it is sufficient to show that a modest enhancement of the basic risk model generates vicious cycles of risks, with a resulting dynamic behaviour of risks escalation. In fact, we show that the escalation causes both inner-sector and inter-sector cascading effects.

Identification of Missing Causal Links and Their Consequences

Enhancing the basic risk model by adding a few more obvious causal links among the risks described in Scenario 18.2 'Cyber attack on electronic communications infrastructure' (Norwegian Directorate for Civil Protection, 2020, p204-207) generates several vicious cycles of risks.

To enhance the basic risk model, the third author of this paper, the crisis manager of the Kristiansand municipality, Norway, added causal links to the risk model. He has ample experience with *Strategyfinder* as he was lead participant for the Kristiansand municipality in the Systemic Pandemic Risk Management project 2020-2023 (Bryson et al., p24-30). The project used *Strategyfinder* and promoted a significant extension of the capabilities of the software. As champion of the approach, after the completion of the Systemic Pandemic Risk Management project, the crisis manager of the Kristiansand convinced the municipality to adopt *Strategyfinder* for systemic risk assessment and management.

On Fig. 3 the added causal links are shown as red arrows. The rational for the added causal links follows on p10:

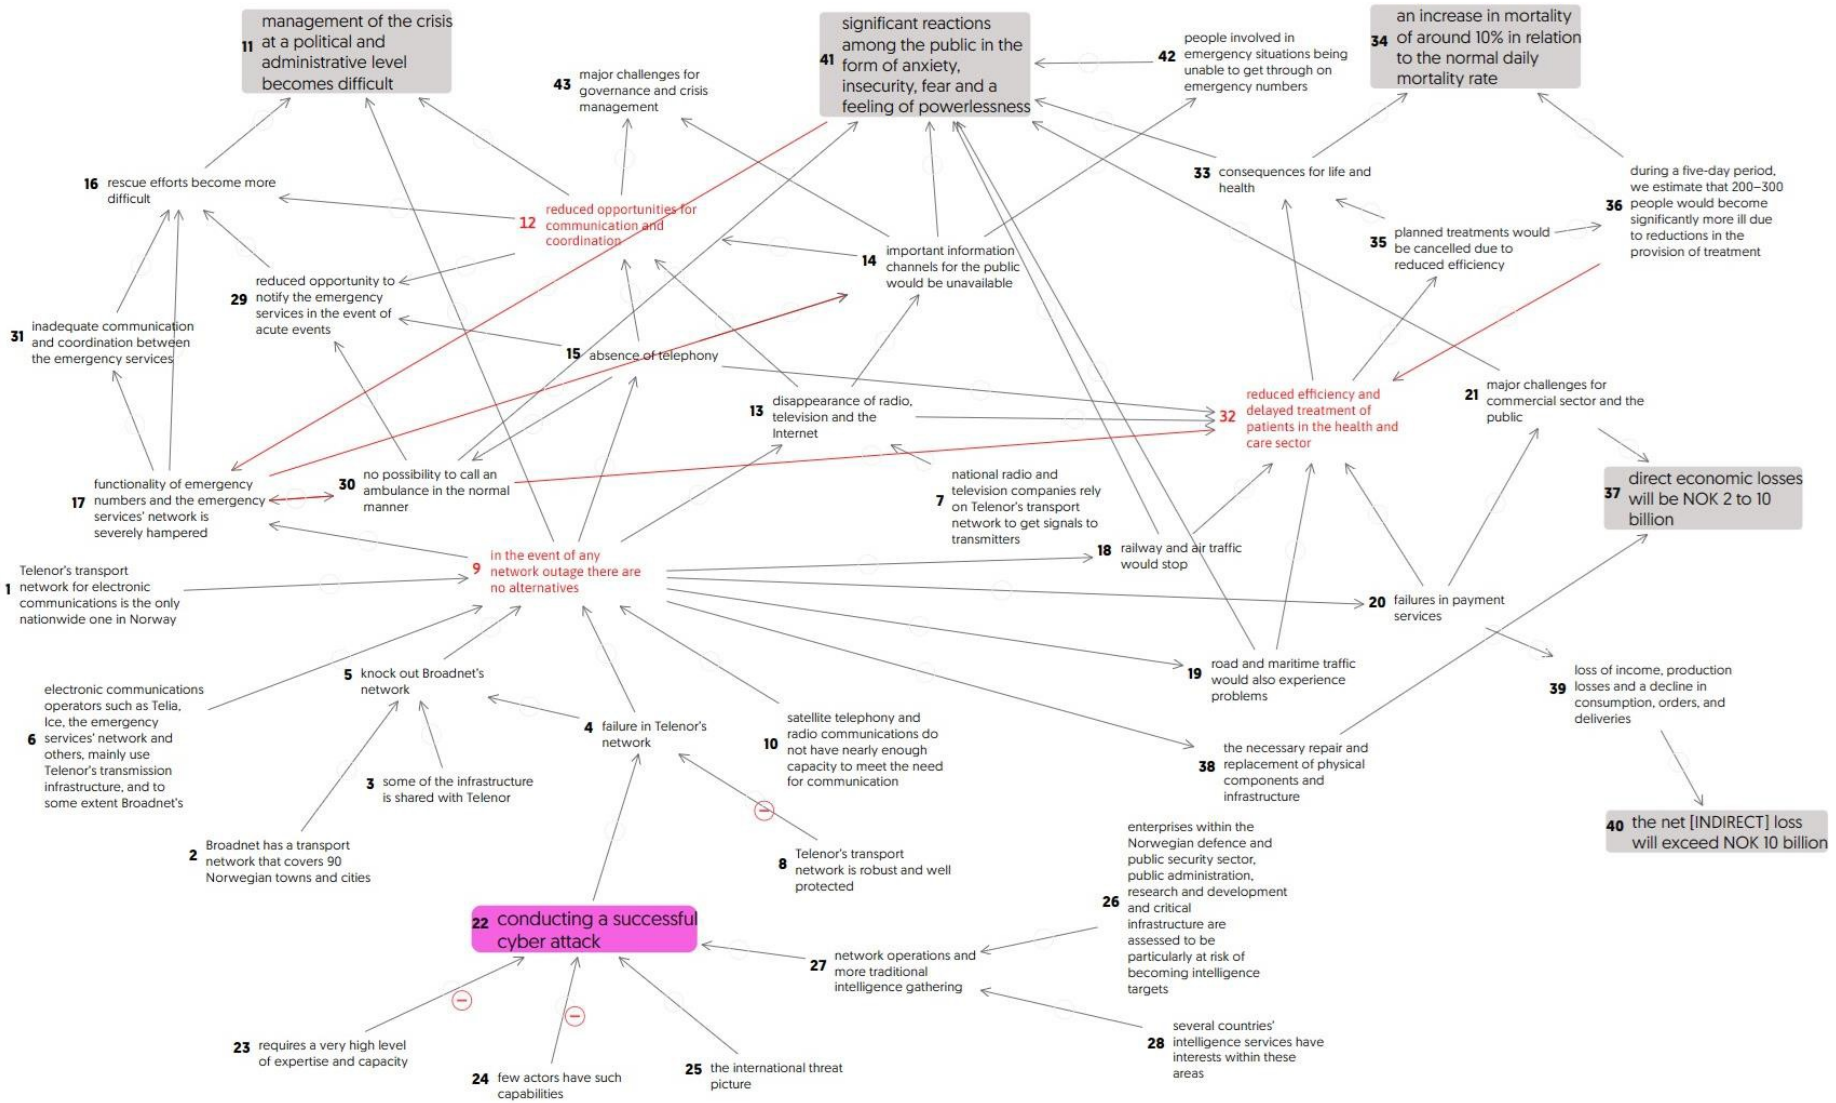

Figure 3 Risk model with added causal links (shown as read arrows). See the main text for the description of the added causal links.

ADDED CAUSAL LINKS AND THEIR EXPLANATION

- #17→30: The functionality of the rescue networks being severely hampered impacts on the ability to call an ambulance in the normal manner.
- #30→17: Not being able to call ambulances in the normal manner adds to the inconveniences hampering the functionality of rescue networks.
- #41→17: Significant reactions among the public (anxiety, fear, hopelessness) is likely to exacerbate conditions that may need request of rescue (which, lacking normal ways of communication, would often be delivered via messengers demanding attention from pressed rescuers).
- #30→32: No possibility to call ambulances impacts on the efficiency of treatment of patients and adds delays.
- #17→14: Since rescue services may detect conditions that demand alerting the public.
- #36→32: A significant increase in serious illnesses will reduce the efficiency treatments in hospitals and cause time delays

In the resulting risk model (Fig. 3), *Strategyfinder* detects 7 feedback loops, all acting as vicious cycles. Fig. 4 shows the result of the analysis.

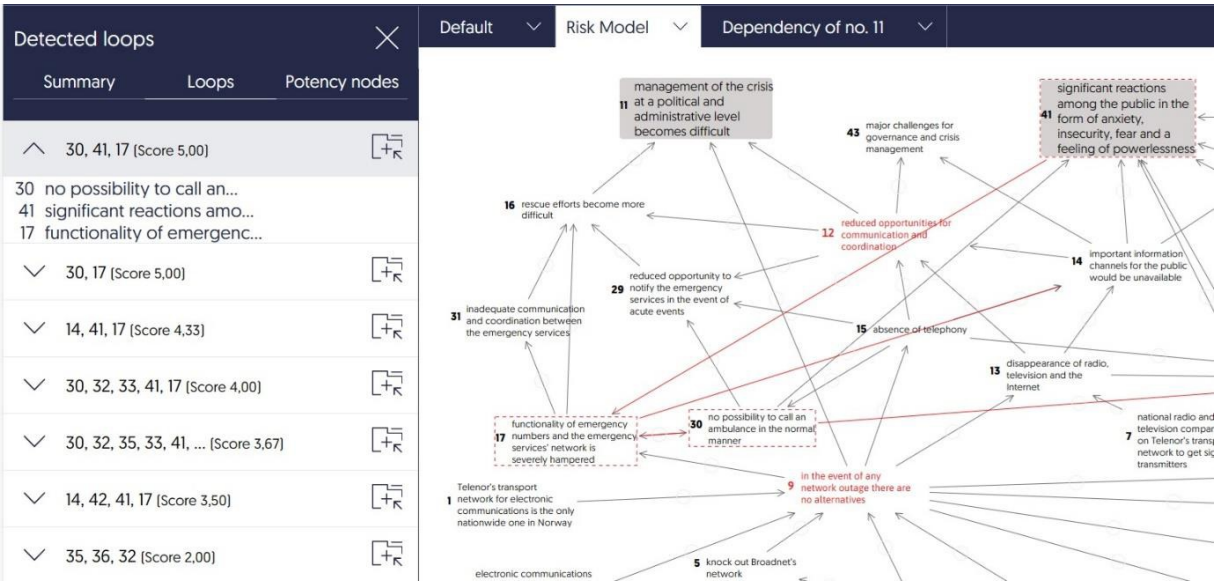

Figure 4 Detected feedback loops. Clicking on a detected loop (here, 17→30→41→17), selects the corresponding risk nodes on the risk model (shown in red colour framed with dashed lines).

We skip the explanation of the scores, since they are not relevant for the purpose of this paper (other than to comment that higher scores mean more potency of the risks).

The symbol to the right of the score indicates that clicking on it creates a new view and the view displays the corresponding loop.

Figure 5 shows the new view (labelled 'Loop 30,17') and the loop (vicious cycle) #17↔#30; note that #17 impacts on #30, and #30 impacts back on #17.

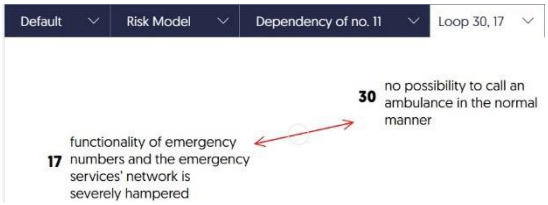

Figure 5 The loop #17↔#30. See main text.

Risk #17 belongs to the electronic communication infrastructure, whereas risk #30 belongs to the public health infrastructure. In other words, the vicious cycle #17↔#30 causes inter-sector cascading effects.

This loop #17↔#30 is part of 4 vicious cycles and the risk #17 participates as node in 6 vicious cycles.

Figure 6 is a composite figure where the 7 feedback loops detected by *Strategyfinder* in the enhanced risk model are shown.

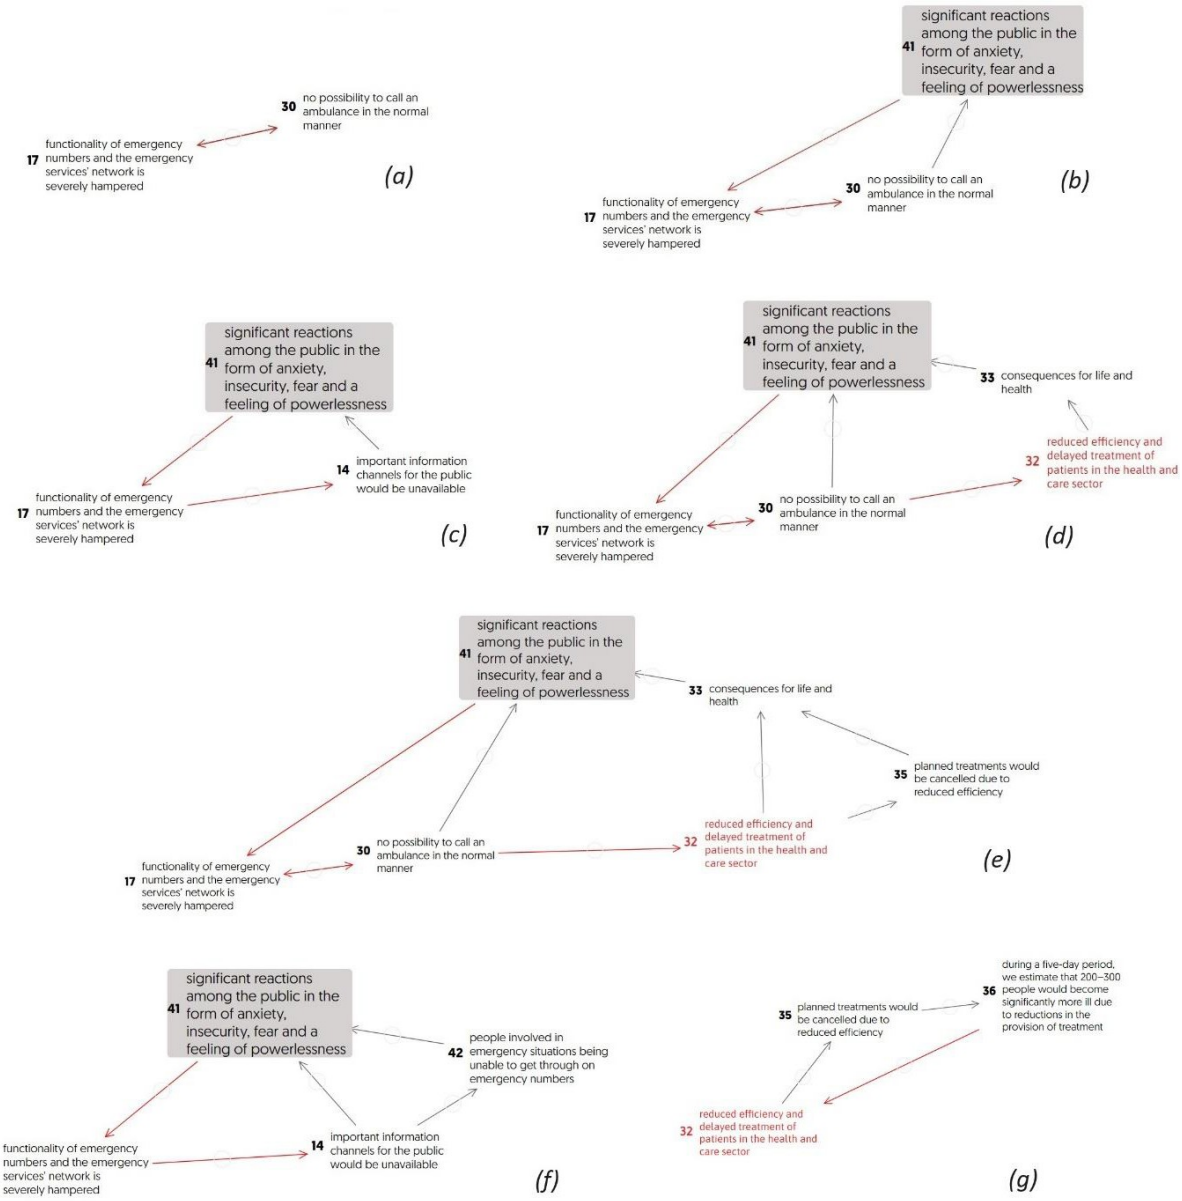

Figure 6 The seven feedback loops in the enhanced risk model, each loop acting as a vicious cycle.

The loop labelled (a) on Figure 6 is identical to the loop #17↔#30. It was discussed in the previous page.

The loop labelled (b) is a nested loop, consisting of two single loops, viz. #30 ↔#17 and #30→#41→#17→#30, which share the node #17. In a nested loop, each of its components act as a single vicious cycle and the interaction between the single loops potentiates their impact. As in the case of the vicious cycle labelled (a), the vicious cycle labelled (b) causes inter-sector cascading effects. As mentioned earlier, risk #41 is likely to generate riots, affecting yet another critical infrastructure (security services). However, the scenario 18.2 does not mention this likely consequence.

The loop labelled (c) is the single loop #14→#41→#17→#14. This loop causes inter-sector cascading effects.

The loop labelled (d) is a nested loop, consisting of three single loops, viz. #30↔#17, #30→#41→#17→#30, and #32→#33→#41→#17→#30→#32. Alternatively, it could be described as consisting of the nested loop labelled (b) on Figure 6, and the single loop #32→#33→#41→#17→#30→#32. This loop causes inner-sector and inter-sector cascading effects.

The loop labelled (e) is also a nested loop. For simplicity, it can be described as consisting of the nested loop labelled (d) – which is itself nested – and the single loop #35→#33→#41→#17→#30→#32→#35. This loop causes inner-sector and inter-sector cascading effects.

The loop labelled (f) is also a nested loop. It consists of two single loops, viz., #17 →#14→#41→#17 and #17→#14→#42→#41→#17. This loop causes inner-sector and inter-sector cascading effects.

Finally, the loop labelled (g) is a single loop: #32 →#35→#36→#32. This loop causes inner-sector cascading effects.

Consequences for Mitigation Strategies

Unmitigated vicious cycles escalate the risks over time and increase the impact of cascading effects. Adding only five more obvious causal links to the basic risk model already generated 7 vicious cycles. If the basic model had been extended by adding more risks (e.g., risks belonging to the energy, the public security infrastructures and food) the number of vicious cycles would have risen significantly. A full extension of the basic model is out of scope. Notwithstanding, using the example below we can explain the principle for how to prioritise targets for mitigating strategies.

The straightforward answer is to target those risks which are in the most vicious cycles, the most potent risks. Figuratively speaking, killing as many birds as possible with one stone (Gonzalez et al., 2021).

Figure 7 displays the outcome of the *Strategyfinder* loop analysis.

The 'nodes' (the risks) in the model are evaluated regarding how many loops (here, vicious cycles) that would be killed by a successful mitigation strategy targeting the node (the 'potency' of the node).

The risk #17 has the highest potency, viz., 6.

Indeed, a glance at Figure 6 shows that #17 is in 6 of the 7 loops. Thus, a strategy mitigating that the cyber attack hampers the functionality of the emergency numbers and the emergency services will counteract the escalation driven by 6 vicious cycles.

Next, the risk #41 has potency 5.

Indeed, a glance at Figure 6 shows that #41 is in 5 of the 7 loops. Thus, a strategy mitigating that the cyber attack causes significant reactions among the public will counteract the escalation driven by 5 vicious cycles.

The reader can compare Figure 7 with Figure 6 and check that the potency of each risk appearing on Figure 7 always corresponds to the number of times the risk is part of a vicious cycle.

The *Strategyfinder* analysis tool reveals much more useful information for strategy development, such as dependencies of a node on other nodes (Fig. 1 is such an outcome), busy nodes (such as #9, #12 and #32) or negative goals (viz., #11, #34, #37, #40 and #41). As to negative goals, cf. p6. The interested reader finds the freely available manual 'Analysis Tools' on https://www.strategyfinder.com/.

Potency	#	Statement
6	17	functionality of emergency numbers and the emergency services' network is severely hampered
5	41	significant reactions among the public in the form of anxiety, insecurity, fear and a feeling of powerlessness
4	30	no possibility to call an ambulance in the normal manner
3	32	reduced efficiency and delayed treatment of patients in the health and care sector
2	33	consequences for life and health
2	35	planned treatments would be cancelled due to reduced efficiency
2	14	important information channels for the public would be unavailable
1	42	people involved in emergency situations being unable to get through on emergency numbers
1	36	during a five-day period, we estimate that 200–300 people would become significantly more ill due to reductions in the provision of treatment

Figure 7 The Strategfinder feedback loop analysis reports the potency of the risks (see main text).

DISCUSSION AND CONCLUSION

The 2019 Global Assessment Report on Disaster Risk Reduction strongly emphasizes the pressing need for a fundamental shift in approaches to managing systemic risk (UNDRR, 2019, p.44). A significant ongoing challenge remains in ensuring that research is not only conducted but also effectively utilized and applied (Boaz & Hayden, 2002).

A recent review by Oliver et al. (2022) focuses on identifying existing activities that engage with research and policy, as well as assessing the impact of these activities on both research outcomes and decision -making processes. The review concludes that many researchers have yet to successfully bridge the gap between scientific knowledge and practical application, resulting in what is described as a substantial and growing volume of unfocused activity, lacking in effectiveness (Oliver et al., 2022, p.704).

Similarly, a recent article by Reichstein et al. (2021) in the prestigious journal Nature emphasizes the importance of creating models that are not only comprehensible but also directly applicable to policymaking. Advocacy for research utilization in practical settings is deemed essential (Boaz & Hayden, 2002, p.440).

The research presented in this paper set out to investigate whether national civil protection agencies account for systemic risk in their national risk assessments. To the best of our knowledge, the approach used in our paper, strategy mapping, is the only one that demonstrably has achieved useable and used mitigation strategies of systemic risk (Gonzalez et al., 2021; Gonzalez & Eden, 2022; Abildsnes et al., 2023; Gonzalez & Eden, 2023; Eden & Gonzalez, 2023; Bryson et al., 2023). The approach uses participatory modelling involving stakeholders, mostly practitioners, experts from different relevant disciplines, and – very important for the implementation of the mitigation strategies – power brokers.

Surprisingly, two decades into the realisation of the systemic risk notion by the disaster risk reduction community, no evidence was found that systemic risk is accounted for in the national risk analyses presented in the OECD countries report (OECD, 2018). From a national security perspective, this might potentially represent a deliberate exclusion by national governments if they deem it sensitive to disclose a thorough analysis of national risks .

Nevertheless, the aim of conducting risk assessments by national civil protection agencies is arguably to 1) provide overviews to politicians and business leaders; 2) communicate risks to a wide audience; and 3) as input for exercises and emergency planning at a regional level. We believe that the importance of systemic risk is too significant to justify its omission in national risks assessments. Emergency planning at the municipal and regional level, where the first line of disaster response will be effectuated, must be detailed and specific. Considering that regional risk assessments must involve sectors with critical infrastructure according to their presence and role, omitting systemic risk assessment at the highest level (national) would hardly encoura ge consideration of systemic risk at the regional level.

The OECD report was published in 2018 and there is a possibility that systemic risk since has become an important part of national risks assessments in some of the countries covered by the OECD report. However, we doubt that systemic risk is sufficiently accounted for in national risk assessments. Our doubt is based on two facts.

First, the most recent report from the United Nations Office for Disaster Risk Reduction (GAR, 2022) acknowledges (ibid, p146) that little progress has been done in this regard over the three years period following the previous global assessment report (GAR, 2019). Arguably, if national risk assessments had employed a novel method to account for systemic risks, the GAR2022 authors would have noticed and reported it.

Second, Norway has not yet conducted *national* risk assessments accounting for systemic risk despite acknowledging its importance and the availability of relevant methods. The Corona Commission established by the Norwegian government in response to the COVID pandemic released a report (The Norwegian Corona Commission, 2020) stating that “In its emergency preparedness efforts, the Government has paid little attention to how risk in one sector is affected by risks in other sectors. A crisis preparedness system in which each sector evaluates its own risks and vulnerabilities, will fail if no one takes responsibility for evaluating the sum of the consequences for society at large. There is a need for a cross-sectoral system that can accommodate the interaction of risks across all sectors. This is a lesson applicable to preparedness in general”.

Systemic risk assessment *has* been developed and applied in Norway recently, but then at the *regional level* in the Systemic Pandemic Risk Management project 2020 -2023 using strategy mapping with *Strategyfinder*. The Systemic Pandemic Risk Management project included partners from the municipality of Kristiansand and the regional hospital (Bryson et al., p24-30), as well as international partners. Carefully selected stakeholders (both experts and decision-makers) participated in online workshops to create, analyse, and validate the risk model, to finally propose effective and practical mitigation strategies and identify roles to monitor and implem ent the strategies (Abildsnes et al., 2023, Bryson et al., 2023). Nonetheless, the Norwegian national authorities have not

yet adopted the method developed and applied at the regional level (in the Systemic Pandemic Risk Management project) for national risk assessments and mitigations strategies.

We mentioned several times that the purpose of strategy mapping is to develop strategies. But answering our research question did not require developing mitigation strategies. Our research question, whether national civil protection agencies account for systemic risk in their national risk assessments, only required examining 1) whether systemic risk was explicitly accounted for in the national reviews described in (OECD, 2018); 2) if there was evidence to that effect after 2018; 3) if there was evidence of feedback loops in a highly promising risk scenario 18.2 provided by the Norwegian Directorate for Civil Protection (2020).

The development of risk mitigation strategies for scenario 18.2 would have demanded a considerable extension of the risk model, i.e., it was out of scope.

On p2 we posed the question whether there is a fertile ground in future national risk assessments for using the recent advancements in strategy mapping. We hope to have created awareness that the method of strategy mapping for assessing and managing systemic risk originating in the field of complex project management deserve being adopted by the disaster risk reduction community.

Hence, we believe that the national civil protection agencies could significantly improve their risk analyses using strategy mapping to account for systemic risk. The report from the IBM Center for the Business of Government reviews strategy mapping (Bryson et al., 2023, p8-15, p41 and p43-46). The report also contains a section on the application of the Systemic Pandemic Risk Management project on mitigation strategies of systemic pandemic risk (ibid, p24-30). Finally, the report has an extensive comparison of different methods and tools for strategy mapping (ibid, p49-53).

CLARIFICATION

None of the authors has ownership in the *Strategyfinder* software and none of the authors is employed by the company owning the software.

ABSTRACT

Increasingly long-lasting and complex crises and disasters can cause psychosocial effects on certain population groups with different vulnerabilities. To increase a population's resilience, it is necessary to examine these effects more deeply by systematically monitoring the psychosocial situation, integrating different types of data and making this data researchable, visible, and documentable via a multi-modal platform. Following a systems thinking approach, this paper presents a full approach to developing a "Multi-Functional Crisis Information Platform for Psychosocial Situations" (CIP-PS) for Germany, which includes the integration of an ontology- and filter-based research component (CIP-REP), a filter-based dashboard component (CIP-DAB), and a documentation component (CIP-DOC) into a complete information platform. In sum, this platform fulfills the requirement of comprehensively integrating different psychosocial data (e.g., survey, meta data, or question item data) into a system capable of fully linking all components and related data to healthcare informatics.

Keywords

Crisis information platform, psychosocial situation, data integration and visualization, dashboard and research platform, vulnerabilities

INTRODUCTION

The number of crises and disasters – such as, e.g., the Corona pandemic or extreme weather events – are increasing worldwide (Boin, 2019), posing risks and threats to the population (e.g., Munich Security Conference, 2023). When crises become more long-lasting, complex, intertwined, or transboundary (Boin, 2019), negative *psychosocial consequences* can emerge, such as post-traumatic stress disorder (PTSD), anxiety, or depression related to crises or disasters, which differ in relation to the vulnerabilities (*risk factors*) in certain population groups (Bonanno et al., 2010). This means that not only the physical condition of people affected by crisis or disaster is important when monitoring their effects. In coronavirus crisis management, for instance, psychosocial experts address the psychosocial situation of the population in addition to virological concerns (Hering et al., 2021), so as to increase the population's (psychosocial) resilience in times of crisis and disaster.

The main goal is thus to increase the population's resilience. Resilience is defined as a system's or an individual's ability to manage changes and continue developing (Moberg & Simonsen, 2011). The rise in complex and systemic crises leads us to take the approach of systems thinking: we understand society as a complex adaptive system (Carvalhaes et al., 2021) in which every stakeholder contributes to crisis preparation. This holistic approach is called the "system of systems" thinking (Cavallo, 2014). Additionally, Carvalhaes et al. (2021) speaks of a "wicked complexity" causing deep uncertainty and requiring new approaches to understanding how society functions. In order to assess resilience, combining quantitative and qualitative methods are seen as an innovative approach (Carvalhaes et al., 2021). According to the disaster resilience approach by Cavallo (2014), it is important to create an overall perspective, including top-down and bottom-up processes for unknown risks, and to regard crises management as an all-hazard-approach (Carvalhaes et al., 2021) to widen the situation picture, detect signals and see the bigger picture which is important to cope with the crisis (Leidner et al., 2009). Also, a shared understanding of the situation among all stakeholders as well as a modularization for software reuse is important for coordinating response activities and making it possible to reuse software in future projects (Leidner et al., 2009). This requires both a common knowledge base of psychosocial terms and situation definitions and a platform using individual components that can function alone and be applied in other crisis contexts. Furthermore, given the increasing importance of knowledge transfer, scientific knowledge should be prepared for target groups and co-developed in common projects aimed at actionable knowledge tailored to the needs of particular groups (Treffeisen & Grosfeld, 2022). Standards of transparency and verifiability ensure that society can trust this knowledge, which can be distributed on service platforms for the stakeholders concerned (Treffeisen & Grosfeld, 2022).

This raises the main research question:

> *How can an information platform contribute to increasing the population's (psychosocial) resilience in times of crisis and disaster?*

When appealing to the ability and resilience of citizens as their own crisis managers (see Boin, 2019), *individual resources* as well as the *perception* of and *behavior* in different crises should be monitored to derive suitable risk or crisis communication strategies to cope a crisis[1]. Also, other psychosocial information sources such as studies on help-seeking behavior in crises or field protocols on psychosocial emergency care have to be integrated into a system that monitors the overall psychosocial situation of the population at large as well as of those directly affected. Therefore, these different data concerning psychosocial topics should be combined in an information tool that makes them systematically researchable, visible, and documentable. That is, survey-based psychosocial situation pictures of the population as well as information on help-seeking behavior and psychosocial emergency care in times of crisis and disaster must be harmonized and fed into a platform targeting crisis managers as well as (government) decision-makers and authorities, the scientific and media community, and the public at large. This platform should be able to handle different psychosocial topics and related data accessed in different components depending on what the user is interested in. It must allow for an efficient and quick access to the components requested.

[1] We define the psychosocial situation picture using five psychosocial categories: perception (e.g., risk perception), behavior (e.g., protection behavior), risk factors (e.g., age) as well as resources (e.g., resilience) and psychosocial consequences (e.g., stress) (Gerhold et al., 2022; Lüttschwager et al., 2022).

This raises the more technical question:

> *How should an information platform be technically constructed so as to integrate different data types and connect different components with one another?*

Information, research, or dashboard platforms that collect and present various data in crises, disasters, or more general contexts do exist. While entire information platforms such as INFORM (European Commission - Disaster Risk Management Knowledge Centre [EC-DRMKC], 2023) or dashboards such as the Natural Disasters Dashboard (Office for the Coordination of Humanitarian Affairs [OCHA], 2023) use statistical or process data, only few information or dashboard platforms use survey data like the Smart Data Disaster Management (Smart Data, 2023) or PACE (University of Erfurt et al., 2023). Research platforms with functionalities similar to ours are rare. They include the IFRC GO (Red Cross Red Crescent [IFRC], 2023) for disasters in general or the paneldata.org-explorer (German Socio-economic Panel [GSOEP], 2023) in generic contexts using statistical/process or survey data, among others.

To the best of our knowledge, there are to date no information platforms combining survey, systematic review, and psychosocial emergency care data.

In terms of application, the question becomes:

> *How can different data be integrated and aggregated into a tool that researches, visualizes, and documents them?*

We answer these research questions by first explaining our research methodology, then reviewing the current research, including an overview of existing information, research, and dashboard platforms, before showing in greater detail how we developed the "Multi-Functional Crisis Information Platform for Psychosocial Situations" (CIP-PS). Therefore, we explain the overall structure and outline the data used for integration into the entire system. Next, we describe the single elements of the research component CIP-REP, the dashboard component CIP-DAB, and the documentation component CIP-DOC, including their technical and visual implementation and how they link to one another. We then present different use cases for CIP-REP and CIP-DAB in different scenarios. The final sections discuss challenges and limitations, followed by a conclusion and future steps.

RESEARCH METHODOLOGY

In this section, we explain our research methodology, following those in information systems (IS) summarized in Kilani and Kobziev (2016) and the design science research[2] IS framework by Peffers et al. (2007). First, we defined the problem as a lack of information platforms providing information on the psychosocial situation in crises using state-of-the-art research. We addressed this in several research steps, such as tool programming and data collection/processing, development, and prototyping (Archer, 1984). In general, we followed a two-stage approach, by looking at CIP-PS as a whole (stage 1) and then its components CIP-REP, CIP-DAB, and CIP-DOC (stage 2), using both a qualitative and a quantitative approach.

In stage 1, we exploratively developed CIP-PS by means of data collection steps such as state-of-the-art research on established information platforms (see below), and a target group analysis (with our project partner from the German Red Cross as the first target group). Next, we created an overview of the psychosocial topics and conducted further group interviews with aid organization members in order to explore the potential use of our platform. Our research strategy entailed multiple use cases (shown below), addressing precise potential problems, target groups, and processes. The (technical) validity and reliability of the platform was ensured by applying scientific standards and established solutions of User Interface (UI) and User Experience (UX) research in its development. Components from other projects were reused to create synergy effects. CIP-PS systematically presents psychosocial topics in order to illustrate the complex psychosocial crisis situation and reduce complexity in a model that can be analyzed and that explains the situation and its interdependencies in an understandable and transparent way. This serves target groups as a decision support system and improves individual resilience, the core purpose of CIP-PS (as set forth in the Introduction).

In stage 2, the different components as a "system of systems" (see above) are treated with different sub-methodologies.

CIP-REP follows a qualitative approach by integrating results of documents and study outcomes using meta-

[2] Simon (1969, p. 55) as cited in Peffers et al. (2007) stated, that "[w]hereas natural sciences and social sciences try to understand reality, design science attempts to create things that serve human purposes".

analysis and the qualitative content analysis research strategy (Mayring, 2015). The terms of these documents were deductively derived into ontologies, filters, and contents and can be inductively expanded with new concepts.

CIP-DAB, by contrast, follows a quantitative research strategy using quantitative data on surveys and protocols, which are deduced from the framework of psychosocial situation research (e.g., Gerhold et al., 2022) and represented in validated and reliable question constructs. These are presented in a statistically reproducible and clear way (e.g., plots) differentiated by scientifically derived risk factors.

Finally, CIP-DOC applies scientific principles of transparency and documentability to both components by storing easily accessible documentation of studies, questionnaires, and protocols.

STATE OF THE ART AND RELATED WORK

We define an information platform as a "software-based platform" and core functionality with different modules as software subsystems which can then "extend the functionality of the platform" (Hein et al., 2020, p. 88). The information platform as an overall framework embeds sub-systems such as CIP-REP as well as CIP-DAB. CIP-REP is an IR (Information Retrieval)-based component for semantics-enabled searches of project artifacts, whereas a dashboard is a visualization "of a consolidated set of data for a certain purpose" (Matheus et al., 2020, p. 1) with different types of presentations, such as geographic, numerical, or temporal (Schulze et al., 2023).

Table 1 illustrates some examples of information platforms like the INFORM (EC-DRMKC, 2023), HEIMDALL (German Aerospace Center [DLR], 2021), or the Global Crisis Response Platform (International Organization for Migration [IOM], 2023) that integrate different elements and crisis-related data into one platform. Research platforms such as the IFRC GO (IFRC, 2023) or Google Crisis Response (Google, 2023) allow users to systematically research the data that is also presented visually, while general research platforms such as paneldata.org (GSOEP, 2023) enable the user to search for survey variables similar to our CIP-REP component with its psychosocial situation monitoring survey data. In terms of dashboards, there are examples of tools integrating survey data, such as the PACE project (University of Erfurt et al., 2023) or the Covid-19 National Survey Dashboard (CAMH, 2023), with many others visualizing statistical or process data on the environment, natural disasters, or crises in general (e.g., Community Risk Assessment: Netherlands Red Cross, 2023; Natural Disasters Dashboard: OCHA, 2023; Global Crisis Risk Dashboards: United Nations Development Programme, 2020). Another selection of dashboards can be found in Sterl et al. (2023) or, for public health data, in Schulze et al. (2023).

Table 1. Examples of information platforms (MIP), research platforms (REP), and dashboards (DAB)

Type of platform	Type of crisis	Type of data	Specific content	Example of tool (Citation)
MIP	Environment/climate/humanitarian crises	Statistical/process	Information about crises in general (focus on, e.g., risks, warnings, climate change)	INFORM (EC-DRMKC, 2023)
	Natural disasters	Statistical/process	Disaster-relevant information	HEIMDALL (DLR, 2021)
	Medical crises	Statistical/process	Information about coordination and decision processes (concerning crises/medical emergencies)	COncORDE – Crisis Management Platform (Konnektable Technologies, 2021)
	General disasters	Statistical/process/survey	Real-time data on crisis-relevant information (e.g., water levels, stress levels, social	sd-kama (Smart Data, 2023)

			network structure)	
	General crises	Statistical/process	Crises-relevant information	Global Crisis Response Platform (IOM, 2023)
REP/DAB	Disasters in general	Statistical/process	Disaster-relevant information	IFRC GO (IFRC, 2023)
	General crises	Statistical/process	Crises-relevant information	Google Crisis Response (Google, 2023)
REP	General	Statistical/process/survey	Information on, e.g., research data	paneldata.org (GSOEP, 2023)
	General	Statistical/process/survey	Information on, e.g., research data	GESIS search (GESIS - Leibniz Institute for the Social Sciences, 2023)
DAB	Covid-19	Survey	Covid-19 information (main focus on the mental health and substance use in Canadian population)	COVID-19 National Survey Dashboard (CAMH, 2023)
	Environment/climate crisis	Survey	Information about the climate crisis (focus on, e.g., attitudes, behavior, risk perception)	PACE Explorer (University of Erfurt et al., 2023)
	Environment/climate/ humanitarian crises	Statistical/process	Information about affected areas in humanitarian crises	Community Risk Assessment (Netherlands Red Cross, 2023)
	Natural disasters	Statistical/process	Disaster-relevant information	Natural Disasters Dashboard (OCHA, 2023)
	Ukraine crisis	Survey	Information about the Ukraine crisis	GeoPoll Ukraine Crisis Data Tracker (GeoPoll, 2022)
	General crises	Statistical/process	Information on global risks	Global Crisis Risk Dashboards (United Nations Development Programme, 2020)
	General crises	Statistical/process	Crises-relevant information (e.g., geographical,	The Emergency Dashboard (World Food Programme,

	funding, and performance-related information)	2023)

Note: This represents only a small sample. Another selection can be found in Sterl et al. (2023); a much wider selection can be requested from the authors of this paper.

In sum, there are many platforms and components that focus on crises, disasters, or general events. However, most tools primarily integrate process-produced information instead of population surveys, literature reviews of scientific studies, or information on psychosocial emergency care that would present an overall picture of the psychosocial situation in times of crisis and disaster.

To explore the information items concerning survey and statistical data, mature techniques can provide adequate means for a broad range of target users.

The approaches presented here focus on the integration of three diverse, almost independent views (see Sterl et al., 2023):

1) Research and exploration offering an interface for the semantic retrieval of domain-relevant data
2) Statistical interdependencies with CIP-DAB utilizing enhanced visualization techniques for statistical data
3) Documentation library, inspecting static, document-oriented artifacts

Given the above, we see two gaps in the research:

First, based on the systems thinking approach and the knowledge transfer paradigm, we bring together different data on psychosocial topics into one platform to reduce complexity, and to help users systematically research, visualize, and document all the data in a way that is tailored to their needs and addresses the main goal of increasing resilience in the population.

Next, our IS fully connects not only a dashboard visualization component but also a research and documentation component in the front as well as backend layer to help the users visualize the information required for their decisions.

We conclude that the development of CIP-PS is – to the best of our knowledge – innovative and fills in the research gaps we noted above. The next sections present in greater detail the overall structure of CIP-PS as well as its single components CIP-REP, CIP-DAB, and CIP-DOC.

DEVELOPING THE CRISIS INFORMATION PLATFORM CIP-PS

General Concept

CIP-PS is divided into three different layers, including the psychosocial topics: “Psychosocial situation in Germany” (PSG), “Help-seeking behavior” (HSB), and “Psychosocial emergency care” (PEC) (*Figure 1*). Depending on what topic the user selects, the respective CIP-REP, CIP-DAP, or CIP-DOC opens. For both PSG and PEC, CIP-REP, CIP-DAB, and CIP-DOC are displayed, while for HSB, CIP-REP and CIP-DOC are shown. Further, descriptions of each psychosocial topic are shown after clicking on the appropriate information text section.

The overall platform design is structured as a micro frontend. That is, CIP-REP, CIP-DAB, and CIP-DOC are micro frontends independent of each other and linked via an integration layer. The complete frontend is composed of different, independently working components. The data which is called up by the user is pre-processed using a proxy server and then integrated into a data format representing the specific characteristics of every frontend. CIP-REP, CIP-DAB, and CIP-DOC can be deployed singularly regarding the other elements, while CIP-PS is highly responsive and restricted to tablet mode following the principles of high UI/UX standards using the bootstrap 4 library with their own guidelines (Bootstrap, 2023). Regarding app functionality, the CIP-PS is designed as a Progressive Web App (PWA; Tandel & Jamadar, 2018) working offline. This means that it loads all the required data when it is first established or called up by the user, and thus runs much more quickly in subsequent single uses. The data required in the respective component is saved in the background so that the user can keep researching free from interference. Since a PWA also works offline running directly on the device, the CIP-PS can be used without an Internet connection.

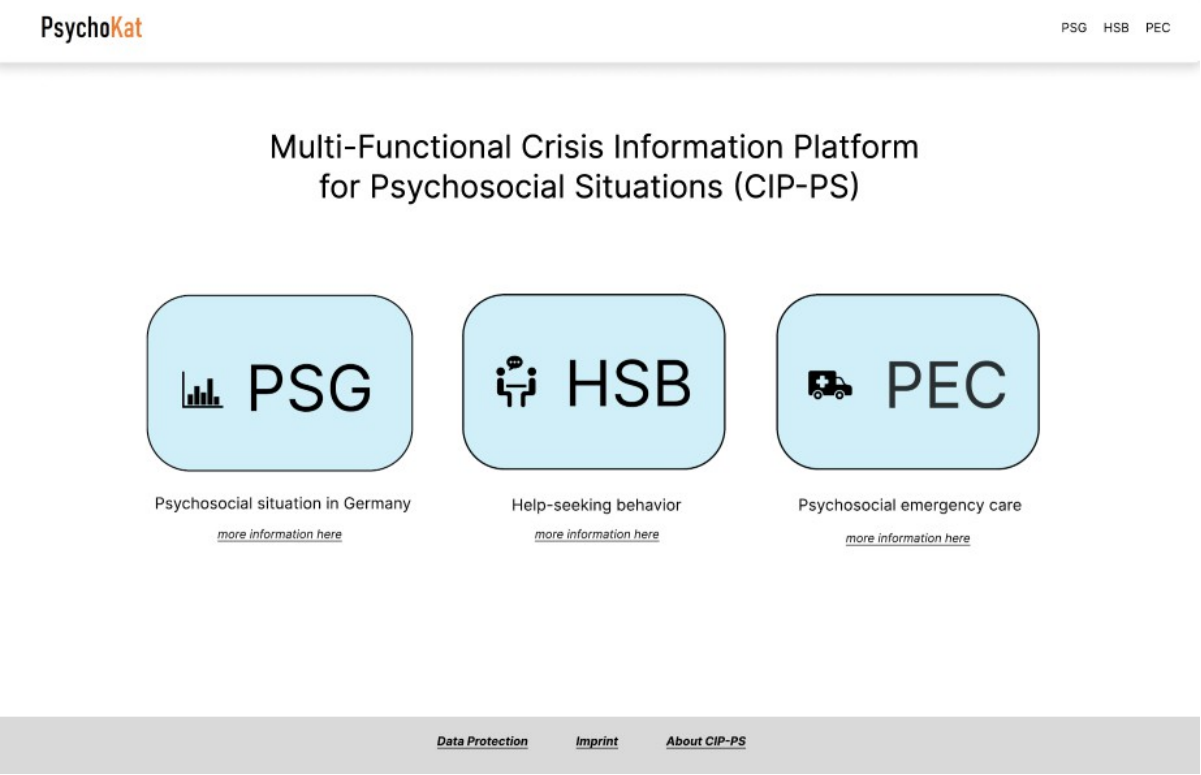

Figure 1. Screenshot of the overall structure of CIP-PS

Research Component: CIP-REP

CIP-REP is dynamic and includes filter- as well as ontology-based research on PSG, HSB, and PEC (see *Table 2* and *Figure 2* below). For PSG, data includes questionnaires, codebooks, as well as descriptive statistics of both the national and model regions per survey wave. Users can search psychosocial variables using the search field or a topic or word cloud. As a result, for instance, variable names, questions, and value labels as well as descriptive univariate statistics are shown in the form of an overview. For PEC, data consists of documentation (e.g., field/operation protocols, research, literature). For HSB, there are scientific studies on crises and disasters. Certain words or phrases can be used to find PEC or HSB results filtered by, e.g., year of publication or research method. Data must be uploaded manually and can be expanded with further information in the form of, e.g., questionnaires for PEG.

Table 2. Structure of CIP-REP

Psychosocial topic	1. PSG 2. PEC 3. HSB
Integrated data by psychosocial topic	1. Codebooks, questionnaires and descriptive calculations of national/model region surveys per survey wave 2. Documentation on PEC (e.g., field/operation protocols, research, literature) 3. Documentation on HSB in crises and disasters (e.g., individual studies)
Result displays (e.g.)	1. Question wording, question values, type of crisis 2. Publication year, title, author 3. Publication year, research method, population group
Overall content use/data upload/data base	- Dynamic/manual/expandable
Searches	- Filter- and ontology-based
Additional remarks	- Ontology representation according to SKOS standard, additional authoring component

One of the technical requirements for the multi-modality of CIP-REP is a component design which should be particularly integrative. For the core information model of CIP-REP based on the integrated data in *Table 2* (e.g., codebooks, questionnaires, or descriptive calculations), it is important to avoid duplicating shared information structures and increase and maximize the reprocessing of common structures, especially patterns. Apart from these classic data-oriented information structures, ontologies as well as the corresponding search and exploration of the underlying data are crucial attributes. Various domain ontologies, based on different data sources and represented by the SKOS standard (World Wide Web Consortium [W3C], 2012), stand for the specific vocabularies of the particular domain. The multi-ontology approach focuses on genericity in order to dynamically support exchanging domain ontologies. This can be separately applied to various domains, e.g., the medical domain (Billig & Krebs, 2014). Here we adapted mature partition techniques from Decker et al. (2005) and ontology matching techniques from Billig et al. (2007).

Dashboard Component: CIP-DAB

CIP-DAB is also structured in a dynamic and interactive way and uses filters for the psychosocial topics PSG and PEC (see *Table 3* and *Figure 3* below). For PSG, it involves longitudinal survey population data on the psychosocial situation, cross-sectional survey data on preparedness for special crises (e.g., heat, terrorist attack), and model region survey data on PEC per survey wave in Germany. The results include statistically pre-processed longitudinal data (e.g., CI-plots, bar charts) on psychosocial variables such as risk perception, protective behavior, or coping strategies collected for diverse crises (Ukraine crisis, Covid-19, climate change, or inflation) by risk factor (e.g., age or sex) or region (e.g., German states). For PEC, there is simulated data on PEC field protocols and information on PEC units of an aid organization operating in German communities, which then are displayed descriptively using univariate and bivariate statistics (e.g., bar charts or tables). Data such as survey data for PSG, for instance, must be uploaded manually but can be expanded with further information.

Table 3. Structure of CIP-DAB

Psychosocial topic	1. PSG 2. PEC
Integrated data by psychosocial topic	1. Longitudinal survey data on the psychosocial situation, cross-sectional survey data on preparedness for special crises (e.g., heat, terrorist attack), model region survey data on PEC 2. Simulation survey data on PEC field protocols, information on PEC units of aid organization in German communities
Result displays (e.g.)	1. Univariate/bivariate statistics on survey variables, risk factors, region (e.g., CI-plots, bar charts, summary) 2. Univariate/bivariate statistics on simulated variables of emergency care field protocols (e.g., CI-plots, bar charts, summary); descriptive information on PEC units
Overall content use/data upload/data base	- Dynamic/manual/expandable
Searches	- Filter-based
Additional remarks	- Contains a map, graphs, data input; uses libraries such as leaflet map, Bootstrap-select or D3.js

The dashboard consists of three main components using various libraries, for data input, map, and graph section. For the data input, five select elements were built with the Bootstrap library (Otto & Thornton, 2023). Further, using a map section, the affected regions can be displayed on a map with polygons of varying thickness. The map was implemented with Leaflet (Agafonkin, 2023) and the polygon data is provided by a GeoServer. Finally, the graphs, which serve as the main response view, were implemented separately with the D3.js library (Mike Bostock and Observable, 2023) and are added to the project via dependency injection. Some of the advantages of CIP-DAB are the ability to separately deploy the visual controls of the dashboard as well as its capacity for working with a large amount of data.

Documentation Component: CIP-DOC

CIP-DOC is a static tool for downloading information on PSG and PEC in order to quickly obtain required files (see *Table 4*). For PSG, survey information such as questionnaires, codebooks, and short descriptive reports of survey waves are integrated and downloadable in a readable and portable file format. For PEC, data comprises documentation on PEC (e.g., standardized field/operation protocols, research, literature) which can be downloaded as a ready-to-read file. Finally, all the data is uploaded manually and expandable by adding further information.

Table 4. Structure of CIP-DOC

Psychosocial topic	1. PSG 2. PEC
Integrated data by psychosocial topic	1. Codebooks, questionnaires, and short survey reports 2. Documentation on PEC (e.g., standardized field/operation protocols, research, literature)
Result displays (e.g.)	1. Readable and portable files of codebooks, questionnaires and short survey reports 2. Readable and portable files of documentation on PEC (e.g., field/operation protocols, research, literature)
Overall content use/data upload/data base	- Static/manual/expandable
Additional remarks	- Download function, different search methods

The documentation page is a pure, static HTML with a list of cards showing information with the help of the Bootstrap library (Otto & Thornton, 2023). Each card shows a summary of the information; for a detailed view, the user has to click on the card. The information on the documentation page is stored on the server and can be updated, with each card displaying its update date. Furthermore, users can type terms they are searching for into an input field, with a meta data scheme in the backend. Running in the background and not visible for the user, a local search in the meta data or a global search using the texts themselves is also possible. In addition, CIP-DOC contains filters differentiated by psychosocial topic. For CIP-REP, as explained above, CIP-DOC delivers textual artifacts for expanding the domain ontologies used in the CIP-REP component.

USE CASES

CIP-PS addresses crisis managers, such as decision-makers from aid organizations, public authorities (e.g., the Red Cross or public health institutes), and government (small regions to federal states). Thus, CIP-PS is a decision support system for those directly working with the psychosocial situation in times of crisis and disaster. Furthermore, representatives from the media and academia as well as citizens at large can access CIP-PS for a descriptive overview of the situation. The following use cases show different applications of CIP-PS.

CIP-REP: Researching Variables and Concepts

In use case 1, the target group includes a researcher (RE) in the psychosocial field wanting to use our survey data for scientific purposes. These secondary data are collected and stored under the highest data protection and anonymity standards. RE is interested in the research question "Which factors are relevant for private emergency preparedness in a heat event?" and is guided by the protection motivation theory (Rogers & Prentice-Dunn, 1997) in which risk perception is key. As RE does not know what variables are in our dataset, they choose "risk perception" as a construct in CIP-REP (see *Figure 2*). If this variable exists, RE would like to know, what *category* it is in, the *wording of the question*, *values*, the *type of crisis*, and the *survey waves* the variables were measured for. According to *Figure 2*, RE's search can be narrowed to specific topics shown on the left. Moreover, the word cloud in the center as well as the filters on the left include specific characteristics to further narrow down the search, thereby bringing about results more effectively and efficiently. Upon completion of the search, the results display all the variables in our dataset matching the criteria RE has provided. Now, RE has a list of possible variables to analyze and could use our data for this purpose.

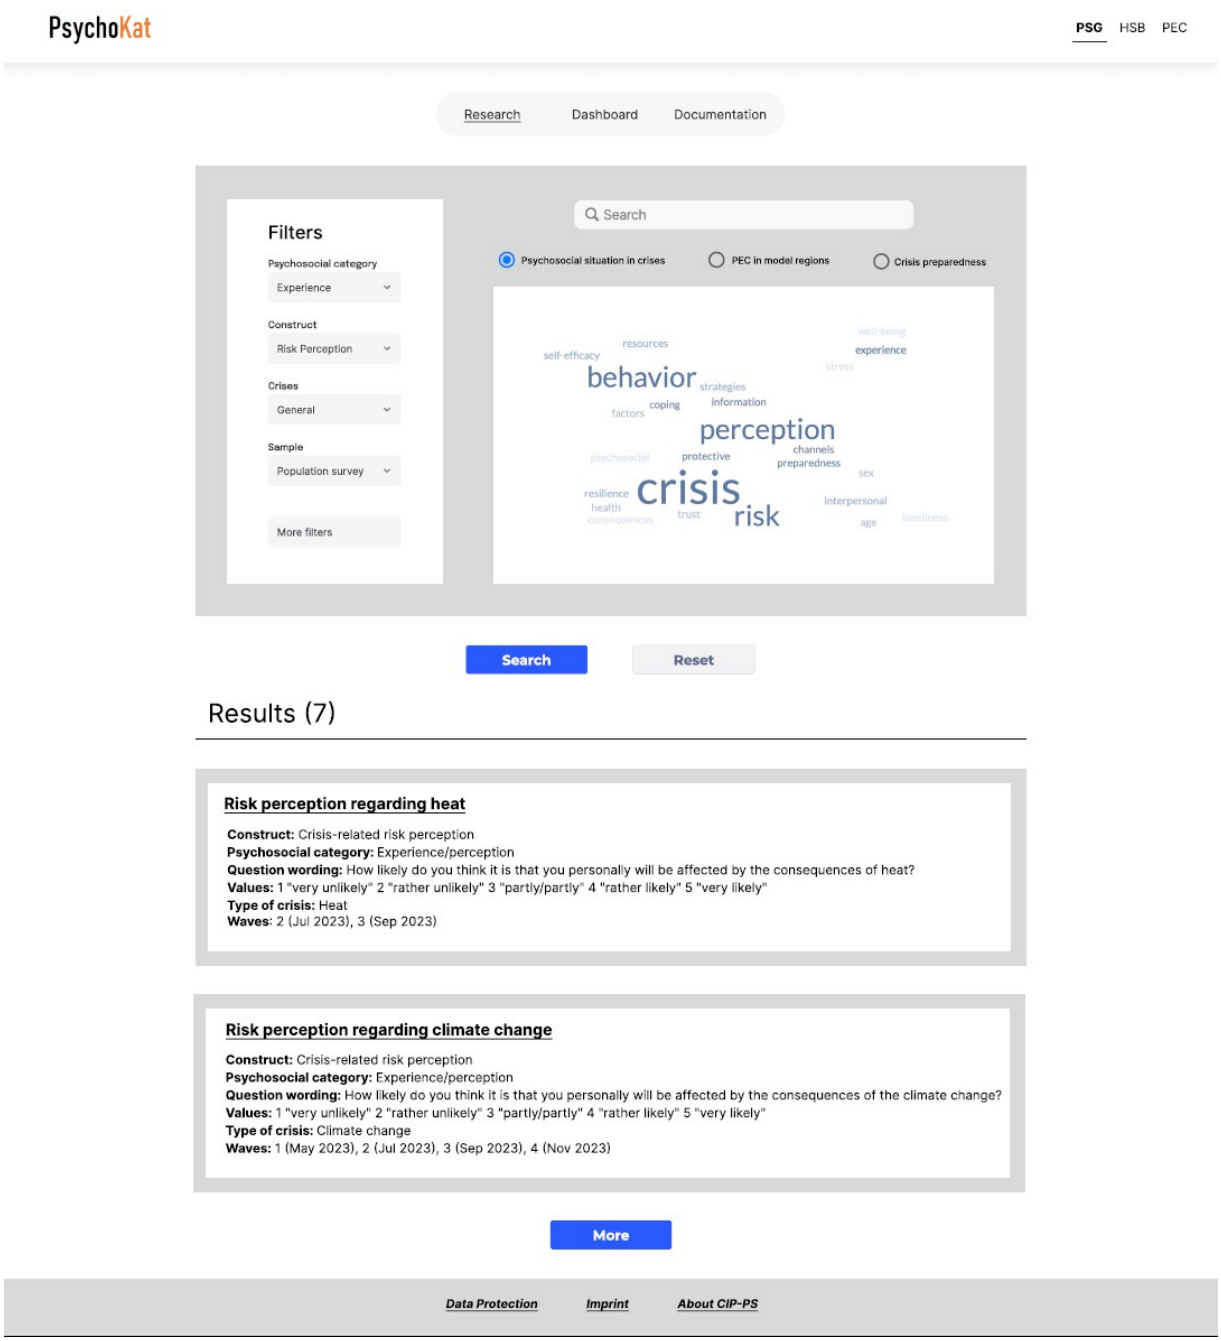

Figure 2. Screenshot of CIP-REP (use case 1)

CIP-DAB: Visualizing Risk Perception and PEC in Multiple Crises

In use case 2, the user is a crisis manager (CM) in an authority. CM wants to develop an effective risk communication strategy tailored to specific at-risk groups and is interested in the current state of the population so to be able to identify vulnerable groups (Bundesamt für Bevölkerungsschutz und Katastrophenhilfe [BBK] & Bundesinstitut für Risikobewertung [BfR], 2022). To this end, CM searches for information shown on CIP-DAB, focusing on the risk perception of different population groups, differentiated geographically as well as historically. As shown in *Figure 3*, CM can select "Crisis-related risk perception" as a psychosocial variable to monitor. Also, CM is interested in age group as a risk factor in all German states. Furthermore, CM selects climate change out of all crises measured since May 2023 as a trend survey design. *Figure 3* shows the input fields, as well as a map with different values of risk perception by age group using a mouseover effect as well as a CI-plot and bar plot as visual controls (among other visuals such as a summary table of statistical values and a correlation matrix). Using the CI-plot, CM can tell if there are significant differences in mean values of risk perception between different age groups at one survey time and between different survey waves. Further, the bar plot includes absolute as well as relative frequencies of risk perception (using a mouseover effect) differentiated by age group and survey wave.

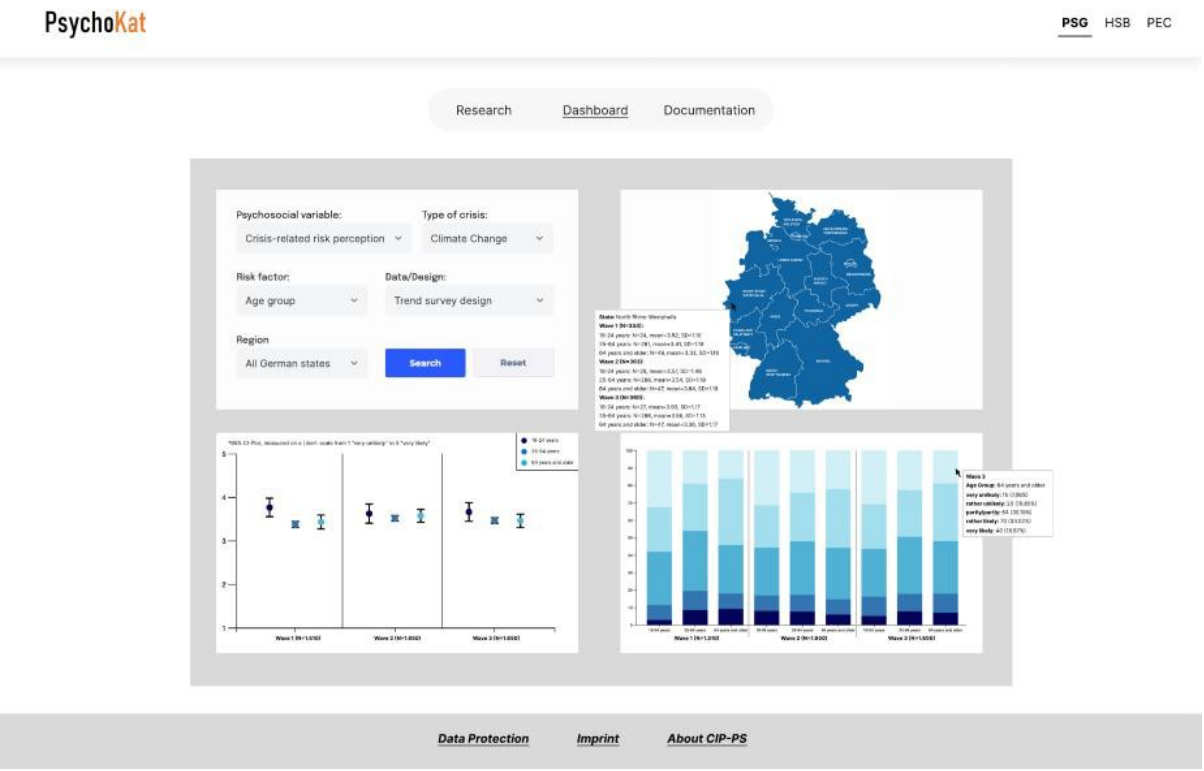

Figure 3. Screenshot of CIP-DAB (use case 2)

For the sake of clarity, we omit a figure for use case 3. Here, the head of the community level (HC) of PEC is interested in survey data on the knowledge about and personal usage of PEC in crises. The goal of HC is to advertise the service of PEC in these regions and to determine whether more resources are needed within the aid organization's structure. This information was measured for several model regions where PEC is offered by the aid organization. Thus, HC selects model region survey data in CIP-DAB obtaining the questions "Before participating in this survey, did you know what PEC is?" and "Have you ever used PEC from the respective aid organization in your region?" which will immediately provide HC with information that will help ground decisions on the investment of further resources.

CHALLENGES AND LIMITATIONS

Challenges

A general challenge is to accordingly align the technological development of the system components to the reuse of information substructures; namely, because joint patterns within the general information structure can be identified. For example, different ontologies, stemming from the three psychosocial topics (see *Figure 1* and *Table 2*), can share common concept spaces. Furthermore, common metadata sub-structures have to be identified and integrated accordingly.

One challenge of developing the dashboard is designing it as a micro frontend that has not been established yet. Its components were implemented using various libraries as shown above and function independently of each other. The great advantage of this micro-frontend architecture is that the dashboard can be deployed outside CIP-PS. The diagrams can also be deployed individually as a widget on a platform. This means that, for instance, the map would not cause a complete failure of the dashboard as happens with standard websites. The number of output diagrams can be expanded, and the individual diagrams can be built with different libraries.

A further design challenge is posed by the structuring and designing of the single elements within CIP-PS. The aim is for all elements to be customized to the needs of the user according to the highest standards of UI and UX. The platform should be easily understandable, handy, and user-friendly, so that the user (e.g., crisis managers, authorities, decision-makers) can obtain all the information they need and use it as a support system for their evidence-based decisions. At the same time, the principle of parsimony should ensure that using CIP-PS should not lead to information overload. For instance, an onboarding process with help texts would support this aim.

As concerns privacy regulations, the platform follows the principle of different user roles, meaning that it can be secured by using a safe login procedure. Further, all the data is stored on secure servers and is not available without permission.

As concerns data challenges, the data which is sent to CIP-PS and its individual components must be pre-processed. Using a data-centered approach, the national and model region survey PSG data is prepared and saved into single data files with a high number of possible combinations (e.g., different psychosocial variables by different risk factors). Data on PEC and HSB comprises studies and other documentation that have to be reviewed manually before saving all the information required for the different filters into differently structured tables.

The growth of "computing power, more complex algorithms and the availability of ever more potentially complimentary data online" (Quinn & Malgieri, 2021, p. 1583) means that the amount of sensitive data is increasing. This leads to social challenges, such as the need to protect sensitive data to prevent risks such as discrimination and harm to vulnerable groups in society. Naturally, there are high data protection standards when it comes to collecting survey data. This type of data is then also handled carefully, is anonymized and aggregated to make sure it cannot be traced to individual respondents, and is stored on a secure server. For the secondary use of the survey data, regional information such as postal codes or other identifying information about respondents is left out to ensure total anonymity, as a combination of only a few characteristics can potentially lead to identification (Bampoulidis & Lupu, 2019). For HSB, the individual underlying studies are not provided in the CIP-REP, but are freely accessible under scientific license conditions. The PEC literature is also freely accessible and no sensitive data, such as interview protocols, are stored in the CIP-REP or CIP-DOC. The PEC data for CIP-DAB consists of completely simulated data on protocols (no real data) in order to protect privacy, while the survey model region data is also aggregated and secured.

Limitations

Naturally, the development of CIP-PS is also subject to some limitations. Next, this section concerns limitations regarding the data of the psychosocial topics and general limitations in the technical development of CIP-PS and CIP-REP, CIP-DAB and CIP-DOC.

In terms of PSG, we have collected data in short intervals online-representative of sex, age, and German states, both as concerns the national situation as well as the three model regions. Although collected quite frequently, this data is nevertheless limited in time and space when it is integrated into CIP-DAB. Furthermore, the model regions were selected according to criteria on the occurrence of PEC teams, population size, and the number of single districts we can then apply multi-level models on. But these regions are not representative of all locations in Germany. Thus, we cannot monitor the psychosocial situation in (rural) regions, communities, or smaller

locations where disasters such as extreme weather events or wildfires (e.g., the flooding in Germany in 2021 or wildfires in 2023) occur. Moreover, CIP-DAB data only represents the German population, while disaster and crisis events happen all over the world, having more or less of an impact on the psychosocial situation of the population affected or involved. It would thus be essential to develop a cross-cultural international research network studying different perceptions and behaviors of the various populations in different or same crisis or disaster events.

In terms of PEC, only simulation data of operation protocols can be generated and integrated into CIP-DAB for data protection and security reasons. At this stage, it is not possible to process data from real people affected or involved in crisis or disaster situations. We will respond to this by developing an interface facilitating the connection between real data and CIP-DAB, with the aim of creating a framework with a full data protection scheme.

One limitation with respect to the technical development is that the data used by the components CIP-REP and CIP-DOC cannot be dynamically changed during system runtime. Thus, for example, artifacts such as questionnaires, studies, etc. have to be maintained offline. Furthermore, there are limitations in the development of the domain ontologies: first, the language expressivity of ontologies for CIP-REP is restricted to SKOS expressivity; second, new versions of ontologies cannot be dynamically added at runtime.

Although CIP-DAB is relatively flexible, there is a rather passive limitation when it comes to the resolution. That is, CIP-DAB is responsive in tablet mode only and is not necessarily suitable for mobile phones. Furthermore, CIP-PS and CIP-DAB both need an Internet connection when updating results. The PWA, however, as described above, helps keep recent searches stable before updating.

CONCLUSION AND OUTLOOK

In this paper, we described in detail the full development of our CIP-PS. In a first step, we introduced our conceptual foundation by explaining why it is important to monitor the psychosocial situation of the population during times of crisis and disaster, our systems thinking approach to increasing individuals' resilience, and which psychosocial topics need to be addressed. Thus, psychosocial aspects such as monitoring the situation to identify vulnerabilities in the population as well as summarizing studies on HSB and PEC information of aid organizations are crucial for drawing an overall picture of the situation. After explaining our two-stage research methodology approach, we presented a list of relevant recent platforms (see *Table 1*). This made clear the need for an information platform that follows a highly integrative approach.

Our main research question was: *"How can an information platform contribute to increasing the population's (psychosocial) resilience in times of crisis and disaster?"* The platform as IS delivers information to find correlations in different psychosocial data through an integration of different components. As both crises and the psychosocial situation are becoming more complex, the platform looks at statistical relationships in the data, reduces complexity and builds a system of systems (Cavallo, 2014, our three components) to model (psychosocial) reality at a manageable level. By integrating different components into the system of CIP-PS, it is thus possible to reach potential user groups from crisis managers to researchers and the public, thus fulfilling a policy need as well as responding to a research interest. Furthermore, spill-over, crowding-out, or habituation effects (Martin-Lapoirie et al., 2024; Weber, 2010) in different crises mean that there is a need to compare the concurrent behavior and perception of the population in multiple crises represented in CIP-PS. Other IS on surveys look at one crisis only (e.g., PACE, University of Erfurt et al., 2023), so that information has to be collected from different sources when developing action plans or communication strategies for the population at risk. Moreover, integrating different components improves statistical dependencies between them: thus when, for example, PSG in CIP-DAB shows that the elderly are more vulnerable in a particular situation, CIP-REP can help identify facilitators for appropriate HSB to further increase or restore the vulnerable group's resilience. Studies in CIP-REP, in turn, can lead to a derivation of new psychosocial variables to monitor in PSG. In conclusion, the different levels of complexity of crises and disasters make it difficult to identify people or population groups who are more or less vulnerable and foster or maintain their resilience accordingly – hence the need to monitor psychosocial consequences in the long run using an integrative approach of a system of systems.

The second question: "*How should an information platform be technically constructed so as to integrate different data types and connect different components with one another?"* addresses a technical aspect of the development of CIP-PS. We answered it by explaining the general concept of CIP-PS, its design framework (see *Figure 1*), as well as the technical functionalities concerning micro frontends, including the use of a PWA. We also gave a technical description of CIP-REP, CIP-DAB, and CIP-DOC.

We answered the third research question: "*How can different data be integrated and aggregated into a tool that researches, visualizes, and documents them?"* by describing the psychosocial topics and respective data each individual component integrates as well as how they display results and provide ways to edit and add further data into the systems (see *Tables 2–4*). Also, the functionality of CIP-REP and CIP-DAB was illustrated by three different use cases differentiated by user group, scenario, and data used, in order to show the diverse situations, the multi-functional crisis platform can be used for (see *Figures 2* and *3*).

While we have presented here a full development of our CIP-PS, we also want to mention future steps. First, additional national and model region survey data on several subsequent waves and short survey reports will be collected, processed, and sent to CIP-PS in order to expand all three components. The ontologies based on the data on PSG, PEC, and HSB will also be expanded to make the search using CIP-REP more efficient and effective. In addition, we plan further publications with both a theoretical and methodological focus (e.g., developing further the ontologies used or making the platform more responsive) in order to address gaps in the research.

In technical terms, the multi-modal system can be extended with respect to CIP-REP and CIP-DOC. In particular, integrative aspects like interlinking of semantically similar artifacts of CIP-REP and CIP-DOC could play a prominent role. Furthermore, an authoring element for all three CIP components and their related data could be established. Beyond the features of a classic Content Management System (CMS), this authoring element would support cooperative editing of, for example, codebooks, studies, or ontologies tailored to their individual structures. Further UI and UX improvements are planned for CIP-DAB.

All in all, we conclude that our CIP-PS addresses two major research gaps: first, based on the systems thinking approach and the knowledge transfer paradigm, it links different data on psychosocial topics together into one platform, thus reducing complexity. It helps the users systematically research, visualize, and document all the data, which is customized in favor of their needs and requirements, with the main goal of increasing resilience in the population. Second, CIP-PS proofs a full connection of a CIP-DAB visualization as well as a CIP-REP and CIP-DOC in both the frontend and backend, helping the users to obtain and visualize the information required as a decision support system. Hence, it is essential to present psychosocial data by topic independently as well as efficiently and effectively in the sense of a tool valuable for disaster public health and healthcare informatics.

ACKNOWLEDGMENTS

We would like to thank our research intern Lea Malcharczyk for her invaluable support in writing this article.

ABSTRACT

Community health workers (CHWs) play a vital role in connecting communities, healthcare systems, and crisis response authorities. During a public health crisis, minority populations face increased disease and economic burdens, making adherence to health guidelines challenging. Despite numerous efforts to mitigate these impacts, the effectiveness is greatly compromised by communication gaps between communities and health authorities. Our study strategically employs the collaboration of CHWs and simple technology (Zoho Forms) to bridge gaps and enhance information flow between diverse hard-to-reach communities and public health authorities. We emphasize the unique contributions of CHWs to disaster response and the benefits of equipping CHWs with simple technology for effective communication during a public health crisis. Our work improved COVID-19 guidelines adherence, reducing infection spread while addressing critical mental health and resource needs within the communities served.

Keywords Community Health Workers (CHWs), COVID-19, Information Management, Public health Crisis Response, Simple Technology, Diverse Communities

INTRODUCTION

Efficient disaster management and response are dependent on effective information sharing and coordinated actions (Aung & Whittaker, 2012; Frassl et al., 2010; Iakovou & Douligeris, 2001)**.** These coordinated efforts require the quick assembling of response teams/systems made up of multiple cross-agency collaborations, to facilitate work distribution, increase response tempo, and, in public health crises, ensure the effective dissemination of critical information among diverse sections of the population (Castillo et al., 2018). Integrating community health workers (CHWs) as both key actors and information brokers between minority or marginalized communities and traditional public health response agencies is an important task during events like the recent COVID-19 pandemic. CHWs are uniquely positioned because they are embedded in communities that may be difficult for traditional response agencies to reach because of cultural, linguistic, and logistical barriers (Stevenson et al., 2022). However, CHWs are typically not considered part of the public health crisis response infrastructure, are not integrated into disaster planning, and are personally unfamiliar with communication and coordination protocols. A challenge faced by authorities during disasters is ensuring that the needs of individuals from minority populations/communities are adequately met as these populations are often reported to bear a greater burden during disasters (Hanson, 2021).

As of July 2023, Milwaukee County has reported 347,383 COVID-19 cases, and 2,532 deaths (USAFacts, 2023). At the onset of the pandemic, predominantly black and Latino communities in Wisconsin bore most of the burden of reported cases (Wisconsin Department of Health Services, 2020; The COVID Tracking Project, 2021). Studies conducted in Milwaukee County reported a high burden of COVID-19 infections among racially marginalized groups. In addition, several studies across the United States have consistently reported racial disparities in the incidence, mortality, and economic hardship related to COVID-19 (Alcendor, 2020; Park, 2021). In response to these disparities, the Milwaukee Health Department initiated a STOP-COVID-19 initiative in 2020 during the peak of the pandemic. The initiative was aimed at preventing the spread of COVID-19 in Wisconsin communities, particularly within racially diverse communities, and addressing the psychological needs of high-risk populations where traditional risk communication strategies may prove ineffective. As a result, a 3 -tiered strategy was employed to rapidly improve guidelines in these communities as well as meet their economic and psychological needs by 1) Increasing public awareness of key infection control information using culturally tailored messages, 2) Leveraging local media to implement culturally adapted micro-campaigns for risk reduction, and 3) Addressing psychological and wellness needs by leveraging community strength through CHWs. Identifying ways to optimize response operations with CHWs as a specific type of human-in-the-loop challenge offered specific practical, political, and ethical problems given the emphasis of the effort to ensure culturally adapted public health interventions in four distinct communities. Rapidly and equitably integrating CHWs into the Public Health response framework tested institutional abilities to manage high volume communication, making quickly deployed “off-the-shelf” or “lowest common denominator” technologies key to effective management of this process.

Here, findings are presented from a partnership involving the city of Milwaukee Health Department (MHD), the Medical College of Wisconsin (MCW), and Community Health Workers from four communities of color - African American, Hispanic, Hmong/SE Asian, and Native American working to rapidly form an ad-hoc organization to flexibly respond in culturally and linguistically adapted ways. These efforts required the rapid deployment of simple communication strategies to ensure that the frontline CHWs were able to move crucial, hyper-local information to traditional response agencies in a way that respected the unique contributions of these workers. Throughout this effort, rather than developing new technologies or deploying complicated mobile technologies, we focused on identifying off-the-shelf technology tools that were easily adapted and well understood by even the least technologically oriented personnel within the response team. For example, in other COVID-19 logistics efforts, we augmented Google Sheets by flowing information out of Sheets to SQLite for some processing, and then flowing the information back to the same Sheet so that all agency representatives could engage with the data (Franco et al, 2021). With the CHWs, we also focused on a lowest common denominator technology, in this case using Zoho Forms with some workflow logic to capture quick operational snapshots from each CHW that were then shared with the lead CHW for that community as well as with the Health Department and Medical School partners. The formal response agencies used this information to nuance the delivery of public health information, and food and financial relief; and focus staff and political actors' attention on the needs of these communities in ways that would have left the “on the ground " or residents’ voices out of the process.

PUBLIC HEALTH DISASTERS

The onset of an infectious disease outbreak is considered a public health emergency, necessitating the establishment of new protocols and the implementation of strategies and methodologies to address the swift changes caused by the outbreak (Maciel et al., 2020). The consequences of such outbreaks are highly potent and extend beyond the infected individual(s), subsequently encompassing the entire population, economies, public health systems, and social interaction (Hu & Qiu, 2020). An example is seen in the most recent infection outbreak (COVID-19), originating in Wuhan City, China in December 2019, resulting in widespread fatalities, reduced quality of life, economic hardship, reduced global trade and travel, as well as constrained social interactions (Bhaumik et al., 2020). Within the context of disease outbreaks of high magnitude like the COVID-19, Ebola, and H1N1 viruses, effective emergency management hinging on efficient systems and the harmonious working together of both internal and collaborative governmental bodies are essential components for implementing containment measures within the framework of emergency management (Hu & Qiu, 2020). Some of the key contributors to this collaborative emergency management approach include the state Department of Health, hospitals, community clinics, NGOs, businesses, healthcare workers (including doctors, nurses, microbiologists, and CHWs), and most importantly the individuals that make up the population (Palafox et al., 2020).

Disaster Communications

During disasters, effective risk communication is vital to addressing public fears, stigmas, informed decision-making, and adherence to established guidelines (Porat et al., 2020). Risk communication and community engagement (RCCE) are those processes and methodologies used to systematically consult and dialogue with communities at most risk of infection, or those whose cultural, religious, or ethical practices impact risk (Adebisi et al., 2021). Furthermore, the chains of communication during disasters are multifaceted, for example, during the COVID-19 pandemic, the World Health Organization's (W.H.O.) guidelines on risk communication encouraged a two-way dialogue/communication pattern with communities, the public, and stakeholders that ensure that information is accurately tailored to their specific circumstances (World Health Organization, 2020). In addition to this, a community-based participatory approach (CBPR) is required, one that allows individuals free access to information on potential risks and provides them with the right to participate in the disaster response process (Nylund, 2022).

COMMUNITY HEALTH WORKERS (CHWs)

According to the International Labor Organization (ILO), community health workers (CHWs) play a vital role in providing health education, support, and referrals encompassing diverse services. Their responsibilities extend to assisting individuals, families, and communities in adopting preventive health measures and facilitating access to appropriate healthcare and social services (Bezbaruah et al., 2021). Particularly, CHWs drawn from marginalized communities occupy a unique position as trusted sources of health information (Ayodele et al., 2024). Their status as members of the communities they serve grants them invaluable insight into cultural norms and health-belief models. The credibility of CHWs serves as a crucial link between communities and healthcare organizations, wrestling in heightened community health literacy and improved access to essential resources through their coordination efforts (Wennerstrom et al., 2013; Scheib & M. Brinton Lykes, 2013).

CHWs have received increasing attention as they may play a pivotal and distinct role in the disaster response framework (Nicholls et al., 2014). The Centers for Disease Control and Prevention (CDC) defines CHWs as "frontline workers who are trusted members or individuals who have a good understanding of the communities they serve" (CDC, 2022). CHWs are an essential part of public health disaster management processes, serving as a bridge between communities and the resources they need. Their main responsibilities involve building trusting relationships between communities and stakeholders, eliminating barriers to access, and lending a voice to issues affecting the communities they serve (U.S. Department of Health & Human Services, 2019). The inclusion of CHWs in disaster management, however beneficial, is plagued with its unique challenges in that CHWs have limited knowledge of official language, might have trust issues with large institutions same as the population they serve, and are oftentimes not considered as formal employees. In addition, CHWs differ from traditional medical or public health crisis responders as they bring a different skill set, community social capital/relationships/connections, and responsibilities to the crisis response team (Pinto et al., 2020).

Role of CHWs in Public Health Disaster Management

During disease outbreaks of high magnitude such as the COVID-19, Ebola, and H1N1 viruses, the alignment of both internal and collaborative governmental bodies are essential components for implementing containment measures within the framework of emergency management (Hu & Qiu, 2020). While numerous studies have demonstrated the efficacy of CHWs in reducing the burden of chronic diseases such as diabetes and hypertension in minority and underserved populations (Nassar et al., 2013; O'Connor et al., 2020), a lack of information exists on the use, management, and information flow between CHWs and public health systems in widespread disaster events, such as a pandemic. Even less is known about how CHWs interact with technology in the context of crisis events.

The importance of CHWs in disaster preparedness stems from the personal ties they have to the communities they serve, and thus their ability to educate and recruit help, monitor the effectiveness of interventions, and fill in gaps in health service (Boyce & Katz, 2019). Previously, CHWs were mobilized to identify the healthcare and social needs of individuals during Hurricane Sandy. CHWs were effective in setting health goals for patients with chronic medical conditions, identifying community resources, and counseling patients (Russell et al., 2018). Similarly, during the 2017 Peru floods, CHWs were trained to support mental health interventions by conducting screenings for depression and domestic violence and connecting individuals to the necessary support services (Contreras et al., 2018). They also implemented activities that allowed children to relieve stress while building emotional management skills and forums to encourage community participation. The post-disaster interventions exposed the inadequacies of the health systems in addressing the needs of those marginalized communities and the role CHWs can play in bridging those gaps.

Employing CHWs provides several key operational advantages within a public health disaster management framework. Based on our observations working with about 12 CHWs as a fundamental institutional healthcare approach to managing COVID-19 (Franco et al., 2023; Stevenson, 2023), we found several essential characteristics exhibited by CHWs when viewed through the lens of crisis logistics, actions, information flow, and situational awareness:

1. **Autonomous by nature** - Each CHW functions as a largely autonomous agent within their community, operating independently throughout most of their work, only occasionally checking in to provide information and take directives. While this is both good and bad - if carefully selected, they don't require much instruction about what to do and can make independent decisions without creating a burden for these decisions on traditional crisis response managers for most tasks. On the other hand, because the crisis is rapidly unfolding, and their check-ins are relatively infrequent there may be substantial delays in information transfer, redirection of high-level activities, etc (Malcarney et al., 2017).
2. **Hub and Spoke** - Outside of a crisis context, CHWs typically operate in a hub and spoke model of organization, with each CHW reporting to a central command element independently – this model is a key strength, as it relies on high levels of trust between CHWs and the command element from the healthcare system. This relationship is, in a perfect world, fairly mutual – such that the CHW is regarded with respect even though they are very different from the traditional healthcare system. This respect is demonstrated through non-hierarchical access directly into the healthcare system.
3. **High Community Trust** - Benefiting from high levels of community trust, CHWs possess valuable insight into the community's experiences and needs. This trusted position enables them to identify areas where the public health system may fall short in addressing the community's needs.
4. **High Quality, Difficult to Obtain Information Flow** - Because the community trusts them, they can provide direct, unfettered views of things on the ground (remote sensing) that can be sent back to the public health agency in the form of text message updates, photographs, brief videos (Baker et al., 2024, Taylor et al., 2017).
5. **Culturally Competent Information Flow & Sense Making** - CHWs are excellent at translating or transliterating complex, linguistically, and culturally opaque information for the public health response agency. They have a unique ability to convey intricate details in a manner that aligns with both public health agencies and the community's language and cultural context, thereby enhancing the effectiveness of information flow and sense-making in response efforts (Griffith et al., 2023).
6. **Trusted Asset Logistician** - CHWs can distribute essential supplies like personal protective equipment (PPE), food, diapers, baby formula, and monetary donations or gift cards to individual households that had COVID-19 positive household members and needed to isolate to prevent workplace infection

spread and were in financial need - in part because they have were trusted with these tasks before the pandemic, and because they have hyper-local networks through which the assets can be channeled, etc.

However, despite their numerous benefits, CHWs frequently encounter challenges while performing their duties, some of which include:

1. **Excessive Autonomy:** Sometimes, the heightened level of autonomy CHWs possess raises concern that their initiatives could run counter to or do not assist the public health agencies' primary goals.
2. **Loss of Shared Situational Awareness in transition to Hierarchical Structure** – Even though we wanted to preserve the hub and spoke model and they are largely autonomous, the complexity of the COVID-19 response meant that the formal response structures were rapidly overwhelmed by information and asset requests from the CHWs. We had to switch to a hierarchical model in a respectful, culturally competent way. However, this meant that we then lost direct insights into what was happening on the ground because the information from most of the CHWs was being filtered through a lead CHW for each community — this became in the crisis response literature a "shared situational awareness" problem. Critical information available to a CHW lower in the hierarchy might be filtered out before reaching the Public Health Department.
3. **Coordination Challenges**- Coordination problems arise in the identification and resolution of needs across diverse communities. This often involved understanding the intersections of hyperlocal networks among CHWs and determining how these shared networks can be leveraged for more effective collaboration and response, while also respecting boundaries and not moving past the level of trust the CHW developed.
4. **Safety and security of CHWs in the field:** In utilizing the help of CHWs for crisis response, there is a paramount concern around guaranteeing their safety and security in the field.
5. **Mental Health of CHWs:** Additional concerns also revolve around acknowledging and addressing the mental health and well-being of CHWs as they perform these crucial tasks (Johnson et al., 2022).

Balancing the multifaceted role of CHWs in public health disaster management necessitates striking a balance between the strengths and weakness of the CHW model at the interface with formal response structures, thereby necessitating a need for cultural tailoring, strengthened supervisory systems, and a continuous communication and feedback loop to ensure that the positive impacts of CHWs in disaster management prevail while addressing potential pitfalls to maximize their effectiveness.

OFF-THE-SHELF HEALTH INFORMATION SYSTEMS IN DISASTER MANAGEMENT

Over the years, the integration of technological tools in disaster management has yielded significant benefits. These tools have been used in forecasting, hazard monitoring, disaster mapping, emergency response, and information coordination, all of which collectively contribute to a comprehensive framework for addressing and mitigating the impact and damages caused by disasters (Rathore, 2016; Eguchi et al., 2008). Dating back decades, major public health disasters have utilized the strategic deployment of advanced technological tools as an intricate component for effective response and recovery efforts exemplified by historical events such as Hurricane Andrew in 1992, and the 1994 Northridge earthquake. During these disasters, Geographical Information Systems (GIS) played a pivotal role by providing visual and geospatial information for efficient response. Similarly, the aftermath of the World Trade Center attacks saw the utilization of technological tools for conducting damage assessment, and facilitating recovery operations (Eguchi et al., 2008). In more recent instances, the Ebola outbreak in Sub-Saharan Africa, and the ongoing COVID-19 pandemic have further underscored the benefits of technological tools in designing, planning, and implementing best practices for infection control, the provision of response to affected individuals and communities (Whitelaw et al., 2020).

While many of these events have reported the use of sophisticated and advanced technology, simple off-the-shelf technology has also been beneficial for disaster management, most importantly for disaster communication and management (Gómez, 2010). A study led by Kavota et al., 2020 analyzing social media adoption and its usefulness in disaster management found that user adoption was driven by perceived ease of use and advantages including data accessibility and flexibility. Further, their study concluded that of the approximately 3.848 billion active social media users in the world, 3.256 billion of these access social media via their smartphones (Kavota et al.,

2020). Other key advantages of using social media during disasters include bi-directional communication, increased awareness of rapidly changing conditions, and geolocation of users. For example, people impacted by Hurricane Sandy in 2012 posted upwards of 800,000 hurricane images using #Sandy, each of which documented visual evidence of changing conditions and showed the geographic location where the picture was taken (Sakurai & Murayama, 2019). These events both summarize the impactful role of simple technology and underscore the significance of accessible tools, and social networks in disaster communication and management.

METHODOLOGY

This research is presented as a practice based, in-depth case study (Kuhlicke, 2013; Kankanamge, Yigitcanlar & Goonetilleke, 2020). When the COVID-19 crisis struck, we rapidly shifted toward a response footing, interestingly moving some of us with extensive crisis research backgrounds, but little practical crisis response experience in responder roles. Thus, the case study is grounded in an action research approach (Landgren, 2010; Lempinen & Rajala, 2014). Because the authors were forced to switch roles from researcher to responder, we were in effect designing information systems on the fly to solve problems as they came up (Cross, 1982). Wearing both hats, the response work took precedence. Data collection was therefore primarily opportunistic instead of dictated by a predetermined research question or hypothesis. By shifting back to a research perspective and reconstructing the complete case study after the fact to be reported to the crisis management research community, we were allowed an opportunity to reflect and capture as much of this process and the learnings from it as possible. This event reconstruction approach allowed us to pause and understand these additional elements for the first time as a group, and we worked to ensure that each of the authors on the response team was satisfied that the telling of the events accurately represented their understanding within the overarching effort as best as possible. This approach afforded us a much more comprehensive view of the actions taken and paints a picture of the complexity encountered by response teams in completely improvised settings (Zhang & Mendonça, 2020). Notably, this perspective includes only the healthcare and public health agency perspectives, not those of the CHWs, which are presented elsewhere (Stevenson, et al. 2023).

RESULTS

The onset of the Covid-19 pandemic brought multiple challenges to CHWs including the need for quick action, ever-evolving information, and large-scale impact throughout the community. Our previous work with CHWs used a dedicated supervision model, however, the COVID-19 pandemic required a significantly larger reach and therefore we moved to a cascade system.

STOP COVID-19 Community Health Workers

During COVID-19, we sought to provide CHW support to four communities of color in Southeastern Wisconsin, specifically within African American, Hispanic, Hmong/SE Asian, and Native American communities. The overall STOP COVID-19 project and the CHW program embedded within this public health crisis response effort are detailed elsewhere (Franco et al., 2023; Stevenson et al., 2023). Each of the four communities of color served was designated one CHW lead and 1-3 additional CHWs reporting to each lead. As such, technology was recognized as a critical means of communication between our 4 teams of CHWs, their respective team leads, and project leadership. In this project, CHWs were short-term employees of the City of Milwaukee through the STOP COVID-19 grant, and data provided here was administratively gathered as part of this paid role. The information was used to manage the overall crisis response.

Zoho CHW Impact Form

The form used in the STOP COVID-19 Initiative was labeled “CHW Impact Form”, this allowed all CHWs and Team Leads to submit weekly progress reports and issues/ needs (DS Table 1). Zoho online forms utilize a ‘drag and drop’ builder allowing for rapid creation and customization of the form. The data entry burden was minimized using checkboxes and predefined options that were defined through rapid collaborative design processes (Klein et al., 2003) with the CHWs, while also providing several areas for free-form entry. At the onset of the project the form captured immediate issues, agencies served, family services provided, community education/ outreach,

and team activities. Following vaccine availability in February 2021, additional questions were added to capture vaccine compliance, concerns, and education within the four communities.

Although not unique to Zoho Forms, we selected this option over more basic tools like Google Forms because Zoho has built-in form logic, which allows data elements used in the form to act on form submission. Upon form submission, a PDF report was automatically emailed to the respective CHW Team lead and project leadership at MHD and MCW. This ensured direct communication by CHWs reached all levels of leadership unfiltered, and facilitated response to community needs while reducing overall volume of communication. While the same types of conditional logic can be accomplished through other projects or scripting language augments to Google Forms, we had limited access to a programmer and elected to use the programmer's time for a more complicated logistics management effort (Franco, et al., 2021).

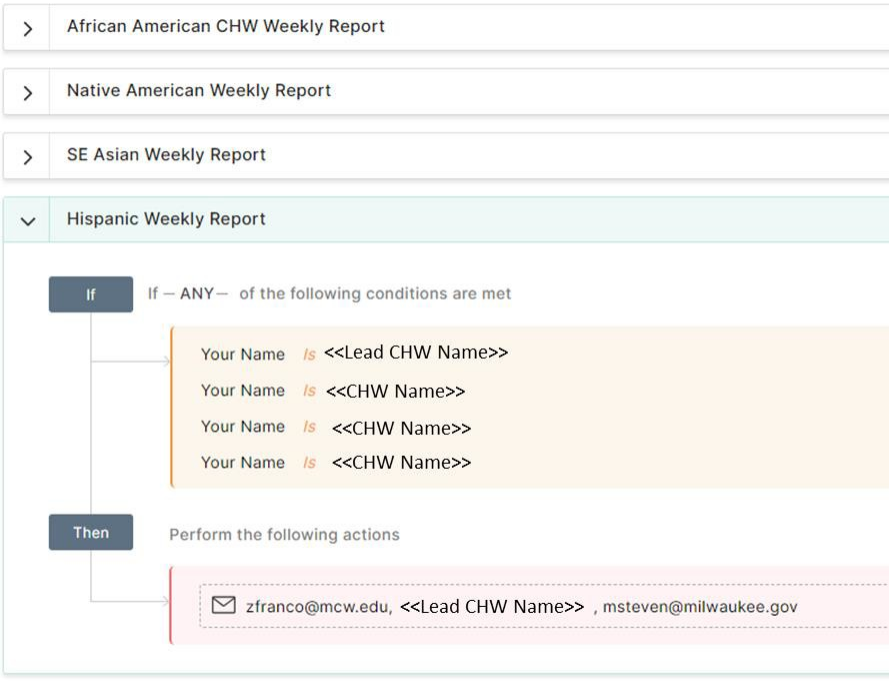

Figure 1. Data Entry by CHWs Automatically Triggers &Generates Situational Reports Sent to Leadership at MHD and MCW via Zoho Forms.

CHW Social Information Context & Overwhelm

Notably, we observed that the CHWs were operating in a very different information environment, working directly with residents in their neighborhoods through things like private Facebook groups, individual and group SMS Text, and Facebook Live to broadcast information about things like food pantries (notably these FB live events were often narrated in the CHWs primary language), and older technology approaches like phone trees and phone check-in lists. One of the CHWs reported that their team was contacting hundreds of households a week by voice phone call check-in. Importantly, the Zoho form approach created a single channel of information for the command layer of this project from the CHWs. The intensity of communication from the lead CHWs, who had direct phone and text access to the project managers, alone threatened to overwhelm the command layer (Rao et al. 2017, Misra et al. 2020). We were forced to push most synchronous upward communication from the CHWs to the lead CHW for their population group, adhering to a hierarchical model. However, the Zoho form allowed unfiltered information from the CHWs to still reach the program staff and be evaluated and actioned asynchronously. In addition to the Zoho forms, a Facebook group for all CHWs (regardless of population served), lead CHWs and program staff to view operationally related photos asynchronously.

Responses

CHWs submitted 150 responses to the form over a one-year period between August 2020 and August 2021 spanning the height of the pandemic into the early vaccination and recovery phase. Hispanic CHWs returned 62 community updates, African American CHWs 34, Native American 42, and SE Asian 12. The low numbers for the SE Asian community likely reflect the tenuous connection we had to this community beyond the lead CHW, although information provided by three SE Asian CHWs was provided.

COMMUNICATION FLOW BETWEEN CHWs AND STAKEHOLDERS:

CHWs were asked to complete the Impact Form at least once a week, whereupon submission, the form was sent automatically to CHW Leaders, the Public Health Department, and MCW (see Figure 1).

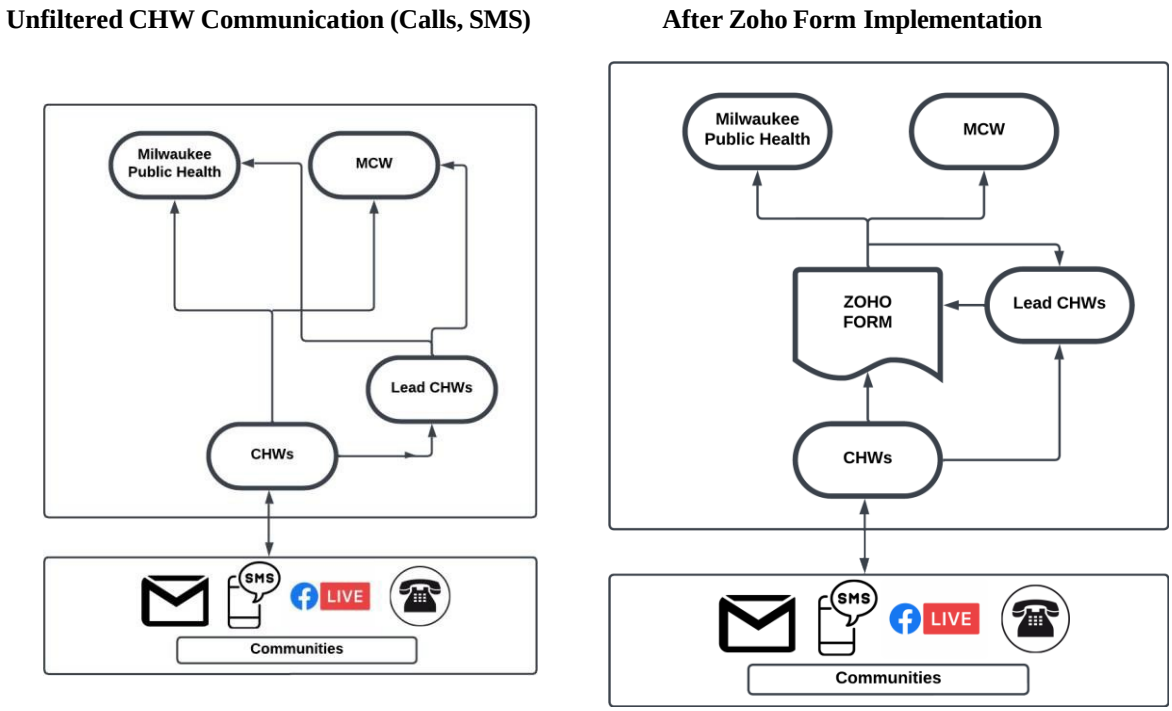

Figure 2. Weekly updates using simple ZOHO Form and submitted automatically to Milwaukee Public Health, Medical College of Wisconsin (MCW), and the Lead Community HealthCare Workers.

Below, we provide a detailed summary of key efforts implemented across these communities based on information obtained from Zoho Forms.

DS Table 1. CHW-Generated Reports from Zoho Forms for Agencies Served

ZOHO FORM DATA FIELD	EXEMPLAR INFORMATION
Agencies Served	
Agency Types Served this Week? (check all that apply): Church, Social Service agency, Clinic, Food Pantry, Homeless Shelter, School, Other - Please describe	**Other agencies reported included:** • Community leadership programs • Other Native American Tribes (e.g. • Stockbridge-Munsee Tribe) • Home Health agencies • Local newspapers • Financial services companies • Check cashing locations • Retail cell phone stores • Culturally specific food stores • Cultural/spiritual events (Unity Fire, Sobriety Fire) • Consulates • Voting drives • Toy drives
Notes on Agencies served/ Number served (free text) *Any impact information you think would be helpful for us to know about, questions that came up from agencies, etc?*	**Native American (09/04/2020)** *I dropped off a total of over 300 masks at the Potawatomi Foundation Leadership Program and the Southeastern Oneida Tribal Services, as well as some posters and COVID-19 information. At the Water Walk Milwaukee 2020 I passed out masks and cards with COVID-19 information. Finally, at the Natives in MKE Photo Campaign 2020, I passed out masks, distributed food, and gave out support resources.* **African American (09/07/2020)** *Met with NAACP and discussed the distribution of masks and resource information at a voter registration event 9/19/20.* *Met with the American Legion Post in Kenosha to assist in distributing masks at an event in Kenosha.* *delivered Pampers to Mexican Fiesta, along with masks to <Native American CHW>* *Contacted United Way for essential COVID-19-related supplies, United Way will be delivering items to Dryhootch on Brady St. hygiene kits, (diapers, masks, sanitizer, and other essentials) I will be contacting CHW leads for distribution of items this week. Working with Feeding America to process food orders for CWH leads.*

DS Table 2. CHW-Generated Reports from Zoho Forms for Families Served

ZOHO FORM DATA FIELD	EXEMPLAR INFORMATION
Families Served	
Types of Family Services Provided This Week? (check all that apply): COVID-19 information, Mental Health Resources, Food, Masks, Household Goods, Advice/ Personal Support, Referral to government services (e.g. rent, support etc.), Support to Families with COVID-19 positive in households, Phone calls with families, Coordinating with other CHWs or agencies, Other - Please specify	• Transportation assistance • Christmas gifts for children • CHW generated live stream family support event. • Assistance editing job resumes. • Diapers, wipes formula • Referral to immigration, criminal, and family lawyers • Cancer screening • Feminine sanitary products
Notes on families served/ number served (free text) Any impact information you think would be helpful for us to know about, questions that came up from families, etc?	Hmong Community *The Hmong community is having to cope and grieve non-traditionally and I am coping a family through losing a loved one. Also, I am working with families to get them access to food pantries and culturally specific foods.* *09/11/2020* *I am continuing to work with a teen who lost his dad due to COVID-19. The entire family is having a hard time coping and I am making referrals and being another source of support. I am also receiving more food donations. I am individually dropping them off at family's homes.* *09/18/2020* *I am doing regular check-ins with a family. The mom is on her way to recovery but they mentioned to me how even after COVID, things do not go back to normal. The community puts a stigma on them as if catching coronavirus was a curse. People are afraid of their families even after they have recovered from COVID-19. She has physical limitations that were not there before covid such as tiredness from just going up the stairs, breathing still hurts, and physical tiredness. The youth I am working with is finding support through opening up to friends and family again. I think sometimes talking to close friends and family isn't always the best option, so talking to me has been helpful.*

DS Table 3. CHW-Generated Reports from Zoho Forms on Community Empowerment

ZOHO FORM DATA FIELD	EXEMPLAR INFORMATION
Community Education/ Outreach/ Other	
Notes on Community Education, Outreach, and Coordination (free text)	
Team and Learning Activities	
Types of team activities? (check all that apply): Assisted another team member, attend a conference/ presentation, Attended a training	
Notes on Team and Learning Activities (free text)	**Hmong (9/18/2020)** <Native American CHW lead> needed another mask for this cultural art project and so I assisted him in that. I made masks at Mexican Fiesta with <Hispanic CHW Lead), <Native American CHW>, and <Hispanic CHW>. I also met with <Hispanic and African American CHW leads> at <Organization Name> and picked up some supplies for distribution. <African American CHW lead> has been helpful in getting materials to me and the team. My team and I are getting ready to put kits together to distribute. Kits will include Health Department masks, hand sanitizer, latex gloves, and the COVID info card.

Mental Health Support: A MH webinar was conducted across all 4 communities to provide training to CHWs enabling them to act as a MH first response worker within their communities. Guidance on accessing MH support, and referrals to government-owned facilities were also provided to the CHWs, hence equipping them with the necessary tools to address the MH crisis on the go.

COVID-19 Support: CHWs were able to identify resource gaps within their communities that could prevent infection spread, and through their active reporting via the Zoho forms, efforts were made to distribute face masks, provide tailored information on COVID-19 testing and masking protocols across all 4 communities. The CHWs also created awareness and dispelled rumors and negative societal stigma associated with the virus.

Facilitation of Local Community Support Teams/ Systems: Aside from their commitment to reporting first-hand information to leadership (MCW, Milwaukee Public Health Department & CHW Leads), the CHWs through the data collected helped in facilitating outreach work between local churches and the communities they serve. As a result of these efforts, churches, and other non-profits were able to meet the resource needs of individuals financially constrained due to the pandemic by providing food pantries, rental support, clothing, and hygiene supplies.

DISCUSSION

Our study provides an in-depth narrative of the pivotal role CHWs play in navigating the complex terrain of public health crisis response, particularly within diverse communities. We have underscored the role of communication and information management during public health crises while highlighting the various tiers of partnerships and

communication efforts employed by health departments to obtain information from hard-to-reach populations. Adding to the significance of CHWs in public health crisis response, a distinction to our approach is the strategic integration of simple technology as illustrated by the use of Zoho forms in our study. Our approach emphasizes the need to look beyond conventional technological solutions requiring expertise and infrastructure for information management during a crisis. The dynamic integration of CHWs and Zoho forms during the Stop-COVID-19 efforts across four diverse communities in Milwaukee proved beneficial for on-the-go crisis management efforts. Equipping the CHWs with this simple technology was a crisis response strategy that transcended the barriers of complex tech adoption. Furthermore, in keeping the tools simple, we were able to empower CHWs and streamline information flow thereby establishing a robust infrastructure for the disaster response frameworks within these diverse communities.

While the simplicity of the technology used in our study was a strength of our COVID-19 crisis response efforts, we however acknowledge the potential challenges that may arise concerning data security and privacy (Kim et al., 2017). In terms of data privacy and security concerns, while Zoho forms as a security component to ensure data safety and privacy, we however, think it is additional efforts must be made to ensure CHWs are informed on additional measures they must take to ensure the data they collect within the communities they serve are properly secured, in addition to this, CHWs must also assure communities from which this information are obtained about the safety of their health information to avoid mistrust and potential loss of the life-long partnership already established between CHWs and the communities they serve.

CONCLUSION

In healthcare systems, Community health workers have been proven to provide substantial and indispensable support for routine care activities, disease management, and infection prevention during public health crises. Including their roles with additional support for crisis reporting and information management will further enhance crisis management efforts by public health authorities. Our study, centered on leveraging the use of Zoho forms as a simple technology during the Stop COVID-19 efforts in collaboration with Milwaukee's public health department, academic partners at the Medical College of Wisconsin, and community leaders in tandem with CHWs, demonstrated significant benefits in communities mostly impacted and in dire need of resources. While we can say that our study successfully met its objectives within the target communities, we, however, emphasize the need for a continuous commitment to identifying and enhancing public health communication and information management within these communities during public health crises and beyond. We emphasize the importance of leveraging CHWs and empowering them with simple technologies like Zoho forms, to facilitate their work. Further work should begin to explore strategies to consolidate the role of CHWs as essential contributors to public health crisis response frameworks. In addition, incorporating user-friendly and quick reporting tools for information management, reporting, and distribution, while upholding privacy, ease of use, and confidentiality should be considerations for their uptake and impact.

Our study advocates for a continuous commitment to securing and strengthening the role of CHWs and integrating accessible technologies into the frameworks of efficient public health crisis management.

ABSTRACT

Purpose: With the increasing frequency of disasters, the focus of this paper is on the acute and long-term stress and strain resulting from the 2021 flood disaster and the role of social media in this. Methods: Data was collected through group discussions in the context of world cafe´ sessions. In April 2023, three workshops were carried out with various groups of people in the Euskirchen district. Minutes and transcripts were analysed using Mayring's qualitative content analysis. Results: The results indicate a high level of stress for those affected due to environmental, social and psychological factors on an analogue and digital dimension. The strain was usually recognised and acknowledged in the aftermath of the crisis situation. Conclusions: It is recommended that the inhibition threshold for mental health and psychosocial support be lowered further and that a psychosocial situation report be kept over a significantly longer period of time.

Keywords

natural disasters, stress and strain, social media, disaster management, mental health and psychosocial support

INTRODUCTION

In recent years, combined hazard situations in the form of geophysical, hydrological and meteorological crises and disasters (CaD) have increased (UNDRR & CRED, 2020). In particular, the number of natural disasters, especially floods, has almost doubled in the last 40 years (ibid.). The significant impact of natural disasters on a large proportion of the population affects both people's lives and the environment (Berz, 2014). CaD are characterised by a sudden and unexpected discrepancy between perception and coping, as well as heterogeneous and significant impacts on the well-being and functioning of those affected (Quarantelli, 2005). A width of sidewalk can separate a fate of destroyed livelihood from integrity. Those affected show individual reactions and psychological consequences, as well as subjective perceptions of the circumstances. In particular, the emotional and psychological aspects associated with such events, such as fear, loss and survival instincts, depend on individual experiences and characteristics. Mental health is a crucial aspect of overall preparedness and crisis management. Mental health and psychosocial support (MHPSS) aims to reduce the likelihood of clinical symptoms occurring in the aftermath of a CaD. Even today, in 2023, many counselling centres are still maintained and accepted by the population.
In CaD, the available coping resources and basic environmental, psychological and social needs change. As a result, those affected have an increased need for information and communication. Because of their interactive nature, social media (SoMe) provide a platform for private and public exchange. SoMe are already part of everyday life for 70 % of

*corresponding author

users (Paulsen et al., 2023). Among other things, people can share their thoughts, feelings and challenges with and receive support from others (Grieve et al., 2013). As a result, SoMe is increasingly being used in CaD to manage the crisis situation (Norris et al., 2008). To date, scientific research has focused thematically on the needs in the acute phase of CaD and, in terms of target groups, primarily on authorities and emergency personnel (AEP). This article therefore focuses on stress and resource-strengthening factors in the acute and reconstruction phase (RQ1) as well as perceptions and experiences with MHPSS services (RQ2). Starting with a general description of the 2021 flood disaster, scientific findings on stress factors and resources in crisis situations and MHPSS, a detailed description of the methodology used and the data basis is provided. The derivation of the research questions is integrated into the description of the associated studies. Taking these principles into account, the results are presented, discussed comparatively and methodological limitations are highlighted. Finally, specific recommendations for decision makers and conclusions are drawn.

BACKGROUND AND RELATED STUDIES

2021 European Floods

Natural disasters are extreme events caused by natural phenomena that have a variety of characteristics, including the type of underlying hazard, speed of occurrence, duration, predictability, warning potential and magnitude of impact. They can be categorised into geophysical, hydrometeorological and biological disasters, with floods, earthquakes and hurricanes being the most common (Jha, 2010).

The flood disaster that occurred in many European countries in July 2021 was a devastating natural disaster caused by heavy and prolonged rainfall.The countries affected included Germany, the United Kingdom, the Netherlands and others.Caused by a low-pressure system called "Bernd", intense rainfall occurred within a few days, causing water levels to rise rapidly and causing many rivers to burst their banks. The masses of water led to landslides and the destruction of settlements and infrastructure (Jungha¨nel et al., 2021). Around 180 German cities and communities were affected by the flooding (Radio Euskirchen, 2022). The federal states of North Rhine-Westphalia (Euskirchen district and Hagen) and Rhineland-Palatinate (Ahrweiler and Bad Neuenahr-Ahrweiler) were particularly affected. In some areas, 150 litres/m² were measured within 24 hours (compared to the average rainfall in Germany in 2021 of 805 litres/m² (Deutscher Wetterdienst, 2023)). The flood disaster lasted several days. Although meteorologists had warned of the intense rainfall, the extent and spatial distribution of the rainfall was difficult to predict. In total, more than 180 people died in Germany, about 48 of them in North Rhine-Westphalia (Schro¨der, 2022).

Stress Factors and Resources in Crises and Disaster situations

Every CaD is a massive collective stressor for the population (Vitaliano et al., 1987), which affects individuals in different ways and forms at the micro (individual), meso (organizational) and macro (societal) level. Personality as well as temporary physical and psychological states act as moderators (Paton & Flin, 1999). Consequently, there are significant individual differences in response to emergency stressors that influence the magnitude of the perceived stress response. The term *stress* refers to all influences affecting a person, both positively and negatively, without any subjective evaluation. Depending on the type of CaD the incurred stress and its processing vary (Galea et al., 2005). Strain can be understood as a negative emotional experience aimed at reactive adaptation in the form of predictable biochemical, physiological and behavioral changes. According to Baum, a distinction can be made between changing the external stimulus through manipulation of the situation and changing the internal effect as an adjustment to the individual interpretation (Baum, 1990). The stresses that AEPs and the population can face have been extensively researched (Leon, 2004) and the physical and psychological health impacts of natural disasters have also been highlighted (Makwana, 2019).

Nevertheless, the perceptions and external stimuli are changing due to the paradigm shift from a passive population to prosumers (Lang et al., 2020). Those affected communicate through SoMe to actively share and search for information (Reuter & Kaufhold, 2017)This can also give rise to stressors from the digital space, such as disruptions in people's lives, relationships and communities (Carroll et al., 2009). Among other things, long periods without new information, long working hours, lack of social support, noise and hazardous substances as physical/chemical factors and reduced boundaries between work and private life can have psychological impact. In summary, there is a need for a comprehensive understanding of stress that takes environmental (primary), psychological and social (secondary) stressors into account (Pearlin, 1989). The factors cannot be viewed in a clearly differentiated manner, but rather determine each other in causal relationships.

The **environmental impacts** of flood disasters include impacts on water quality and infrastructure, as well as the situational factors such as noise and stale smell. Environmental conditions can also have an impact on psychological distress. Noise can lead to hearing damage and trigger stress reactions with long-term exposure to 70–80 dB(A) (Gross, 2012). **Social stressors** in flood disasters are diverse and include both immediate and long-term impacts

in interaction with the social environment, such as significant life changes in relationships or socioeconomic disadvantage (Rufat et al., 2015). In the context of crisis communication, it is already known that defensive crisis communication can damage the credibility of individuals or authorities (Allga¨uer & Larisch, 2011) and that it is better to communicate negative information openly and transparently than to hide it (Frewer et al., 2002). Affected people actively search for information, including on SoMe. Furthermore, they disseminate information rapidly and in some cases provide specific situational information that is not available through traditional media (Liu & Austin, 2010). Exposure to flooding can have significant **psychological impacts**, with symptoms of post-traumatic stress disorder, depression or anxiety (Mason et al., 2010). These effects can be compounded by secondary stressors such as health concerns, relationship problems (social), and loss of sentimental items (environmental) (Tempest et al., 2017). In addition, encountering the suffering of others can lead to secondary trauma (Daniels, 2008). Due to the user-generated nature of SoMe, an exchange of information can occur that can lead to exposure to traumatizing media content among unaffected populations (Kreutzer & Köllner, 2020) or to rumors (Nestler, 2017). SoMe has become not only a stressor but also a crucial resource in CaD, fulfilling various functions (Mu¨ ller et al., 2023). These primarily include social factors such as information dissemination, resource mobilization and psychosocial support through emotional relief and strengthening a sense of community (Simon et al., 2015)Because psychological strain is not only a consequence of the stressors, but also a result of the way a person perceives and evaluates the situation, taking into account their own resources (Lazarus & Folkman, 1984), there is still a lack of knowledge about the long-term strains and resources of the population during CaD (Walker-Springett et al., 2017). Perception is influenced by various factors. One factor is anchoring bias, which illustrates how individuals use a given starting point or anchor when evaluating information or values and anchor their evaluations to that reference point (Tversky & Kahneman, 1974). Another factor, especially in stress-dominated situations, is selective perception. This is characterized by the rapid interpretation of information through the individual lens of one's own expectations, perspectives and experiences, despite the belief that reality is perceived objectively (Glaser, 2019). Furthermore, the negativity bias causes the tendency to pay much more attention to negative information than to positive information (Vaish et al., 2008). In particular, there is a need for further research to examine today´s stresses and resources of the German population after a specific event. Therefore, we propose the first research question (RQ1).

RQ1: Which stress and resource-strengthening factors were particularly relevant for those affected by the 2021 flood disaster in the acute and reconstruction phase?

As SoMe play a crucial role in today's CaD, we also focused on stresses and resources in the digital space.

Mental Health and Psychosocial Support in Crises and Disaster Situations

Since the success of physical reconstruction after CaD also depends on the psychological functioning of the population, early interventions to prevent psychological disorders after natural disasters are particularly important (Kessler et al., 2012). In CaD MHPSS as a system of psychosocial interventions includes (1) strengthening individual and social coping resources, (2) promoting resilience and (3) preventing psychological trauma disorders (Beerlage, 2021). The measures relate to CaD and connected stressful operational situations (e.g. death or danger to one's own life). Grawe distinguishes four psychosocial basic needs: (1) attachment, (2) orientation and control, (3) enhancement of self-esteem, and (4) pleasure gain/avoidance of displeasure. Attachment is the need for interpersonal relationships. Social support therefore plays an important role in individual psychology and has a positive effect on stress management, adaptability and life satisfaction (Cohen & Wills, 1985). Conversely, the lack of social connections can have negative effects on mental health (Baumeister & Leary, 1995). The return to one's own ability to act as an essential act of psychosocial support promotes the satisfaction of orientation and control needs as well as the strengthening of self-esteem (Kernis, 2003).

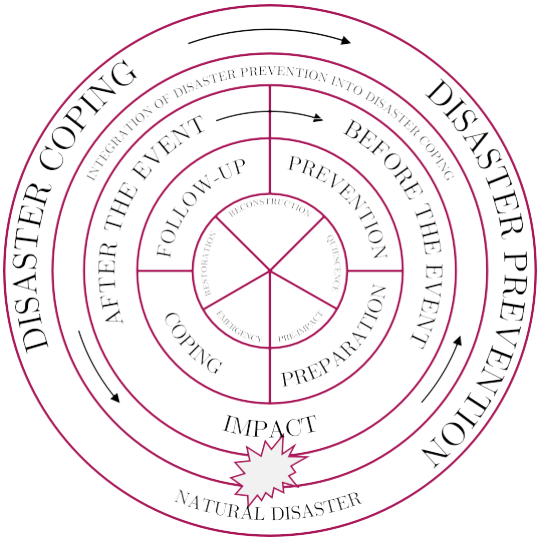

Figure 1. Disaster cycle, combined and revised from (BBK, n.d.; Glade & Alexander, 2013)

MHPSS measures vary depending on the individual characteristics and reactions. However, they also vary depending on the current phase of the disaster management cycle. Figure 1 visualizes this cycle at different levels based on

(Glade & Alexander, 2013). In principle, crisis management is divided into the four cyclical phases of 1. prevention, 2. preparation, 3. coping and 4. follow-up (BBK, n.d.). The psychosocial measures are divided into A pre-activity phase, B activity phase and C the phase after the disaster response (Umeda et al., 2020), whereby phase C can be further broken down on a time scale of two months to several years into relief phase, rehabilitation phase and rebuilding phase (Rao, 2006). Phase A is particularly characterized by preparatory measures aimed at experiencing stressful situations and one's own perception of stress. Due to their preventative nature, these measures are primarily carried out for AEPs (Umeda et al., 2020). The activity phase (Phase B) is characterized above all by immediate physical care and medical care, but also by connecting survivors with sources of support, culturally appropriate forms of mourning for the deceased and normalization of activity and routine as far as possible (Rao, 2006). After the disaster response, activities are geared towards returning to routine and sharing and processing experiences (Umeda et al., 2020). Here (relief phase), primarily empathic and active listening as well as relaxing methods are necessary to support those affected (Rao, 2006). The rehabilitation phase is characterized by the realization of those affected that they must become active themselves and help themselves. Family support and the social environment as well as acceptance and supportive reactions from others are particularly important here (ibid.). Detached from the disaster cycle, MHPSS can be differentiated into two dimensions: (A) temporal and (B) target group-oriented. MHPSS actors act in the short, medium and long-term support, advice and therapy for those affected in CaD (A) (Beerlage, 2021). The target group-oriented dimension (B) takes certain groups of affected people into account when assessing the need for MHPSS measures due to different initial conditions, needs and perspectives. A distinction is made between B.1 measures for survivors, relatives, witnesses and/or missing persons and B.2 measures for AEP. Measures for affected group B.1 are primarily aimed at satisfying the needs for security, reassurance, regaining self-efficacy/control, connection with loved ones, confidence and information (psychoeducation) (Mu¨ ller-Cyran & Zehentner, 2013). Measures for affected group B.2, on the other hand, also focus very much on preventative measures as part of the integration into health and occupational safety and the employer's duty of care (Beerlage, 2021).

Due to the individuality of reactions and coping processes, it is not only important to understand the perceptions and experiences of those affected and to gain insights into the effectiveness of MHPSS interventions, but also to adapt future psychosocial support services appropriately to the needs of the community. MHPSS interventions are a developing field with few established interventions. This in turn limits the level of awareness of available interventions, as many of those affected are unaware of their existence and implementation. Due to the sensitive nature of personal data, there are numerous data protection restrictions when contacting people who are being supported. An open research question in this thematic field is therefore the RQ2 considered here.

RQ2: How did those affected by the 2021 flood perceive and experience the MHPSS services?

METHOD

As part of the study, workshops were held with people affected by the flood disaster in 2021 in the Euskirchen district, Germany. Qualitative research makes it possible to survey opinions, motives and attitudes in a rule-based manner.The workshops took place on three different occasions with different groups of participants who were involved in the disaster in different ways, see table1. During the workshops, the groups engaged in a dialog using the "world cafe´" technique. The debates were documented for each topic and then transcribed. The transcripts were analyzed in accordance with the research questions using qualitative content analysis according to (Mayring, 1991). Figure 2 visualizes the basic process from recruiting interviewees to analysis.

Participant Recruiting and Data Collection

In cooperation with the Euskirchen district, a large-scale open web survey was carried out in March 2023. Integrated into this survey was a request for further willingness to participate in other exchange formats and consequently the recruitment of participants for the group discussions. The survey was disseminated by the University Wuppertal and the Euskirchen district via various communication channels (radio, SoMe, etc.). As a result, over 1,400 complete sets of responses were obtained from those affected by the 2021 flood disaster as well as spontaneous helpers and AEPs. 215 persons were willing to participate in group discussions (101 of them with characteristics of the target groups). Based on specific queries, three group discussions were held, each with at least 12 persons from different target groups. The discrepancy in the number of people between those on standby and participants is due to logistical restrictions, lack of acceptances and no-shows. Within two weeks in April 2023, thus almost 2 years after the flood disaster 2021, different topics were examined from different perspectives on three different days, see table 1.

The methodical implementation took the form of a world cafe´, a process that records discussions on various issues in rounds and with changing group composition and thus offers a supplement to other established methods of qualitative data collection (Lo¨hr et al., 2020). As a participatory method, this form of group discussion not only

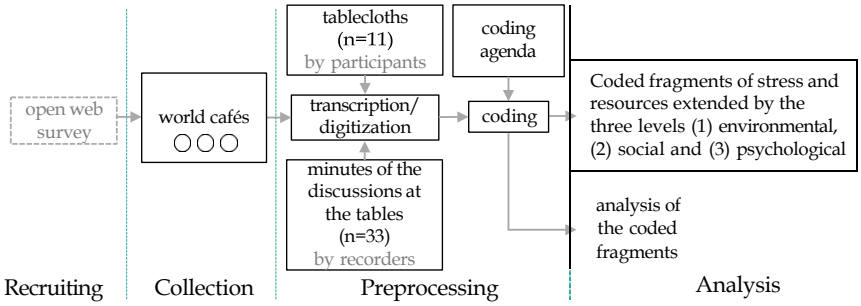

Figure 2. Framework methodology process

provides data for the researchers, but can also be useful for the participants, as they can reprocess their experiences from the 2021 flood disaster in dialog and psychoeducationally facilitate the recording of their own needs (Steier et al., 2008). The participants' discussions were led by the hosts and recorded in writing by minute-takers. In addition, the participants were also asked several times to note down important key points and topics on writable tablecloths. All hosts of the three simultaneous discussion rounds were instructed in advance by the project management and prepared for the methodology with the help of rules and sub-questions on the discussion topic. Minutes were taken using a semi-structured template.General notes on the course of the discussion were recorded, and frequent or controversial topics were explicitly noted. In order to be able to identify particular focal points across the different groups, the note-takers were also asked to note topics discussed twice and to set time stamps.

preparation and training	development wishes MHPSS	development wishes MHPSS
role of SoMe		

Data Preprocessing and Analysis

Both the protocols and tablecloths were transcribed after the events and coded deductively-inductively as part of a content-structuring qualitative content analysis (Schreier, 2014). The core of the content-structuring approach was to identify and conceptualize categories within the framework of selected content aspects and to systematically describe the material with regard to stressors, resilience factors and experiences as well as perspectives on MHPSS. Based on the modified version of the procedure according to Steigleder, a combined deductive-inductive formation of super- and subcategories was implemented. The upper categories were formed thematically, while the subcategories were identified as in vivo codes (Steigleder, 2008). A total of N=996 codes were allocated to a category, with the possibility of multiple codings.

RESEARCH FINDINGS

The 2021 flood disaster (14/15.07.2021) was a natural disaster with severe flash floods and various damages. 73 % of respondents to our open web survey indicated at least a medium level of psychological stress in relation to the impact on their own household (approx. 10 % no stress at all), more than 87 % in relation to the wider social environment. Up to one month after the flood disaster, the subjectively perceived at least medium high stress is assessed by the majority (81 %) due to the impact on the immediate social environment (4 % not at all, 5 % very low, 10 % low), approx. 67 % in relation to the impact on their own household (15 % not at all, 9 % very low, 9 % low). Overall, both primary and secondary traumatization put a heavy strain on the population, which extends beyond the coping phase.

Stress and Resource-strengthening Factors During the Flood Disaster 2021 (RQ1)

During the emergency phase (see figure 1), the focus of those affected and AEPs was on saving lives and taking the acutely necessary measures to prevent or minimize damage. During the group discussions, it became clear that the focus of all participants with different degrees of involvement was and is on the stress factors and less on the resilience factors. In a direct comparison, 57 % of the coded fragments were categorized in the "stressors" category, 43 % in the "resources" category (n_{total} = 402 coded fragments). Risk and crisis communication in relation to the flood disaster was discussed very controversially. The information required to assess the risk was not received by everyone and was also interpreted differently. In particular, the indication of the expected amount of water in l/m² was negatively emphasized, as many did not know how to interpret the warning. Crisis communication was felt to be inadequate not only before the prevention phase, but also during the disaster coping phase. The lack of communication about what was happening in the Euskirchen district led to uncertainty. Furthermore, the extent of the damage in the Euskirchen district was hardly discussed during the coping phase. This led to a feeling of not being seen and not having one's suffering acknowledged until the group discussions almost two years after the event. However, the psychosocial stress was overshadowed by the material and acute life-threatening stress during the coping phase. Figure 3 schematically illustrates this temporal relative relationship. In order to coordinate crisis management and to react appropriately to a CaD a general situation report is created and maintained. The psychosocial situation report, as a specialised form, supplements the overall picture with the aspect of the psychological factors and needs of the population groups. The need for MHPSS depends on various factors and the course of mental coping is described as fluctuating, but above all as lasting. Consequently, the psychosocial situation reportand crisis management must be maintained beyond the period of the general situation report. During the group discussions, noise and specific smells, such as the musty smell of the basement, were still described as significant stress factors in the coping phase and triggers for physical and emotional reactions, even two years after the flood disaster. In the first few weeks after the event, there was no way to mitigate the noise pollution through cleanup, heavy machinery and other vehicles, or to find a quiet place to rest. The sludge and exhaust gases emitted by the machines led to unpleasant odors in the long term. In addition to these factors, rumors in particular were mentioned as a burden from the digital space (especially SoMe) with an impact on analogue events. What is particularly striking here is that it was not the quantitative amount of rumors, but rather the impact of individual ones that was actively discussed by all groups. A key point here were the so-called "flood tourists". The resulting burden was not necessarily due to the value of the looted items, but rather to the fact that those affected could not imagine looters wanting to profit from their suffering. The same effect was achieved by people who traveled to the flood areas for self-promotion purposes on SoMe in order to supposedly help there and thus generate more followers.

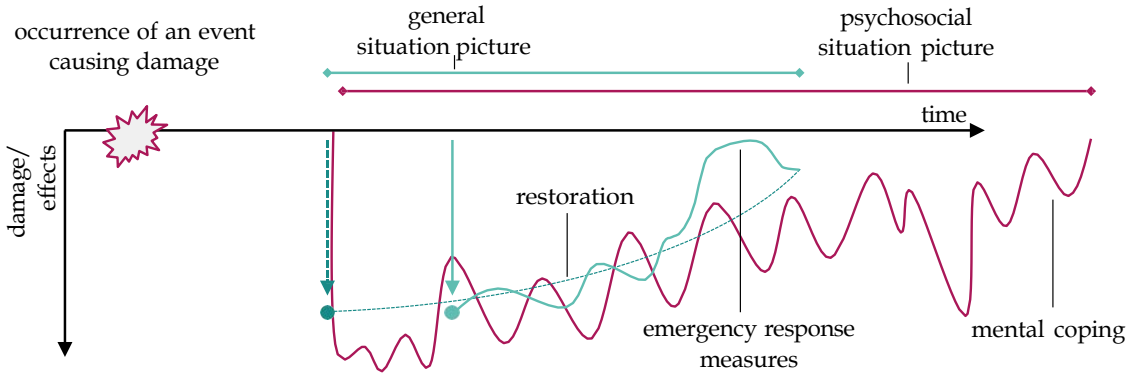

Figure 3. Schematic progression of crisis management, broken down by material/environmental (mint) and psychological consequences (pink), revised and expanded from (BSI, 2023)

SoMe were highly valued as a communication medium. First, it allowed individuals to reach out to friends and family and inquire about their well-being. Second, it made it easier to organize self-help groups and relief campaigns. SoMe was used to launch appeals and set up support groups. After the disaster, thousands of volunteers from all over Germany traveled in cars and buses to help. Donations of relief supplies were also received from large corporations. In addition, SoMe played a role in informing the public during the disaster. However, those affected noted that communication was not always possible. During the acute phase and shortly afterwards, the mobile phone network collapsed, making telephone calls and internet access impossible. The inability to monitor the well-being of their social environment and the lack of protection from external factors were identified as sources of stress. SoMe were therefore, only when usable, a resource to strengthen the community. The sense of community between

those affected and those helping them was cited several times by all groups as the most important resource-creating factor. The gratitude for the large number of people who selflessly helped in the CaD areas was still discussed immensely two years after the event.

Perception and Experiences with the MHPSS Services (RQ2)

The perception of circumstances is subject to many influences that can distort them. As a result, even the same stresses lead to different strains. The significantly different levels of stress in the course of the flood disaster led to a population with very different levels of strain. During the group discussions, many of the participants rated their own stress in relation to the known extent of damage to others. This also resulted in a corresponding classification of their strain, which in turn led to a trivialization of their reaction. On the micro level (individual), this showed an alignment of the reported stress with the macro level (group-specific), which was also visible between the different dates and target groups. Both those affected and the AEPs described communication problems, noise, smells and flood tourists as stress factors. However, it was also often stated that the stress on others from the immediate or wider social environment caused individual reactions, even to the point of strain. A danger from this can be that as the comparison number increases with SoMe, the subjective feeling of strain and the probability of seeking help decreases.

One significant difference between the target groups of AEP and those affected was in the perception of MHPSS. While both groups rated the services extremely positively, for the AEP the service was clearly known and sometimes mandatory in group settings, while not all those affected had information about the services (in the open web survey, almost 30 % of respondents said MHPSS was not known). The timing for disseminating information from MHPSS services was explicitly highlighted in the discussions. In the early stages of the coping phase, several initiatives, brochures and MHPSS services were provided. The offered MHPSS services were available during the day, particularly during clean-up operations. Some affected people said they were unable to accept such offers because of their focus on the cleanup efforts. From the perspective of the helpers of MHPSS (third date), the demand for MHPSS services exceeded the availability of various MHPSS offerings around three months after the event. The use of support services was perceived to be very fluctuating. Coping with a CaD presents individuals with numerous challenges in terms of preparation, assessing the situation, making decisions and dealing with stress (Enander, 2021). This process is not linear, see also figure 3. Although many people are open to using the support services, the fluctuating psychosocial demands and the partial lack of self-reflection result in the intensity of the population's use of MHPSS services fluctuating over time. Building on this, it was repeatedly pointed out in all three groups that the inhibition threshold for MHPSS measures needed to be lowered and awareness of the need for such support needed to be increased. The fear of social repercussions such as disrespect from one's own environment or the stress of having to explain oneself often outweighs the inclination to seek help. The terminology "psyche" also plays a negative role in the evaluation. In order to lower the inhibition threshold, the participants suggested measures such as active contact, more advertising, transparent information or organized meetings in cafe´s or similar places. A combination of active and passive (come and go structure) should be aimed for here.

DISCUSSION

The aim of the study is to investigate stress and resource-inducing factors of the 2021 flood disaster, with a special focus on the digital space (SoMe) and experiences with MHPSS services. Three group discussions were conducted as world cafe´s with affected persons, AEP and MHPSS staff in the Euskirchen district. Participants mainly focused on stress-triggering factors, and the psychosocial situation outlasted the general crisis. The digital situation significantly influences the analogue situation (RQ1). MHPSS, as a resource-enhancing factor, was perceived positively in the group discussions, but awareness was rated as insufficient and utilisation was not low-threshold enough (RQ2).

Comparative Discussion

The results of the structuring content analysis align with other scientific findings. The **focus on negative information**, encompassing stress-inducing factors, has been previously discussed under the term negativity bias (Vaish et al., 2008). The identified referencing of one's own stress to the macro level has similarly been analysed in the context of the anchor effect and selective perception (Glaser, 2019; Tversky & Kahneman, 1974). The anchor serves as a comparative value referencing a negative experience of another person in the context of the anchor bias. In the context of selective perception, those affected assume that others are more affected and neglect their own affectedness. To date, there is no external evidence that individuals downplay their own impact in CaD. Similarly, there is a lack of evidence as to whether others underestimate the extent to which they are affected by such disasters or whether this

influences the utilisation of MHPSS. Nevertheless, Plapp (2003) examines this issue and concludes that personal relationships with the affected area determine the degree to which CaD are relativised. Further research in this area is necessary to analyse the identified "**diffusion of stress**" more deeply. Further, **crisis communication** should be comprehensible, precise, specific, call for action and locally controlled (Aguirre, B. E., 2014). Communication should take place via various media, including SoMe. The provision of information via SoMe was a key factor for those affected. The lack of information and the lack of attention to the extent of the damage in the media was perceived as an additional stressor.

Frewer et al. (2002) argues that some information, even if insufficient, is preferable to no information at all. An information status display also reduces the likelihood of rumors, frequently discussed as a negative factor in the digital space affecting analog events. However, it's not the quantity of misinformation that matters, but rather its quality, credibility, and dissemination. The study by Fathi and Fiedrich (2022) revealed that only 5 % of social media posts related to the flood disaster were misinformation, yet this could have a significant impact.
Exposure to **noise and odour** is particularly relevant in the area of occupational health and safety. Loud and persistent noise poses a potential risk to health and is categorised as a hazard in the occupational health and safety risk assessment. The multifactorial exposure causes a link between the environmental conditions and the emotions and feelings. This link between sounds or images and the triggering of post-traumatic stress disorder has already been well researched (Pausch & Matten, 2018). Interestingly, the sight, i.e. physically seeing the flooding and destruction, was not explicitly mentioned as a stress factor in the group discussions conducted. Further research is needed to determine whether this was simply not addressed due to its obviousness or whether it may be a case of desensitization from watching disasters on TV or similar.
The shared experiences of disaster-affected individuals foster the development of **group affiliation** or community, recognized as a crucial factor in resource mobilization. According to the social identity theory proposed by Tajfel and Turner, people tend to categorize themselves and others based on shared characteristics like gender, ethnicity, and religion, leading to community formation. Social media (SoMe) facilitated communication within and beyond these communities, a point underscored during discussions. Currently, organizational and communication practices via SoMe are considered typical Zisgen et al.

The coping response in CaD may require MHPSS services, yet the reluctance to seek counseling remains a significant issue. While some guidelines acknowledge the challenge of seeking psychological help, the existing barrier is often deemed too high (Nikendei, 2012). To address this, the group discussion suggested promoting active contacts and transparent information provision by the Federal Office of Civil Protection and Disaster Assistance. The study's results indicate that psychological stress lingers long after the event, suggesting a prolonged need for psychosocial situational awareness. Solomon and Green suggests psychological consequences can last up to three years, with most symptoms subsiding after 16 months (Solomon & Green, 1992). The peak of symptoms occurs one year after the disaster, followed by gradual improvement (Goldmann & Galea, 2014).

Methodological Limitations

The chosen combinatorial structuring content analysis methodology, relying on minutes and tablecloths from various world cafe´s, has limitations. Participants were recruited through an open web survey, lacking random sampling or representativeness. This generated a sample of intrinsically motivated individuals willing to participate in both the survey and group discussions. The extent of the damage made it difficult to clearly distinguish between the groups of people on the three dates. The group formation and invitation was carried out in waves, whereby acceptances from the participants' social environment were also taken into account. The study aimed for qualitative insights, not quantitative data. Gathering information from other regions could enhance findings. Conducted almost two years post-flood, there's a risk of recall bias alongside selection bias. Distance to the event may distort memory accuracy. However, selective perception in CaD doesn't weaken surveyed factors' relevance. Methodological limitations include information bias due to different hosts and minute-takers impacting participant involvement. For reasons of clarity, no distinction was made between stress and strain in the group discussions, meaning that it was no longer possible to differentiate between them when coding. In addition, the content analysis lacked a reliability check. Further validation is planned through open web survey and interview analyses, with knowledge application in practice through practitioner exchanges.

Implications for Decision Makers

Implications for decision makers in CaD, drawn from group discussions with affected persons, AEPs, and MHPSS staff of the 2021 flood disaster, include:

1. Establish trust in SoMe early in the prevention phase for effective risk and crisis communication. Ensure open communication, sufficient personnel, and clear language. Use practical comparisons and explicitly name potential hazards to raise awareness and assess individual vulnerability. Consider that naming the extent of damage is crucial for those affected.
2. Stress from rumors in the digital space is influenced by proximity and reach, not volume. Early denial by public bodies, supported by credible SoMe accounts and consistent communication, can mitigate this stress. Enhancing population media skills is essential.
3. Support the population during the restoration phase by distributing personal protective equipment, such as earplugs or odor inhibitors.
4. Increase awareness of psychosocial stress and MHPSS services. Psychoeducational measures should cover stress reactions, secondary traumatisation, and the use of MHPSS. Offer services in a flexible structure integrated into community activities during the coping phase.
5. Maintain a long-term psychosocial situation picture and crisis management beyond the coping phase.

CONCLUSION

The flood disaster in July 2021 caused deaths and extensive damage due to heavy and prolonged rainfall, affecting people across regions. They faced challenges such as unclear crisis communication, theft, and the loss of loved ones. The changing society and the rise of digital communication led to the first research question:
RQ1: What stress and resource-strengthening factors were particularly relevant for those affected by the 2021 flood disaster in the acute and reconstruction phase?

Group discussions highlighted analog stress factors, like noise and stale smell, with a strong emphasis on the lack of crisis communication, including via SoMe. Various groupings noted that information from SoMe impacted physical events and actions of those affected. Discussions suggested addressing population needs not in the acute phase but during coping. The interrupted flow of communication and a lack of information about the social environment, due to everyday use, added an additional burden, deviating from everyday life in today's networked world.

MHPSS played a major role in processing deviations from everyday life in the 2021 flood disaster. To gain further insights into CaD with a focus on MHPSS, the study explored the second research question:
RQ2: How did those affected by the 2021 flood perceive and experience the MHPSS services?

While MHPSS services are not universally known, group discussions predominantly reported positive experiences. Various development wishes were discussed, indicating optimization potential in this area.

Further research is crucial due to the increasing likelihood of natural disasters. Investigation into factors contributing to stress and resources in CaD in today's society is essential. Identifying consistent factors through comparisons with other disasters and assessing the effectiveness and acceptability of MHPSS in CaD require additional research. As part of the research project #sosmap, further quantitative and qualitative data will be collected to shed light on the current status of the MHPSS and explicitly the role of SoMe from the various perspectives of the population as well as the authorities and emergency services. The data already collected as part of the study (survey results and interview transcripts) will be analyzed in greater depth with various objectives in mind. These include the perception of the MHPSS and a comparison between self-reported use of SoMe compared to identifiable information in publicly available sources.

ABSTRACT

Rescue dogs are used in disaster response because of their ability to find victims using their excellent sense of smell, supported by dynamic decision-making skills. Disaster area environment is hazardous for both dogs and dog-handlers. Therefore, new technology is being developed to assist. In this article we argue that if new technologies are developed with the aim of making search and rescue missions in disaster zones safer and more successful, then there is a need to research how such technology can support communication between dog, handler, and incident command; in particular, how is shared situation awareness developed and supported. We present a model that scopes the interactions between human, dog, and technology together with advanced techniques for assessing those interactions through measurement of (shared) situation awareness and understanding. With such a wide range of potential technologies (such as VR, AR, 360-degree online video streaming, gas detecting sensors and special communication vests for dogs) having a clear view of how different parts of a team interact, and how to assess those interactions, is crucial. The use of technology (e.g. AR) is not limited to use in the implementation of search and rescue procedures, but can also be used in testing, and training for, other new technologies.

Search and Rescue Dogs (SAR Dogs), Dog-Handlers, Quantitative Analysis of Situation Awareness (QASA), Technology Enhanced Actual Situation Awareness Model for Dog-Handlers working with Search and Rescue Dogs (TEASAM-DH & SAR Dogs)

INTRODUCTION

Every year man-made or natural disasters occur all-over the world. New technologies are constantly developed to improve the safety and effectiveness of first responders, while also saving the lives of victims. New technologies including virtual (and/or augmented) reality, robots and advanced sensors are being tested to replace dogs and humans operating in hostile environments (Sanfilippo & Rañó, 2023). Because dogs have long been established as excellent partners for first responders with the ability to operate autonomously while looking for victims in

disaster areas, robots are usually built to mimic dogs' capabilities in the disaster area, such as the ability to move over rough terrain (Bellicoso et al., 2018). At the same time technology enhanced vests are designed to be used with rescue dogs and their handlers (Arnold et al., 2019; Kasnesis et al., 2022). New wearable devices are being developed that allow sensing, geolocation, and monitoring of the state-of-health of the search and rescue (SAR) dog. Such devices also support dog-handler communication, including sending commands to the dog (Contini & Martins, 2024). While such new technology has the potential to be of great benefit, it is important to conduct research to establish whether such benefits include, for example, improved situation awareness (SA) for first responders and incident commanders (Roldán et al., 2017).

Dogs, with roughly 40 times more smell-sensitive receptors than humans (Kumar, 2022), rely heavily on their sense of smell as their primary sense. Currently, no robots or sensors can match a dog's sense of smell. Unlike the human brain, which prioritizes a large visual cortex, the dog's brain is primarily dominated by an olfactory cortex (Correa, 2011). A dog has more than 100 million olfactory receptors in its nose (see Table 1), while humans have only 5 million (Padodara & Jacob, 2014). Dogs (and humans) also have a vomeronasal organ (also called Jacobson's organ) which is located above the palate and behind the upper incisors (Correa, 2011), that is particularly sensitive to pheromones. Dogs' sense of smell has led to them being trained for search and rescue missions (SAR missions), to search for victims in disasters or missing people around the world – and to detect for, amongst other things, narcotics, drugs and contraband agricultural products, homicide victims and forensic materials from corpses.

Table 1. Scent-Detecting Cells in Humans and Dog Breeds
(adopted from Padodara & Jacob, 2014 who reference Stanley and Sarah, 2013)

Species	Number of Scent Receptors
Humans	5 million
Dachshund	125 million
Fox Terrier	147 million
Beagle	225 million
German Shephard	225 million
Bloodhound	300 million

Urban search and rescue (USAR) teams are governed internationally by regulations published by INSARAG (International Search and Rescue Advisory Group). It is mandatory that all rescue teams include technical search units for the search and detection of victims under collapsed structures in earthquakes and other disasters. Currently, there is no more effective and efficient mechanism for searching for victims than trained dogs. These dogs are the main tool of the technical search teams of USAR groups. Given the current effectiveness of dogs within USAR teams, it is essential that any new technologies should be integrated appropriately, and the success of such integration assessed. We propose a model to support the development and integration of the technologies in such a way that the co-operation of dogs and their handlers improves and that, crucially, such improvement is manifest in (and can be assessed by) improved situation awareness.

We use a definition of situation awareness (SA) first proposed by Endsley (1995), that SA is the: "perception of the elements in the environment within a volume of time and space, comprehension of their meaning, and the projection of their status in the near future". In the event of a disaster, SAR dogs and their handlers (as well other first responders, inhabitants, and victims) need to quickly be aware of elements of the disaster such as the location (GPS coordinates) of SMS-warnings, sirens, drones, collapsed buildings, safe areas etc. Individuals and teams within the disaster zone then need to be able to integrate the available information to comprehend the situation and, at highest level of SA, to predict the most effective and safe activity in that situation. While technology has the potential to enhance SA at all levels and for all involved, it is crucial not to assume that the mere adoption of new technological tools will automatically bolster SA; thorough research is necessary. Additionally, it is important to emphasize that the implementation of any new technology requires the adjustment of standard operational procedures, and the training of both dog-handlers and dogs, to effectively integrate those new technologies.

MEASURING SITUATION AWARNESS

While the general concept of SA has become well established and researched in a number of domains, the use of simulation-based training scenarios as a method to improve SA has been the subject of relatively little research (Polikarpus et al., 2019, 2022). Nevertheless, Model-based Design is suggested for complex systems when real-

time simulation are needed (Bélanger et al., 2010) and a Venn diagram is the world's most recognizable graphic approach to visualize and learn from similarity and matches (Koll et al., 2023). We combined our practical experiences of training SAR dogs and dog handlers using technology to measure SA into Technology Enhanced Actual Situation Awareness Model for Dog-Handlers presented as a Vienn-diagram below in the paper.

Endsley (Endsley, 2021) reviewed a number of methods for measuring SA one of which, Quantitative Analysis of Situation Awareness (QASA – although the attribution in Endsley's paper is incorrect) has the unique feature of being able to measure *negative* SA – indicating not only that somebody has no awareness of the situation, but that they also misunderstand it. In disaster situations, under heavy stress, such misunderstanding could easily happen to the extent that the dog-handler does not understand that his/her dog is threatened by the hazard from environment.

QASA measures both actual situation awareness (ASA) and actual situation understanding (ASU). See Table 2 for an overview of abbreviations and descriptions. ASA and ASU are rather novel terms used in recent projects, such as the FireFront project (Thoelen et al., 2020), compared to Endsley`s well cited SA definition. ASA refers to an awareness of the 'ground truth'. That is, the situation as it objectively really is. Good SA is, arguably, a necessary, but not sufficient, criterion for effective performance. An individual (or team) needs to not only be aware of the situation, but they also need to understand it - ASU.

QASA also measures *perceived* SA (PSA) and perceived SU (PSU). PSA/U refers to how good an individual *believes* their awareness/understanding of the situation to be. It is not guaranteed that ASA/U and PSA/U will necessarily match, and the cause of some catastrophic accidents can be traced back to a mismatch of ASA/U and PSA/U. It is therefore desirable to assess not only ASA and ASU, but also PSA and PSU. Good ASA can tell you that the technology is doing its job in delivering the necessary information, ASU can tell you whether the information is presented in such a way that the end user can understand it. PSA/U can tell you whether the individual has an *awareness* of their own performance level. Given the range and sophistication of the technique, we therefore propose the use of QASA (Edgar et al., 2018) to measure aspects of SA and SU while using The Collaborative Authoring Process Model for Virtual Simulations (CAPM) (Polikarpus et al., 2022) to assess the impact of new technologies on SA and SU, as shared across teams.

Table 2. Overview of abbreviations and descriptions

Abbreviations	Description	Reference
SA	Situation Awareness	Endsely, 1995
SU	Situation Understanding	Thoelen et al., 2020
PSA	Perceived Situation Awareness	Edgar et al., 2018
ASA	Actual Situation Awareness	Thoelen et al., 2020
ASU	Actual Situation Understanding	Thoelen et al., 2020
PSU	Perceived Situation Understanding	Thoelen et al., 2020
QASA	Quantitative Analysis of Situation Awareness	Edgar et al., 2018

MEASURING DOG-HANDLER COMMUNICATION AND DOG SITUATION AWARENESS

Dogs have been a part of human society for longer than any other domestic species (Benz-Schwarzburg et al., 2020), and they have a certain level of SA/U, although it may not be as sophisticated as that of humans. As discussed, SA/U involves understanding and interpreting what is happening in the environment, and dogs exhibit this ability in various ways. Research has shown that dogs are capable of assessing their surroundings, using their senses (including sight, hearing, and smell) to recognize familiar people and objects, and responding to changes in their environment (Benz-Schwarzburg et al., 2020).

The real bond between humans and dogs is marked by cohabitation in the same living space (Kuhne, 2016). Research has suggested that canine domestication has uniquely endowed dogs with two essential abilities for cooperative dog-human problem-solving: social tolerance and social attentiveness. These capabilities enable dogs to adapt their behavior to that of their human partners (Ostojić & Clayton, 2014). Collaboration necessitates such partners dedicating ample attention to one another to adapt or coordinate their actions. Additionally, social learning involves focusing on a demonstrator's actions and the context in which that action occurs (Huber et al., 2009).

In the case of human-dog interactions, the level of attentiveness is significantly influenced by the relationship between the dog and the human (Horn et al., 2013). Dogs have proven successful in several tasks that are thought to require high attention towards humans, as demonstrated by experiments on social learning, social reflecting, communication, responding to unequal rewards, and cooperation (Benz-Schwarzburg et al., 2020). Based on these processes, dogs make informed decisions about proper behavior (Huber, 2016). Studies have investigated the

effects of training methods on the performance of working dogs e.g.(Alexander et al., 2011) while others have emphasized the role of the dog-handler relationship e.g. (Lefebvre et al., 2007). In their study, Lefebvre et al. (2007) noted that working dogs residing in their handler's household, and participating in sporting activities together, exhibited increased sociability, obedience, and efficiency. The bond between humans and canines was found to have a positive impact on the dog's focus on its handler, leading to improved communication and, in turn, heightened performance among working dogs. Figure 1. shows a SAR dog, alert and focused on its handler, patiently awaiting instructions. Further, Szetei et al., (2003) found that in their study that, when locating a hidden object, SAR dogs may favor human communicative signals, such as pointing, over olfactory information.

Figure 1. SAR dog waiting for instructions (Private photo Kristine Steen-Tveit)

While searching for possible victims the tasks of the dog could be described in the following steps:

1. **Searching** for scents in the area of interest;
2. **Detecting** the location of the first relevant odor particles in an area;
3. **Locating** the origin of the desired odor, or the place with the highest concentration of odor particles;
4. **Manifestating** the appropriate behaviour - the dog decides the area on which it will focus its attention and then manifests the appropriate behavior to demand the handler's attention.

The first three steps could be seen as closely related to situation awareness levels: the dog collects the (sensory) information from the area, comprehends the meaning (picking out the appropriate odour to indicate a person in distress), and then makes the correct response in summoning the handler.

In step four, fixation or manifestation, barking is the most used alerting behavior for dogs in disaster areas. Currently, the barking alert is essential in the process of searching for victims in collapsed structures, as there is no technological tool that is sufficiently precise and safe to replace the barking alert. When the dog finds the person, s/he must indicate the position of the victim to the handler either by remaining in the immediate vicinity of the person and barking until the handler arrives – or use his/her teeth to acquire the "bringsel" hanging from his/her collar. The dog then returns to the handler carrying the “bringsel” in the mouth (see Figure 2) (Hiljanen & Nordin, 2012) and, on receiving a specific command, will show the handler the location of the victim.

Figure 2. Dog with bringsel (Private photo: Kristine Steen-Tveit)

With the addition of GPS technology, however, the dog could “mark the victim” by sitting or lying down and, if the GPS indicates that the dog stays in position for more than 5 seconds, a signal would be sent to the dog-handler.

Another way in which technology could be utilized would be to develop technology that detects the dog’s activity and barking in real-time, and alerts the dog handler that the dog has found a victim, and where the dog (and victim) is located (Kasnesis et al., 2022).

Given that there is an appropriate behaviour for the dog at any particular point in the search process, we could measure dog and dog-handler ASA and ASU by measuring the dogs’ actual behavior against the optimum behavior (considered further below). More conventional measures could be used to measure handler ASA and ASU.

The dog handler stops a dog working via voice or whistle (vile) command, but this means that means that the dog must stay within earshot of the handler. Some GPS collars now have the capability to emit a sound or vibration initiated from the handler's GPS device, and which the dogs can be trained to interpret as a "find owner" signal. Currently, however, all the devices developed to locate dogs during a search are not viable to locate dogs during their work under rubble, since the devices lack reliability and safety. Research shows that if dog is more than 60 meters from handler the contact breaks (Contini & Martins, 2024). Therefore, still now if the dog locates a victim out of sight of the handler (under debris or in a hidden place), the only way to signal the discovery to the handler is by means of an audible signal (barking) or by means of a dog body signal (remaining in position such as sitting or lying or taking bringsel into mouth). If these dogs’ signals could be interpreted by a technical tool that then sends a warning signal to the dog-handler, it has a potential to speed up the search and rescue process and improve dog-handler ASA. For safety purposes, such technology need not be mounted on the dog. The dogs’ behaviours could be monitored remotely by networked drones or robots, potentially vastly increasing the ‘area coverage’ for

any one handler and dog. In terms of SA, the 'perception' aspect of the handler is greatly increased.

If technology is to be successfully used with SAR dogs, then another crucial area of research is to study how dogs interact with that technology. The authors have noticed, for example, that dogs, without any training to interact with technology, will ignore everything on a television show - except animal shows. Such shows appear to draw the dog's attention and lead to the dog approaching the TV (see Figure 3). There is research that explores the ability of canines to interact with touchscreen interfaces in order to improve service dogs' communication with their handlers (Zeagler, Zuerndorfer, et al., 2016). Animal-computer interaction research has enhanced the creation of computer-aided systems that allow handlers and dogs to work together better while conducting SAR tasks (Zeagler, Byrne, et al., 2016).

Figure 3. Dog watching animal shows on TV (Private photo: Stella Polikarpus)

Extending the idea (discussed above) of using technology to simply detect a dog barking, there is research on using artificial intelligent (AI) to convert dog barks into English (Adamson, 2018) or to allow the dog to send signals using a worn vest in emergency situations (Kasnesis et al., 2022; Zeagler, Byrne, et al., 2016). Dogs have been trained to alert another human to a problem using a vest that includes a handy mechanical lever which, when pulled by the dog, plays an audio message such as: "My handler needs you to come with me!" (National Geographic Kids). AI can also be used to assess the behavior of dogs in a particular situation (Farhat et al., 2023) which, when compared with identified optimal behavior would provide a semi-automated, and real time, measure of ASA and ASU.

MEASURING THE ACTUAL SA OF HUMANS AND DOGS WITH THE HELP OF TECHNOLOGY

Technology mediated systems lend themselves well to knowledge-based measures of SA as there is often a clear, and recorded, path of information flow around members of the team (including IT systems). One such knowledge-based technique, as discussed above, is QASA (Edgar et al., 2018) that has been successfully used to assess ASA, PSA, ASU, and PSU in simulated safety critical situations (See table 2 for a reminder of descriptions). QASA is based on probing team members SA/SU (and this could include IT systems) using true/false (T/F) statements drawn from the situation, combined with an underlying analysis based around signal detection theory (SDT). While this approach works well for human and (potentially) IT elements of a team, the training overhead in getting dogs to respond to T/F probes is likely to be extreme. There are, however, performance-based measures of SA e.g. (Burge & Chaparro, 2012) or (Collier & Follesoe, 1995) that are also based around signal detection theory and so would dovetail well with QASA. These measures compare actual performance with optimum performance and could (in theory!) be readily adapted to assessing the performance of dogs (and hence their underlying SA/SU) in a safety critical context such as SAR.

If methods of assessing SA/U in a team can be developed then those methods could be used to assess the effect of introducing technologies such as smart phones, GPS positioning, 360º camera streaming, advanced sensors, robots or drones, dog vests, artificial intelligent, machine learning, augmented reality, local data networks, radios, and much more. As the interactions of dogs and handlers are increasingly mediated by technology, the effectiveness of that technology can be assessed by measuring SA/U. Different technologies may impact different aspects of SA. For example, improved communication systems (between, dog, handler, and incident command) (Arnold et al., 2019) may improve SA. The use of VR and AR (for example by handler) for data fusion and presentation could potentially increase SU. Assessing such effects is vital. One thing that additional technology almost always brings is additional information (e.g. 360º camera streaming is proposed instead of images processing (Arnold et al., 2019)). This could be an excellent support for SA (and SU) or it could overload the individual causing a loss of SA/U (a handler too busy trying to understand the camera output and missing a signal from the dog, for example). More is not always better.

The use of dogs in disaster areas raises traditional questions of ethics, such as whether dogs should be used in hazardous areas involving gas leaks, bombed buildings etc. Introducing technology, however, raises a whole new range of issues around such things as data protection, data transfer, and other cyber security issues. It is therefore necessary to scope the SAR task in terms of the elements (human, dog, technology) and the interactions between them. It would be helpful to have a simple model for crisis management research that embodies the areas of

overlap between elements of a system and the different facets of SA (and SU) that are generated by those overlaps. Such a model allows the assessment of new technologies to be targeted and interpreted as a part of the 'big picture. In Figure 4. we propose a Technology Enhanced Actual Situation Awareness Model for Dog-Handlers working with SAR Dogs. For simplicity, at this stage, we have only scoped for SA (not SU, although the regions would be similar).

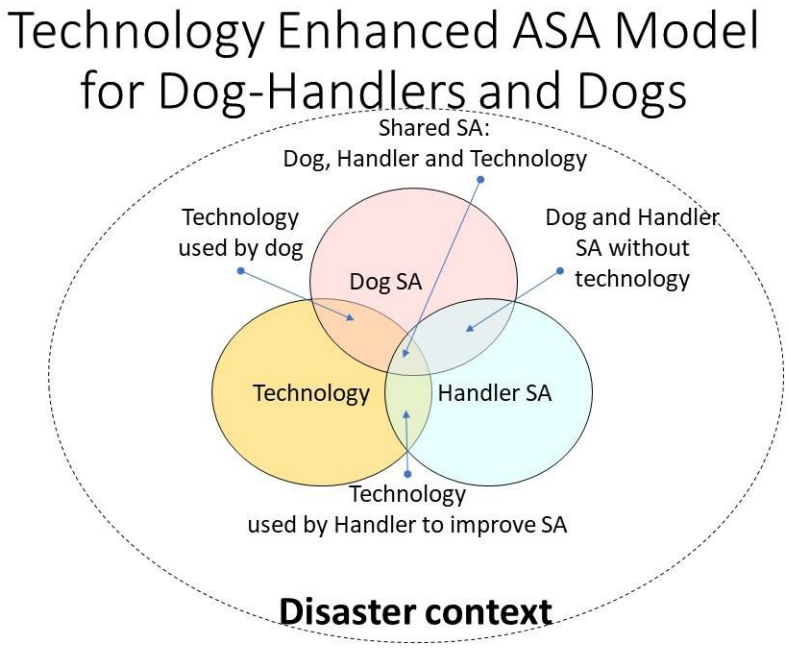

Figure 4. Technology Enhanced Actual Situation Awareness Model for Dog-Handlers working with Search and Rescue Dogs

In the model (Figure 4.) seven different areas can be identified; three discrete areas and four overlapping. The first discrete area is the dog with its unique set of characteristics, experiences and training that help it to make dynamic decisions in specific context. The second is the dog-handler who has same factors influencing his/her decision-making as dog but with additional factors and possibilities to gain situation awareness from command center. The third is the technology like 360-degree video streaming, GPS, communication, and observation technology as well as AI. Each element will develop its own awareness (SA) of the situation. For example, technology can have false positive alert in image recognition (Arnold et al., 2019). There are then three dual overlaps. The first dual overlap is the dog and handler, here belongs behaviours dog and handler use to communicate with each other, and standard operation procedures based on what dogs are certified. The second the dog and technology where most used have been vests with different technologies attached to it (GPS positioning, sensors, communication tools) but also dogs might learn to use specific technology themselves to communicate like touchscreens (Zeagler, Zuerndorfer, et al., 2016). The third component is the handler and technology, and dog handlers should be able to use all technological tools and information systems needed to gain "big picture" and follow standard operational procedures.

These overlaps will mediate the SA of each of the overlapping elements and, one would hope, improve SA rather than impair it. For example, introducing technological communication systems might improve the handler SA (they could receive information from other handlers, the 'big picture' from incident command, and so on). The last area in Figure 4. is a triple overlap between handler, dog, and technology and this is, effectively, where the 'shared SA' of the team (handler, dog, technology) resides. It is, perhaps, in this area where the disaster context specific technologies could have most impact on enhancing the effectiveness and safety of both dogs and handlers.

FROM CURRENT PRACTICES TO FUTURE STRATEGIES: ADVANCING CANINE TRAINING

Regardless of the type of SAR activities, canine training is extensive. Training programs are conducted in many countries worldwide, such as Germany, Japan, Australia, and Norway. Although the training processes in different countries often share similarities, different countries and regions may have specific protocols and standard operational procedures. Standards for the certification of SAR dogs also vary by certifying organization. The

National Association for search and rescue (NASAR) has, however, established voluntary qualification standards for, among other roles, disaster search (Jones et al., 2004).

The overarching goal of all training is to prepare the dogs and their handlers for effective SAR operations in different disaster contexts. The canine training process is a rigorous process that requires dedication, time, and specialized skills and includes obedience training, scent discrimination, search techniques, trailing, and avalanche/disaster training. The foundation of SAR dog training is socialization. Dogs are frequently brought out into public settings to get as accustomed to a wide range of situations and people as possible. Since leash control is crucial in SAR, obedience, and the capacity to obey directed instructions are also crucial. For dogs that are trained to search in both urban and wilderness settings, athleticism and agility are essential. Dogs are taught to move boldly, but cautiously, over surfaces that they would normally avoid. Urban SAR canines train extensively on debris, which might include broken concrete, old cars, uneven terrain, chain link fences, and rebar. Urban search and rescue dogs are required to climb ladders, negotiate tunnels, and rappel with their handler (see photos in Figure 5.). As opposed to patrol dogs, aggression towards humans or other animals is not tolerated in SAR dogs (Jones et al., 2004).

The future of SAR canine training is likely to see a significant integration of technology to enhance the safety of both the dogs and their handlers, as well as to improve SA. Examples can be smart vests for dogs equipped with sensors that can provide real-time data on the dog's position, vital signs, temperature, and overall well-being (Contini & Martins, 2024; Kasnesis et al., 2022). Exploring ways to enhance communication between SAR dogs and their handlers through technology could improve the efficiency and effectiveness of search operations. Integrating technologies into canine training requires a balance between innovation and reliability and a means of assessing whether inclusion of that technology has been beneficial. It has been already observed in the research that new training requirements must be developed to integrate effectively technologies to be used by service dogs (Zeagler, Zuerndorfer, et al., 2016). Additionally, considerations for ethical and humane treatment of the dogs, as well as the need for adaptability in various operational contexts, will be essential in shaping the future of SAR dog training.

Figure 5. Urban SAR dog training. (Private photo: Marita Poulsen)

CONCLUSION

It is important that the context and characteristics of dogs and their handlers are taken into account when new technologies are introduced with the aim of improving ASA and, by extension, dogs and handlers' safety, communication, performance, standard operating procedures, ease of standardization etc. Improved performance of the team means being better able to assist victims in different disaster areas. The proposed Technology Enhanced Actual Situation Awareness Model for Dog-Handlers working with SAR Dogs is provided as a way of scoping out the interactions and issues inherent in any complex team; and a team involving humans, dogs, and new technology, is likely to be complex. The approach in this paper proposes the model as a way of scoping those complex interactions, combined with advanced techniques for measuring SA/U to assess the impact (both good and bad) of such interactions. Such assessment will necessarily involve possibly disparate communities such as technology developers, researchers, and practitioners. The overall aim is, however, to further improve the effectiveness of SAR dogs through the use of technology, and the ISCRAM community has all the competencies needed to achieve this.

ABSTRACT

This work-in-progress paper presents preliminary findings from an exploratory workshop on disruptive technologies in emergency management in Aotearoa New Zealand. Thematic analysis identified three main themes on the role of disruptive technologies: (1) creating a common operating picture, (2) enhancing interaction, and (3) organising information. Despite the transformative potential of disruptive technologies, there are several challenges, including reliability and consistency of information, managing large volumes of data, integration and interoperability, and security and privacy concerns over data usage, among others. The study highlights the need for robust collaboration and resource-sharing mechanisms to leverage disruptive technologies in New Zealand's emergency management landscape. Future work will investigate these identified themes through additional interviews and workshops involving emergency management professionals. Further focus will examine the preliminary findings to the broader concept of situational awareness in emergency contexts.

Keywords

Disruptive technologies, emergency management, thematic analysis, exploratory study

INTRODUCTION

Aotearoa New Zealand (NZ) faces a range of natural hazards, including geophysical and hydrometeorological hazards. Earthquakes, a significant hazard, register approximately 20,000 events annually, with around 33 exceeding a magnitude of 5.0, posing risks to infrastructure (GeoNet, 2023). In the hydrometeorological context, flooding is the most frequently occurring hazard, projected to occur every eight months in NZ due to climate change implications (Mason et al., 2021). Cascading impacts could also trigger further hazards such as tsunami and landslides.

The consequences of hazards extend beyond the physical environment and can also have social impacts. As Goffman (1974, p. 379) aptly describes in his framework analysis, such negative experiences can result in a phenomenon he refers to as "reality anomically flutters". This phenomenon extends beyond individuals, manifesting on a macro level in the face of natural hazards, triggering a process of renegotiation and normalisation during highly destructive events. Such processes are pivotal, especially when emergency management teams and decision-makers synchronise their various perceptions with on-site realities. Therefore, efficient handling of information plays a key role in creating a picture of the situation that is as reliable as possible (Jayawardene et al., 2021). This process can be facilitated by technologies that sit in a moderating position between the individual and the situation (Hörl, 2011).

Previous studies have shown that technology can be important in the complex and dynamic emergency management system to support effective and timely decisions (Endsley, 1995; Prasanna et al., 2017). However, technology keeps evolving. Emerging and disruptive technologies such as artificial intelligence (AI), the Internet of Things (IoT), and Big Data are changing many fields, including disaster risk reduction and management (ITU,

2019). This evolution enables faster processing and sharing of critical information, adapting to the changing nature of disaster risks (Munawar et al., 2022). In this rapidly changing landscape, it is imperative that we update and advance research on exploring how technologies can be leveraged to enhance disaster risk reduction.

This study investigates disruptive technologies in emergency management in NZ. This work-in-progress paper presents preliminary findings from a workshop held in Auckland, NZ, on 7 November 2022, in alignment with the ISCRAM Asia Pacific Conference. The objectives of this study are twofold: (1) to investigate the role of technologies in the production process of generating the necessary information for responding to a disaster, and (2) to examine the challenges in using the information for the subsequent response process. Note that the data gathering for this study was conducted before major flooding events in January and February 2023. [1] Therefore, it is not within the scope of this study to include lessons learned from these events.

BACKGROUND

This section delves into key concepts underpinning the study and provides a brief overview of the current research landscape, crucial for understanding the interplay between disruptive technologies and emergency response.

Key Concepts

These terms are defined to provide context and assist consistency in addressing the topic of this study of disruptive technologies in emergency management.

- **Disasters** are multifaceted events causing damage, losses, and disruption to societies or communities (Peek et al., 2021). As defined by the United Nations Office of Disaster Risk Reduction, a disaster is a "A serious disruption of the functioning of a community or a society at any scale due to hazardous events interacting with conditions of exposure, vulnerability and capacity, leading to one or more of the following: human, material, economic and environmental losses and impacts." (UNDRR, 2017)
- **Disruptive technologies** are new technologies that can give rise to a new avenue of doing business or research (Munawar et al., 2022). In this study's context, these are technological developments that can provide potential solutions for improvements in emergency management (ITU, 2019).
- **Emergency management** encompasses the organisation and management of resources for addressing all aspects of emergencies, including preparedness, response, and recovery (UNISDR, 2009).

Current Research on the Topic

In recent years, emergency management has witnessed significant disruptions facilitated by technological advancements (Munawar et al., 2022). Academic publications in the past five years (2019 onwards) have frequently highlighted the pivotal role of various technologies in reshaping the landscape . Noteworthy technologies frequently mentioned in recent literature include Artificial Intelligence (AI), big data, sensors, Internet-of-Things (IoT), autonomous vehicles including unmanned aerial vehicles (UAV), blockchain, and fog/edge computing (see Table 1). It's important to note while Table 1 summarises the applications for these disruptive technologies and outlines the associated challenges, the list is not exhaustive. These examples provide a snapshot of prevalent technologies discussed in the field.

From the literature, these technologies can play a crucial role across the entire disaster lifecycle. However, the integration of disruptive technologies also has challenges. According to Munawar et al. (2022), one significant challenge is the absence of policies, especially on data governance. Much of the needed information (e.g. real-time data, infrastructure details) lies within city or municipal governance and policies, which may be hard to access. Data integration protocol is also needed to ensure the new technologies are aligned to provide information from proper data gathering and modelling (Akter & Wamba, 2019). For example, for a disaster management system to use big data, an enormous amount of location-specific data may come in during a disaster; the system should be capable of aiding agencies to usher this big data to become useful information to provide real-time actionable services to the people in need (Akter & Wamba, 2019).

[1] The January Auckland flooding and Cyclone Gabrielle were significant natural hazard events for NZ in 2023. insurance costs for these events are estimated at NZ$1.65 billion (ICNZ, n.d.) These events also resulted in loss of human life, with four people killed in the Auckland floods (RNZ, 2023a) and eleven people losing their lives during Cyclone Gabrielle (RNZ, 2023). Many individuals were left stranded and hundreds needed to be rescued from rooftops.

Table 1. Summary of frequently discussed disruptive technologies, applications, and challenges

Technology	Examples of applications	Challenges	References
Artificial intelligence	• Accelerate disaster management across all phases, e.g., geospatial data analysis for disasters. • Hazard assessment (e.g. cyclone intensity, floods, and landslides) • Impact assessment (e.g. infrastructure damage) • Crowd management and situation analysis, prediction, and evacuation planning • Sentiment analysis: find opinions or emotions on a specific topic	• Requires precise data with effective feature selection. • Large amounts of data and accuracy of data. • Fragmented efforts on narrow use cases without broader stakeholder collaboration; AI tools underutilized in decision-making. • Data sources may be inaccessible or incompatible with other datasets; data may not captured systematically.	(Arora et al., 2023; Munawar et al., 2022)
Big data (including social media) and cloud services	• Use of GIS and GPS for integrated hazard analysis with large datasets. • Use of social media and location data to find trends and threats for real-time monitoring (e.g. bushfires) • Helps identify critical events and needs assessment • Gauge public opinion to influence decision-making and offer early feedback on government policies.	• Protecting data confidentiality, privacy, and ownership • Storage and processing systems may struggle with performance delivery • Capability, including infrastructure & personnel • Availability, scalability, quality & interoperability.	(Akter & Wamba, 2019; Arora et al., 2023; Bania et al., 2023; Munawar et al., 2022)
Autonomous vehicles (e.g. UAV)	• Images captured by drones can be used for impact assessment to evaluate the situations.	• Battery, physical load, processing power, difficult manoeuvring conditions	(Munawar et al., 2022)
Blockchain	• Blockchain in disaster management aids collaboration through peer-to-peer communication and smart contracts. • Blockchain's sharing economy boosts resource management accountability and auditability. • System democratisation enables multi-disciplinary involvement whilst increasing the quality of decision-making.	• Lack of trust or understanding amongst stakeholders on blockchain technology.	(Cheklin et al., 2022; Krichen et al., 2024; Vermiglio et al., 2022)
Sensors, internet-of-things (IoT)	• IoT paired with AI enables early prediction using real-time data. • IoT tracks equipment in disaster management. • Sensors and IoT aid data collection, analytics, and early warnings. • Wireless autonomous networks assist communication without pre-existing infrastructure. • Supports both centralized and decentralized network architectures.	• The heterogeneous nature of interconnected devices poses several interoperability challenges.	(Arora et al., 2023; Bania et al., 2023; Munawar et al., 2022; Prasanna et al., 2022)
Fog/edge computing	• Ability to process data in real-time, closer to end-user devices, resulting in reduced response times without the intervention of the cloud; enables quick access to data and faster decision-making.	• Limited resources at the edge. • Data communication challenges.	(Bania et al., 2023; Militano et al., 2023; Prasanna et al., 2022)

With disruptive technologies, significant concerns such as security and privacy arise, as data availability also increases the risk of manipulation and unauthorised use (ITU, 2019). Another significant challenge lies in the high implementation and maintenance costs of these cutting-edge technologies (Akter & Wamba, 2019; Cheklin et al., 2022). There is a need for cost-effective solutions that deliver long-term benefits.

Much of the existing literature focuses on testing and providing sample use cases, but further research is needed to understand their implementation and performance during and post-disaster (Munawar et al., 2022). Understanding the role of collaboration is a research opportunity when utilising technologies. Closer collaboration facilitating effective sharing of resources is needed to utilise disruptive technologies for emergency management (Cheklin et al., 2022). Disruptive technologies cannot be fully utilised or scaled up when there is incomplete data sharing and ineffective use of resources (Cheklin et al., 2022).

Acknowledging the existing work, gaps, and opportunities in this area, this paper investigates more closely how emergency managers and technology researchers view the needs and challenges of utilising disruptive technologies for emergency management in NZ.

METHOD

Data Acquisition

A workshop was conducted to understand the technology needs and challenges for emergency management in NZ. The workshop was held on 7 November 2022 in alignment with the second ISCRAM Asia Pacific Regional Conference with the theme "Dealing with the Unexpected". The conference was held at RMIT University in Melbourne, Australia, with a satellite venue at AUT in Auckland, NZ. The workshop was held in Auckland to reach the target NZ-based participants.

The workshop was designed with two objectives in mind: (1) to investigate the role of technologies in the production process of generating the necessary information for responding to a disaster, and (2) to examine the challenges in using the information for the subsequent response process. With these, the workshop focused on exploring the technological desires and requirements of the emergency management sector. Particularly through a large-scale crisis scenario centred on situation awareness and decision-making needs. The workshop was held with subject matter experts (academics) and emergency management practitioners. The participants were formed into four focus groups to investigate the patterns of *doing-crisis* approaches. This method helps to connect unrelated individuals (and thus perspectives) from various backgrounds. Furthermore, the fluid nature of focus groups might trigger knowledge, experiences and emotions more effectively than face -to-face interviews (Witkowski et al., 2021). The workshop obtained peer-reviewed approval (Project number: 4000026842) under the ethical conduct code of Massey University for research with human participants deemed "low risk".

Participant Recruitment and Composition

Invitations for the workshop were dispatched to the Civil Defence Emergency Management (CDEM) groups, the National Emergency Management Agency (NEMA), scholars in disaster research and ISCRAM Conference attendees. This procedure ensured that academics (13 participants) and practitioners (18) were adequately represented in this focus group. Specifically, the latter group contains members from regional councils (8), representatives from different ministries (3), employees from NEMA (4), and participants from the lifelines sector (1) and the private technology sector (1). There were no admission prerequisites except for being physically present in Auckland. Conducting an in-person workshop in Auckland presents a limitation, as it could potentially introduce bias through the barrier of limiting attendance for those living further away.

Workshop Structure and Guide Questions

The workshop is centred around a hypothetical emergency scenario, which was presented to the participants: The Greater Wellington region is affected by long and strong ground shaking due to an earthquake (Magnitude 8.9, with shaking up to 10 MMI in Wellington) on the south-eastern coast of NZ's North Island. In addition to the damage caused by the tremors, the earthquake unleashed a series of tsunami waves that caused widespread flooding throughout the affected area.

The participants were then formed into groups, with each group consisting of academics and practitioners. Each group was tasked with the (imaginary) coordination of a national intelligence task force in their position as emergency management leaders during the post-disaster response phase in the first week. Against this, the focus group deliberated on tackling this situation for two hours, based on five guide questions aligning with the research objectives (see Table 2). The questions revolve around informa tion and technology—questions 1 and 2 focus on

efficiently handling information in response to the event. Questions 3, 4, and 5 revolve around using technology as part of the response strategies to the hypothetical earthquake.

Table 2. Guide questions to stimulate the discussion

Topic	Question	Aligning to objectives
Focus on information	1. What are the *information/intelligence needs* to build situation awareness for the initial first week to achieve your goals for response and recovery	(1) to investigate the role of technologies in the production process of generating the necessary information for responding to a disaster
	2. What *challenges* do you expect to arise when acquiring and using information during the first week of response and recovery?	(2) to examine the challenges in using the information for the subsequent response process
Focus on technology	3. What technological tools and solutions are *currently* available (in practice or research) to address the information needs and problems?	(1) and (2)
	4. What *new* technological tools and solutions can be developed to enhance situation awareness?	(2)
	5. What technologies should be *prioritised* to be researched, re-evaluated, and developed?	

Data Analysis

Qualitative research methodology is employed to analyse the workshop data. Following this epistemological understanding, the experiences of each speaker contribute to institutionalising a shared, intersubjective reality (concept originating from Berger et al., 1967). Braun and Clarke (2006) suggest a reflexive thematic analysis (TA) to convey the general trends of focus group discussions. As per their suggestion, single themes could be understood as "pattern(s) of shared meaning" (Braun et al., 2019, p. 845) that are arranged around a central concept. In consequence, the (1) themes are detached from single speaker positions, and the (2) themes emerge through (a) discourses within the focus groups and (b) through the active, moulding role of the researcher (Braun et al., 2019). Responses were not coded or differentiated according to the speaker's identity or affiliation due to the methodological preconditions of the thematic analysis and privacy concerns. The thematic analysis follows a six-step process, as detailed in Table 3.

Table 3. Thematic analysis (based on Braun et al., 2019)

Phase	Explanation/ justification	Application
Transcription	Make the data material accessible for systematic analyses	AI-supported conversion from audio to text
Familiarisation	Getting used to data	Rereading, making casual notes
Coding	A systematic process of making sense of the data	Deductive coding of the semantic meaning of each segment (through the guide questions)
Constructing themes	Merge codes with similar meanings to provisional themes	Unstructured, inductive organisation of codes around similar semantic meanings (independent of pre-given structure)
Revising themes	Define and establish themes within itself and in their relation to each other.	Rigorous merging of code groups; investigating similarities on latent meaning within each group, leading to a differentiation process to other themes.
Producing report	Final coherence check how well themes can be augmented	Presenting the final themes to a scientific audience

The thematic analysis started with transcribing the recording of each focus group discussion with the assistance of AI technology. Following a brief familiarisation period with the database, the coding process began by tackling the transcribed data sequentially through each guide question, and every segment was allocated a label denoting its semantic meaning. The deductive themes guided by the workshop questions are illustrated in Figure 1.[2] The

[2] This includes the initial segments from Q1 to Q4. As Q5 does not contain any new aspects (it only highlights

codes were then categorised based on comparable explicit sense, where analysing the data was not limited to the guide question structure in this process. No longer limited to pre-defined structures, the codes were aggregated and re-organised by collapsing and combining the codes with similar semantic meanings.

Further into the thematic analysis process, the research team identified three main themes (See Figure 2), which were then reviewed to ensure clear definitions and distinctions. This also necessitated the generalisation of meaning by transforming the themes into a more implicit and latent level. The methodological approach used in this study is thus aligned with the principles of grounded theory, which includes theoretical sampling, transcription, coding, and contrasting (Bryant & Charmaz, 2007)[3].

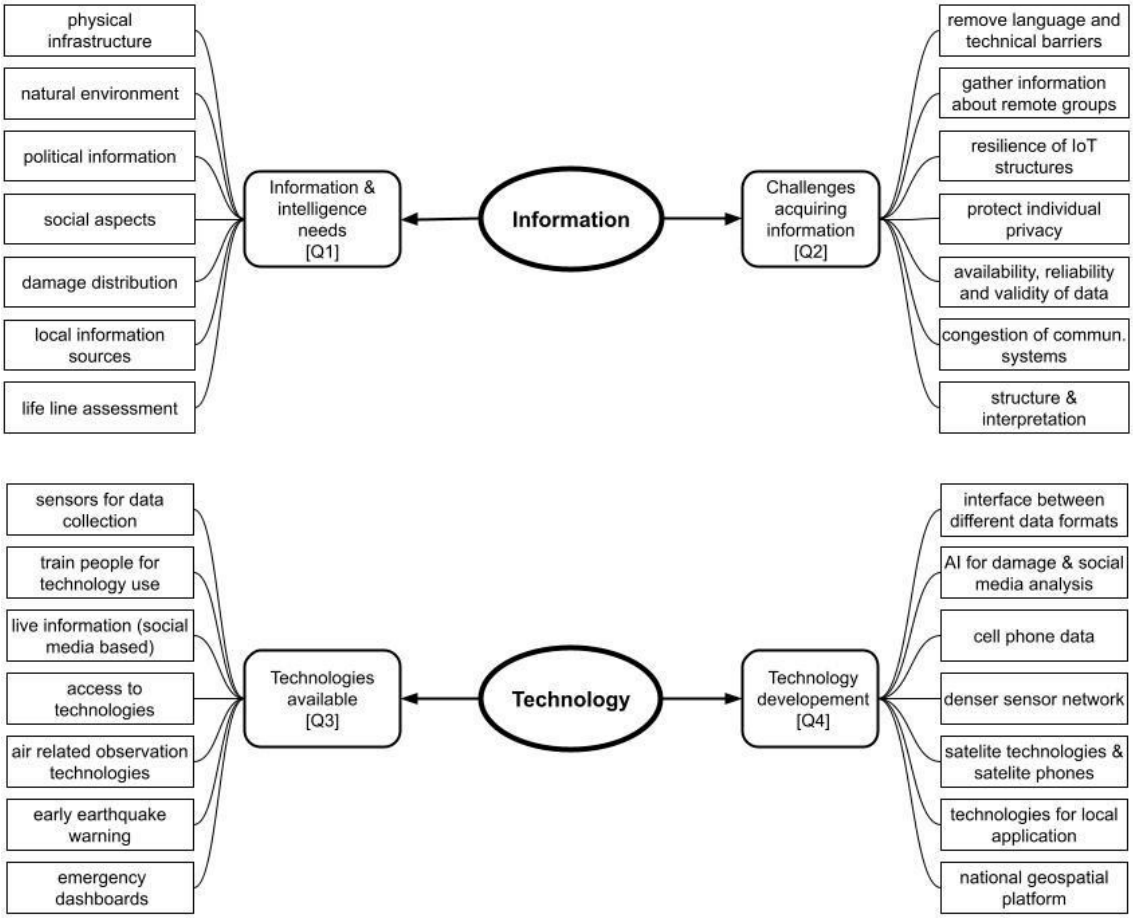

Figure 1. Initial themes deducted from guide questions

PRELIMINARY RESULTS

Through the production process of generating necessary information for response, the preliminary findings show that there are three main themes for disruptive technologies' role in emergency management: (1) the common operating picture (COP), (2) the interaction (IA), and finally, (3) the organisation of information (OI). Figure 2 illustrates the graphical composition of the resulting thematic analysis. Alongside these themes, we highlight some of the challenges encountered.

Common Operating Picture (COP)

The first theme is *associated with achieving a stable information status* for all involved in the emergency

aspects already mentioned as important), it is not included.

[3] Guest et al. (2012, p. 13) stress, that the Thematic analysis "method does not preclude theoretical development", which is also part of the grounded theory idea. However, he does not clarify whether this implies a totally autonomous macro theory or a middle-range proposition. The latter could be provided by the thematic analysis during the generalisation step.

management processes; this concept was commonly referred to by the participants as the 'Common Operating Picture'. The participants desire a reliable and statically rendered common picture to make sound decisions. Statically rendered means information that is consistent and with little ambiguity. The following participant's quote highlights the detailed questions that can arise from responders to help develop COP for decision-making:

> *Are the roads open or shut? My top priority is to know whether the state highways are open and then the local roads. Next, are the ports impacted? Can [they] roll on, roll off? […] Can gear ships and other kinds of ships operate? What's the impact on the fuel system? From the wharves at the ports to the tank farms, which are normally low-lying at [parts]? […] Impacts on service stations and […] the impacts on the airports, […] all of these tell us what the impacts on the supply chain are. Can food be delivered, and water and response activities be done?* (Group C participant)

When discussing the COP theme, the participants were particularly interested in learning about the status of lifelines, the physical environment, and the social aspects of the situation. Their interest in lifeline assessment looks into information about the availability of essential goods; this includes power, fresh water, food and medical support in hospitals. The physical aspects of COP relate to knowing more about the built environment, including evaluating critical infrastructure, such as accessibility to ports, roads, railways, and airports. The COP theme also involves learning about the disaster situation's social aspects, covering the damage distribution from a social needs perspective.

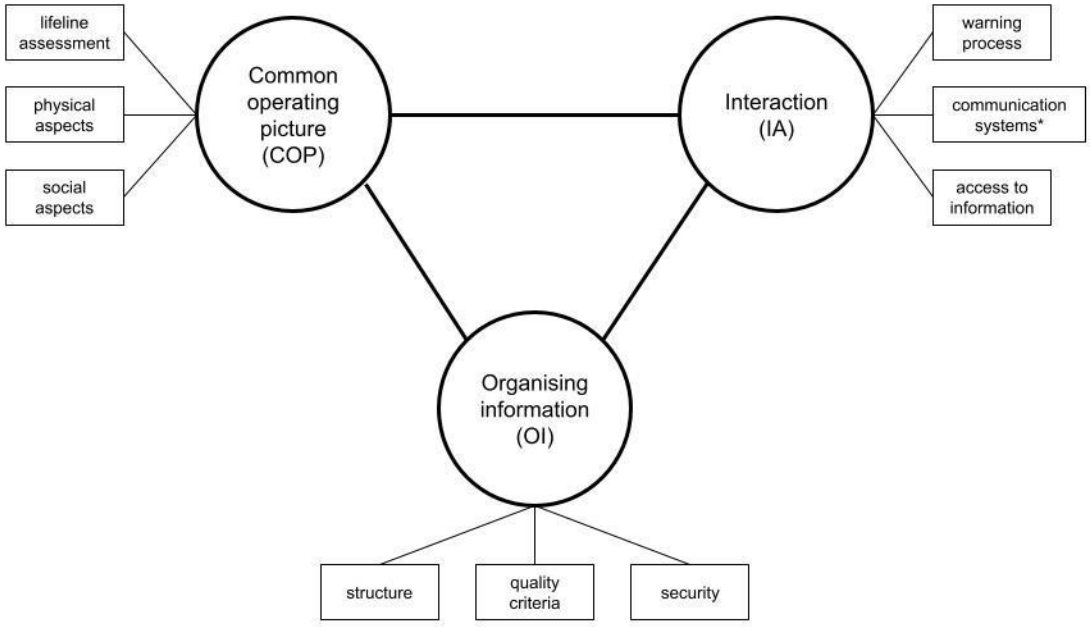

Figure 2. Visualisation of the preliminary results from the thematic analysis

To build a COP, participants acknowledge the importance of detailed information, which may be voluminous and come from multiple sources. Participants recognise the dynamic and emerging nature of disasters and thus multifaceted. Therefore, disruptive technologies' role is to gather reliable data and ensure the stability of the picture to withstand and integrate new players and emerging information. Hence, COP, although desired to be stable, must be adaptable, always to construct a more reliable awareness of the current situation. The technologies participants identified relating to COP include remote sensing and resilient sensor networks to aid impact assessments. The participants also mentioned the need to have the ability to process large amounts of information in quicker timeframes (i.e. AI and big data).

Interaction (IA)

The IA theme describes a *dynamic information exchange process* within and between the emergency managers and affected people. This flow of information can involve different technologies and revolves around multiple stakeholders, including providing information within and from the authorities and ultimately interactin g with the

information from those affected. Quotes from the participants highlight the interaction theme with emergency managers and the affected people:

> *I've just said one of the initial challenges is going to be actually around communications and actually being able to share data and share intelligence. Yeah, because it's going to be significant losses of infrastructure like fibre breakages, yeah* (Group C Participant).
>
> *I guess how accessible is it both from […] a physical device but [also] is it in a way [in a] language you understand or a format you understand?* (Group B Participant)

When the discussion relates to the IA theme, it often revolved around interactions regarding the overall warning process, the role of communication systems, and the accessibility of information. An effective *warning process* is essential to give people the best chance to take protective actions. Participants highlighted that the process is not just technological but involves human and organisational processes. A working *communication system* is the core basis for all interaction during emergencies. Therefore, its maintenance is a crucial aspect of emergency response and thus holds great priority among workshop participants. Participants emphasised that excessive communication volume can pose a considerable challenge to the system, especially on the initial day following the disaster. This escalates the likelihood of system failure due to congestion during this critical phase. Participants highlighted that disruptive technologies can be the source of congestion (e.g., multiple da ta points, including social media) and a solution (e.g., IT systems incorporating AI, big data, and cloud services).

Participants highlighted multiple examples of disruptive technologies that aid in providing access to crucial information. This includes satellite imagery, use of UAVs, sensor networks, and social media. The ability to receive and communicate this message also relies upon access to suitable technical apparatus. On a societal lev el, access to information lies in reducing barriers to interpreting warnings and instructions, for example, eliminating language barriers and designing warnings with minimal complexity for ease of comprehension. The distribution and receipt of information also depends on various facts, among others, such as age (i.e., digital divide) and way of life (i.e., urban vs. rural). Access to crucial information serves as the basis for engaging with affected individuals.

Organisation of Information (OI)

The OI theme describes the *all-encompassing mechanism to store, analyse, and extract justifiable meaning* from incoming data. This includes data gathered automatically or through human input. Particular topics highlighted in the OI theme include: structure of incoming data, aspects and challenges around quality standards, and a secure handling of sensible information. Quote from participants highlights the OI theme:

> *I think definitely AI is coming. […] so this can help us to quickly identify whether, for example, the building has been damaged or it is not […] So you have texts, pictures or also other 3D geospatial data, so you need different type of technologies to process them. But I think, in general, AI I think can help us to reduce the human efforts.* (Group B Participant)

Different data types become available during emergencies and interpreting them will require effort. For example, for social media, data types include pictures, text, or geotagged information. Even geographical data can be presented in different formats (e.g. polygons vs. points vs. lines). Participants highlighted that in NZ, there is no national consensus on how to manage data, so every institution (e.g. different regional councils) maintains their own data collection. As a result, participants highlighted the role of disruptive technologies in standardising data types and making them interoperable. It was mentioned that AI holds a significant role in structuring incoming data. Therefore, AI-based methods such as targeted filtering for specific keywords and hashtags (for social media analysis), natural language processing, and sentiment analysis can be used. [4]

The quality of the information is another significant topic for OI. Quality includes the data's reliability (trustworthiness) and validity (no bias). Evaluating data quality can strain human resources during a crisis; this is where AI can help cross-check various data formats and sources to enhance the quality of interpretations. The evaluation will also ascertain which councils or platforms offer the most accurate information on the physical environment and infrastructure as part of the quality review process.

[4] Note that the workshop was held before the public release of ChatGPT on 30 November 2022 (Lock, 2022).

Finally, since the data can come from multiple sources and may contain data about human beings, attention is also needed to the security aspects. Participants also highlighted the importance of honouring data privacy concerns.

DISCUSSION

In answering the paper's first objective of investigating the role of technologies in generating information for response, the results have shown multiple insights into disruptive technologies' role in emergency management through the three themes: COP, OI, and IA. These themes, in practice, are not isolated but influence each other, shaping decision-making processes during emergencies: forming a reliable COP relies on the structured interpretation of data within the OI, which informs the coordination of interactions (IA) during emergencies. COP is a critical bridge between OI and IA, facilitating informed and strategic decision-making in crisis scenarios.

To fulfil the second objective of the paper on examining the challenges in using the information for the subsequent response process, we have found several challenges relating to COP, OI, and IA. There are challenges related to the reliability and stability of the COP due to the dynamic nature of disasters and the need for consistent yet adaptable information. Managing large volumes of diverse data from multiple sources and integrating emerging information poses significant difficulties. Interaction (IA) challenges include maintaining effective communication and data sharing among stakeholders, managing technology congestion, and ensuring information accessibility and interpretation for diverse populations. Organisation of Information (OI) challenges encompass managing data structure and quality, validating data authenticity, and addressing security and privacy concerns. Aside from the themes, general challenges involve achieving interoperability across different platforms, mitigating human resource strain through AI-assisted data evaluation, and navigating ethical and security concerns associated with data usage and integration.

Aligning with the challenges highlighted in the workshop, recent events such as the Auckland Floods and Cyclone Gabrielle that occurred in NZ (after the workshop was conducted) have highlighted the vulnerability of existing, more traditional technologies to provide sustained sensing and communication networks during and post-disaster scenarios (Bush International Consulting, 2024). These incidents have exposed the limitations of current systems, particularly in maintaining continuous data transmission and providing good situational awareness for decision-makers. The disruption to sensing networks and communication channels during such events poses significant challenges for frontline responders and wider emergency management authorities in making timely and informed decisions (Delgado-Ferro et al., 2022).

Compared to more traditional technology-based systems, disruptive technologies have significant potential to aid disaster management, as highlighted in the literature (e.g. Munawar et al., 2022) and workshop discussions. While existing technology-based systems support various functional roles of emergency management and the associated tasks, they still face several limitations that may hinder their efficiency and effectiveness. Operationalising traditional technology-driven systems is often constrained by high costs, limited scalability, centralised architectures, and vulnerable technology infrastructure, hindering timely and effective disaster response and recovery efforts (Prasanna et al., 2022). Therefore, ensuring the reliability of our technological systems and infrastructure is paramount and foundational. Regarding post-event infrastructure management, connectivity, serviceability, and restoration are key elements to consider (Kongar et al., 2017).

Robust communication systems and infrastructure are fundamental components of effective emergency management. This includes the need for an adaptive but reliable COP, a working system for IA that incorporates the whole warning process to ensure communities have access to information, and for OI to have a structure that ensures data quality and security. However, despite its capabilities, the successful integration of disruptive technologies hinges on robust policy frameworks that facilitate stakeholder collaboration and resource sharing. However, realising the full potential of disruptive technologies in NZ necessitates addressing challenges related to incomplete data sharing and ineffective resource utilisation.

Limitations

Study limitations warrant consideration. Method limitations, such as the potential biases due to the in-person format and the workshop location in Auckland, may have influenced the workshop outcomes. Future research should address these limitations by expanding the scope of data collection, including holding multiple more data gathering options, including workshops and interviews with online options to attend, to ensure comprehensive coverage of relevant stakeholders and perspectives.

Temporal constraints imposed by the workshop's timing may limit the comprehensiveness and applicability of the workshop findings due to technological developments and disaster events. Notably, the workshop was held before the public release of ChatGPT, a significant development in generative AI, which could potentially alter perspectives on AI's utility in emergency scenarios. Furthermore, data gathering for this study was conducted

before major flooding events in NZ during January and February 2023. Subsequent data collection efforts with subject matter experts and emergency manager practitioners could provide valuable insights into the changes and adaptations following these events.

Future Work

While this study provides preliminary insights into the COP, OI, and IA themes and the associated challenges, future investigation by the research team will delve deeper into the sub-themes in this study and explore the intricate interconnections between COP, OI, and IA in greater detail. Comparative analysis between COP and the broader concept of situational awareness could provide valuable insights into their overlapping and distinct aspects, further enriching our understanding of information management in emergency contexts. Future work by the research team includes conducting follow-up interviews or workshops with more emergency managers in NZ.

Moreover, future studies should focus on use cases in simulated or testing environments. Implementation and evaluation studies would provide insightful, actionable recommendations for enhancing NZ's emergency management practice and policy development. Furthermore, social science studies could explore opportunities to study collaboration and partnerships between researchers, practitioners, and policymakers. By translating the insights gained from this research into practical interventions and policy recommendations, stakeholders can effectively address challenges related to data sharing, resource utilisation, and technology integration in emergency management.

Vision for Emergency Management: Conceptualizing Mission-Critical Ecosystems

Jaziar Radianti
Centre for Integrated Emergency Management
University of Agder, Norway
jaziar.radianti@uia.no

ABSTRACT

Emergency management is seldom viewed through the lens of enterprises/industries, which aim to safeguard their critical missions to deliver seamless services. This article advocates for an integrative perspective on mission-critical (eco)systems. In the digital transformation landscape, the traditional notions of "mission-critical systems," often associated with physical spaces like control facilities or hardware-software crucial for business operations, are challenged. Based on document reviews, this article argues for a holistic comprehension of an organization's mission-critical ecosystems, considering internal and external factors across physical, digital, and human aspects. The article uses renewable energy and e-health as cases. The overarching goal is to expand the research scope in emergency management by examining current concerns and current trends in emergency management domain, combining preparedness, resilience, and cybersecurity. This comprehensive approach aims to enhance our ability to navigate and respond effectively to emergencies in an increasingly complex and interconnected world.

Keywords

Mission-critical ecosystems, digital resilience, risks, cybersecurity

INTRODUCTION

Numerous studies in the emergency management domain often focus on cooperation, coordination, and collaboration among public responder agencies to save lives and protect properties. However, many organizations including private companies and industries are also vulnerable to physical and digital threats and often dependent on external actors to conduct their operations. Business entities in society play critical roles as pillars for economic resilience. Some businesses are essential in running critical services such as companies involved in supplying energy, health, and care services. In operating the businesses, there are always specific entities of private or public organizations encompass persons, information systems, and digital infrastructures that are critical, and should continuously be protected to avoid operational disruptions, i.e., mission critical functions. The sources of interruptions to mission-critical functions can originate from either inadvertently or advertently made disasters. The impacts can be harmful, ranging from the loss of reputation, trust, monetary assets to the loss of human lives. These critical units, internal infrastructure, actors, or services in this article are referred to as "mission-critical ecosystems."

Rooted from the ecology science (Mars et al., 2012), the concept of ecosystems itself has been metaphorically applied across various scientific areas (Pickett & Cadenasso, 2002), including organizational ecosystems and management (Mars et al., 2012; Pavlikakis & Tsihrintzis, 2000), or even digital ecosystem metaphor (Krivý, 2023) that can cover the whole planet. Scholars acknowledge the complexity of ecosystem concept, which is subjected to continuous change in space and time, characterized by interconnectedness, dynamics, and scales—at which ecosystem processes operate, with human playing a significant role (Pavlikakis & Tsihrintzis, 2000). Boundaries of ecosystems exist but they may be defined arbitrarily because of spatial and temporal changes of the ecosystem. The open and dynamic character of the ecosystems does not support rigid guidelines for boundary delineation

WiP Paper – Visions for Future Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

(Pavlikakis & Tsihrintzis, 2000). In this article, mission critical ecosystems (MCEs) are defined as an integration, and interconnectedness between the critical *internal arrangement* of organizations (actors, knowledge, digital platforms, critical facilities, supply chain) with *external stressors* that pressing organizations to adapt, respond or change to fulfill their goals (e.g., protect essential service functions or core businesses) which sometimes require interactions with external stakeholders. Thus, critical infrastructure can be one of the components of mission critical ecosystems, while critical services can mean the core businesses of industries fall within societal critical functions or they can mean any critical functions in organizations that vital for seamless business operations.

Indeed, there are substantial body of literature on business continuity management (BCM) and continuity of operations (COOP) planning (Cerullo & Cerullo, 2004) which addresses the maintenance of an organization's mission-critical functions during disruptions to critical infrastructure caused by various physical, cyber, public health and other hazards. This focus is also a part of governmental emergency management efforts as evidenced by publications from the US Federal Emergency Management Agency - FEMA (2018; 2020) and Cybersecurity and Infrastructure Security Agency - CISA (2024), which tackle both physical and cyber threats. Notably, as a managerial function concerned with coordinating "whole community" efforts, emergency management in these publications underscore the necessity of involving industry and community organizations in mitigation and preparedness activities to uphold essential services during crises.

COOP literature offers practical guidelines to cope with the disturbances, but they do not fully address what counted as MCEs. Moreover, MCEs are becoming blurry with recent digital transformations when industries gradually rely heavily on internet of things, cyber-physical (social) systems, internet of service and smart factory. Reliance on "interconnectedness" between devices, applications, sectors, information/ digital/ physical infrastructures are a key in the so-called industry 4.0 premise. Moreover, such "smart arrangement" often requires elevated needs of hardware, software, and services to make mission-critical infrastructure to function in a more efficient manner through outsourcing to the third parties, and sometimes go beyond the national boundaries. Thus, physical, digital, and service supply chain are unavoidably a part of the MCEs. Todays´ ubiquitous connectivity, the use of Internet of things and cloud services, digitalization of critical infrastructure including health services, and other digital trends, have triggered the needs for understanding such landscape from the organizational viewpoints, and the idea of the digital disasters (Hansen & Nissenbaum, 2009; Van der Meulen, 2013) and digital resilience (Boh et al., 2023; Magutshwa & Radianti, 2022).

Digital resilience often includes building resilience of entities that are vulnerable to cyberthreats including human, technologies, and digital infrastructures. Thus, cybersecurity aspects are inseparable from societal security. The Covid-19 pandemic can be considered as a health disaster, that further triggers emergency management, and the need for understanding cybersecurity better, because solution services are delivered digitally (Magutshwa, 2022; Magutshwa & Radianti, 2022). Another example, many countries such as Norway are in the energy transition from usage of fossil-based energy fuel to renewable energy and battery technology. There have been intensive political and scientific discussions for building more energy sources such as offshore and onshore wind power (Dahl et al., 2022), moving toward battery sources for ground, air, and sea transports (Figenbaum, 2023; Schulz & Rode, 2022; Thorne, Hovi, et al., 2021; Veisten et al., 2024).

The significant shift in Europe, particularly in Norway, aims to prepare for future scenarios with limited fossil fuels by exploring new forms of renewable energy beyond hydroelectric power (Skjærseth & Rosendal, 2023), as one of the oldest and largest sources of renewable energy. While various renewable energy sources exist (solar, geothermal, and bioenergy), Norway leans towards among other things offshore and onshore wind power, aligning with higher prominence in the political agenda (NOU, 2023a). Additionally, battery power emerges as a pivotal energy storage, especially with the increasing adoption of electric vehicles in Norway. For instance, in 2023, 83.4% of new cars sold in the country were electric (source: www.elbil.no), equipped with 40-50 kilowatt-hours (kWh) batteries (Innovasjon-Norge, 2023). City buses as critical transport infrastructures are gradually adopting batteries with an average capacity of 125 kWh.

The infrastructures controlling these new sources of renewable energy are also changed, and more digitalized. From a societal perspective, companies provide critical services facing unknown risks, challenges, societal conflicts, and potential disasters, including digital disasters, which require new understanding of emergency management. Again, the MCE is a way to entangle interrelated aspects of future emergency management involving new digital-related challenges and digital disasters.

Moreover, the increasing use of digital health services, as evidenced in the e-health case example (Helsedirektoratet, 2023), will require a robust communication infrastructure. This transformation undoubtedly elevates the demand for a more seamless electricity supply (Thorne, Aguilar Lopez, et al., 2021). This change is intricately linked to the current green ambitions in Europe towards achieving net-zero emissions. This overarching

goal is encapsulated in the vision to "Make Europe the first climate-neutral continent by 2050" (EU-Commission, 2023).

This paper argues on the need of moving our understanding from mission-critical *environment* and *systems* to *mission-critical ecosystems*. In the industrial context, numerous layers of entities, units, and environments interact to influence MCEs, which are essential for delivering sustainable services. I propose the following research questions:

- RQ1 How to define a framework for studying mission critical ecosystems?
- RQ2 How to apply the mission critical ecosystem framework to derive emerging issues within critical services?

We need to gain better understanding of what are counted as MCEs. This paper aims at contributing to research agendas to define and expand the idea of MCE as one of potential future direction for emergency management research. The cases and examples were taken from European setting especially Norwegian example, with two selected critical services, i.e., the e-health service and energy sectors.

This paper´s contributions are threefold. *First*, it proposes a definition of the MCE concept that guides this study to find the research gaps in existing literature related to business continuity/ emergency management. *Second*, the MCE concept is essentially examining the wider set of components not only infrastructural interdependency, but also issues such as green shift, new emergency management knowledge and competencies due to changing threat landscape. Current approaches to business continuity/emergency management planning and preparedness efforts are likely to overlook these dependencies, rendering essential services vulnerable during crises. *Third*, the paper proposes an integrated framework i.e., MCEs and applies to examine strategic documents to identify future new challenges that are worth research.

LITERATURE REVIEW

In this section two interrelated concepts are elaborated based on the literature review, i.e., mission critical systems and business continuity planning. Finally, the section summarizes research gaps and highlights this paper's position.

Mission-Critical Systems in the Literature

The complexities described earlier trigger the need to build a new understanding of "mission-critical (eco)systems" that are now becoming blurry. Traditionally, mission-critical systems are often associated with the critical physical infrastructure and facilities, and often are associated with the 24/7 environments such as operation centers, network equipment rooms, standby emergency power, business continuity and technology recovery room, business operation control room, command center—to name few (Curtis, 2021; Hebert et al., 2018). There are many specific rooms and areas within facilities in today's ever-changing environment. In this book, Curtis (2021), defines the Critical Environment (CE) as the "*physical space and the systems within a facility that are uniquely configured, sized and dedicated to supporting specific critical business operations as defined by the user*". Before 2010, mission-critical systems often were associated with Mission-critical Computer Resources (MCCR) such as hardware/software/firmware (Austin & Larkey, 1992) and critical servers (Johnson, 1999).

Table 1 summarizes various definitions used in the literature, to broaden our understanding, how the concept has been applied in contexts beyond "critical facilities" and "critical systems."

Table 1 Overview of the mission critical concepts derived from literature.

Main Concepts	Definition
Systems or Process (Bernardini et al., 2013; Magutshwa & Radianti, 2021; Weger et al., 2023)	**A system or process** is one in which a failure or interruption comes with intolerable operational or human cost. The system is **essential to the survival of an organization** and **will adversely affect society when it fails.**
Systems health state; socio-technical interaction (Bernardini et al., 2013)	A 'mission-critical system' is a system whose '**health state**' is crucial to the successful completion of an organization's core operations. Many mission-critical systems can be characterized as **complex socio-technical systems**, that depend on the interactions among human and social factors and technical infrastructures.
Criticality scale (Microsoft, 2023), *Approaches, and methods* (LeSaint et al., 2015)	**A criticality scale** that covers significant financial cost (business-critical) or human cost (safety-critical) **associated with unavailability or underperformance**. As an approach, it refers to methods for assessing vulnerability in mission-critical systems.

Table 2 Overview of the mission critical concepts derived from literature.

Main Concepts	Definition
Function or Critical Services (Zuo, 2013)	**A function whose failure would lead to catastrophic consequences** that would place public security at risk. Mission-critical systems provide **vital services and must be reliable and dependable** to withstand malicious attacks and system failures (e.g., the electric power grid, telecommunications networks, healthcare systems, water management systems), hardware and software failures, operator errors, power outages, environmental disasters, and attacks by adversaries
Hardware, software, applications, communication facility, IoT (Ali & Ware, 2021; Austin & Larkey, 1992; Cao et al., 2021; Johnson, 1999; Weger et al., 2023)	**The hardware, software, and communication facilities**, that allow mission-critical users to communicate with each-other and liaise with command centres securely for providing mission-critical services, wherever and whenever the services are needed. It includes applications that critical, e.g. to support Internet of Things (IoT) that essential for autonomous driving, factory automation and tele-surgery.
Business Ecosystems (Mattos et al., 2020)	**Continuous process in a business-to-business (B2B**) mission-critical systems: customer and users can be different customer can subscribe for their users, or they become users in itself; Ownership products and data issues
Leadership (Yip et al., 2009)	**Leadership as a mission-critical:** Horizontal and vertical boundaries, requirements for groups to work across boundaries. Traditionally, managers learn to manage vertically — to work with senior colleagues and downward with direct reports. In today's interconnected world, it is critical for managers to work effectively across functions, locations, and with external stakeholders
Innovations in public agencies (Breznitz et al., 2018)	**Enhancing innovations**: mission-critical systems have been linked into the need for tools and structure of successful innovation agencies to be one of the following organizational typologies: upgrader, productivity facilitator, state disruptors, transformation enabler
Organizational capacity (Hannah et al., 2009)	One or more extreme events are occurring or are likely to occur that may **exceed the organization's capacity** to prevent and result in an extensive and intolerable magnitude of physical, psychological, or material consequences to – or in close physical or psycho-social proximity – to organization.

The usage of the "mission-critical" concept in Table 1 shows the varieties of this concept applications, which are then aggregated to define the component of MCEs. The learning points from this review are:

- "Mission-critical" (systems, processes) are often treated as a singular topic, either specifically discussing the concept within a particular application area or in a very general sense to refer to important activities.
- The term refers to both the technical development of mission-critical software, apps, and communication, and to the critical spaces, or facilities.
- In the organizational context, the term is often associated with risks, the sustainability of business operations, structure, leadership, and the organizational capacity to cope with stress. Frequently, the term is related to the concept of "cascading effects" resulting from the failure of one critical service, impacting other sectors and business units.

Literature on Business Continuity Planning (BCP)

A related perspective in the literature that addresses the maintenance of business operations is CP framework. BCP entails preplanning disruptive events (Reid, 2021), establishing a plan to counter mitigate risks and minimize the impact of a crisis while reducing the time needed to restore conditions to normal operations (Cerullo & Cerullo, 2004). The aim of BCP is to prepare for, provide to, and maintain control and capabilities for managing an organization's overall ability to prevent operational discontinuity during disruption (Mukherjee et al., 2020).

Reid (2021) points out that BCP is analogous to Continuity of Operations Planning (COOP), with the distinction that BCP is often applicable for private sectors, while COOP typically refers to continuity of government or public sectors, which has been accepted as a part of the emergency preparedness landscape since 1955 in the US (Rucks et al., 2011), and continuously updated (FEMA, 2020). Rucks et al. (2011) that suggest templates developed for emergency management agencies during planning stages and their utility during activations or response phases. FEMA also provides practical examples of templates for continuity plans (FEMA, 2020). Thus, BCP is often manifested as a playbook designated to guide response in the event of disruptions. Specifically, COOP illuminates the efforts within individual organizations to ensure that essential functions continue during disruption of normal operations (FEMA, 2018, 2021). Typical instruments to identify critical functions include conducting Business

Impact Analysis (BIA), assessing associated risks, and formulating mitigation plans (Cerullo & Cerullo, 2004; FEMA, 2019) as well as creating Disaster Contingency Recovery Plan (DCRP) to outline procedures to follow when a disaster occurs (Cerullo & Cerullo, 2004).

Inspired by Covid-19 crisis, Grace et al. (2023) introduce continuity planning for cyber-physical infrastructure to maintain essential functions at existing or alternative workplaces thorough the crisis. The article discusses the interdependence of cyber-physical-social infrastructure in continuity planning for public health emergencies and suggests the need to expand business process/impact analysis to recognize dependencies and impacts on critical infrastructure that occur when other organizations' essential functions are impacted. Grace et al. (2023) particularly highlight the need for multiple-level redundancies to maintain continuity of operations and achieve organizational resilience.

Summary and Research Gaps

In the business and industrial context, highlighting the urgency of emergency management is clearer when using concepts like BCP or "mission-critical ecosystems," as any threats to digital and physical infrastructure, critical functions, or lacking critical teams and leadership are immediately recognized as crises requiring response. Existing studies, however, appear to focus on a limited set of infrastructures and not the expansive set of inter-organizational infrastructure components—ecosystems—that organizations depend on to maintain operations during a crisis. One of the gaps in the BCP framework is its inadequateness in addressing emerging risks such as new cyberthreats, climate change impacts and zero emission requirements assigned to organizations. This includes considerations such as prioritizing human centric approaches over reliance on automation, integrating climate risk management for sustainability, and incorporating social dynamics, as suggested by Industry 5.0.

Moreover, there is a gap where the mission-critical (eco)systems are not portrayed holistically, by considering all the ecosystems, and allowing the organizations to assess their weaknesses in a more thorough way. This article proposes that "Mission critical ecosystems encompass core technologies, physical infrastructures, the individuals, and teams who interact with the technologies, organizational and supply-chain environments that support critical (business) operations. A failure in one or more of these factors within this ecosystem can result in undesirable cascading risks and consequences for both business and society."

METHODOLOGY

Approach: Multi-Vocal Literature Review (MLR) Approach

This study is designed as qualitative research involves exploring research questions through collecting and analysing data using typical qualitative data collection methods. The study employed ***multi-vocal literature review (MLR) approach,*** especially because we want to include overarching themes laid down by strategic documents related to selected cases (e-health and energy). "MLR comprises all accessible writings on a common, often contemporary topic. The writings embody the views or voices of diverse sets of authors (academics, practitioners, journalists, policy canters, independent research and development firms, and others).

They reflect different purposes, perspectives, and information bases. They address various aspects of the topic and incorporate different research or non-research logics" (Garousi et al., 2019, p. 102).

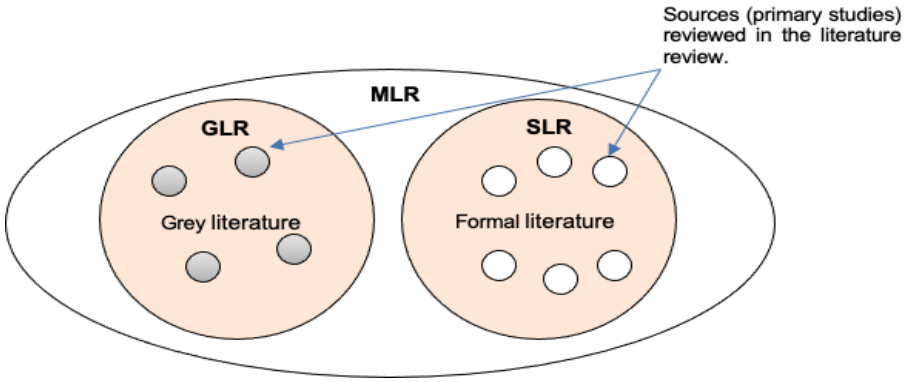

Figure 1 Venn diagram showing the relationship of SLR, GLR and MLR studies (Adapted from Garousi et al, 2019).

Data Collection Method from Academic and Grey Literature

This study uses documents as the main data sources, which then be coded and analysed to find patterns and themes, i.e. scientific literature, and grey literature (GL). The usage of grey literature in research have been discussed by scholars. The 1997 Luxembourg Convention defines the term as "*literature that is produced on all levels of government, academics, business, and industry in print and electronic formats, but which is not controlled by commercial publishers i.e., where publishing is not the primary activity of the producing body*" (Garousi et al., 2019; Kamei et al., 2021). Such literature is not obtainable through traditional publishing channels that typically require peer-review processes prior to publication to control publishable materials. Garousi et al. (2019) suggest three levels of GL. **The first tier** encompasses books, magazines, government reports and white papers with high outlet controls and high credibility such as reports, books, magazines government reports and white papers. **The second tier** has moderate outlet control and credibility such as annual reports, news articles, presentations, videos, question-answer sites, Wiki articles and so on. **The third tier** encompasses e.g., blogs, emails and tweets as low outlet control and credibility. Scholars argues on the importance of GL as it has the potential to understand the contextual contemporary information and provides valuable insights for research in fields where there are still received limited scholarly attention (Garousi et al., 2019).

The overall procedures conducted in this study is captured in Figure 2. In this study, scientific literature was used to map the components of "mission-critical (eco)systems". The search term "mission-critical" were applied in Scopus database and Google Scholar. Highly technical-oriented papers were filtered out. The selection focused on articles that tailor mission-critical term with organizational context. This procedure help deriving the mission critical ecosystem framework that integrates its component into a single framework (Figure 3). On the GL part, this study benefited from the government strategic documents publicly accessible, published between 2019-2023 by Norwegian Government or agencies that touch upon energy sectors, emergency preparedness, health preparedness and the green shift. Using the framework derived from the literature in Figure 3, I extracted emerging themes from the identified government reports that serves as vision for emergency management.

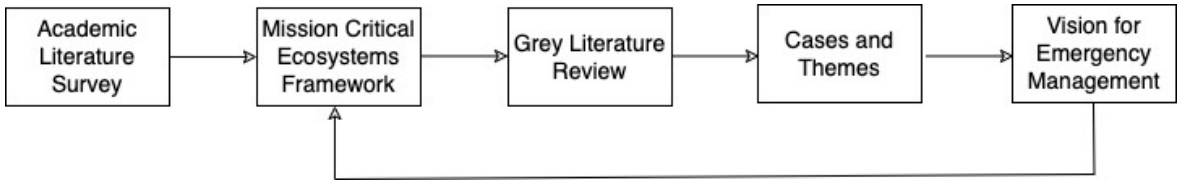

Figure 2 Procedure for deriving vision for emergency management

Data Analysis Method

The documents were coded thematically using a qualitative software Nvivo with simple criteria: renewable energy and health and societal security topics. However, whenever a new concept comes, it was treated as a new sub-theme during the analysis, which then was mapped into the broader theme. This framework was then used to map the government documents and strategies that dealing with more concrete e-Health and energy cases and to derive visions for future emergency management.

RESULTS

Figure 3 depicts a simplified MCEs framework derived from scientific literature, which subsequently utilized to map emerging themes within selected application areas and beyond. Figure 3(A) lists sources of instability both internally (on the right side) and externally (on the left side). The core circle captures various necessary applications, software, hardware, and various technologies and digital infrastructures needed to sustain the organizational operations. The second inner circle represents the "space", where these supporting technologies reside, while the third inner circle (mission-critical users) comprises the core teams and human resources interacting with the technologies, ensuring seamless operation of the organizations. The fourth inner circle represents the criticality of organizational layer where the leadership, organizational cultures (safety, security, and risk cultures). The outermost circle portrays the supply-chain of goods (e.g., raw materials, equipment, critical components of industries), services (consultancies, software as a service, expertise for hire), and digital supply chain (e.g., digital technologies, data analytics, predictive analytics, Internet of things (IoT)-based services). While in Figure 3A the whole landscape of the MCEs seems disjointed, in reality there are dependencies among these factors as has been simplified in Figure 3B.

Externally (left side of Figure 3), there are known and unknown factors that affect businesses´ resilience such as:

- extreme events (e.g., snowstorm, floods, terrorist actions, landslide, pandemic)
- risks, threats and cyberthreats (e.g., black-swan events, cyberattacks, cybercrime and extortion)
- new demands for customers (e.g., preferences, desired services, sophistication levels, platforms)
- contemporary trends (e.g., industry 4.0, industry 5.0, sustainability, green deals demand, new competencies)
- new national and international strategies (e.g., stronger privacy laws, new highlights in governments´ regulations, artificial intelligence act, and so on)

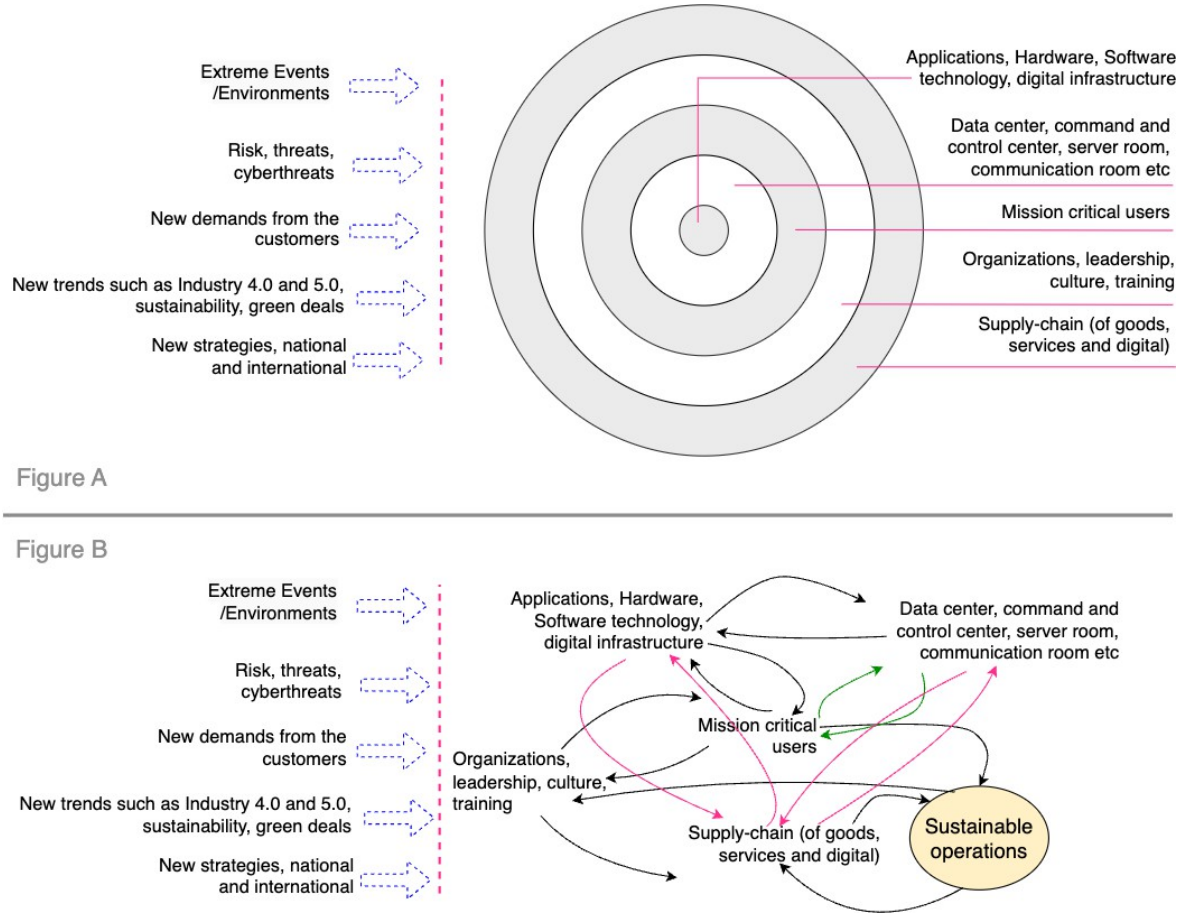

Figure 3 A Framework to untangle the mission-critical ecosystems.

We applied this MCEs as thematic analysis framework into two selected cases, i.e., challenges in renewable energy and e-health sectors that affect societal security. The following trends are identified and reemphasized:

Applying the MCE Framework for the e-Health Case

As our focus is to identify the e-health themes, the following issues within the MCEs framework were identified:

- **Digital and critical infrastructure**: Themes such as digital infrastructure, information security, managing security breaches, secure communication, security-privacy consequences, risk assessment and management, and secure IT operation with access control have repeatedly emphasized (DEH, 2023; Meld.St.5, 2023; NORMEN, 2018, 2022a, 2022b, 2023). The ICT solution is a backbone of the eHealth service. Organizations should capable of assessing the risks and consequences regarding the unavailability of the service (NORMEN, 2021).
- **Facility:** The inclusion of e-health initiatives in health preparedness aims to enhance monitoring, detection, and analysis of e-health digital threats and vulnerabilities, the relevance of Computer Emergency Response Teams (CERTs), and required facilities for conducting these activities (Meld.St.5, 2023).
- **Critical users:** There are lacking competence and knowledge in some sectors including basic research in the development of pharmaceutical, diagnostics and vaccines, medical technical equipment, and digital health.

The health sector should be prepared against crisis and catastrophes (*Veikart Helsenæringen*, 2023), and ICT security competence to understand threats and risk control (Meld.St.5, 2023).

- **Organization, leadership, and culture:** The themes touch upon the issues of strengthening system for health preparedness, resilient health preparedness, and understanding of risk and vulnerability. Health organizations should cooperate on societal security based on systematic risk management. Prevention and preparedness must be prioritized (Meld.St.5, 2023). In eHealth, the organizations should comply with the requirements for information security (NORMEN, 2022a).
- **Supply chain**: Sometimes health organizations act as data controller by collecting health data, which may be processed further by the third-party data processors on behalf of the data controller. Data controller organizations sometimes act both as data controller and data processor. In other instances, suppliers come as data processors in the cloud services or operational services, maintenance (physical service) and remote access, or even outsourcing the ICT functions. These suppliers should adhere to the existing requirements to avoid potential data breaches (NORMEN, 2022a)
- **External issues:** Examples of themes include feared threats and risk scenarios involving digital infrastructure in e-health including human errors, accidents, technical failures, and extreme weather are highlighted. The risks are annually assessed by relevant national agencies such as policy security service, intelligence services, national security authority and Health-CERTs. Relevant risks, threats and vulnerabilities that will harm the availability, confidentiality and integrity of personal information should be understood (NORMEN, 2022b). There are also concerns on software dependency, dependencies related to the supply chain and digital infrastructure, as well as the development of artificial intelligence, and its consequences (Meld.St.5, 2023).

Applying the MCE Framework for Power Sector Scenario: "New" Renewable Energy and Battery

The themes derived from energy case are coded and aligned the MCEs framework, for instance, automation and digitalization, which significantly contribute to increased power consumption (Motvind-Norge, 2019), alongside the electrification of the transport systems. The following themes were identified:

- **Technology and digital and critical infrastructure**: The energy storage system such as battery is a key for keeping excessive energy production originated from use of renewable energy such as wind power (Motvind-Norge, 2019). Such energy source development has changed the risk picture from the societal security perspective (NOU, 2023b). The energy white-paper document (NOU, 2023a) indicates the emergency management work should include the understanding of the new incident risks caused by such power sources and how to manage them (NOU, 2023b).
- **Facility:** Many energy companies active promoting the energy-intensive data center and the energy usage will increase, thus this development is a part of the calculated future energy needs (NOU, 2023a)
- **Critical users**: The theme stresses the shortage of personnel with practical risk management skills, hindering the effective implementation of risk analysis and measures in practice (Johnsen & Lysgaard, 2022). This knowledge gap can impede the procurement of ICT systems, particularly in assessing their security risks. There is a pressing need for clearer roles for policymakers and other stakeholders to enhance the resilience of critical infrastructure and systems (NOU, 2023a)
- **Organization, leadership, and culture**: the themes point out the need for a better coordination and cooperation among relevant organizations such as Power supply Emergency Preparedness Organizations (KBO). Culture for sharing information is also need improvement (NOU, 2023a, 2023b).
- **Physical and digital supply chain:** the transition to e.g., wind power or battery, triggers higher demand for raw materials, minerals, and metals. Thus, industries are more dependent on a number of goods such as aluminum, cobalt, copper, steel, zinc and lithium (Motvind-Norge, 2019). The supply chain also involves complex arrangement of suppliers involved in infrastructure construction. The digital supply chain receives high attention due to its role as a gateway for cyberattacks, with statistics indicating a rising trend in attacks among suppliers, leading to digital disasters. It encompasses the delivery structure between businesses, involving digital services, software, or hardware in each delivery (DSB, 2020). Thus, ICT security risk management of the supply chain is especially important in many sectors, especially energy (Johnsen & Lysgaard, 2022). Understanding the supply chain is becoming relevant and crucial to safeguard mission-critical core of the business.
- **External issues**: There is high fluctuation of electricity supply from "new" energy such as wind power. In certain European countries, dual wind power sources, offshore and onshore, are common, but they present challenges such as construction and funding. The potential of onshore energy for power balance is recognized, yet barriers have caused delays, due to environmental concerns and local conflicts, such as community acceptance of onshore wind facilities. Harsh environments can heighten the risk of infrastructure damage

(NOU, 2023a). Likewise, on the offshore part, the risks of marine ecosystem damage and other ocean-related interests can be affected negatively. These are an example as well how the mission-critical business core can affect societal security, especially with the societal conflict risks, and vulnerable physical infrastructure.

Societal Security and Cybersecurity in relation to eHealth and Energy Scenario

A strategic document called "Risk 2023" advices businesses to have better visions on security work in a larger context, and take measures to protect themselves against espionage, sabotage, terror, and complex threats (NSM, 2023). Kvadsheim et al. (2023) pinpoint that the security quality is closely connected the preparedness. Energy-related organizations need to establish preparedness plan (how to respond), structure (role and responsibilities), training (to test if the preparedness plan works), evaluation and learning. The Norwegian *Total-preparedness* strategy justifies the preparedness and management in energy supply and recommends measures to handle unwanted threats (NOU, 2023a), including digital security and preparedness for digital response (NOU, 2023b).

The *total-preparedness* strategy covers also health preparedness, aimed at safeguarding lives and well-being by ensuring continual provision of medical treatment, nursing, and care for individuals affected by crises, including major natural disasters, terrorist attacks, war, and pandemics and typically causing death or severely injured victims (NOU, 2023b). This health preparedness highlights the importance of services in emergency medicine, emergency room, municipal health service and specialist health services. Swine-flu pandemic 2009 and Covid-19 pandemic are examples of the importance of good infection controls as public health measure. Overall, the *total-preparedness* strategy underlines improved risk analysis and management for better health preparedness, including the protection of critical infrastructure to maintain seamless electronic communication services in crisis events. Battery has been mentioned as an important energy storage, to back up the energy sources for critical infrastructure during the power outage.

DISCUSSIONS AND REFLECTIONS

The identified trends or issues highlighted in the previous sections indicate that organizations are often vulnerable, facing both new and interrelated threats that may go unnoticed without a comprehensive analysis of the overall ecosystems. The listed trends in the previous section, derived mainly from the Norwegian experience, specifically in e-health and energy sectors, may not align with other countries' experiences. For example, differences in the adoption of electric cars, levels of digitalization for critical infrastructure systems, reliance on electricity in daily life, and dependence on renewable energy sources vary among nations. In fact, Norwegians build their preparedness system based on trust, a societal value that highly appreciated in their society, may not be applicable to countries with more fragmented social structures and higher level of distrust. However, certain general topics consistently emerge, and generally applicable in building emergency management:

- The strategic documents emphasize the significance of ***the preparedness stage*** in emergency management. A well-crafted preparedness plan, outlining response procedures, organizational structure, role delineation, training protocols, and continuous evaluation, is crucial for an effective crisis response. Systematic research on building excellent preparedness plans across diverse and emerging scenarios could be a relevant research agenda.
- The ability to conduct thorough ***risk assessments*** is pivotal in creating realistic preparedness plans that account for new threats and are regularly updated. Research on risk analysis, risk perceptions, systemic risks analysis, intertwined risks, and cascading risks within the emergency management and response domain could contribute significantly to the field.
- Examining ***organizational ecosystems*** is crucial in establishing emergency plans and conducting risk analyses. The proposed mission-critical framework, focusing on each component or layer, aids in understanding threats and defining preparedness plans.
- ***Digital transformation*** is inevitable in various sectors, including emergency management. However, limited studies exist on digitalization within this domain, including potential "digital disasters." Research on the implications of digital disasters and their relevance to emergency management is needed.
- The increasing connection between ***cybersecurity and emergency management*** is noteworthy. Understanding digital risks, security, and privacy protection becomes integral to post-digital transformation. Research should explore events that resemble cybersecurity incidents but trigger emergency management responses, such as a cyberattack on a transport control system causing citywide traffic chaos.
- Resources with skills in risk analysis, cybersecurity, and ICT supply chain security are limited. Research on ***human resources in the digitalization era*** within emergency management, focusing on capabilities, competencies, and training ideas to address gaps, is essential.

To sum up, this study provides valuable lessons that can guide efforts to derive new research areas in the emergency management domain that put business and industries into the picture, particularly when examining individual scenarios like those are relevant for the e-health and energy as critical services. Moreover, to repeat that we have proposed the definition MCEs as an integration, and interconnectedness between the critical *internal arrangement* of organizations (actors, knowledge, digital platforms, critical facilities, supply chain) with *external stressors* that pressing organizations to adapt, respond or change to fulfill their goals (e.g., protect essential service functions, core businesses) which sometimes require interactions with external stakeholders. By applying this framework during the analysis stage, several pressing issues on each category of component in mission critical ecosystems have been identified. The implication for research among other things is how to identify detailed components of mission critical ecosystems, and how to detail the green transition within industrial mission critical ecosystems. There is a newer model in the BCP literature such as Eco-centric BCP that build on four pillars: 1) reduction in emission from industry; 2) sustainable use and reuse of ecosystem services; 3) legislation-and implementation, and 4) sustainable energy usage and consumption. In the Eco-centric BCP Model, environmental aspects are highly dominant and translated as e.g., environmental norms, waste production and reduction, emission treatment, certification for sustainable indexing, circular economy, and emission management. This can be explored as further study encompassing their relevance for mission critical ecosystems, and how organizations move forward with the eco-centric BCP (Mukherjee et al., 2020).

CONCLUSION AND FUTURE WORK

This article argues for the necessity of adopting a less siloed approach to emergency management. As technology plays an increasingly integral role in emergency response, the distinction between emergency management and cybersecurity becomes more challenging. Various technologies are now utilized in emergency response activities, encompassing tasks such as data collection, exchange, and storage. The proposed mission-critical framework serves to map and comprehend the emergency management landscape from an organizational standpoint. This study relies on a single-country case and a few industrial or business scenarios, however, it sheds light on diverse and promising research directions. Moving forward, it is essential to explore additional scenarios, examine deeper into case studies and leverage the mission-critical ecosystem as a framework for enhancing emergency management preparedness and response.

ABSTRACT

The DIREKTION project, funded under Horizon Europe, aims to revolutionize disaster resilience through advanced technology and collaboration. Addressing the challenges posed by climate change, infrastructure vulnerabilities, and dynamic population densities, it seeks a paradigm shift in emergency responses. By integrating innovative technologies with the practical needs of responders and policymakers, DIREKTION enhances cross-sectoral harmonization and fosters stakeholder communication. Early outputs include drafts of the DIREKTION Assessment and Screening Framework and D-SAT tool, establishing a foundation for future development. The project's presentation at ISCRAM invites valuable feedback and engagement, highlighting its commitment to improving disaster management practices and fostering a more resilient society.

Keywords

Disaster resilience, Capability-based approach, Stakeholder collaboration, Emergency response management.

INTRODUCTION

In response to the increasing complexity and frequency of disasters, the DIREKTION project was initiated in October 2023 and is scheduled for a 36-month duration. Funded under the Horizon Europe's cluster 3 security call HORIZON-CL3-2022-SSRI-01, the project aims to improve disaster resilience through a combination of technological innovation and collaboration among multiple stakeholders. The need for DIREKTION arises from multiple challenges, including climate change, aging infrastructure, geopolitical instabilities, and the complexities of managing dense, dynamic populations. These challenges necessitate a new approach to emergency responses, which DIREKTION seeks to address by fostering better knowledge sharing and developing technologies that address the needs of emergency responders and policymakers.

The project focuses on integrating innovative technologies into disaster management practices through thorough assessments of existing solutions, identifying gaps, and prioritizing future research and innovation efforts. It utilizes outputs from previous EU Horizon projects and creates a network of industry stakeholders, small and medium-sized enterprises (SMEs), research organizations, and practitioners to build a more resilient and prepared society.

This paper presents the DIREKTION project, outlining its goals, methodology, and expected impact on disaster resilience and crisis management. We invite the research and practitioner communities to join a collaborative dialogue to improve our collective ability to anticipate, respond to, and recover from disasters.

BACKGROUND

Facing escalating challenges like climate change, technological disruptions, and societal shifts, there is an urgent need to enhance civil security and crisis management capabilities. The European Union has launched the Horizon Europe call HORIZON-CL3-2022-SSRI-01 under its flagship research and innovation program, aimed at advancing research and innovation in this field (European Commission). One of the projects funded under this initiative is DIREKTION, designed to bolster disaster resilience and management using innovative technologies and methodologies. Horizon Europe's Cluster 3, titled "Civil Security for Society," aims to improve security through solutions for combating crime and terrorism, managing borders, enhancing cybersecurity, and building disaster-resilient societies (European Commission). The DIREKTION project supports these goals by adopting an integrative approach to crisis management that emphasizes advanced technology and cross-sectoral collaboration.

The increasing impacts of climate change, evidenced by more frequent and severe weather events (Kron et al., 2019, p. 82), alongside new technologies, including those developed to cope with climate change, such as electric mobility (Liu et al., 2023, p. 9), that present new firefighting challenges, underscore the urgency of these initiatives. These developments complicate traditional disaster response mechanisms and underscore the need for a flexible, comprehensive approach to civil security. The mission of the DIREKTION project aligns with Horizon Europe's broader goal of creating innovative, inclusive, and sustainable solutions to contemporary challenges. Strengthened Security Research and Innovation (SSRI), a key focus of the program, advocates for transcending sector-specific biases and dismantling existing silos that impede the spread of common security solutions (European Commission).

DIREKTION's integrative approach to crisis management emphasizes advanced technology and cross-sectoral collaboration. By connecting a "network of networks" that includes established fire and rescue organizations, academics, research entities, industry stakeholders, and policymakers, DIREKTION facilitates a comprehensive strategy to address capability needs and gaps, technology screening and sourcing, assessment of technology and project results, co-development of technologies, research programming, and practical standardization aligned with practitioner needs. Additionally, acknowledging the critical role of human factors in crisis management, DIREKTION focuses on designing user-centric solutions tailored to the requirements and capabilities of first responders and affected communities, aiming to enhance both technological and social capacities for effective crisis response.

This collaborative model, supported by Horizon Europe’s framework, underlines the significance of international cooperation and knowledge sharing in addressing global security challenges. DIREKTION exemplifies the program’s vision for a unified European research area focused on societal safety and well-being. Reflecting on DIREKTION's alignment with the objectives of Horizon Europe’s Cluster 3 demonstrates that the project is not just a response to a funding opportunity but a strategic effort to push the boundaries of civil security research and innovation, embodying the EU’s dedication to using scientific research for societal benefits and setting new standards in disaster resilience and crisis management.

METHODOLOGY

In this paper, we detail the methodology adopted by the DIREKTION project, aimed at addressing the fragmented nature of the research projects and the small-scale, highly fragmented security market. Recognizing the limitations of existing taxonomies based solely on technological solutions, DIREKTION employs a capability-based approach to enhance cross-sectoral and cross-departmental harmonization, improve access to research results and market solutions, and foster communication among interdisciplinary stakeholders in civil security. This methodology leverages the results of prior research (e.g. ACRIMAS[1], ResiStand[2], FIRE-IN[3], MEDEA[4]) and integrates the 13 functional areas identified in the European Commission's study of the EU security market (Deloitte LLP et al., 2022), facilitating a comprehensive mapping of capability needs and solutions.

The project is structured into seven interdependent work packages (WPs) (see Figure 1), each with specific objectives.

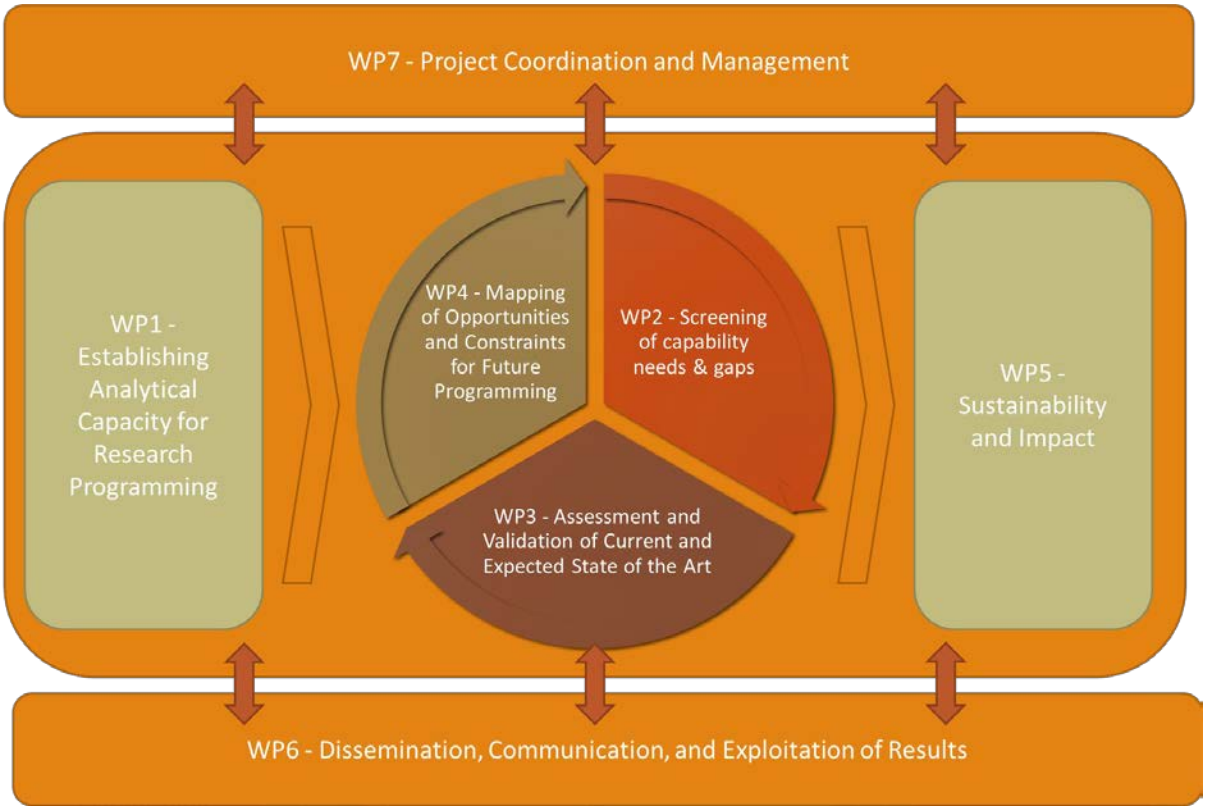

Figure 1. work package structure of DIREKTION

In *WP1 - Establishing Analytical Capacity for Research Programming*, the cornerstone of DIREKTION's methodology, a common, sustainable framework that underpins the entire project is being developed. This work package draws upon a wide range of sources, including previous research findings and the taxonomy of the EU Security Market study, to establish a comprehensive categorization system. This system is designed to facilitate the identification and classification of capability needs and solutions, thereby addressing one of the critical challenges: the fragmentation of the security market. By developing a common language and framework for capability needs, WP1 lays the foundational groundwork for the project's success, enabling more effective communication and collaboration among stakeholders.

The WPs 2 to 4 built an iterative process of 3 cycles over the project duration, starting with WP2. *WP2 - Screening and Mapping of Capability Needs & Gaps* focuses on the meticulous identification of current and future capability needs and gaps within the security domain. This involves a thorough analysis of operational requirements, technological advancements, and emerging threats to ensure that the project's efforts are squarely targeted at areas of critical need. WP2's objective is to systematically map out these needs and gaps, providing a clear direction for research and innovation activities. This mapping process is essential for prioritizing research efforts and ensuring

[1] https://cordis.europa.eu/project/id/261669
[2] https://cordis.europa.eu/project/id/700389
[3] https://cordis.europa.eu/project/id/740575
[4] https://cordis.europa.eu/project/id/787111

that the project's outcomes are both relevant and impactful in addressing real-world security challenges.

Based on the WP2 outcome *WP3 - Assessment and Validation of Current and Expected State of the Art* is pivotal in evaluating the operational capacity of existing and forthcoming solutions against identified capability needs. This work package employs a rigorous validation process to assess the alignment, efficacy, and potential of solutions to meet the articulated needs. By involving practitioners and stakeholders in this assessment, WP3 ensures that the solutions are not only technologically advanced but also practically viable and tailored to operational contexts. This alignment between solutions and needs is crucial for the successful operationalization and adoption of new technologies in the security sector.

WP4 - Mapping of Opportunities and Constraints for Future Programming undertakes a comprehensive analysis of the factors that influence the successful implementation and uptake of new solutions under consideration of the WP2 and WP3 findings. This includes examining market drivers, barriers to standardization, and the ethical and societal implications of security innovations. By identifying these opportunities and constraints, WP4 provides valuable insights that inform the strategic direction of future research programming. This work package plays a crucial role in ensuring that DIREKTION's efforts are not only technologically sound but also market-ready and socially responsible.

WP5 - Sustainability and Impact is dedicated to fostering innovation and enhancing multi-stakeholder cooperation within the DRS community. Through the establishment of networking activities and the introduction of awards for innovation, WP5 aims to build a vibrant ecosystem that supports the exchange of ideas, resources, and best practices. This work package is instrumental in promoting the uptake of new technologies and methodologies, ensuring that DIREKTION's outcomes have a lasting impact on the field of civil security.

WP6 - Dissemination, Communication, and Exploitation of Results seeks to amplify the reach and impact of DIREKTION's findings and innovations. By implementing a targeted communication strategy, this work package ensures that the project's results are effectively shared with a broad audience, including industry partners, SMEs, researchers, and practitioners. It should be noted here that the aim is an exchange and not a one-dimensional flow of information. WP6 plays a vital role in establishing a platform for the dissemination and exploitation of solutions, facilitating the transfer of knowledge and technology from the research domain to operational practice.

WP7: Project Coordination and Management ensures the seamless execution and governance of the DIREKTION project. Entrusting the steering role to practitioners from the consortium, this work package embodies the project's commitment to a capability-driven approach. By involving practitioners in the leadership and decision-making processes, WP7 guarantees that the project's developments are closely aligned with the needs and realities of the DRS community, fostering innovation that is both relevant and impactful. Our approach emphasizes a capability-driven strategy for developing new solutions, involving practitioners early in the research process to ensure that future innovations meet operational requirements and market expectations.

By incorporating a mix of foresight capabilities, operational assessments, and strategic cooperation, DIREKTION aims to bridge the gap between demand and supply, facilitating the development of solutions that are both innovative and practically applicable. This methodology not only aims to overcome market fragmentation but also establishes a sustainable framework for enhancing civil security research and innovation, ensuring that future projects are aligned with the real-world needs of practitioners and stakeholders.

Our approach emphasizes a capability-driven strategy for developing new solutions, involving practitioners early in the research process to ensure that future innovations meet operational requirements and market expectations. By incorporating a mix of foresight capabilities, operational assessments, and strategic cooperation, DIREKTION aims to bridge the gap between demand and supply, facilitating the development of solutions that are both innovative and practically applicable. This methodology not only aims to overcome market fragmentation but also establishes a sustainable framework for enhancing civil security research and innovation, ensuring that future projects are aligned with the real-world needs of practitioners and stakeholders.

PRELIMINARY RESULTS AND STATE OF THE PROJECT

The DIREKTION project, in its initial stages, has made considerable progress in developing its foundational elements, namely the DIREKTION Assessment and Screening Framework and the associated DIREKTION Solution Assessment Tool (D-SAT) drafts and its supporting user guide. These preliminary outputs are critical in shaping the project's approach to identifying capability needs and gaps within the domain of Disaster Resilient Societies (DRS), as well as in screening and assessing existing and state-of-the-art technologies. Although these outputs are currently in draft form, they mark a significant step towards establishing a structured methodology for enhancing disaster resilience through innovative technology uptake.

DIREKTION Assessment and Screening Framework (DASF)

The DIREKTION Assessment and Screening Framework (DASF) has been developed within DIREKTION's work package 'Establishing Analytical Capacity for Research Programming' (WP1). It resulted in the initial version of a robust framework of methods for identifying capability needs and addressing gaps, as well as implementing screening and assessment processes, to be used for programming future research.

To create the initial DASF, existing methods from both EU projects and external sources are screened beforehand. Methods that align with the needs of the DIREKTION project, either partly or fully, are integrated into the DASF. One of the challenges in developing the DASF was dealing with the complexity of how disaster management is organised, as EU Member States have their own organisational crisis and disaster management structures, culture, traditions and administrative arrangements which are not expected to be changed easily. This has caused a lack of common standardized language in the disaster resilience domain in the EU. Therefore, to identify and describe capability needs and gaps of the EU and all its Member States, a harmonized and well-balanced approach is needed which takes into account the differences in the way they have organized disaster management and the need for standardized terminology. While reviewing existing methods, it became evident that the ResiStand[5] project (H2020) developed a generic framework for disaster management tasks (Stolk et al., 2017). This framework covers all phases of the disaster management cycle – preparedness, response, recovery, mitigation – with the aim of establishing standardized terminology and practices. This framework from ResiStand helped shape the DASF. For practical reasons scoping within the disaster management cycle was needed. The current DASF mainly focuses on the preparedness and response phase instead of elaborating on the entire disaster management cycle; as these are typically the phases in which first response organizations are involved in. Another important role has the FIRE-IN methodology. The FIRE-IN project aimed to enhance the capability development process in the Fire & Rescue sector across Europe. The FIRE-IN method, at its core, consists of an iterative process of identifying capability gaps by workshops and assessing solutions. (Sakkas et al., 2023)

The DASF consists of a set of four methods that include ten steps in total. In Figure 3 these steps are shown as a linear set of subsequent steps. The complete set of steps is meant to be executed regularly, to get an updated insight in the most actual capability needs, capability gaps, potential solutions and to regularly update the roadmap for EU-Research opportunities. As such, the DASF provides the basis for a sustainable process for research programming.

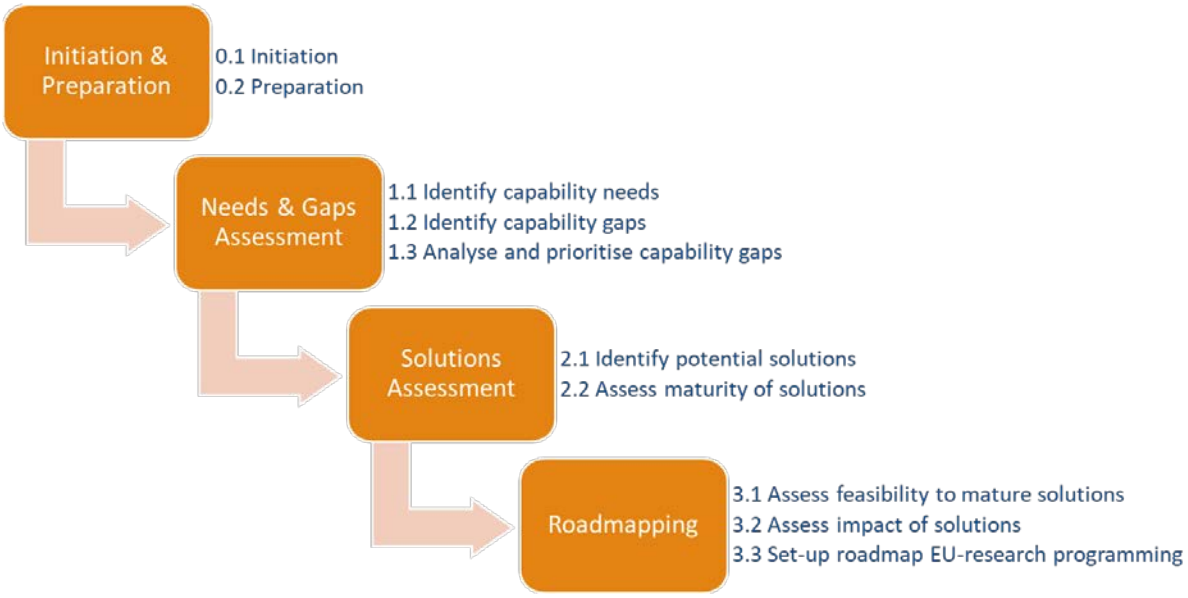

Figure 2: Overview of the methods and steps in the DASF

The initial phase, "Initiate and Prepare," is divided into two sub-steps:

- Step 0.1 – Initiation: This step involves preliminary activities that define the framework for the subsequent assessment cycle. Key actions include assigning roles and responsibilities to participants, determining the scope of the assessment (e.g., general disaster response or focusing on specific threat mitigation), and overall project planning.

[5] https://cordis.europa.eu/project/id/700389

- Step 0.2 – Preparation: Following initiation, this step involves preparatory actions to ensure readiness for further assessment and screening in later steps. Activities include identifying, selecting, and informing stakeholders, developing necessary documentation, and preparing supporting tools for steps 2 (Needs and Gaps Assessment) and 3 (Solution Assessment).

The Needs and Gaps Assessment comprises:

- Step 1.1 – Identify capability needs: Using risk and trend analyses, historical accident data, scenarios, and consultations with end-users and experts, this step gathers capability needs for disaster resilience and security (DRS) activities within the EU, for the present and future.
- Step 1.2 – Identify capability gaps: This involves comparing existing disaster management capabilities with the identified needs to highlight capability gaps.
- Step 1.3 – Analyse and prioritise capability gaps: The identified gaps are analyzed to assess their impact on current and future DRS capabilities, determining which gaps should be prioritized for resolution.

Solution Assessment includes:

- Step 2.1 – Identify potential solutions for bridging the gaps: This step involves gathering information on potential solutions, including mature solutions available on the market, as well as prototypes and promising research activities.
- Step 2.2 – Assess maturity of potential solutions: The maturity of these solutions is evaluated based on technical, societal acceptance, integration, and commercialization aspects.

The Roadmapping phase is structured into three sub-steps:

- Step 3.1 – Assess feasibility to mature potential solutions: For solutions still in development, this step assesses the feasibility of developing these into fully mature solutions, including potential challenges toward commercial availability.
- Step 3.2 – Assess impact of potential solutions: This step evaluates the potential impact of solutions on bridging one or more capability gaps.
- Step 3.3 – Set-up roadmap for EU-Research Programming: Aims to propose a research programming roadmap for the short (3 years), medium (5-10 years), and long terms (15+ years), integrating findings from the previous steps to plan future DRS research in Horizon Europe.

DIREKTION Solution Assessment Tool (DSAT)

DSAT is designed to support emergency management organisations in systematically comparing and assessing multiple solutions in the context of identified and prioritised capability gaps. The tool builds on the core principles of maturity models. Maturity models have been successfully applied across a range of fields to assess capability. A maturity model is “essentially a classification scheme that places patterns in developing organizational capabilities under a certain capability stage, assuming linear progression from an existing mature state to a higher maturity level” (United Nations Development Programme [UNDP], 2022, p. 10)

D-SAT is an excel based tool that is designed to be easily accessible to multiple users. It involves four components that can be flexibly combined to suit assessment needs. The different components are targeted at different stakeholder groups, with the overarching aim of supporting collaboration and dialogue between supply and demand side actors, successful solution development, and market entry and uptake. D-SAT focuses on two key stakeholder groups. Solution providers (see Figure 2, in orange) and emergency management organisations (Figure 2, in blue) and their interaction in the context of innovation (orange and blue).

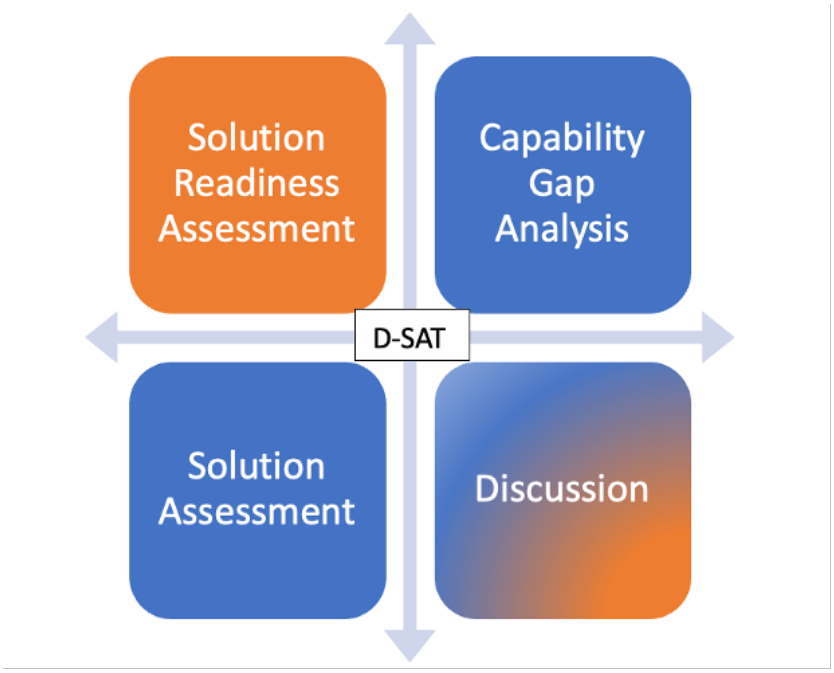

Figure 3: D-SAT Components by Stakeholder Type

The 'Solution Readiness Assessment' component is completed by the solution provider and provides information on the readiness of the solution on a variety of scales: technology; societal; manufacturing; integration; commercialisation; legal, privacy, and ethical; and security. This component is intended to provide a structured space to capture information on the readiness of the solution and builds on the ongoing work of the EU-funded project MultiRATE[6].

In the 'Capability Gap Analysis' component the assessment owner will score identified capability gaps using a maturity scale (from 0-5). The maturity of capability gaps is analysed by capability elements: infrastructure; interoperability; technology; human; organisation; regulatory., building on the results of the EU-funded project MEDEA. Results are then assigned a complexity domain according to the Cynefin framework (Snowden & Rancati, 2021) and matched with potential solution functionalities drawing on the results of the EU Security Market study. (Deloitte LLP et al., 2022). This analysis of capability gaps will provide a baseline assessment and allow users to determine the level of response required when choosing and investing in a solution.

In the 'Solution Assessment' component the assessment owner score solutions (from 1-5) against two sets of criteria. The first assesses the likelihood that a solution(s) will improve the maturity of your capability elements. The second assesses the importance of several high-level priorities for the adoption and implementation of the solution being assessed. These are grouped according to three intersecting topics: 1) legal, societal and ethical; 2) user needs; and 3) market. These groupings are flexible and often overlap with one another. The level of importance of these factors varies depending on the kind of solution being assessed. For example, the relationship between these factors and solutions based on AI technologies is rapidly evolving. At the same time changes in supply chains and the shift to thinking in terms of the environmental costs of manufacturing and production are changing how we assess the value of current solutions. Thus, the importance of these factors is linked to the context of the specific solution assessment and its expected use case.

In the 'Discussion' component a range of questions are presented to promote discussion about the factors that enable and hinder the adoption and implementation of solutions. These questions are grouped according to three broad topics: 1) Solution Adoption and Implementation; 2) Solution Impact; and 3) Innovation collaboration, with a focus on EU research. These questions have been adapted from previous DRS research (e.g. ResiStand) and designed to promote the process of reflecting on the value of engaging in innovation collaboration and the adoption of innovation outcomes and results. And to support the identification of potential barriers and enables for the uptake of research and innovation results.

If the solution is on or close to market, the assessment results can help to guide and refine the procurement process. The assessment results should allow emergency management organizations to see if the solution will meet their

[6] https://cordis.europa.eu/project/id/101073929

capability gap needs and provide guidance on how best to use resources. If the solution is still under development, the results can be used to guide collaboration and engagement with providers on what is needed next, either for the solutions assessed or future needs identification. A comparison of the readiness levels assigned to the solution by the solution provider and the results of the assessment will help to see how well supply and demand perspectives are aligned. Finally, repeating the assessment process will allow emergency management organizations to check if the solution has improved their maturity score over time, or if further investment is required. Repeating the capability gap analysis, even without a solution to assess, will also allow emergency management organizations to track how their capability gap needs have evolved over time.

Extant literature has highlighted the role innovation solutions play in the disaster management, especially in the face of an evolving risk landscape (Izumi, et al. 2019; Rahman and Fang, 2019). Research has also demonstrated the bi-fold challenges related to 1) bringing innovative solutions to market (Butler, 2008) and 2) achieving meaningful uptake and adoption of solutions. This is further complicated by a lack of frameworks dedicated to the assessment of innovation potential of solutions (Klessova et al, 2022). Add to this, the fact that responder organisations are traditionally slow to adapt their existing practices and techniques, there is a well-established need for supportive tools to improve demand and supply interaction in the context of innovation assessment (Webster and Gardener, 2019; Nepelski and Van Roy, 2021).

DSAT aims to meet this need by providing a flexible tool to develop and strengthen collaborative solution assessment and better match supply and demand side needs (see Krikigianni et al, 2022). Existing efforts to do so have focused either on a specific solution type, primarily technology, or domain of application, e.g. flooding, wildfires. However, DSAT has been designed to be applied to a range of solution types, including methods and standards. In addition, it adopts an all-hazards approach, providing further flexibility.

The application of the tool will be tested in the context of the DIREKTION project to address a range of solution types across three stages of innovation readiness: 1) close to or on the market solution, 2) under development solutions, and 3) early-stage solutions. The assessment of these solutions will be matched to the identification and prioritization of current and future capability gaps. DSAT seeks to go beyond state-of-the-art approaches through the integration of existing best practices to develop a generalizable framework that will allow for a systemic assessment of solutions and provide a baseline for comparison of solutions across assessing organisations and actors.

As we prepare for the presentation at the International Conference on Information Systems for Crisis Response and Management (ISCRAM), these early results highlight the project's potential impact and its commitment to addressing the complex needs of disaster management. Presenting DIREKTION at this stage offers a dual benefit: it allows for the integration of valuable feedback from a diverse audience of experts, practitioners, and researchers, and it opens avenues for active engagement and collaboration within the project's growing network. This early dialogue is essential for refining the project's outputs and ensuring their relevance and applicability to the challenges faced by the DRS community.

By sharing these preliminary results, we invite constructive feedback and collaboration, laying a foundation for the iterative development of the DIREKTION project. This approach ensures that the project remains responsive to the evolving needs of disaster management and maximizes its contribution to the field.

CONCLUSION

The DIREKTION project marks a significant advance in the field of disaster resilience and crisis management. As global societies face an increasing frequency and complexity of disasters, driven by factors such as climate change, technological advancements, and geopolitical shifts, there is a critical need for innovative approaches that enhance the capabilities of communities and emergency responders. Funded under the Horizon Europe framework, the DIREKTION project, part of the "Civil Security for Society" cluster, aims to fill current technological and operational gaps in disaster response while promoting a culture of preparedness that extends beyond traditional sectoral and national boundaries.

At the core of the project's methodology is a capability-based approach, which shifts the focus from reactive to proactive and predictive disaster management strategies. This approach involves evaluating existing solutions, pinpointing capability gaps, and focusing research and innovation efforts to develop technologies that meet the practical needs of frontline responders and policymakers. Such alignment is essential to ensure that technological advancements lead to real improvements in operational capacity during disaster responses.

DIREKTION is structured around seven work packages that collectively aim to achieve its ambitious objectives. These packages range from developing analytical capacities for research programming to enhancing sustainability and impact through multi-stakeholder cooperation. The project places a strong emphasis on dissemination, communication, and the exploitation of results to ensure the broad application and maximal impact of the

innovations developed.

Initial outcomes include the development of the DASF Framework and the D-SAT tool, which are major steps forward in structuring disaster management practices. The DASF Framework provides a systematic approach to research programming, while the D-SAT tool enables emergency management organizations to evaluate technological solutions against specific capability gaps. These achievements illustrate early successes in linking technological innovation with operational needs.

In conclusion, the DIREKTION project contributes significantly to enhancing disaster resilience. Through its methodological rigor, collaborative structure, and commitment to incorporating stakeholder feedback, DIREKTION not only pushes forward the state-of-the-art in crisis management but also builds foundations for a more resilient and capable society. As the project progresses, its focus on stakeholder engagement, capability-driven research, and feedback integration will be key to its ongoing success and relevance in an ever-changing world.

ABSTRACT

The utilization of Augmented Reality (AR) holograms in firefighters' training presents a significant opportunity for the acquisition of first responders' practical skills. Nevertheless, given that AR represents a nascent and evolving technological paradigm, its integration within the framework of the crisis management cycle has not yet been firmly established. We analysed three hologram characteristics: dimension, scalability, and interactivity and report on the results of using five holograms (one 2D and four 3D) in a training application FightARs. The holograms were tested among in-service firefighters and commanders with the purpose of improving their knowledge in pre-disaster traffic accident training involving hazardous materials. The results indicate that QR-code scanning to open non-interactive non-scalable holograms can be used effectively to integrate holograms into physical training environments. A full-scale holographic scene is useful for training situation awareness. We propose that 3D non-interactive scalable or non-scalable holograms should be used to exercise practical skills. The paper emphasizes the necessity of extensively testing and incorporating AR into the training of first responders prior to its application in the response phase of crisis management.

Keywords

Augmented Reality (AR), Hologram types, FightARs, Holographic scene, firefighters' training

INTRODUCTION

Historically, a variety of methods have been employed to enhance the training process through the visual presentation of information. Many technologies are used to create and display 3D visual content (Ahmad et al., 2021) and one of the most important 3D display technologies is an Augmented Reality (AR) device which allows to augment a three-dimensional virtual element into the real world (Rauschnabel et al., 2015) such as HoloLens 2. The utilization of AR in firefighters' training presents a significant opportunity for the acquisition of practical skills. Looking ahead, it is anticipated that augmented reality (AR) devices will become more cost-effective, reliable, and proficient in data management, while Wi-Fi technology is expected to achieve greater speeds. Artificial intelligence (AI) could be effectively employed for the rapid analysis of multimodal data derived from algorithms and sensors. Nevertheless, the integration of augmented reality (AR) technology within the crisis response phase is currently ready solely for training purposes and remains a target yet to be achieved in real-world applications. In the project RESCUER, a smoke-removal algorithm, an object detection model and AR HoloLens 2 application were used for visualisation purposes (Gkika et al., 2023). In the FASTER project, the same device

was used to improve situation awareness by marking the points of interest (Christaki et al., 2022). In this project, the experiences created with HoloLens 2 were called "a real Mixed-Reality experience" (ibid p. 758). The RESCUER project was designed to enhance the capability to locate individuals in smoky environments, while the FASTER project focused on identifying points of interest on maps and employing HoloLens in the real world. These aforementioned applications developed for first responders were meant to be used in the response phase of crises. Notwithstanding, the learning experience was not the main focus of these studies. The authors simply noted that the HoloLens applications required some initial practice by the majority of participants, due to the participants lack of prior experience with the developed technology (Christaki et al., 2022).

To successfully integrate any new technology into educational settings, three critical dimensions must be considered: the technology, the pedagogical approach, and the learning content (Kurt, 2019). Firefighters use simulation-based training extensively (Polikarpus et al., 2021), and the trainer's role of choosing a suitable pedagogical approach for virtual simulation-based training has been highlighted (Keskitalo, 2022; Polikarpus, Luik, et al., 2023). If trainers are unable to operate the technology and have not acquired the necessary vocabulary for instructing trainees, they might experience difficulties in conducting situated learning (Herrington & Oliver, 1995). Furthermore, "hologram technology differs from augmented reality in several aspects, as the way in which the three-dimensional images are created and the properties of the images itself (Elmahal et al., 2020)". Even if the use of holography in education has a positive trend in last five years, the studies are limited to small age groups, subjects, and the technological support needed to achieve learning outcomes are still unclear (Yoo et al., 2022).

Therefore, it is important for the ISCRAM community and the trainers of first responders to further study using new technologies during training so that they could be more effectively used to prepare for future crises. Preparedness activities, primarily training and public education within pre-disaster hazard management, are crucial for enhancing survival during disasters when effectively implemented (Bullock et al., 2013). Processes like preparing, teaching, simulating, and training are essential for an efficient transfer from the post-disaster phase to the pre-disaster phase in the crises management cycle (Aligne & Mattioli, 2011).

This paper is organized as follows: initially, we present the related work on using AR in education and describe hologram characteristics. After this, we present the holograms used in the FightARs project in four case studies. the ensuing section, we explore the integration of HoloLens 2 hologram types with different phases of crisis management, suggesting the appropriate hologram for each crisis management phase.

RELATED WORK

Mitigation, preparedness, response and recovery are seen as the four classical phases of disaster management (Bullock et al., 2013). To emphasize the significance of context, the initial two phases have been combined into a single phase, resulting in three phases (see Figure 1): pre-disaster, response, and post-disaster (Aligne & Mattioli, 2011). To the best of our knowledge, the potential of firefighters using AR has so far been focusing on the response phase of crises (Christaki et al., 2022; Gkika et al., 2023), as this is where it has the biggest potential to save lives by improving the situation awareness of first responders. Nevertheless, the training needs of the users of AR were not studied.

In education, three-dimensional (3D) learning environments are used as it gives a possibility to view a given problem from different perspectives and include virtual activities that are difficult to practice safely in real life (Reisoğlu et al., 2017). Virtual reality (VR) is the use of computer-based simulation enabling a user to interact with a 3D synthetic environment which often simulates a real world or imaginary scenario (He & Zhu, 2022). VR offers possibilities of making trainings both safer as well as repeatable when compared to other methods that have proven to be expensive or pose considerable risks to firefighters (Heldal & Wijkmark, 2017; Polikarpus et al., 2019). Virtual simulation-based training has been shown to be an effective way to train dynamic decision-making across all levels of crisis management (Lamb et al., 2021) and immersive VR based simulation for training firefighting skills are being developed for simulated fire extinguishing (Wijkmark et al., 2021, 2022). However, a significant limitation of virtual simulation-based training, whether utilizing virtual reality or computer-simulated videos, is that trainees are immersed in a virtual environment rather than interacting with the real world. Consequently, trainees are unable to practice their skills in virtual reality with the same level of practical application as they would in real-life scenarios.

AR mainly consists of the real world and is supplemented by virtual images generated by a computer, (Ma & Choi, 2007) and it has not gained widespread adoption in firefighter training programs (Hofmann & Polikarpus, 2022). A *hologram* is a special type of 3D object which can be seen with the eye and there are various types of hologram technologies (Elmahal et al., 2020). Yoo et al. (2020) propose that contemporary applications of

holography in educational settings could be categorized into three distinct types: (a) pseudo-holograms, (b) analog holograms, and (c) digital holograms and they attributed all AR and VR device-assisted holograms into digital holograms. Işik, (2014) introduces the concept of "dimensional holograms," defining a 1D hologram as a linear recording along one of the x, y, or z axes. Conversely, a 3D hologram is described as a luminous, transparent, three-dimensional image that is visible from all viewpoints and can be physically circumnavigated. Consequently, all studied holograms in this paper are 2D or 3D digital holograms produced with augmented reality glasses Hololens 2. Furthermore, holograms generated by the HoloLens 2 invariably contain data along the x, y, and z axes. As a result, merely distinguishing between 2D and 3D holograms does not provide software developers with sufficient information to accurately classify the type of hologram.

Holographic-type communication (HTC) will facilitate the transmission and interaction with holographic data across a network from remote locations (Clemm et al., 2020). HoloLens 2 already enables HTC when the “Dynamics 365 Remote Assist” app is used (Microsoft, 2024). For HTC, it is crucial to understand the specific characteristics that the transmitted holograms should possess. During the study of the FightARs application, the digital twin served as an object that allowed firefighters to interact with it virtually (The Fightars Partnership, 2021), whereas the scientific definition of a digital twin is that it “is a virtual representation of a physical object or process capable of collecting information from the real environment to represent, validate and simulate the physical twin’s present and future behaviour (Botín-Sanabria et al., 2022, p. 1)”.

Prior research did not give any suggestions on which hologram characteristics help to train firefighters knowledge and skills using HoloLens 2. Consequently, end-users of HoloLens 2, such as firefighters and trainers of first responders, lack the ability to specify to developers the types of holograms required for future training sessions, assessments, or the response phase to improve knowledge and skills in crisis management.

HOLOGRAM CHARACTERISTICS AND DATA COLLECTION

The FightARs project aimed to introduce a new AR device HoloLens 2 to the training of firefighters and rescue incident commanders (FightARs, 2022). We aim to answer the following research question: “**what type of holograms supports firefighters' knowledge and skills' training in which crisis management phase?** We categorized the holograms used in the FightARs' application based on three characteristics: *dimension* (2D or 3D), *scalability and interactivity* (see Figure 1 and Table 1). In our case study we linked HoloLens 2 hologram characteristics and firefighters' preparedness to use AR in the crisis management cycle taking account the current technological level in firefighters' training in Estonia.

For our case study, we used the results from four different empirical studies. All the HoloLens 2 holograms presented in this paper have been tested with success by 30 in-service first responders in fire stations in Estonia by students (Guž, 2023; Liping, 2023; Pärnamets, 2023; Rasva, 2023). The aims of the bachelor theses, FightARs testing methodology as well as the results are published online in the Estonian language (Polikarpus et al., 2023). In our case study we first look at the dimensions of holograms, we then analyse whether the holograms are scalable or not and thirdly, we considered whether the trainee could interact with the hologram or not (see Figure 1).

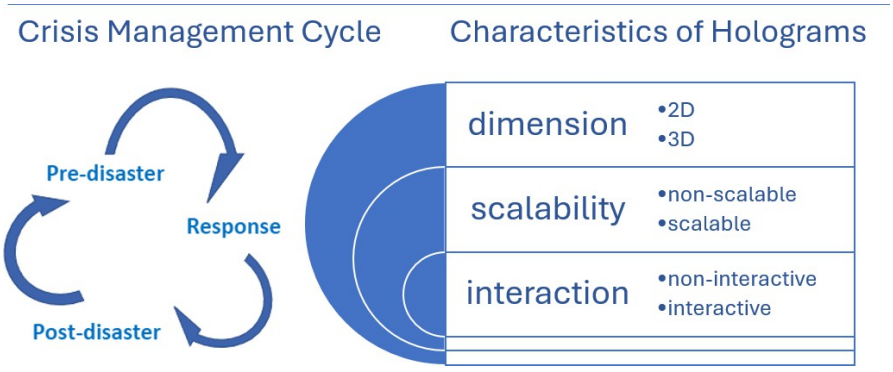

Figure 1. The characteristics of holograms and the crisis management cycle

AUGMENTED REALITY APPLICATION DESIGNED TO TRAIN FIREFIGHTERS: HOLOGRAM TYPES IN FIGHTARS

The FightARs application was developed within the FightARs project. HoloLens 2 augmented reality glasses

were used (Figure 2), where the holograms were tested and integrated in addition to which educational materials were also created. The topics of educational materials covered: first aid, situation awareness, UN marking of dangerous goods and deactivation of an electric car. The FightARs application and its code, QR-codes, voice commands' guide, pedagogical guidelines and FightARs best practice guide can be downloaded from the project homepage (http://fight-ar.com/) free of charge.

Figure 2. HoloLens 2 augmented reality classes and their use (Photo by Stella Polikarpus)

The application was connected to a learning management system (LMS) (Figure 3). Figure 3 shows the connection of 2D (the blue menu on the left) and 3D holograms (see in the centre of the figure). The project homepage and LMS are published on a WordPress web-based platform. 2D holograms were linked to the LMS specific pages in the FightARs course (an example can be seen in Figure 3 on the right). Connecting the AR application with a web-platform through 2D holograms meant that the learning materials could be automatically updated.

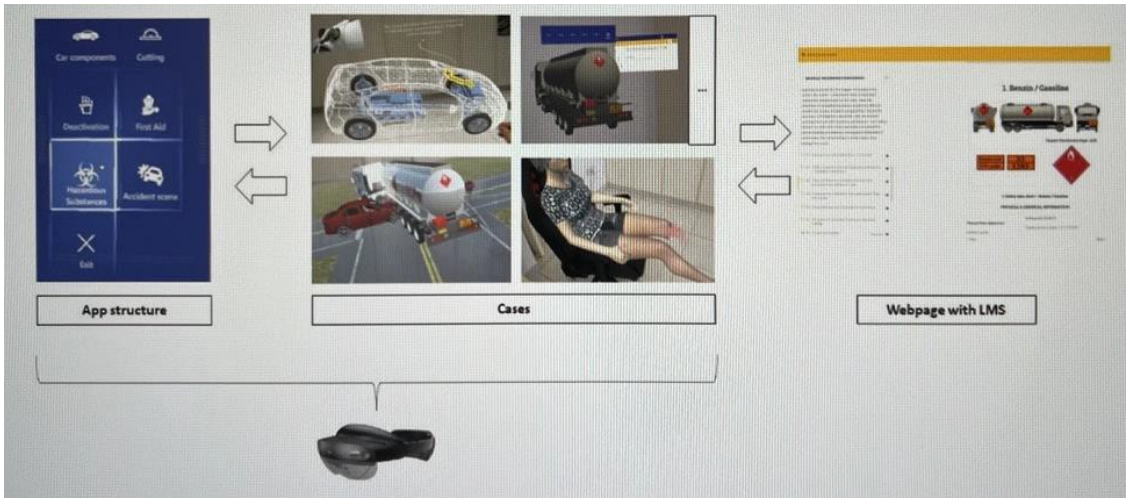

Figure 3. FightARs application connection to holograms and LMS (FightARs Partners 2023)

If the FightARs application is installed in HoloLens 2, the app icon could be found on the menu list (see Figure 4). In the first picture on the left we have illustrated the main menu of HoloLens 2. The right picture is the 3D hologram that pops up when FightARs application is “clicked” on in the main menu. The user needs to push the play button (Figure. 4 right) to open the 2D main menu of the FightARs application (Figure 5.).

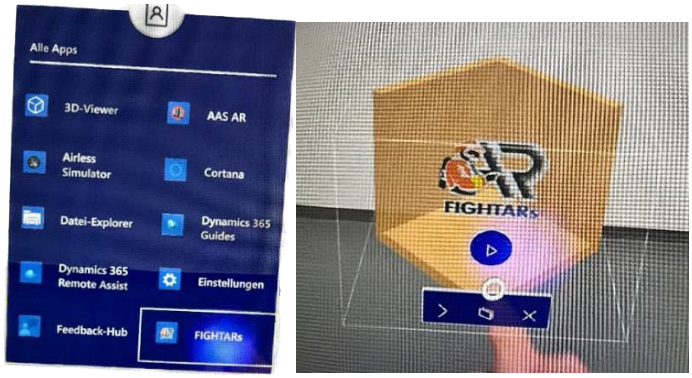

Figure 4. FightARs application icon in HoloLens 2 menu (FightARs Partners 2023)

The FightARs application menu gives access to all learning content and holograms created in the project. To access these designated sections, referred to as 'chapters,' users were required to select them from the main menu of the FightARs application (see Figure 5).

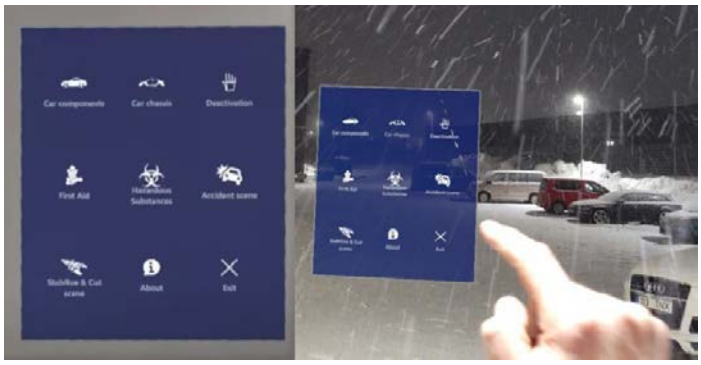

Figure 5. FightARs application menu (FightARs Partners 2023 and Liping, 2023)

First, we looked at the *dimensions of holograms*. In this paper, 2D holograms are holograms where the menu of the AR glasses is opened to move around in the application (e.g. Figure 5). Secondly, we identified if it is a *scalable hologram*, which implies that the user has the capability to independently modify the x, y, or z axis, or alternatively, adjust all axes simultaneously while maintaining consistent proportions (see the two upper photos from the case studies in Figure 3). If it is a non-scalable hologram, the user might be able to decide where in the physical room he/she wants the hologram to appear, but the user cannot reduce or increase its size (see the two lower photos indicating a woman and a collided truck in Figure 3).

The third important characteristic of a hologram is whether the user can interact with it or not. By *interaction*, we consider a hologram that the trainee can “click” on or in the future type something into the hologram and then the application checks the accuracy of the answer. Not every interaction with a hologram constitutes a digital twin, as the hologram may not simulate a real-life process. Instead, it could be designed to assess the correct sequence of the activities of the trainee (e.g. interaction in the form of a 2D hologram such as quizzes created using H5P). In FightARs two interactive holograms were used: car cutting and electrical car deactivation. These interactive 3D holograms were programmed inside the application to be responsive to the actions of the trainees and therefore can also be called digital twins. An overview of the dimensions, scalability, and interactivity of the FightAR's holograms and use cases are provided in Table 1.

Table 1. FightARs' hologram types, characteristics and use cases

Hologram types in FightARs	Dimen-sion	Scalable / non-scalable	Interactive / non-interactive	Description of use cases

2D hologram	2D	LMS window is scalable	Non-interactive or interactive e.g. H5P content	Used in the app to open LMS or application menus
3D non-interactive hologram	3D	Scalable	Non-interactive	Used to review firefighters' knowledge about UN hazard marking on a digital twin truck (Guž, 2023)
QR-code scan for 3D hologram	3D	Non-scalable	Non-interactive	Used to train triage of digital twin victims and first aid (Pärnamets, 2023)
Holographic scene	3D	Non-scalable	Non-interactive	Used to measure incident commanders' situation awareness with quantitative analyses of situation awareness on a digital twin accident site (Liping, 2023)
3D interactive hologram	3D	Scalable	Interactive	Used to train firefighters to respond to traffic accidents with digital twin electrical car (Rasva, 2023)

Non-Interactive Scalable Holograms

2D holograms linked to LMS in the FightARs app gave some freedom to trainers to tell a new story or give a new task with the same 3D hologram. This approach significantly enhances the efficiency of updating educational content, as it primarily involves modifications to the webpage, thereby reducing the necessity for extensive programming efforts. The only issue with this type of holograms is that HoloLens 2 needs to be connected to Wi-Fi, the connection must be stable, and the trainee must log onto the LMS. These 2D holograms could not be scaled, but they moved and some of them could be pinned in the air to fix their location in the physical room. As opposed to this, the windows of the LMS could be scaled. Rasva (2023, p. 33) notes that using the HoloLens 2 induced fatigue among users, suggesting that tasks typically performed on a LMS are more suitably executed on a flat screen device rather than reading lengthy text via 2D holograms associated with the LMS.

3D non-interactive scalable holograms were used to train firefighters' knowledge about the parts of an electrical car (see Figure 6) and for identifying the markings of trucks carrying hazardous material (see Figure 7).

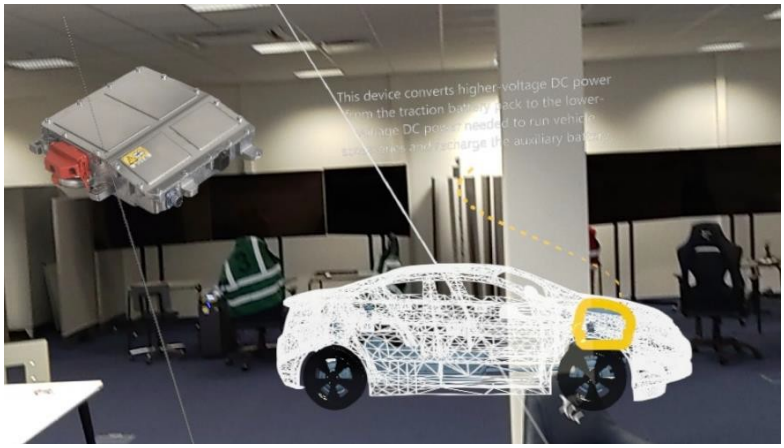

Figure 6. 3D digital twin scalable but non-interactive part of an electrical car

These holograms could be positioned, relocated, rotated anywhere within the room, and scaled to the authentic dimensions of a truck or passenger car. They were used to either gain new knowledge (Rasva, 2023) or review and assess existing knowledge and misconceptions trainees might have had (Guž, 2023).

Figure 7. 3D non-interactive hologram that can be scaled and moved (FightARs Partners 2023)

Non-Scalable Real-Size Holograms and QR-Code Scanning

QR-code scan to open 3D non-interactive hologram allowed to connect specific victim holograms to the physical training environment. In the study a variety of learning scenarios was created to train firefighters' and rescue incident commanders' first aid skills (Pärnamets, 2023). These holograms can be superimposed on dummies, allowing for the practical training of CPR skills, which is why they are non-scalable. These 5 holograms opened with 5 different QR-codes could be used simultaneously and create an accident with multiple casualties (see Figure 8). All these holograms were non-interactive holograms. However, web-based 2D LMS window was opened together with the hologram and their videos, H5P content or something else could be added for interactivity. It was interesting to open the hologram victim by scanning the QR-code in real life. After this, the scanning mode was kept active because sometimes the hologram could be moved in the physical room by moving the paper with the QR-code. If several holograms were opened at the same time, it was sometimes not possible for HoloLens 2 to process the situation well, after which the application crashed.

Figure 8. QR-code scan to open non-interactive 3D holograms. There are three victim holograms on the photo and above two victims head is LMS 2D hologram opened (FightARs Partners 2023)

Holographic scene (see Figure 9) is a term taken into use to describe non-interactive and non-scalable almost real-life sized 3D hologram that is a digital copy for the whole traffic accident scene (Liping, 2023). Navigation within a virtual reality environment is facilitated through the use of input devices such as joysticks, keyboards, gamepads, or other similar tools. Therefore, information collection from the VR scene for attaining situation awareness is different than in real life. To the contrary, a holographic scene allows to gather information similarly as in real life, through walking and getting new information. A holographic scene hologram can be overlayed with

real cars and then practical skills of cutting the car can be practiced. In Figure 9, (see the left picture) the holographic scene is opened in a mat room indoors and in the right picture (see Figure 9) it is opened outside, where the holographic red car with holographic victims is overlaying a real-life red car.

Figure 9. Holographic scene is 3-D is almost real-life size hologram (FightARs Partners 2023)

Interactive Scalable Holograms

A 3D interactive and scalable hologram is the most difficult digital twin type of hologram to program (see Figure 10). However, when this type of hologram is overlayed with real life objects, very interesting mixed-reality experiences can be created for users. In the application FightARs there are two types of this hologram, one is to deactivate an electrical car (upper picture in Figure 10) and the other is to select correct tools to rescue a victim from the passenger car (see the picture below in Figure 10). To use HoloLens 2 and interact with the holograms, trainees needed prior training on how to use HoloLens 2 (Rasva, 2023). Another issue emerging from that study is connected to language. Namely, when translating content in the LMS into all languages is rather easy, then creating the whole HoloLens 2 application in different languages is rather time consuming as it needs to be programmed in different languages and afterwards reinstalled.

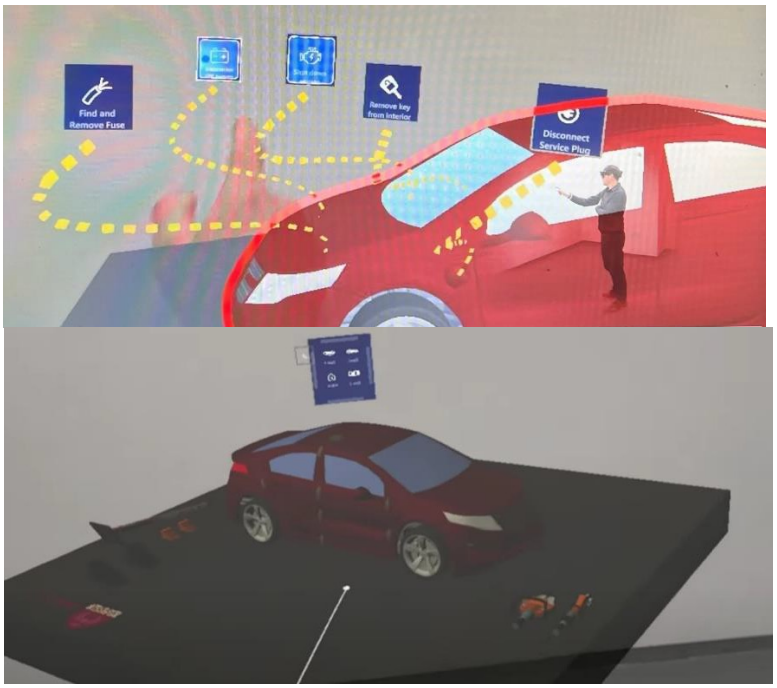

Figure 10. A 3D interactive and scalable hologram as a digital twin model created to interact with the actions of trainees (FightARs Partners 2023)

POTENTIAL USE OF AR IN CRISES MANAGEMENT TRAINING

We suggest that AR firstly needs to be taken into use during the pre-disaster phase. When firefighters and rescue incident commanders are accustomed to train with the AR application, they will have acquired practical skills to use HoloLens 2 like scaling and turning the holograms. If better internet connection were to be integrated into

incident response vehicles, we believe that AR devices could be used in the response phase in the future as well. For example, we believe that communication efficiency could be enhanced with HoloLens 2. A commercialised product Dynamics 365 Remote Assist was tested during the FightARs project and was found to be useful to show others on the screen what the person wearing HoloLens 2 is seeing (see Figure 11).

Needless to say, the utilization of this tool necessitates the acquisition of a licensed program. Nevertheless, we see a big potential for AR and HTC in the response phase of crises, because the "caller" can have their hands free for emergency actions and the "adviser" can see the same visual as the caller. Simultaneously, the advisor is visible for the caller as a 2D hologram and clear audio is heard from the AR-glasses. In addition to this, calls from AR-glasses to AR-glasses are an option.

Figure 11. A trainee using HoloLens 2 vision is seen on screen in class through the Dynamics 365 Remote Assist software. HoloLens 2 could also be connected to screens using mirroring functions.

Post-disaster phase is about learning from real incidents. In the post-disaster phase, feedback from experiences is analyzed to improve the anticipation and forecasting of potential issues, identify risks, and revise established procedures (Aligne & Mattioli, 2011). Naturally, if AR is employed during the response phase, its usage should extend to the post-disaster phase, or at a minimum, experiences from its application should be gathered and the employed procedures, ethics, and equipment critically analyzed. In Table 2 we have brought together the crises management phases and studied hologram types.

Table 2. The connection of FightARs hologram types to crises management phases

Hologram types in FightARs	Phase	Examples	Knowledge and Skills
2D hologram	All 3 phases	Video calls, representation of sensor data, resource allocation, AI decision suggestions, recordings, photos, LMS and H5P in it, guides in pdf files etc.	Standard operational procedures or details of an equipment, or any other text or 2D visual information.
3D non-interactive hologram	In pre-disaster and response phases	Examples Figure 6 and 7. In response phase points of interests (POI) could be marked (Christaki et al., 2022).	To enhance knowledge of firefighters with 3D objects when composition of the object needs to be well understood or POIs marked in learning environment.
QR-code scan for 3D hologram	In pre-disaster and response phases	Example Figure 8. In response phase POIs could be marked (Christaki et al., 2022) using QR-codes and then information could be updated and read from the web.	To create any practical skills training scenario in training ground or to guide self-directed learning
Holographic scene	In pre-disaster phase	Example Figure 9.	Same as above, plus dynamic decision-making training
3D interactive hologram	In pre-disaster phase	Example Figure 10. digital twin.	Better to use VR or LMS, because skill to use HoloLens is need.

DISCUSSION AND FUTURE RESEARCH

AR has the potential to improve situation awareness and through that dynamic the decision-making of first

responders (Christaki et al., 2022) and firefighters while smoke-diving (Gkika et al., 2023). However, to train staff to execute safe actions during incidents, the implementation of new technologies should start from the pre-disaster phase. We analysed AR digital holograms in the training of first responders. We wanted to find out what type of holograms support firefighters' knowledge and skills training in which crisis management phase. For this reason, we analysed three hologram characteristics: dimension, scalability and interactivity in the application FightARs.

In Figure 12 we present the hierarchy of these digital holograms. 3D non-interactive scalable holograms or 3D non-scalable real-size holograms like a holographic scene seem to be the best option to train practical skills, because they can be overlayed with physical objects, or the physical environment can be enriched with holograms using QR-codes. Besides training practical skills like cutting a car or sealing a leak, a holographic scene is a good way to train situation awareness and dynamic decision-making. However, programming these 3D models for AR is rather time consuming compared to VR. 3D interactive scalable holograms or digital twins are the hardest to program and to use. To use these holograms, trainees and trainers first need to learn the skill to use HoloLens 2, they need to get used to the specific movements required for each corresponding action and related processes. These practical skills should be learned by first responders during the pre-disaster phase only if AR technologies will be used in the response phase in the future. Otherwise, it merely consumes valuable training time.

We know from the FightARs project that HoloLens 2 offers a possibility to make video calls (Figure 11), record videos, take photos, scan or place holograms etc. All these new functionalities should be further tested in order to find out how they can support situation awareness and dynamic decision-making and other practical skills training for firefighters. If HoloLens 2 were to be combined with a powerful laptop and great Wi-Fi connection, we could even use AI to help make predictions from sensor data collected by robots or firefighters about gas-cloud movements or fire spread. AR devices in combination with other technologies have great potential in all crises management phases.

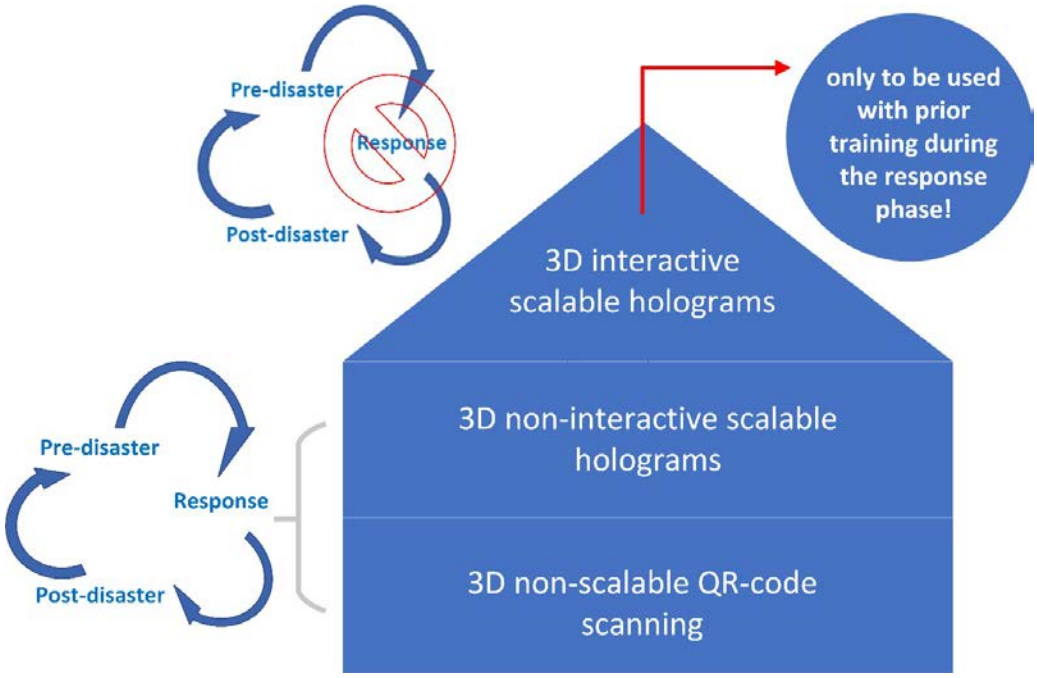

Figure 12. The hierarchy of holograms and crises management cycles

In this article we focused on the ability of HoloLens 2 to produce different holograms. From the experience of implementing VR in first responders' training, we claim that AR will be quickly implemented into firefighters' training if trainers can create 3D non-interactive scalable or non-scalable holograms themselves with the help of VR. VR has been used to train firefighters for a long time, therefore these 3D models already exist in VR. In VR, these models can be combined into holographic scenes and training scenarios (Polikarpus et al., 2021). If the scene or even scenario could be imported into HoloLens 2, it could enhance the research and training of situation

awareness to be more authentic and accessible. We could also train firefighters' practical skills when holograms are overlayed with reusable physical simulators that allow for example the use of hydraulic tools. Simultaneously, a virtual layer might allow interactions and information presentation that is not possible in the physical world.

We are a bit more hesitant about the need to develop interactive holograms by trainers themselves for AR as movements to interact with these holograms require more practical training on how to use HoloLens 2. Additionally, we are not sure if this practical skill of using AR is later needed in the response phase. Earlier research has stated that HoloLens 2 applications required some practice, especially by the majority of participants who had no prior experience with holographic displays (Christaki et al., 2022). We found out that problems with using AR solely appeared when interactive holograms were used, or if the trainee had to scale the hologram him/herself. A holographic scene and QR-code scan to open non-interactive holograms did not require any special skills from the trainee and therefore could these hologram types be more easily integrated into training and the response phase of crises. During the response phase, everything is time critical and has to work flawlessly. Therefore, if AR were to be used in the response phase, then all these types of holograms should be used in the pre-disaster phase in order to train the needed AR practical skills. In addition to using AR in training, the technology needs to be developed to be weatherproof, and not cause explosions or any other hazard for anyone.

Limitations

There are some limitations in our typology of holograms. The term interactivity can be misleading, as clicking on the menu does instigate a new hologram or menu, but we named these 2D holograms as non-interactive. Throughout the testing phase conducted in fire stations it was observed that the holographic scene, which is designed to be non-scalable and of authentic size, encountered spatial constraints within indoor environments. Consequently, its application was occasionally extended to outdoor settings. However, it is pertinent to note that the HoloLens technology is not inherently designed for outdoor operation. Also, the holographic scene had 15 possible holograms and in one case, there was a leak under the truck and in another case the smoke to make the scene more dynamic. Our typology did not discuss whether holograms had moving parts in 3D models. In other studies, they have been differentiated as dynamic and static holograms (Polikarpus, Terep, et al., 2023).

CONCLUSION

The study investigated what type of holograms support firefighters' knowledge and skills training in which crisis management phase. We propose that 3D non-interactive scalable or non-scalable holograms should be used to exercise practical firefighting skills. Mixed-reality experiences and holographic scenes should be created in VR by trainers themselves in future AR applications. The technology should enable being exported from VR and imported to AR to give firefighters and incident commanders a rather cheap, repeatable, and comparable way to train their situation awareness, dynamic decision-making, and other practical skills.

It is important to remember that any new technology used by first responders should improve their situational awareness and dynamic decision-making and end-users should have training and vocabulary to use and develop it. The technology ought to be flawless, easy to use and before being integrated into the response phase of crises, it first needs to be tested and used extensively in the pre-disaster phase during the training of first responders. This foundational integration in training contexts is essential for ensuring an effective utilization in future emergency situations and post-disaster analyses.

ACKNOWLEDGMENTS

We thank all members of the FightARs project and the students who conducted their final papers to test the application in firefighters' authentic training environments. Your contributions were essential for the completion of the project.

ABSTRACT

Cash-based assistance (CBA) programs have become an increasingly common approach as one modality for the provision of humanitarian aid. The use of disruptive and digital technologies (such as mobile money, electronic vouchers) has provided benefits to implementation of such programs in terms of for instance, cost effectiveness, timeliness, coverage, safety, and financial inclusion. Despite the benefits, the digitalization of such programs is very context-dependent, including the needs and characteristics of affected populations as end recipients of the assistance. This research is aimed to investigate the contextual characteristics toward digital transformation addressing the end user's experience. The series of interviews is conducted from humanitarian practitioners based in Uganda. The findings are yet to be analyzed, but some initial findings are discussed, and future research is addressed in the conclusion.

Keywords

Cash-based assistance, digital transition, adoption behavior, refugee camps, aid recipients.

INTRODUCTION

The global crisis is rapidly changing and growing with the lethal mix of conflict (e.g., Sudan, Gaza, Ukraine, Syria), COVID-19 pandemic, food insecurity, and climate emergency. The number of forcibly displaced people due to such crises has continued to increase from 82.4 million in 2020 to more than 103 million, of which 32,5 million refugees, by the end of 2022 (UNHCR, 2023). According to the EU, more than 35% of the humanitarian assistance reaches refugees in the form of cash-based assistance (CBA) (e.g., via different delivery mechanism such as physical cash, mobile money, debit card) (ECHO, 2021) and to a larger scale of cash programs above 10 million euro (DG-ECHO, 2024) . DG-ECHO emphasizes the links between cash and the secure and efficient use of digital tools. The EU promotes cash operations, which build on technological advances and innovations and use technology to strengthen interoperability and link to longer-term solutions. EU humanitarian aid prefers digital solutions such as electronic cash transfers and digital identities. Despite tremendous upward trend toward delivery of CBA programs, the effectiveness and cost-efficiency of CBA implementation is highly dependent on the contextual factors such as the financial and technological infrastructure, regulatory framework, together with market, economic conditions of the host countries, and more importantly the contextual characteristics of a id recipients (Heaslip et al., 2018b; Kian et al., 2022; Piotrowicz, 2018; Wilson et al., 2018).

WiP Paper – Information Systems in Humanitarian Operations
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

Humanitarian organizations (HOs) have been increasingly using digital technologies along the cash operations cycle from needs assessment to the cash transfers via different delivery mechanism such as mobile money, bank accounts or smart card (Jodar, 2021). Digitalization has been implemented and adapted in different ways and contexts with a typical aim of improving access to humanitarian a id. For instance, in Sudan, there has been a shift from emergency food assistance to digital cash transfers. In India, the public distribution system is intervened through digital transformation since 2010, and while in the UK, welfare has been digital since 2012 and from 2016, the humanitarian assistance for asylum seekers is provided through biometrics and debit cards (Jaspars & Sathyamala, 2021). Although using technology for humanitarian CBA is nothing new, the phenomena are relatively emerging, at least in academic literature. In this context, "digital CBA" refers to the "transfer of money from the implementing organization or its delegates to program beneficiaries via electronic means (e.g., mobile, card, or account). That indicates both the financial service provider (FSP) and beneficiary use an electronic medium of transfers (CaLP, 2013).

While aid recipients at the downstream supply chain are at the center of decision -making process, their characteristics must be properly determined to ensure the principle of "do no digital harm" is upheld (Burton, 2020). Digitalized CBA programs are receiving significant attention from scholars, while the need and role of a id recipients as a critical stakeholder in the humanitarian aid setting is understudied. Unlike CBA program, the success of digitalized CBA depends highly on the aid recipient's choice, inclusion, divide and so many others (IOM, 2020; Patil et al., 2020). For instance, factors like digital literacy of the beneficiary, phone ownership, access to internet, ability to use internet, having digital ID, can be detrimental for the success of digitalization of CBA in the humanitarian contexts (Mitchell et al., 2019). One of the main criticisms against such an approach is that it is often exclusionary (includes only those who can use digital technology) and goes against the ethos of humanitarian activities (Burton, 2020) . Specifically, such digital transition is extremely challenging in the response to refugees in disaster-prone areas such as Uganda, Congo, or Sudan. Among those, some studies have found non-significant relationship however, as consumers consider ease of using mobile as unimportant (Aslam et al., 2017). In other cases, aid recipients with long queuing times with mobile service providers have made their complaints over the cash receipt services, and thus perceived the complexity and extra efforts needed for such digital services in Ethiopia (Murray, 2016). Despite, large number of populations receiving CBA through all means of digital, the digital transition varies from country to country particularly in the context of Africa (Burton, 2020; Maghsoudi, Harpring, Piotrowicz, & Kedziora, 2023).

In this study, we aim to investigate and assess the contextual factors that are significant for the success of digitalization of CBA from a beneficiary's or aid recipients' perspective. We rely in interviews conducted in refugee camps in Uganda, minutes of meeting, and several published literatures and reports available in the public domain to build the framework which places beneficiaries at the core of digitalized CBA programs. The results are under work-in-progress.

BACKGROUND

This section includes the summary of findings obtained based on the literature review. Overall, implementing the digital cash-based assistance program in the humanitarian aid sector is complicated and challenged by many factors and surrounding circumstances, including beneficiaries, the country hosting the refugees, the local community, the type and objectives of the assistance, and the partners involved directly or indirectly. The study and the findings are adapted the TELOS framework for assessing the fea sibility of digital CBA programs by focusing on the societal aspects. In this section, we found that the contextual factors of digital CBA are in line with the TELOS framework from a broader perspective. TELOS framework refers to five areas of feasibility criteria (i.e., Technical, Economic, Legal, Operational, Societal). TELOS framework helps researchers to determine an optimal solution to evaluating the level of risks, costs, and benefits of alternatives/options based on several feasibility areas (Drljaca & Latinovic, 2018). The TELOS feasibility model assesses the potential for implementation of a new technology. This framework is used in many fields, e.g., engineering and technology, and has also been applied to medicine (Segawa & Muzinda, 2021). After reviewing HO re ports, and recommendations from digital CBA programs, and aligning the reports' output with TELOS framework, we provide a conceptual evaluation framework including the societal factors obtained from the findings. The finding is synthesized in this section to provide and grasp an overview of factors to consider for the design and implementation of digital CBA in the refugee context.

Numerous factors associated with digital CBA have been reported. However, the context-related factors cannot be comprehended at one point in time since these factors vary based on each case. Such contextual factors are associated with the implementation context's general conditions, such as infrastructures, host country's regulations, technology level, and availability at the program place (Abdelgawad et al., 2023; Juntunen et al., 2023; Maghsoudi, Harpring, Piotrowicz, & Heaslip, 2023; Maghsoudi, Harpring, Piotrowicz, & Kedziora, 2023).

The other association is with program-specific related conditions such, as the specific operational requirements (banking or financial systems and regulations, specific vendors, digital financial service providers, agents networks), besides related societa l factors such as financial literacy, digital literacy, and gender inclusion (Burton, 2020; Heaslip et al., 2018; Tappis & Doocy, 2018).

There are many societal and behavioral issues associated with digital cash assistance, based on what humanitarian organizations have reported. Societal factors can be described as the society and beneficiaries' willingness and acceptance of technology (UNHCR, 2020). These experiences revealed topics such as the long-term socio-economic impact (e.g., beneficiaries' preference, technology acceptance, financial inclusion of digital cash assistance, mobile phone ownership, discrimination in delivering digital cash-based assistance, local community language issues) as well as the responsiveness of digital cash mechanism to the beneficiaries' complaints (CWG, 2020). In addition to the target beneficiaries, some issues are closely associated with the program target beneficiaries (e.g., mobile ownership, SIM card, IDs, and costs of mobile and internet service) (Abdelgawad et al., 2023; Maciej Serda et al., 2020). Furthermore, there are some emerging issues (e.g., beneficiaries' preferences, ease of use, complaint channels, and local language barriers) (Maghsoudi et al., 2023; Jontunen et al., 2023). Since the last decade, the digitalization has been implemented and adapted in different ways and contexts with a typical aim of improving access to humanitarian assistance. For instance, in Sudan, there has been a shift from emergency food assistance to digital CBA, through the establishment of a new national cash-based family support program. The use of digital CBA is even accelerated during the pandemic due to the social-distancing measures and its called for the increased digitalization of humanitarian CBA pushing toward more remote programming and digital delivery mechanisms (Lawson-McDowall et al., 2021).

In the same vein, societal factors are crucial in digital cash-based assistance. From a societal perspective, several issues were identified, such as literacy both technological and financial. In refugees setting the illiterate rate, lack of technological skills, besides lack of recognized ID or documents, all are factors that characterize a refugees community or beneficiaries community in emerging economies (Doocy et al., 2011). The significant factors also beneficiaries related such as the cost of having a mobile phone, smart or appropriate phone due to income issues and the small amount of money that refugees received (CWG, 2020). Owning a smartphone is a challenge for refugees in Uganda and other contexts. Other factors that challenge refugees are acceptance and preference, which represents how the program is perceived and accepted by refugees and the ease of use of the program, particularly for illiterate people and people without technology experience, gender inequality is a big issue, especially for women. Women are more vulnerable because a considerable percentage, around 45 percent of women in low-income countries, do not have IDs. Therefore, they cannot apply for any official transaction, open a bank account, or own a SIM Card since they need IDs and proper documents. All the above factors and other sub-factors characterize the implementation of digital CBA.

RESEARCH METHOD

The research method is qualitative in nature using interviews conducted with humanitarian practitioners based in Uganda. This first round of analysis focuses on interviews conducted with humanitarian organizations (INGOs, UN agencies) responding to the refugee crisis in Uganda. The responded organizations were part of local cash working groups in Uganda covering 14 refugee camps in different locations across the country, and the data collection and interview process was led by one of the project partners loca lly based in Uganda in 2022. Reference group members also assisted the project partners for the data collection process. The interviewees are selected with purposeful sample selection based on their experience in CBA program, availability and accessibility given their contribution in terms of CBA in response to the refugee crisis in Uganda providing different assistance from food, to health, protection and sanitation support. The organizations are included international NGOs, UN agencies, and those with representatives at the local field level with the direct link serving beneficiaries or through their local implementing partners. The interviewee positions are varied from head of CBA program, to community service officer, team leaders, project coordinator and market officer given the extensive knowledge of CBA programs implementation. Most of the interviewees are from top to mid-level manger.

Uganda Case

Uganda was selected for the purpose of study as one-fifth of its population are is still estimated to live under the national poverty line. The backbone of the economy is the agriculture sector with primarily smallholder farmers. Access to productive land varies significantly on the prevalent land tenure system, the country's rapidly growing population is putting pressure on land resources, and the allocation of land to refugees becoming m ore difficult. With over 1.5 million registered refugees, Uganda is the third-largest hosting country in the world (and the largest in Africa)(UNHCR, 2021).

Cash-based assistance in Uganda has a long history. Since 2019, the number of refugees has stayed around 3

million, with occasional increases. Since 2019, nearly 40% of cash transfers have taken place through either mobile money (31.1%) or through bank accounts (9.8%). Other modalities, i.e., pre-paid cards, e-vouchers, and paper cards make just about 1% of the total cash transfer value. Another major observation from Uganda is essentially the nature of cash-based interventions and their modality. About 80% and 61% of cash -based interventions were used for food security in the years 2021 and 2022 (till June) respectively. Almost the entire cash intervention for food security is being handled through the World Food Programme (WFP).

This has been observed by the Uganda Cash Consortium (UCC), a consortium of international NGOs operating out of Uganda, and have made a three-year plan for developing a Multipurpose cash assistance (MPCT) program to make CBA a more inclusive mechanism for a wide variety of assistance programs. UCC identifies that for the successful working of MPCT, they need to focus on a program agenda that includes financial literacy training for beneficiaries, linking long-term livelihood assistance programs with CBA and promoting digital payments, and increasing digital cash transfers. The first phase of MPCT concluded in July 2022 and the second phase is currently underway. Phase 2 focuses on targeting the beneficiaries and linking their needs with the CBA. To this end, UCC focuses on three vulnerability categories, i.e., protection-specific vulnerability, economic-specific vulnerability, and sector-specific vulnerability.

However, it is important to note that, there are certain structural challenges to operationalizing CBA in Uganda in the current form. One most critical challenge are the stark difference in the choice of modality between the financial service providers (FSP) and the beneficiaries. While FSPs overwhelmingly prefer digital transactions, beneficiaries prefer hard cash. This is evidenced by the fact that more than six billion UGX has been transferred through banking institutions in 2019-2020 while less than one billion UGX has been transferred through mobile network operators and microfinance institutions during this period. On the other hand, only 4% of the beneficiaries prefer transfers through banks and the majority (70%) prefer it through mobile money. Some of the arguments form beneficiaries for this preference include ease of access and lack of transport required for beneficiaries, the presence of agents inside the settlement means beneficiaries do not have to travel far from their homes to open accounts and make withdrawals. Hence, beneficiaries see mobile money as more inclusive for people who have trouble traveling long distances, such as older persons, pregnant women, or persons with disabilities. Opening a mobile money account was a relatively simple process for beneficiaries to understand the costs associated with opening and maintaining the account were limited and mobile money is confidential and discreet, especially compared to the highly visible distributions of direct or OTC cash (REACH, 2021).

PRELIMINARY FINDINGS FROM INTERVIEWS

A total of 8 interviews were conducted with humanitarian organizations. The interviews were conducted and transcribed and analyzed in NVivo software. The qualitative framework that was presented divided the interview data into four distinct categories of actors, infrastructure, beneficiaries and financial assistance following the TELOS framework features for the societal aspects. The interviews were transcribed and coded. The coding process was started through initial coding (Saldaña, 2013), where the resea rcher familiarises themselves with the data, breaks it down into parts, examines differences and similarities (e.g., between different stakeholders), and makes notes on the data. Initial coding generally produces a set of topics, under which more specific codes can be placed. The 1st order concepts are themes that emerge from the text. In the data structure, they are summarized significantly, as the number of these themes in the original coding is large. They are then organized into 2 nd order concepts according to common denominators. The aggregate dimensions are determined through the research objectives as well as the first two orders in the data structure. The findings from the interviews are organized according to this structure. The analysis section of the findings is work-in-progress.

The roles of actors, infrastructure and environment, and elements of financial assistance are factors that can be analyzed quite effectively through scientific literature, secondary data, and the interviews already conducted. However, arguably the most important stakeholders', the beneficiaries' perspective remains difficult to ascertain. Through the interviews with stakeholders who regularly work with beneficiaries, we were able to establish the most relevant underlying factors that contribute to successful CBA programs by means of digital technologies.

Actors within these programs and the partnerships that they form in order to design, implement, and manage them are central to the success. This was apparent in the workshop, where participants represented HOs and financial institutions. The workshop was conducted to validate the results. The workshop was organized for the stakeholders who participated in the stakeholder interviews conducted in 2022. The workshop was a success as a total of 9 partners from 8 organizations were present. The workshop took place in Uganda and was also streamed online to give, for example, partners in Europe a chance to participate. It was structured so that after a round of introductions. The workshop then proceeded to the discussion, which was divided into four themes: startin g point

for DigCBA, gender disparities, access to services, and cash-based assistance. These themes were derived from the literature as well as the interviews findings. Before giving the floor to the workshop participants, an audience engagement tool Wooclap was used to gather quantitative data and give some background to the discussion. The workshop with the presentations and discussion lasted two and a half hours and was considered useful by both the participants and the organizers Section 2.2 presents the quantitative results of the Wooclap, along with some additional qualitative analysis. The workshop were held about three hours and with a break in between.

The infrastructure and environment ties in closely with the actors and partnerships, as for example the government is responsible for the regulations regarding refugees. This has significant relevance to the integration of refugees into societies, and whether they reside in camps or urban areas. CBA requires specific contextual elements, such as a functioning market where the cash can be used. Therefore, the type of assistance administered needs to be in line with the infrastructure. The most important factors, however remain the preferences and capabilities of the beneficiaries. The issue of financial literacy was raised, not just in regard to the beneficiaries, but aid workers as well working within the CBA field. Financial literacy is a challenging aspect, as refugees often need to deal with multiple currencies and modes of payment. CBA is also done in collaboration with financial institutions, that may have complex rules and regulations they need to follow. In order for aid workers and NGOs to be able to administer financial literacy training, they must themselves be aware of the complexities of financial aid.

Gender disparities within, for example phone ownership as well as digital and financial literacy were raised as well. Particularly factors such as responsible use of money and using the assistance for its intended purpose were credited to women. This is an issue that requires more empirical research and data, so that appropriate programs can be set up. Finally, Uganda has an effective registration system for refugees, and this was raised in conjunction with the discussion of digital and any type of IDs for refugees. This is also an issue between refugees residing in urban areas rather than camps. If they do not have an official refugee status, they may lose the right to some forms of assistance they may be entitled to.

The factors associated with the beneficiaries still need to be more investigated and validated. Therefore, this deliverable focused on the beneficiaries' issues and validated them for confirmability. In this report we validated several factors by measuring them through sub-items: the validated items **(**Financial literacy, Digital literacy, financial inclusion, Gender inclusion, Digital inclusion, Mobile ownerships SIM card ownership/accessibility, Internet connectivity, Affordability to access digital financial service and assistance, Beneficiary preference and acceptance, Ease of use for beneficiaries, Complaint redressal channel). It can be observed that the financial and digital literacy, especially for women is a significant factor that influence the effectiveness of digital cash-based assistance. Another important factor is the availability of services in the vernacular language of the refugees. This means that UIs of the digital cash-based assistance programs need to be reconfigured to match refugee's langua ge preferences. An interesting observation is that the smartphone ownership and phones with internet access is not the top priority. This can be since the internet connectivity is not as efficient as in developed nations and hence, the reliance on internet for cash transfer may not be the best option. Furthermore, smart phones are expensive, and refugees might not be ready to spend so much on a smartphone and prefer feature phones.

Practical Implication

The possibility of overcoming the difficulties of the implementation requirements must be explored according to the local context. Because the priority of "implementation requirements factors" varies according to the context, it is difficult to generalize the extent of implementation possibility based on a single specific experience. Therefore, it is crucial to conduct a thorough assessment of the local context before implementing the digital CBA program. This will help in identifying the specific contextua l factors that need to be addressed and developing strategies to overcome the challenges associated with them. The preliminary findings can help policy makers, government and humanitarian organizations when thinking of digital transition for CBA program in the context of refugee crisis in low-resource setting. However, this is very practical exception case of Uganda as the technology is booming in the region with high application of for instance mobile money in such context.

CONCLUSION

This research aims to investigate on the contextual factors for the execution of digital CBA programs in humanitarian aid contexts. The literature review and initial findings mainly focuses on the beneficiaries' side since the macro factors such as economic factors, legal factors are generally investigated and discussed in many frameworks, models and studies. The factors associated with the beneficiaries still need to be more investigated and validated. Therefore, this study focuses on beneficiaries experience. It can be observed that the financial and digital literacy, especially for women is a significant factor that influence the effectiveness of digital cash -based assistance. Another important factor is the availability of services in the vernacular language of the refugees. This means that the digital cash-based assistance programs need to be reconfigured to match refugee's langua ge

preferences the case country is multilingual and also hosted refugees from different countries. An interesting observation is that smartphone ownership and phones with internet access is not the top priority. This can be since the internet connectivity is not as efficient as in developed nations and hence, the reliance on internet for cash transfer may not be the best option. Furthermore, smart phones are expensive, and refugees might not be ready to spend so much on a smartphone and prefer feature phones.

One of the research limitations of this project that we faced was the data collection. As happens in Uganda, there are challenges with access to HOs and camp representatives. It was still a timely procedure and hectic to conduct interviews. Due to access and connection issues, some interviews have been received late, so they are not part of the analysis in this report. The study relies thus on eight interviews in addition to publicly published reports and academic literature that have been reviewed. Future research is recommended using multi-research method to complement the outcome of this paper. For instance, using a survey based on data from refugees looking into their perception of digitalization of CBA program, or longitudinal study given the specified timeframe can help organizations to view the trend of digitalization, risks, benefits, and refugee perceptions over time. Furthermore, cross-case comparison is recommended to generalize the findings of this study. Possibly, cross-country analysis can further address the differences and similarities of refugee perception given the enabling environment.

ABSTRACT

In recent years, disaster mitigation measures by greening and demolition of vacant houses to prevent large post-earthquake fire spread have been promoted. However, few studies evaluate its effects on reducing property damage and human casualties, especially in vulnerable areas for earthquakes, such as densely built-up wooden residential areas. In this paper, we develop a model to describe the delay of post-earthquake fire spread between neighboring buildings, and incorporate it into the simulation model. Using the integrated model, we evaluate the reduction of the number of burnt-down buildings and human casualties in densely built-up wooden residential areas, and demonstrate the effectiveness of greening and demolition of vacant houses.

Keywords

greening, demolition of vacant houses, fire-spread model, large earthquake, simulation.

INTRODUCTION

Research Background

Greening policies are being promoted around the world, primarily from the perspective of preserving the living environment, with the hope of reducing CO^2 emissions and alleviating the urban heat island effect. Concurrently, with natural disasters increasing in recent years, the function of trees is being evaluated from the perspective of disaster prevention and mitigation (Shin et al., 2014). The role of trees as windbreak forests and tidewater control forests, for example, goes without saying, but trees can also be expected to have an effect in delaying and blocking the spread of fire in urban areas. Based on a field survey of a large fire in the city of Itoigawa on December 22, 2016, Iwasaki (2019) reported that even inside the affected area were hedges with most of the leaves on the surface of the crown still green. He also reported that the houses that were spared from the spread of the fi re were adjacent to trees or empty lots. If it can be shown that greening policies are effective in suppressing the spread of fires, this could serve as an important argument for promoting greening policies in Japan. The research question of this study is validating whether urban greening can be expected to be effective in reducing fire spread damage followed by a large earthquake. Based on this background, “greening” in this paper is defined as the act of planting plants, especially evergreen or deciduous trees which have higher resistance than coniferous trees to prevent fires, between buildings to increase the effectiveness of preventing and delaying the spread of urban fires.

Recently, the problem of empty homes has worsened (Ministry of Land, Infrastructure, Transport and Tourism, 2017). The question of how to use vacant houses as housing stock is an important issue, but leaving deteriorated houses without occupants is a major problem in terms of preventing disasters and crime. Old wooden houses are

considered particularly problematic as elements that increase the risk of collapse and fire spread in the event of a large earthquake.

Because of these issues, efforts to enhance disaster prevention capabilities by greening and demolishing vacant houses are being made in areas such as those that are crowded with wooden housing (hereafter, densely built-up wooden housing areas). A method for quantitatively examining ways of greening and demolishing vacant houses to reduce property damage and human casualties effectively and efficiently in the event of a large earthquake is required.

Related Research

Li and Davidson (2013) extended their urban fire simulation model to include a fire ignition-spread-suppression process by taking into account firefighting activities and evaluated the effectiveness of the fire department's efforts. They also applied this model to a region in California and conducted parametric studies to investigate the key factors that influence fire spread. Khorasani and Garlock (2017) focused on the past 20 large fires following earthquakes from seven different countries, and reviewed the latest literature on post-earthquake fire mitigation techniques, as well as analytical tools for assessing fire ignition and spread. Manzello et al. (2018) suggested that research on large urban fires that occur after earthquakes and how to reduce the loss of buildings from such fires has lagged, and attempted to develop a roadmap for international research needs to reduce the risk of l arge outdoor fires. Manzello et al. (2020) reviewed experiments, models, and simulations related to firebrand generation, lofting, burning, transport, deposition, and material ignition in large-scale outdoor fire spread. They also pointed out that most of the knowledge in Japan that caused serious large-scale outdoor fires is still not available in English literature. Even if the technology or characteristics are unique to Japan, it is of great significance to communicate in English the experience and knowledge cultivated in Japan, which is prone to earthquake disasters. Vitorino et al. (2024) presented a review of the state-of-the-art on previous post-earthquake fire events, its risk estimation, fire ignition models, and probabilistic loss assessment. They also introduced several mitigation strategies that can help reduce or prevent post-earthquake fires.

Large-scale urban fires have occurred not only in Japan but also in various parts of the world, leading to the development of numerous sophisticated fire spread models. However, Japan's unique characteristics, including building structures (degree of fireproofing), open space sizes, road widths, distances between buildings, and the density of vegetation between structures, pose challenges in directly applying these validated models. Additionally, the rarity of large-scale fire outbreaks necessitates estimating parameters for current models based on surveys such as those conducted for the Great Hanshin-Awaji Earthquake (1995). Consequently, while we will be incorporating some well-established models rooted in earlier research, our focus will remain on post-earthquake fires occurring within Japan's distinctive environment.

The Ministry of Construction’s Comprehensive Technology Development Project (Technology Research Center for National Land Development, 1983) proposed a pioneering method of determining the time required for fire spread, the fire-blocking effect of structures, etc., by calculating the amount of radiant heat when a fire spread between two buildings by using a theoretical equation (solid angle projection ratio). Based on this method and the results of surveys of disasters such as the Great Hanshin-Awaji Earthquake, a model (Tokyo Fire Dept. Model 2001) for describing the spread of fire in urban areas more simply has been proposed (Tokyo Fire Department, 2001).

Excellent research on the fire-preventive function of trees during large fires in urban areas has been performed by Saito and Iwakawa (1982) and Iwakawa (1984). Using experiments and a review of the literature, their research has clarified the relationship between tree shape and heat shielding rate, heat shielding ability, ignition/burning conditions, and fire resistance threshold. Also, Saito and Tabata (1991) incorporated Iwakawa’s approach for calculating the shielding rate of trees into a method for calculating radiant heat in the Ministry of Construction’s Comprehensive Technology Development Project (Technology Research Center for National Land Development, 1983), and examined theoretically the fire-blocking effect as a function of tree height, crown size, etc.

Based on these theoretical models, simulations of fire spread in urban areas that take into account the presence of trees have recently been attempted. For example, using an earthquake fire spread simulation system that incorporates the fire prevention effect of trees, Futagami et al. (Futagami et al., 2006; Futagami and Kunikata, 2015; Futagami, 2023) quantitatively evaluated the fire prevention effect of trees (differences in the presence or absence of trees) by varying wind speed, wind direction, and fire point. Also, Nishi and Futagami (2019) have developed a data input interface for the earthquake fire spread simulation system that takes into account tree species and shapes such as evergreens, deciduous trees, and hedges, and used this to evaluate the effects of existing greenery, hedge placement, setbacks, the removal of vacant houses, tree planting, and planting trees around open spaces. Nagano et al. (2008) targeted densely built-up wooden housing areas in Kanazawa City to examine the

effect of tree belts on preventing fire spread. Their simulation assumed the current state of planting and additional new planting. This was similar to the simulation attempted in the present study and served as a reference. Kumagai et al. (2009) simulated fire spread in an urban area using detailed vegetation distribution data collected by remote sensing.

In research on the effect of demolishing vacant houses on disaster mitigation, Nakai et al. (2012) calculated and compared arrival rates at temporary evacuation centers in densely built-up areas of Osaka City when the sites of vacant houses are converted into roads, used for road widening, or used as temporary evacuation centers. Nakajima et al. (2018) developed a model for predicting the occurrence of vacant houses on the basis of a field survey of an area where fireproofing was being promoted in Yokohama City and made predictions for up to 50 years in the future. They used a fire-spread cluster (Kato et al., 2006) approach to estimate the reduction in the rate of buildings destroyed by fire in the event of a large earthquake that can be expected when vacant wooden houses have been fireproofed and when all vacant houses have been demolished.

As reflected in the abovementioned prior research, many theoretical studies about the effects of trees on delaying and blocking fire spread have been carried out, as well as many simulations of the effects of greening and demolishing vacant houses on reducing fire damage. However, as far as the authors of the present paper are aware, there has been no research that examined the contribution of greening and demolishing vacant houses to reducing human casualties by linking fire damage and the evacuation behavior of residents. We were also unable to find studies that quantitatively examined effective and efficient methods for determining tree placement and vacant house demolition.

Research Objectives

Osaragi and Oki (2017) constructed a comprehensive simulation model that takes into account the interaction between property damage and human behavior (evacuation behavior, rescue activities, and initial firefighting activities) during a large earthquake (hereinafter, property damage/human behavior simulation model). A feature of this model is the incorporation of initial firefighting by local residents. In densely built-up wooden housing areas, the time it takes for a fire to spread from the building of fire origin to an adjacent building (fire-spread time) is short, and initial firefighting by local residents is less likely to succeed (Oki and Osaragi, 2018). If fire spread can be delayed by greening and demolishing vacant houses, it may be possible to improve the success rate of initial firefighting and reduce the number of fatalities and fire-damaged buildings. This was the hypothesis of the present study.

In this paper, we examine a method of incorporating the effect of delaying the time of fire spread between adjacent buildings by greening and demolishing vacant houses into the property damage/human behavior simulation model. Next, we examine the effect that delaying the time of fire spread between adjacent buildings has on reducing fire damage (number of fire-damaged buildings) and human casualties (number of fatalities) in the event of a large earthquake. Finally, we examine effective and efficient tree placement and vacant house demolition.

SIMULATION MODEL FOR EVALUATING THE EFFECT OF TREES ON DELAYING FIRE SPREAD

Method of Calculating Fire-spread Delay due to Trees

Methods proposed by the Ministry of Construction's Comprehensive Technology Development Project (Technology Research Center for National Land Development, 1983), Saito and Iwakawa (1982) and Iwakawa (1984) calculate the fire-spread time when there are trees between the building of fire origin and an adjacent building (hereafter, "Iwakawa model"). Table 1 and Fig. 1 show the variables used in the Iwakawa model. With these variables, it is possible to calculate the amount of radiant heat received between the nearest adjacent poi nts of the building of fire origin and an adjacent building, R [kcal/(m^2·h)], the amount of heat received at a heated point, q [W/cm^2], and the time required for ignition, t [s] (Equations (1)–(3)). Iwakawa (1984) describes the derivation methods in detail, and because these are key equations in this paper, APPENDIX provides a summary. In Equation (1), E is the amount of radiant heat from the radiation test surface (= 44,000 kcal/(m ^{2}h)), Φ is an urban area coefficient described by building area ratio m, F is the configuration factor for the heated point of the radiation test surface that is visible through the trees, e is the mean bright surface ratio of the radiation test surface corresponding to the configuration factor $f(a, b, r)$. Also, transmittance τ is a value determined according to tree type, tree shape, and season.

Table 1. List of variables used in the Iwakawa model

	Variables
E	Radiation from the surface of flame (constantly 44,000) [kcal/(m^2· h)]
h_1	Height of tree [m]
B	Width of burning building [m]
c	Height of heated point [m]
U	Wind speed [m/s]
α	Wind direction [rad]
d	Distance between two buildings [m]
d_0	Distance between heated point and tree [m]
D	Simultaneous burning area [m]
c_1	Ratio of sum of fire-resistant buildings area divided by sum of all buildings area
c_2	Ratio of sum of semi-fire-resistant buildings area divided by sum of all buildings area
m	Building coverage ratio in the town
τ	Transmittance (= 1 - (shielding rate by a tree or a hedge))
R	Amount of radiant heat received between the nearest adjacent points of the building of fire origin and an adjacent building [kcal/(m^2·h)]
q	Amount of heat received at a heated point [W/cm^2]
t	Time required for ignition [s]
Φ	Urban area coefficient described by building area ratio m
F	Configuration factor for the heated point of the radiation test surface
e	Mean bright surface ratio of radiation test surface corresponding to configuration factor
τ	Value determined according to tree type, tree shape, and season
I, J	Heating-side building, Heated-side building
i, j	Heating-side building point, Heated-side building point
N_{IJ}	Set of surface combination
n_{IJ}	The number of elements in the set N_{IJ}
F_{IJ}	Value of the configuration factor for heating-side building I and heated-side building J
F_{ij}	Value of the configuration factor for heating-side point i and heated-side point j
R_{ij}	Amount of heat received by surface j from surface i
R_{Ij}	Amount of heat received by surface j from heating-side building I
R_{IJ}	Maximum value of R_{Ij} over j
t_{IJ}	Fire-spread time from building I to building J
D_0	Simultaneous burning area [m]
h_0	Flame height [m]
θ	Flame tilt [rad]

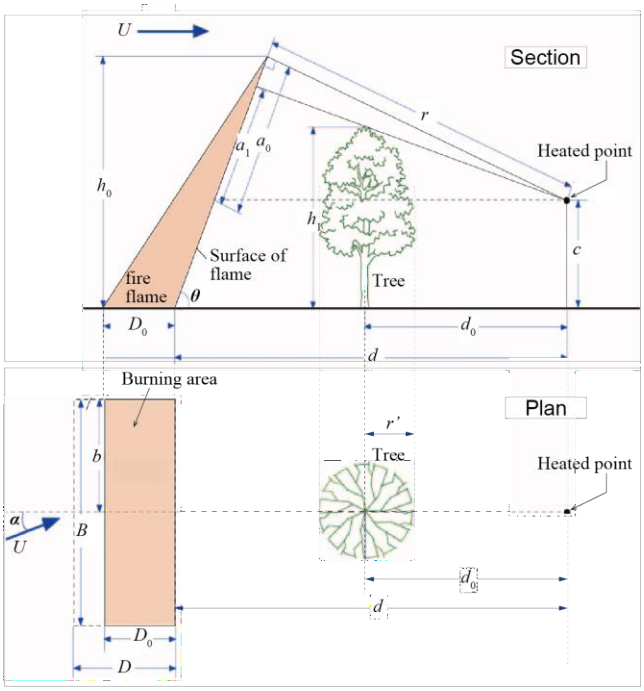

Figure 1. Illustration of variables used in the Iwakawa model

$$R = E \times \Phi^{0.5} \times F \times e \times \tau \quad [\text{kcal/(m}^2\text{h)}] \tag{1}$$

$$q = R \times 1.163 \times 10^{-4} \quad [\text{W/cm}^2] \tag{2}$$

$$t = -1.6 \times 10^3 \times \log_{10}\left(1 - \frac{0.53}{q}\right) \quad [\text{S}] \tag{3}$$

In this study, a more sophisticated model was created by incorporating consideration of the buildings on the heating-side and heated-side as face elements when calculating the amount of radiant heat received, *R*, rather than considering only the possibility of fire spread between the nearest adjacent points of adjacent buildings (Fig. 2).

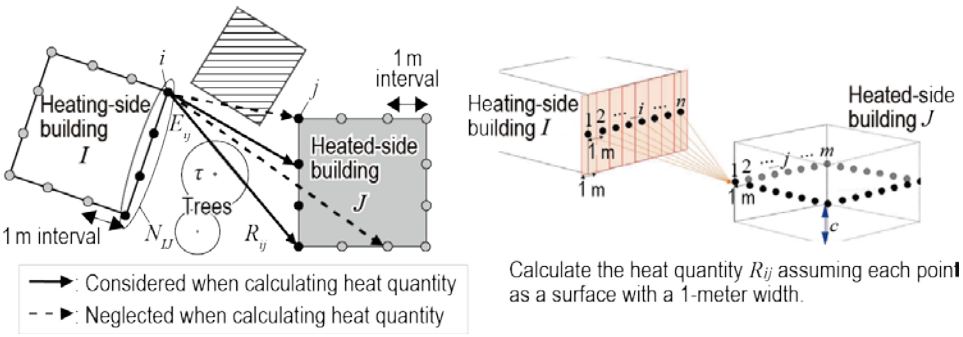

Figure 2. How to consider heating surface and heated surface for calculating the amount of radiant heat received

Specifically, we consider a heating-side building *I* and a heated-side building *J*. First, surfaces *i* and surfaces *j* are formed by dividing the outer circumference of each building into approximately 1 m intervals. Points are generated at equal intervals on the outline of the building using the "Densify" tool of ArcGIS. The interval between points is automatically adjusted to be proximate to the specified interval (here, 1 m) such that the start and end points of the point generation coincide. It is assumed that every surface *i* can be a radiating surface and every surface *j* can be a heated surface. The set of surfaces *i* is denoted by N_{IJ} and the number of elements in the set is denoted by

n_{IJ}.

CoRe Paper – Analytical Modeling and Simulation
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

If the line segment *i–j* established between surface *i* and surface *j* intersects with a building, etc., radiant heat along *i–j* is considered to be blocked and so is not included in the thermal calculations. In this case, the configuration factor for heat received from the area of the radiation test surface *i* ($\in N_{IJ}$) (Fig. 2, right), F_{ij}, can be expressed as follows:

$$F_{ij} = \frac{F_{IJ}}{n_{IJ}} \tag{4}$$

where F_{ij} is the value of the configuration factor, *F*, for heating-side building *I* and heated-side building *J*. In this case, from Equations (1) and (4), the amount of heat received by surface *j* from surface *i*, R_{ij}, is

$$R_{ij} = E \times \Phi^{0.5} \times F_{ij} \times e \times \tau \quad [\text{kcal}/(\text{m}^2\text{h})] \tag{5}$$

When the distance from the center of a tree to the path of fire spread (line segment *i–j*) is shorter than the radius of the tree, the shielding effect, $\tau < 1$, of the tree is considered. Next, the sum of R_{ij} giving the amount of heat received by surface *j* from heating-side building *I* is found, denoted R_{Ij} [kcal/(m²·h)]), and the maximum value of R_{Ij} over *j*, denoted R_{IJ}, is taken to be the amount of heat that heated-side building *J* receives from heating-side building *I* (Equation (6)). This is used to calculate the fire-spread time from building *I* to building *J*, t_{IJ} [s] (Equations (7) and (8)).

$$R_{IJ} = \max_j R_{Ij} = \max_j \sum_{i \in N_{IJ}} R_{ij} \quad [\text{kcal}/(\text{m}^2\text{h})] \tag{6}$$

$$q_{IJ} = R_{IJ} \times 1.163 \times 10^{-4} \quad [\text{W}/\text{cm}^2] \tag{7}$$

$$t_{IJ} = -1.6 \times 10^3 \times \log_{10}\left(1 - \frac{0.53}{q_{IJ}}\right) \quad [\text{s}] \tag{8}$$

Using the above method, the fire-spread time between adjacent buildings taking into account the presence of trees is calculated, and the difference in fire-spread time, Δt, is regarded as the fire-spread delay attributable to trees.

Generally, as a fire spread, heat is received from multiple burning buildings, and therefore the fire-spread time becomes shorter. However, this paper discusses the initial stage of fire spread from the building where the fire breaks out to an adjacent building, not fire spread between multiple buildings.

Incorporation into Urban Fire-spread Model

Using the model developed by Tokyo Fire Department's Fire Prevention Council (Tokyo Fire Dept. Model 2001), this paper describes the spread of fire not only between adjacent buildings but also at the urban area level. In Tokyo Fire Dept. Model 2001, fire-spread time is calculated using parameters that include the distance between adjacent buildings, wind speed, and building structure on heating-side/heated-side. Fire-spread time for between adjacent buildings can be calculated without performing complicated thermal calculations, but it is not possible to directly consider changes in the amount of heat received due to the shielding effect of trees (delay of fire spread).

Therefore, by finding the difference in fire-spread time between with and without trees, Δt, with the method described in the preceding section and adding this value to the fire-spread time, *T*, calculated using Tokyo Fire Dept. Model 2001, the shielding effect of trees can be incorporated into the fire-spread model at the urban area level. Here, two parameters (height of heated point and opening ratio) were adjusted so that the fire-spread time between adjacent buildings without trees approximated the calculation results of Tokyo Fire Dept. Model 2001 (Fig. 3). For wooden buildings, the difference between the two models is minimized by taking the height of the heated point to be half the height of the building on the fire origin side (3 m above ground). For fire-resistant and quasi-fire-resistant buildings, the height of the heated point is set at 3 m above the ground and the opening ratio (percentage of wall height taken up by opening height) at 55%. At a distance between adjacent buildings of l ess than 1 m, the difference from Tokyo Fire Dept. Model 2001 becomes rather large, but this was not considered to be an issue within the realistic range of distances between adjacent houses (Fig. 3). The rationale behind setting specific parameters for particular building combinations stems from the fact that the likelihood of fire spreading is influenced by the combination of building structures on the heating and heated sides. Specifically, wooden buildings have a higher likelihood of catching fire from adjacent burning structures compared to fire-proof buildings. Additionally, the amount of heat generated during combustion, which contributes to the spread of fire to neighboring buildings, is greater for wooden buildings and lesser for fire-resistant buildings.

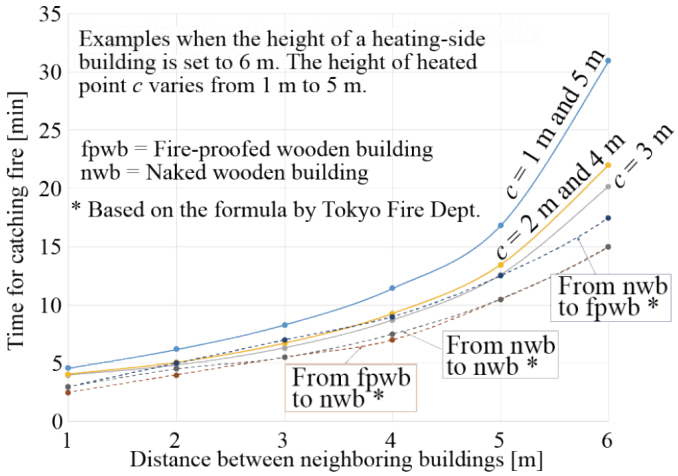

Figure 3. Distance between neighboring buildings and time for catching fire (in case of fire spread between wooden buildings)

Also, when fire spread enlarges, flame height h_0 exceeds 10 m and flame tilt θ also increases due to the effect of wind speed U and wind direction α, so a shielding effect cannot be expected from groups of trees such as those considered in this paper. Therefore, the effect of trees is not taken into account in calculations concerning the stage of fire-spread enlargement that follows the initial stage.

Method of Estimating the Number of Fire-damaged Buildings and Fatalities

The abovementioned effect of trees in delaying or blocking fire spread is incorporated into the property damage/human behavior simulation model (Tokyo Fire Department, 2001) used to examine property damage (number of fire-damaged buildings) and human casualties (number of fatalities) in the event of a large earthquake. This property damage/human behavior simulation model is a major part of the calculation process appearing in this paper. Osaragi and Oki (2017) developed a comprehensive simulation model (Fig. 4) that integrates property damages (building collapse, fire spread, and street blockage) and various activities (rescue activity, firefighting activity, and wide-area evacuation activity) by residents in a large earthquake. This model can analyze the effect and risk of rescue and firefighting activities carried out by residents under the assumption that a large earthquake directly hits the Tokyo area. Furthermore, it can analyze situations where there are many fatal casualties caused by people failing to evacuate, being trapped on streets, and so on. The details of the model is given in Osaragi and Oki (2017).

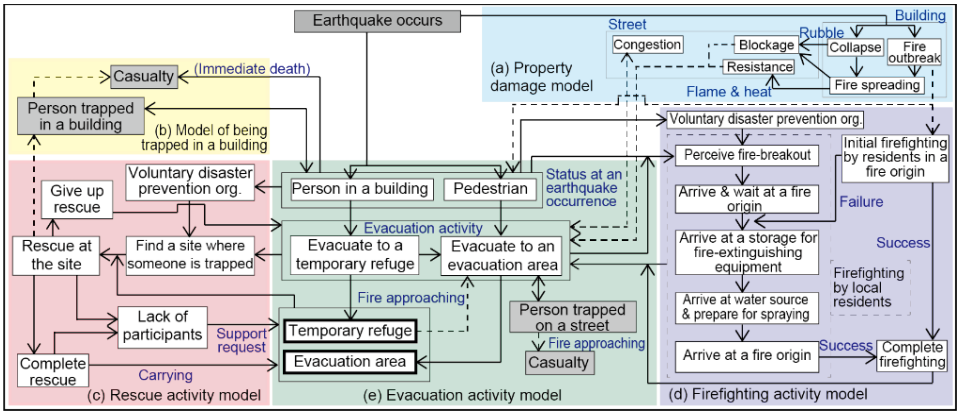

Figure 4. Overview of the property damage/human behavior simulation model (Osaragi and Oki, 2017). This is a comprehensive simulation model that integrates property damages (building collapse, fire spread, and street blockage) and various activities.

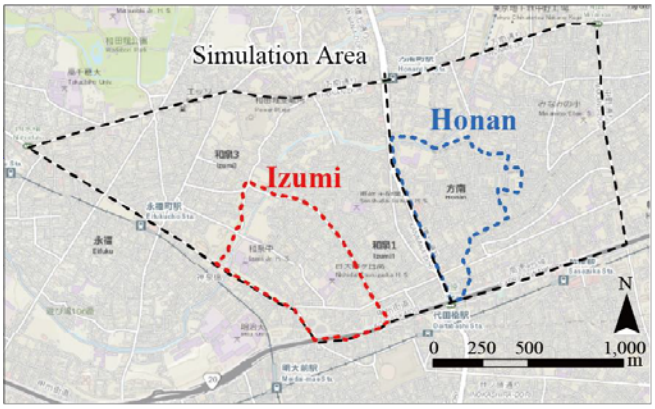


However, many pages would be required for a detailed explanation, and therefore a summary of the model is given in Osaragi and Oki (2017).

The following sections analyze the extent to which the number of fire-damaged buildings and fatalities due to a large earthquake could be reduced by reducing the fire-spread time through greening and demolishing vacant houses. Specifically, it is expected that by reducing the fire-spread time, initial firefighting by local residents using standpipes, for example, could succeed in time to limit the fire damage to the building of fire origin only. A reduction in the number of fire-damaged buildings could reduce the risk of people becoming trapped in buildings or streets being engulfed by the fire. In the Kobe Earthquake (1995), approximately 60% of the post-earthquake fires were attributed to electrical faults, occurring within 4 days following the seismic event. These fires erupted after residents had evacuated. In response to this challenge, the Japanese government has been advocating for the implementation of seismic breakers, which automatically cut off power circuits upon detecting seismic activity. This research focuses on other fires (40% of post-earthquake fires) that emerge immediately after an earthquake and are identified by nearby residents or locals before/during evacuation. When a large earthquake strikes, water pipes may be damaged, and the impact of this cannot be ignored (Osaragi et al., 2022). However, to avoid the postulated event becoming too complicated, this was not considered in the present study.

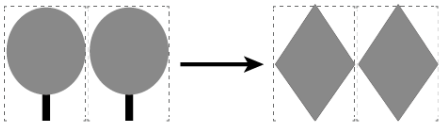
EFFECT OF EXISTING TREES ON REDUCING FIRE DAMAGE

Analysis Areas and Simulation Scope

Honan 1-chome, Suginami-ku (Honan area), which is one of the special fireproof zones in Tokyo's "Ten-Year Project to Advance Fire Resistance in Densely Built-up Wooden Housing Areas" (Tokyo Metropolitan Government, 2023a) and is also considered to be at high risk in the "8th Community Earthquake Risk Assessment Study" (Tokyo Metropolitan Government, 2023b), and nearby Izumi 2-chome, Suginami-ku (Izumi area), which has a relatively large amount of trees, were chosen as the analysis areas (Fig. 5). However, because fire could also spread from outside of these areas, an area surrounded by wide streets that could act as firebreak belts was taken as the simulation scope (Fig. 5). Evacuees were considered to have completed their evacuation when they arrived at any one of these wide streets.

	Izumi area
Number of buildings	1,473
	Honan area
	1,769
Number of people	Izumi + Honan
	6,684

People in buildings and outdoor pedestrians only in Honan and Izumi areas at 6:00 pm on weekdays are considered.
The number of people is estimated by using the Person Trip Survey Data in TMA (2008). The initial position of person in buildings and outdoor pedestrians are estimated by each building and street respectively 20),21).



* Although property damages are considered in the whole simulation area, fire-outbreaks and trees are considered only in Honan and Izumi areas.
* When a person arrives at any wide streets shown by black broken line, he/she is considered to complete evacuation.

Figure 5. Study area: one of the special fireproof zones in Tokyo's "Ten-Year Project to Advance Fire Resistance in Densely Built-up Wooden Housing Areas"

Simulation Assumptions

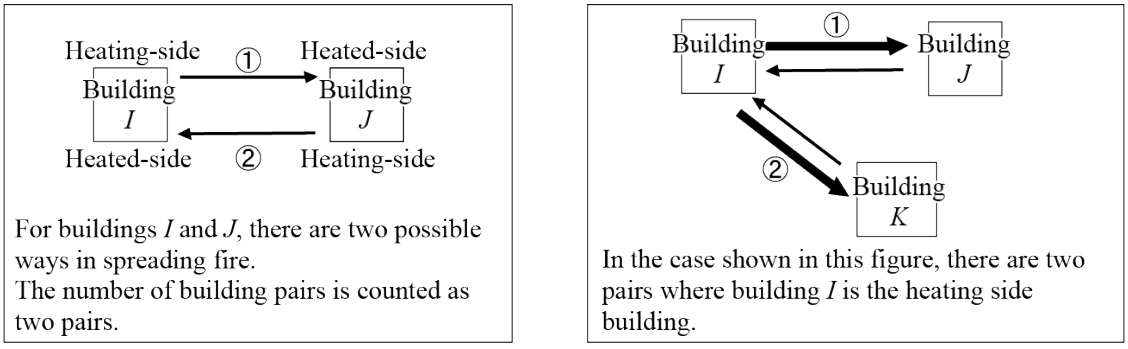
Table 2 shows the simulation assumptions. The "current state" was taken as 2011 for buildings, while for trees, it was taken as the time of implementation of the field survey (2018). Data from 2011 building surveys (ward areas) provided by the Tokyo Metropolitan Government's Bureau of Urban Development were used here. The height of existing trees (three classes: 2 m, 4 m, and 6 m) and the type of tree (evergreen or deciduous) were judged by eye from the field survey (locations that were difficult to see were supplemented by aerial photographs). Tree width was assumed to be half of tree height. Figure 11 (discussed in detail later) shows the spatial distribution of existing trees and buildings (according to fire preventive construction).

Table 2. Assumptions needed for performing simulation analysis

PGV (Peak Ground Velocity)	66 cm/s
Seismic intensity	5.96
Season and weather	Sunny day in winter
Earthquake occurrence time	6:00 pm on a weekday
Wind speed and wind direction	3 m/s, north wind
Shielding rate by a hedge	(Evergreen tree) 0.7837, (Deciduous tree) 0.2105
Shielding rate by a tree (except a hedge) *	(Evergreen tree) 0.7837 x 0.5 = 0.3919 (Deciduous tree) 0.2105 x 0.5 = 0.1053
	* Regarding the part covered by a tree (except a hedge) as a rhombus as shown in the left figure, it can be treated as a barrier wall with half of the area obtained by multiplying the height and width of the tree. Therefore, the shielding rate of a tree trunk multiplied by 0.5 is used.

Effect of Existing Trees on Reducing Number of Fire-damaged Buildings/Fatalities

There are 41,281 building pairs with the potential for fire spread inside the analysis areas (Fig. 6). Because the property damage/human behavior simulation requires a long computation time, the following procedure was first used to narrow down the buildings to those with the potential for reduced damage, in order to efficiently verify the effect of trees on reducing damage. (1) The delay of fire spread between adjacent buildings was calculated for those with trees only. (2) The effect of delaying or blocking fire spread was confirmed in 226 pairs. (3) These 226 pairs were configured by taking 151 buildings as heating-side buildings. (4) Considering there to be a potential for damage reduction when a fire starts from these 151 buildings, fire-spread simulations were performed taking each of the buildings as the building of fire origin. An effect was found for 10 of these 151 buildings (when the fire spreads more quickly between adjacent buildings without trees, the trees do not work to delay the fire spread). (5) Assuming that a fire starts from one of these 10 buildings, the property damage/human behavior simulation was run until 24 hours after the outbreak for 100 cases with different roadblock situations (10 buildings × 100 cases = 1,000 simulations in total).



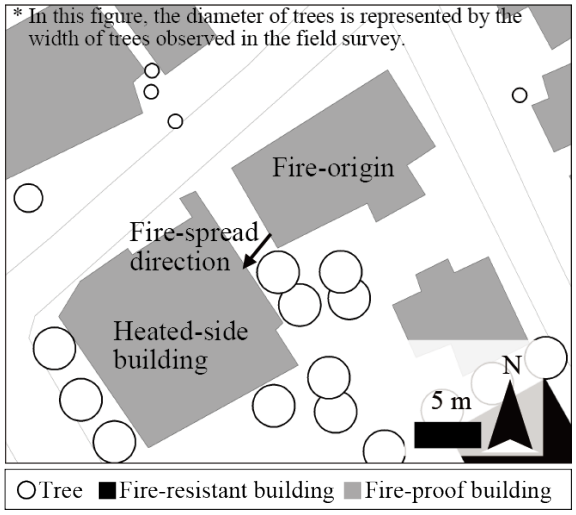


Figure 6. Definition of building pairs with the potential for fire spread inside the analysis areas

Two of these 10 buildings were cases in which firefighting activities succeeded due to the trees delaying the fire spread. Large disaster mitigation effects were confirmed in cases where the roadblocks around the building of fire origin and equipment stores were minor and rapid initial firefighting was possible. Table 3 shows the specific results. For the building of fire origin 1, the fire-spread time was delayed by the trees from 19.1 minutes to 20.8 minutes (Fig. 7). This difference of 1.7 minutes is not large, but initial firefighting activities were successful in 17 of 100 cases, and as a result, the number of fire-damaged buildings was reduced from 2,003 buildings to 1 building (the building of fire origin only). Similarly, for the building of fire origin 2, initial firefighting activities were successful in 26 cases, and along with a substantial decrease in the number of fire-damaged buildings, the average number of fatalities was successfully reduced by approximately 13, and the maximum number was reduced by 58.

Table 3. The numbers of burnt-down buildings and casualties with and without the present trees

* Circled numbers ① and ② indicate the location of each fire-origin building.		Result of fire-extinguishment	①	②
Number of successful fire-extinguishment cases thanks to trees where the fire-extinguishment are failed without trees			17/100	26/100
Number of burnt-down buildings		Failure	2,003	1,751
		Success	1	1
Number of casualties	Ave.	Failure	20.1	28.5
		Success	16.1	15.3
	Max.	Failure	44	71
		Success	21	19
Difference of the number of casualties between successful and failed fire-extinguishment cases	Ave.		-3.9	-13.2
	Max.		-24	-58

Considering the existing trees, time from the fire-outbreak to spread of fire to the heated-side building was delayed by 1.7 minutes (from 19.1 minutes to 20.8 minutes). The delay enabled firefighting activities at the building of fire-origin successful. This resulted in decreasing the number of burnt-down buildings from 2,003 to 1 (only the building of fire-origin itself).

Figure 7. Example of the place where firefighting activities were successful by considering the present trees (corresponding with Table 3①)

The success or failure of initial firefighting activities is extremely important because it greatly influences the extent of damage in densely built-up wooden housing areas. The above simulation results are interesting because they suggest that the delay of fire spread provided by trees could allow initial firefighting activities by residents to succeed. However, it is important that the accuracy of the above calculation results be carefully examined based on the various models and parameter settings incorporated into the simulation.

EFFECT OF DEMOLISHING VACANT HOUSES AND METHOD OF DETERMINING TREE PLACEMENT

Damage Reduction Effect of Demolishing Vacant Houses

This section examines the effect of delaying the spread of fire by demolishing deteriorated vacant houses to obtain empty lots. Taking Honan area as the analysis area, a total of 12 vacant houses were identified by the field survey (Fig. 8). Here too, the buildings were narrowed down using the following procedure in order to efficiently detect the effect of demolishing the vacant houses. (1) The number of fire-damaged buildings after 24 hours was calculated assuming for each of the buildings in Honan area as the building of fire origin. (2) Cases in which the number of fire-damaged buildings was reduced by demolishing the vacant houses were detected. Figure 9 shows a case in which a fire in building A spreads to a large vacant house B and ultimately causes a huge amount of damage (number of fire-damaged buildings: 1,751); however, if vacant house B is demolished, the spread of the fire can be suppressed.

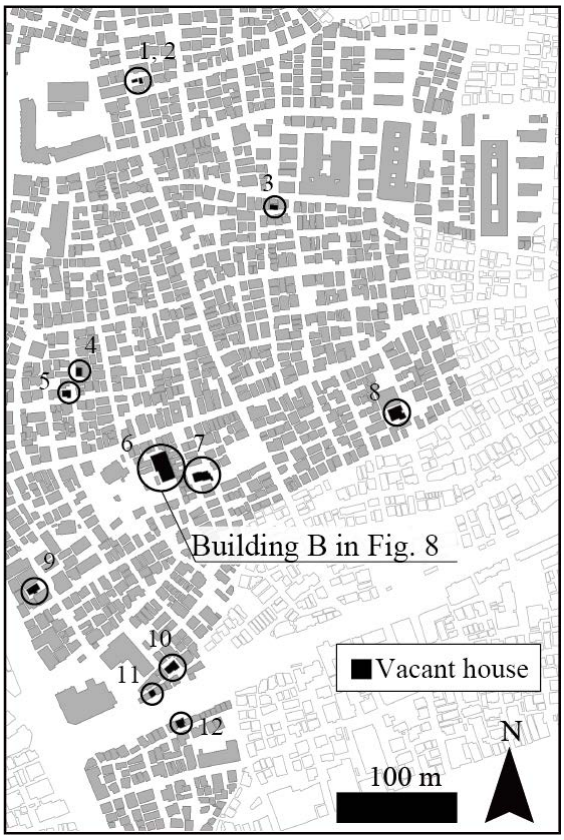

Figure 8. Spatial distribution of vacant houses in Honan area (in the present situation)

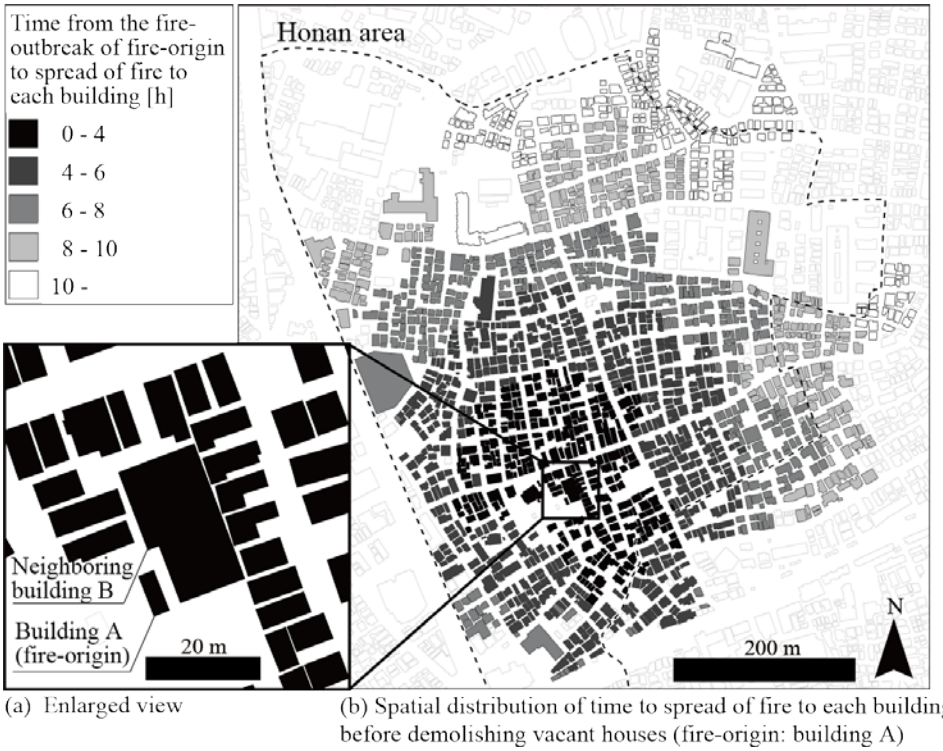

Figure 9. Example of a case where the number of burnt-down buildings is decreased due to the demolition of vacant houses

Taking the outbreak of fire in Building A as an example, the property damage/human behavior simulation was run assuming 100 cases with different spatial distributions of building collapses and roadblocks (1 building × 100 cases = 100 simulations in total). As a result, demolishing vacant house B was found to have the effect of reducing the number of fire-damaged buildings in 13 out of 100 cases (success or failure of initial firefighting was divided). Table 4 summarizes the damage situation in these 13 cases. It shows that as a result of vacant house B being demolished, human casualties in Honan area was halved due to initial firefighting by residents succeeding and preventing the spread of the fire. Simulations were conducted to assess property damage and human behavior under various scenarios involving different spatial distributions of collapsed buildings and street blockages. However, the ignition building was fixed to Building B. In the adopted fire spread model, the range of fire spread remains consistent when the ignition building remains unchanged. Consequently, in the simulated cases, only two outcomes were feasible: either the fire was confined to building A alone, or it extended widely to encompass building B. This is just a single case amid countless combinations of conditions, but it is important as an example demonstrating the importance of initial firefighting in densely built-up wooden housing areas where evacuation routes may get cut off. Building B, an aging wooden structure showing signs of deterioration, not only lacks aesthetic appeal but also poses a potential hazard as it could collapse during a major earthquake, potentially obstructing evacuation routes. Hence, its demolition has been recommended in the community. While demolishing the building incurs financial costs, the benefits of replacing it with a fireproof structure, such as a public facility or housing complex, are expected to be substantial. Moreover, given the scarcity of parks in this area, there is considerable value in transforming the space into a pocket park, providing a safe and recreational environment for the residents.

Table 4. Difference in the number of burnt-down buildings and casualties before and after the demolition of vacant houses

Number of burnt-down buildings [building]		
	Ave.	Max.
Remain	1,751	1,751
Demolish	1	1
Difference	1,750	1,750

Number of casualties [person]		
	Ave.	Max.
Remain	36.1	54
Demolish	16.5	22
Difference	19.5	39

Effect of New Tree Placement on Suppressing Fire Spread

This section examines the extent to which fire damage can be reduced by newly placing trees. Figure 10 shows the method of determining the locations of new trees.

In densely built-up wooden housing areas, it is not always possible to place trees between all adjacent buildings. For the present study, we assumed that trees can be placed if the interval between adjacent buildings is at least 2.5 m (Table 5). Considering placement within residential premises, with reference to Article 128 of the Order for Enforcement of the Building Standards Act (pathways within premises), it was considered necessary to leave a distance of at least 1.5 m from one of a pair of adjacent buildings. Also, based on “greening using medium-sized trees in front of walls” in the Guidebook for Planting Greenery (Setagaya Ward, 2021), the distance from the other building was taken to be 0.5 m. Further, considering the minimum tree width to be 0.5 m (hedge), the interval between adjacent buildings in which it is possible to place trees was taken as 2.5 m or greater (Table 5). However, it is not practical or efficient to place trees wherever placement is possible. Therefore, the following method was used to narrow down the placement locations. Calculate the fire-spread delay between all adjacent buildings where tree placement is possible and a damage reduction effect can be expected (Fig. 10, Step A). Establish an order of priority based on the length of fire-spread delay (Fig. 10, Step B). In order starting from the place with the highest priority, place a certain number of trees using the method shown in Fig. 10, Step C. Basically, trees are placed according to the following rules. Rule 1: Do not place trees where they would overlap with streets or pathways. Rule 2: Plant trees that are as large as possible (Table 5). Rule 3: Plant the minimum number of trees required to block the path of fire spread. Rule 4: When it is possible to place trees on either the heated-side or the heating-side, place them on the side that is most effective.

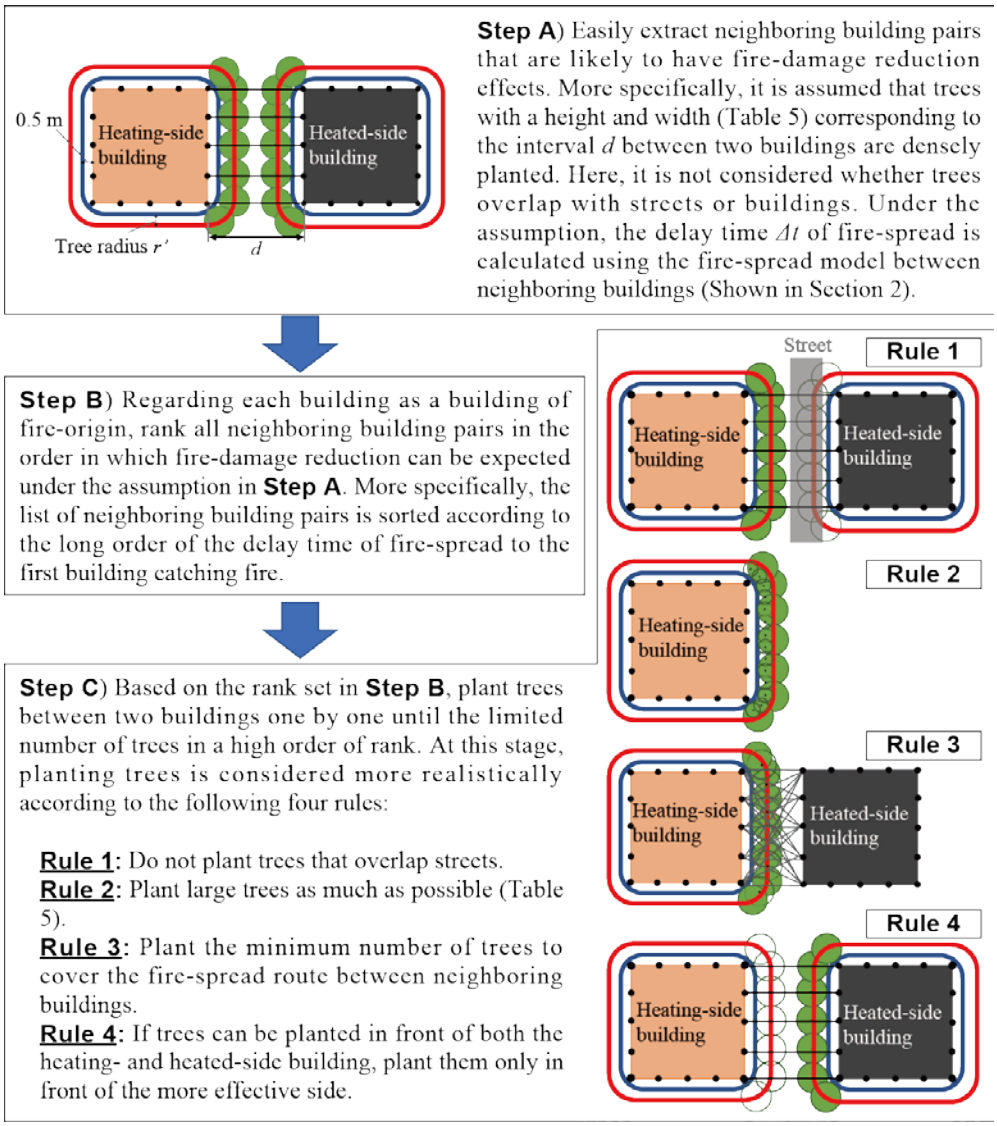

Figure 10. How to plant new trees: methods of determining the locations of new trees

Table 5. Assumption for the interval between two buildings, tree height, and tree width

	Interval d between two buildings	Tree height h_1	Tree width ($2r'$)
Level 0	Less than 2.5 m	Impossible to plant trees	
Level 1	2.5 m or more but less than 4 m	2 m	0.5 m (hedge)
Level 2	4 m or more but less than 5 m	4 m	2 m
Level 3	5 m or more	6 m	3 m

Based on the above assumptions, trees equivalent to approximately 10% of the existing trees (total 894) were placed, and (i) a method in which the trees are placed at random between adjacent buildings and (ii) the method described above in which trees are placed according to order of priority were compared. Specifically, 100 cases with different distributions of building collapses and roadblocks were analyzed (Fig. 11). In assumption (i-1), a total of 96 trees/hedges were placed between 12 pairs of adjacent buildings; in assumption (i-2), a total of 92 trees/hedges were placed between 10 pairs of adjacent buildings; and in assumption (ii), a total of 93 trees/hedges were placed between 8 pairs of adjacent buildings.

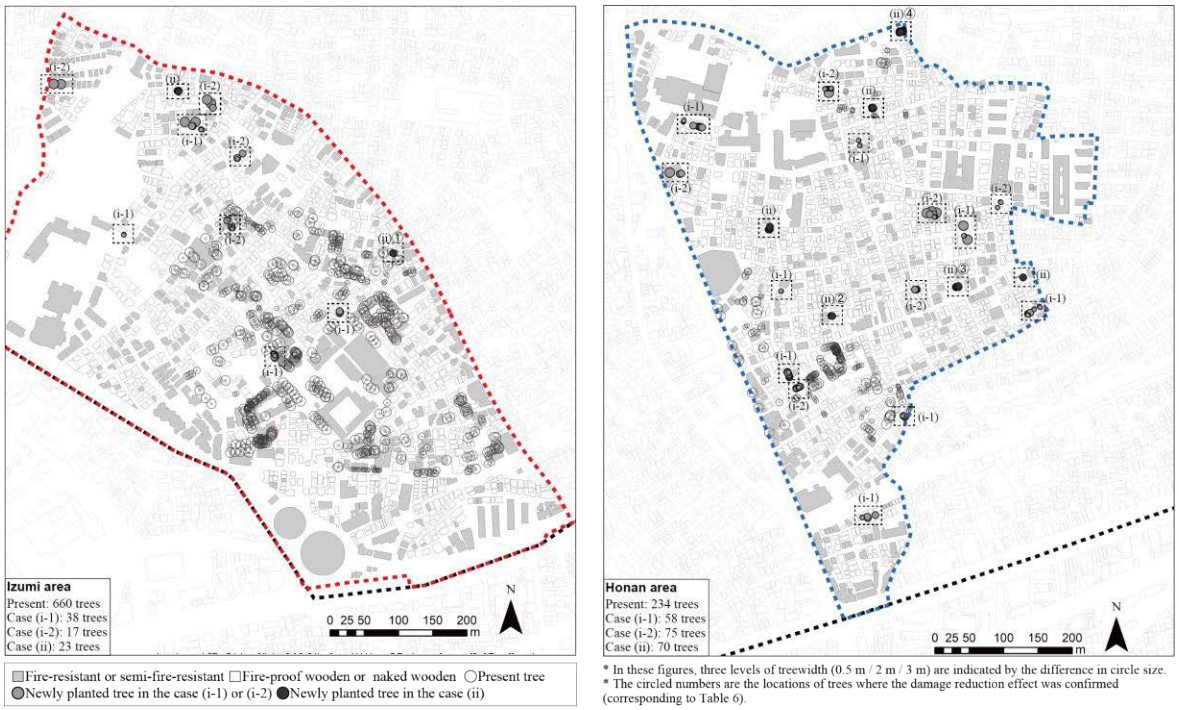

Figure 11. Spatial distribution of present/newly placing trees and the spatial distribution of existing buildings (according to fire preventive construction)

In placement method (i), fire-spread time to an adjacent building was delayed only slightly, and cases in which initial firefighting succeeded due to the addition of trees could not be confirmed. However, in placement method (ii), the effect of the trees was confirmed when the building of fire origin was one of a certain four buildings. Table 6 shows the numbers of fire-damaged buildings and fatalities in these cases (total of 19 cases). The numbers vary depending on the building collapse and roadblock situation, but a case in which the number of fatalities decreased by 89 due to the placement of trees was confirmed (Table 6, Location 3).

Table 6. The number of burnt-down buildings and casualties before and after planting new trees

* Circled numbers ① to ④ indicate the location of each fire-origin building (Fig. 12).		Planting new trees	①	②	③	④
Number of successful fire-extinguishment cases thanks to new trees where the fire-extinguishment are failed before planting new trees			3/100	12/100	2/100	2/100
Number of burnt-down buildings		Before	2,241	1,751	1,751	1,751
		After	1	1		1
Number of casualties	Ave.	Before	19.0	30.1	63.5	29.5
		After	16.7	18.7	15.5	22.0
	Max.	Before	25	52	102	36
		After	19	30	18	22
Difference of the number of casualties between before and after planting new trees	Ave.		2.3	11.4	48.0	7.5
	Max.		6	35	89	14

SUMMARY AND CONCLUSIONS

In this paper, we examined the possibility of reducing damage by delaying the spread of fire between adjacent buildings through greening and demolishing vacant houses, thereby improving the success rate of initial firefighting by local residents. We also examined methods of determining tree placement to reduce damage efficiently. The main results are given below.

First, after summarizing a previous model of fire spread between adjacent buildings and a procedure for calculating the amount of heat received taking into account trees, we developed a more sophisticated model of fire spread between adjacent buildings that assumes not only fire spread between the nearest adjacent points of the heating-side building and the heated-side building, but also fire spread between the heating surface and heated surface. Also, by examining a method of incorporating this model into Tokyo Fire Dept. Model 2001, which is a proven simulation model for fire spread in urban areas, we made it possible to quantitatively evaluate the effect of trees on delaying fire spread. Furthermore, through integration with a simulation model for property damage/human behavior in the event of a large earthquake, we made it possible to evaluate the effect of trees on reducing the number of fire-damaged buildings and fatalities due to a large earthquake.

Using the property damage/human behavior simulation model, we analyzed densely built-up wooden housing areas in Tokyo and evaluated the effect of the existing trees on reducing damage. The results confirmed that, in some cases, trees delay the spread of fire between adjacent buildings and allow initial firefighting by local residents to succeed, leading to a reduction in the number of fire-damaged buildings and fatalities. We also examined the disaster mitigation effect of demolishing vacant houses and confirmed that, in some cases, the number of fatalities could be halved by demolishing vacant houses that create a path of fire spread from the building where the fire breaks out.

Another characteristic of densely built-up wooden housing areas is that, although it is unlikely, if initial firefighting does succeed, an extremely large disaster mitigation effect is obtained. Using the simulation system developed in this paper, it is possible to discover where in an analysis area it would be efficient to newly place trees. We consider this to be a valid method for making effective use of limited space and budgets to improve the safety of an area and simultaneously enrich the green environment of people's everyday lives.

However, these disaster mitigation effects were observed under limited conditions, and effects on the order of our original expectations were unfortunately not obtained. This is considered to be due to the particular spatial characteristics of densely built-up wooden housing areas. Specifically, in densely built-up wooden housing areas, because the distances between adjacent houses are extremely small, the speed of fire spread (fire-spread time) is determined not by adjacent houses with trees but by adjacent buildings with small gaps between them. Trees do not originally exist in these small gaps, and it is difficult to newly place trees in them. Also, in densely built -up wooden residential areas, there are many structurally weak houses with low earthquake resistance located along narrow streets; consequently, many roads become blocked in the event of a large earthquake. This is a factor that impedes the initial firefighting activities of local residents and is why a delay in fire-spread time due to trees cannot be exploited effectively. Comparisons with simulation analyses targeting areas other than densely built-up wooden residential areas need to be performed to examine the possibilities of the disaster mitigation effects of trees and vacant house demolition. Hence, the experimental results obtained in this research are limited by a narrow set of conditions. The authors acknowledge these limitations and would like to incorporate sensitivity analyses to assess the robustness of our findings under various scenarios to enhance the study's validity and strengthen the overall validity of this paper. We intend to address these in the future work.

APPENDIX

The length of the perpendicular line from the heated point to the radiation test surface r [m], urban area coefficient Φ, simultaneous burning area D_0 [m], flame height h_0 [m], and flame tilt θ [rad] are expressed by Equations (a-1)–(a-5).

$$r = \left[\left(d - \frac{c}{\tan\theta} \right)^2 - \left\{ (d + c\tan\theta)\cos\theta - \frac{c}{\sin\theta} \right\}^2 \right]^{0.5} \quad \text{(a-1)}$$

$$\Phi = 1 - 0.6(c_1 + 0.8c_2)\, m \quad \text{(a-2)}$$

$$D_0 = \min\left(D, 50, 1.179\Phi^3 + 10\right) \quad \text{(a-3)}$$

$$h_0 = 4.7 \times 0.0133 \times (D_0 - 10) \times (\Phi - 0.1) + \frac{3.98}{D_0^{0.6}} \times \left(\frac{D_0^3}{U} \right)^{0.2} \quad \text{(a-4)}$$

$$\theta = \arcsin\left(\frac{2}{U} \right)^{0.2} \quad \text{(a-5)}$$

Next, the configuration factor F for the heated point of the area of the radiation test surface is calculated. The length of the radiation test surface when there are no trees a0 [m] and the length of the radiation test surface blocked by trees a1 [m] are expressed by Equations (a-6) and (a-7).

$$a_0 = \frac{h_0}{\sin\theta} - c \quad \text{(a-6)}$$

$$a_1 = \left\{ 1 - \frac{d_0^2}{d_0^2 - (h_1 - c)^2} \right\}^{0.5} \times \frac{(a^2 + r^2)^{0.5}}{\left(\frac{d_0^2}{d^2 - (h - c)^2} \right)^{0.5} \times \sin\theta + \left(1 - \frac{d_0^2}{d^2 - (h - c)^2} \right)^{0.5} \times \cos\theta} \quad \text{(a-7)}$$

Also, the configuration factor for the surface of length *a* [m] and width *b* [m], *f*(*a*, *b*, *r*), and the mean bright surface ratio *e* of the portion of the radiation test surface corresponding to *f*(*a*, *b*, *r*) are found using Equations (a-8) and (a-9).

$$f(a,b,r) = \frac{1}{2\pi} \left[\sin\theta \left\{ \frac{a}{(a^2 + r^2)^{0.5}} \tan^{-1} \frac{b}{(a^2 + r^2)^{0.5}} + \frac{b}{(b^2 + r^2)^{0.5}} \tan^{-1} \frac{a}{(b^2 + r^2)^{0.5}} \right\} - \cos\theta \left\{ \frac{r}{(a^2 + r^2)^{0.5}} \tan^{-1} \frac{b}{(a^2 + r^2)^{0.5}} - \tan^{-1} \frac{b}{r} \right\} \right] \quad \text{(a-8)}$$

$$e = 1 - \frac{h_0 + h_1}{2h_0} \quad \text{(a-9)}$$

From Equation (a-8), the configuration factor *F* for the heated point of the area of the radiation test surface that is visible through the trees is found using Equation (a-10).

$$F = 2\left\{ f(a_0, b, r) - f(a_1, b, r) \right\} \quad \text{(a-10)}$$

ABSTRACT

The utilization of Unmanned Aerial Vehicles (UAVs) for disaster relief has significantly increased in recent years, especially in the fields of aerial monitoring and communication support. At the same time, research on wireless communication channels between UAVs operating in disaster areas and their base station has been neglected, despite its importance for system operability and information transmission. Therefore, this paper addresses requirements of a suitable data channel on the use case of an Aerial Monitoring System for distributed disaster networks. We put special emphasis on possible applications using low-throughput technologies, like LoRa, to enable information transmission on low-cost hardware without centralized infrastructure, which is highly important for UAV applications in disaster scenarios. Specifically, we propose the aggregation of topology information to reduce message sizes and increase usability under challenging network conditions. Our results highlight that the aggregated monitoring information can be transferred to the base station with reasonable delay and reliability, possible with a low-throughput channel as low as 300 $\frac{bit}{s}$. At the same time, the aggregated information still maintains an adequate representation of the monitored topology of the distributed disaster network.

INTRODUCTION

Disaster preparedness and disaster relief are two crucial challenges our society has faced and will always face with natural and human-made catastrophes. Especially large-scale natural disasters caused by extreme weather conditions severely increased in recent years due to climate change (Gallucci, 2018; Ranghieri & Ishiwatari, 2014; Toya & Skidmore, 2018; Universite´ Catholique de Louvain (UCL), 2022). The parallel increase of societal reliance and dependence in everyday life on sophisticated but vulnerable *Information and Communication Technologies* (ICT), like always available high-speed cellular networks, constantly aggravate these challenges during and after disasters. In recent years, several events like Hurricanes in Puerto Rico or large floods in parts of Germany highlighted that vulnerability of our existing ICT infrastructure. Severely damaged or completely destroyed landlines and cellular networks lead to a complete communication blackout. This impaired any effort for disaster relief and mitigation, especially in the first few days before provisional solutions to provide even the most basic communication capabilities, such as emergency calls, could be set up (Gallucci, 2018; German Federal Agency for Civic Education, 2021; Kreienkamp et al., 2021; Zorrilla, 2017). Since communication is vital for an efficient disaster relief, researchers all over the world emphasize the need for more robust and resilient infrastructure (Hagar, 2015; Hollick et al., 2019; Kreienkamp et al., 2021; Mori et al., 2015; Toya & Skidmore, 2018; Whittaker et al., 2013). This also includes the need for new approaches and methods to improve communication and mitigate the effects of destroyed infrastructure in a disaster situation (Fehling-Kaschek et al., 2020; Hollick et al., 2019; Mu¨hlha¨user, 2021).

*corresponding author

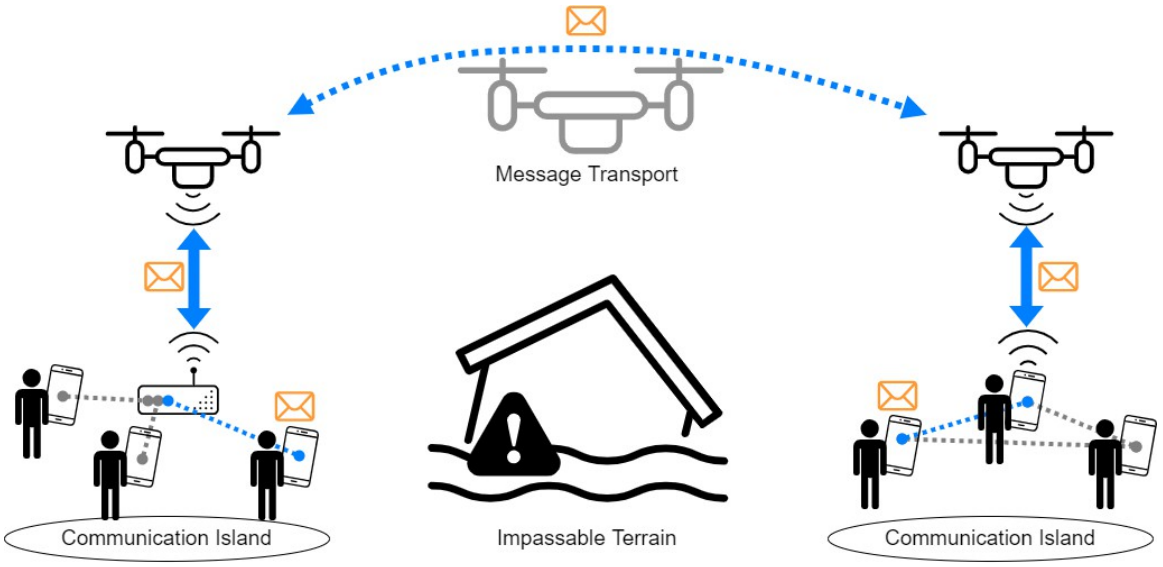

Figure 1. A communication network is separated by impassable terrain, e.g., debris or a flooded area, and traditional ICT infrastructure is not available, resulting in two separated communication islands. The utilization of UAVs as data ferries between the communication islands, independent to the blockades on the ground, provides delayed communication for affected civilians. However, this is only possible when the locations of the communication islands are known to the UAV system. (Flood Icon by Mapps from The Noun Project)

One of these proposed methods to quickly re-establish communication in a disaster area, is the utilization of small, cheap, off-the-shelf *Unmanned Aerial Vehicles* (UAV) as part of a larger aerial communication system. Communication capabilities for first responders and the civilian population can then be restored by providing, for example, a provisional Radio Access Network (RAN) (Chakraborty et al., 2018; Esrafilian et al., 2020; M. Gupta & Varma, 2021; Mahoro Ntwari et al., 2021; Moradi et al., 2018). Such an aerial RAN requires to place a significant number of UAVs over the disaster area to achieve sufficient coverage, demanding a vast amount of resources. Alternatively, UAVs can be used as long-distance data ferries between disconnected communication islands (Bujari et al., 2017; L. Gupta et al., 2016; Lieser et al., 2019; Mozaffari et al., 2017; Zeng & Zhang, 2017), as sketched in Figure 1. This approach requires physical message transport and, thus, provides only delayed message delivery, but is efficiently applicable with only a few available UAVs. In both cases, the provision of communication in the disaster area is paramount for disaster relief efforts and must be executed in the best possible way. Thus, a large part of research focuses on the very important aspects of efficient routing and optimal placement of UAVs. But both problems require precise and up-to-date information on the network topology to find a viable long-term solution. For example, topology information allows to identify communication gaps, which is needed for an initial establishment of routes or finding a suitable placement for access points. Furthermore, the topology in the disaster area may change over time, which requires updates on the topology to enable system adaptivity. The problem is that most research assumes the existence of such information and neglects its active collection, despite the fact that the availability and the acquisition of information from within a disaster area and its transfer to important stakeholders is not an easy task (Hagar, 2015).

In recent years, it was shown that UAVs can be used for the identification of networked communication devices on the ground, e.g., by WiFi or cellular signals (Rubina et al., 2019; Zeng et al., 2019). This ability is utilized in *Aerial Monitoring Systems*, which deploy UAVs to traverse and scan the disaster area to collect information on the network topology. The information is transferred to and collected at the base station, where it is combined and provided to different services, such as rescue services and disaster relief teams working in the area, or a UAV-based communication support system as described above (Arafat & Moh, 2021; Zobel et al., 2022). Similar to visual observation with cameras, signal-based identification and monitoring has a limited range. Thus, this traversal and scanning process of the UAVs is time-consuming, generally increasing in effort with larger disaster areas. Furthermore, the network topology can change over time. As a result, the quality of already gathered information will deteriorate over time without updating it. Therefore, the process must be repeated regularly, resulting in a constant monitoring mission for the *Aerial Monitoring System* (Zobel et al., 2022).

One of the most important aspects for the performance of an Aerial Monitoring System is the transfer of collected monitoring information from the UAVs to the base station. It is, however, also one of the less-researched challenges in this field. In the simplest solution, monitoring data is carried on the UAVs until their return to the base station. There, it is transmitted using physical connections or short-range high-throughput options like WiFi or Bluetooth (Zobel et al., 2022). Carrying collected information back to the base station may even be the only viable option, e.g., when cellular networks are destroyed in the disaster area. Additionally, most cheap, off-the-shelf UAVs do not have cellular or satellite communication interfaces. Due to the possibly long traversal times of a UAV while monitoring an area, carrying information back to the base station comes with the immense drawback of a high Age-of-Information on arrival. This may result in inaccurate or already wrong information given to the base station. Naturally, directly sending monitored information to the base station is a much better choice. But this requires the UAV to have a suitable communication channel, being adequate both in *data rate* to transmit the information fast and in *communication range* to reach the base station in the first place. Without cellular or satellite networks available, the question arises which alternatives for such a data channel can be used instead. New technologies like LoRa, providing robust communication with long communication ranges and low energy consumption, are promising candidates for infrastructure-independent communication in disaster areas. However, this comes with the drawback of small data rates, resulting in a low-throughput channel. Thus, UAVs may be able to reach their base station but probably not to send all monitored information — which requires a tradeoff solution that is yet not researched.

Therefore, this paper investigates the requirements of a suitable data channel for Aerial Monitoring Systems. We focus on the applicability of low-throughput channels like LoRa and possible methods to transmit monitored topology information from a disaster area. Specifically, we show that low-throughput channels are not suited to transfer typical topology information gathered by UAVs or an Aerial Monitoring System. Thus, we propose different concepts for structuring and aggregating network topology information, suitable for monitoring applications and for transmission in low-throughput data channels, respectively. Our concepts and aggregation methods are implemented and simulated in a generalized post-disaster network environment based on previous work (Zobel et al., 2022). With an in-depth evaluation of our concepts, we discuss possible combinations of data aggregation methods and communication channel properties that are suitable for direct data transmission in Aerial Monitoring Systems between monitoring UAVs and base stations on the example of long-range low-throughput communication technologies like LoRa. We show that by using our methods, aggregated monitoring information can be transferred to the base station with reasonable delay and reliability, even with a low-throughput channel bit rate as small as 300 $\frac{bit}{s}$. At the same time, the aggregated information still maintains an adequate representation of the monitored cluster topology of the disaster network. Our approach provides up-to-date information on the network topology, which is critical, e.g., for efficient disaster relief efforts and the resilient provision of a UAV-based communication service in the disaster area to the affected population.

The remainder of this paper is structured as follows. After the introduction and an overview of related topics given in this section, we discuss enablers for data transmission in low-throughput wireless networks as well as concepts for data aggregation and transmission handling. After that, the simulation scenario and the evaluation results are presented in detail, specifically focusing on channel requirements, message sizes, receiving delay, and the quality of representation of topology information from our proposed information aggregation methods. Finally, the paper is summarized and concluded.

ENABLING MONITORING INFORMATION TRANSMISSION FOR LOW-THROUGHPUT NETWORKS

The effective transmission of monitored topology information from Unmanned Aerial Vehicles (UAVs) to their base station is a critical aspect of every Aerial Monitoring System in disaster areas. In this paper, we focus on a post-disaster scenario without working ICT infrastructure, in which a fragmented disaster network based on short-range decentralized device-to-device communication is used (Á lvarez et al., 2018; Baumga¨rtner et al., 2020). The task of the deployed Aerial Monitoring System is to initially detect and subsequently monitor the topology of this disaster network. This information is highly relevant, e.g., for emergency services or UAV-based communication systems, to understand the location and distribution of civilians within the disaster area and efficiently provide support. The areas are scanned using a simple Boustrophedon-style route planning, as sketched in Figure 2. This back-and-forth algorithm is a well-known approach to address coverage path planning problems with deterministic area coverage (Choset & Pignon, 1998; Zobel et al., 2022). Within the scope of this paper, we do not research route planning or how information on a ground-based disaster network is collected in detail. The interested reader is referred to prior work (Zobel et al., 2022) that delves into these topics. Instead, we specifically focus on the transmission of information to the base station *after* its collection on a monitoring UAV. The basic information collected on a UAV consists of the location of a monitored device, a corresponding timestamp of the reading, as well as the network ID of the device itself.

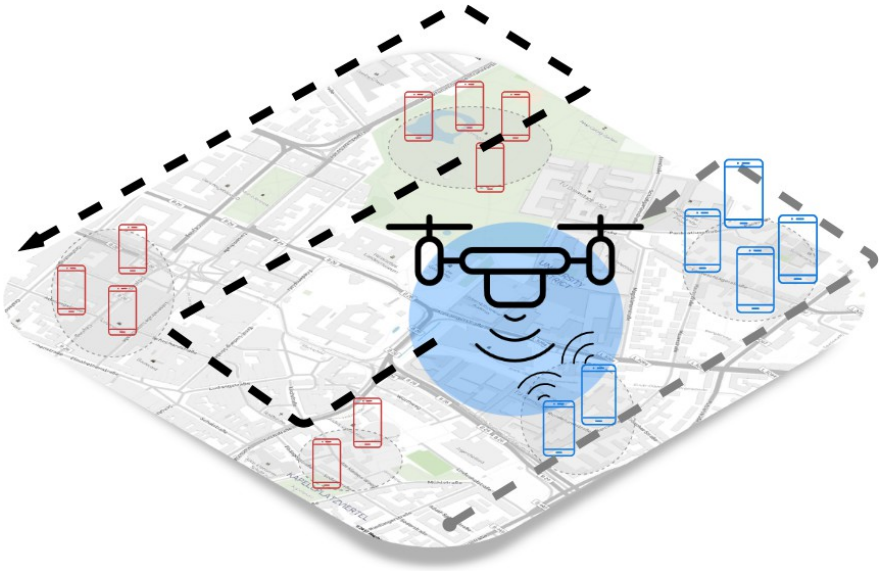

Figure 2. UAV-based detection of mobile devices in a disaster area. Using a Boustrophedon-style coverage path, the entire area is scanned. Devices within reception range of the UAV are detected (blue) by their signals. Due to extensive traversal routes of the UAV, the presence of undetected devices (red) may be unknown for a long time. Similarly, already seen devices can change their position without knowledge of the UAV.

One of the key characteristics of the considered disaster scenario is the highly fragmented network topology of distributed disaster networks (Á lvarez et al., 2018). Each of these fragments consists of individual devices that are connected with each other directly or over a multi-hop connection, but not with nodes of other fragments. Thus, we also speak of individual network clusters or communication islands. Due to the distributed nature of the disaster network, however, a monitoring UAV typically encounters individual nodes, not a cluster as a singular entity. Specifically, individual beacon messages of nodes are received while the UAV flies over the cluster. The UAV has to reconstruct the cluster topology based on connectivity estimations or additional information in beacons. For the former, a distance variable D_{conn}, describing the maximum connection distance between ground nodes, can be used to estimate cluster adherence. For the latter, beacon messages can include further information by which ground nodes themselves identify their affiliation to a cluster, e.g., a hash of all known messages (Khelil et al., 2007) or all known cluster nodes (Zobel et al., 2022). Naturally, data that is directly provided by the disaster network itself gives more accurate information, and thus, also a better representation of the actual network topology than a connectivity estimation.

Another limitation in the disaster scenario is that conventional cellular or satellite networks cannot be used at all by UAVs. We expect both communication interfaces not to be available on small and cheap, off-the-shelf UAVs and especially cellular networks to be impaired or entirely not available in the disaster area. However, the LoRa technology[1], a wireless communication technology originally developed for Internet-of-Things (IoT) applications and Low-Power Wide Area Networks (LPWAN), has shown its applicability as an alternative communication technology in disaster networks in recent years (Baumga¨rtner et al., 2017, 2020). Due to its cost-effectiveness, energy efficiency, adaptivity, and simplicity, LoRa is also increasingly integrated into UAVs and Unmanned Aerial Systems (Ghazali et al., 2021; Saraereh et al., 2020). Nevertheless, the inherent limitation of LoRa lies in its low throughput that comes as a tradeoff with its robust signaling. For typical devices[2], the usable bit rates range depending on the chosen LoRa parameters between 92 bps[3] and 21.9 kbps[4]. Thus, when considering the worst case, it would take a UAV about 0.7 seconds to transmit only a single 8-Byte-location measurement to the base station. Furthermore, this example does not include overhead or other important information, such as the time of the measurement or network information from the encountered network devices. Another heavy restriction is the typical 1% duty cycle of the used frequency bands (European Telecommunications Standards Institute (ETSI), 2018).

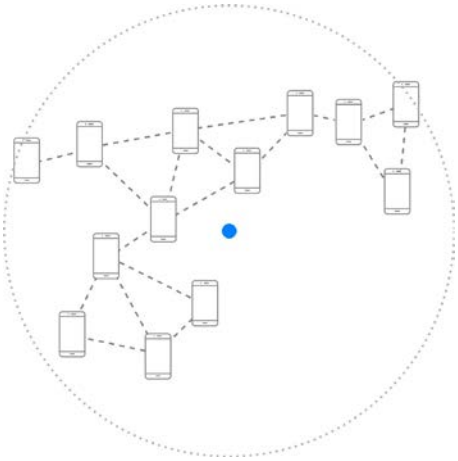
[1]Although we use LoRa as a well-researched example in the scope of this paper, our concepts and results are not exclusive to the LoRa technology and could be beneficial in any low-throughput network.
[2]For example, an ESP32 device using the LoRa SX1262 module.
[3]Parameters: 62.5 kHz BW, SF 12, CR 4:8
[4]Parameters: 500 kHz BW, SF 7, CR 4:5

Therefore, the following sections investigate how the transmission process and the structure of topology information can be optimized, to enable its transmission in such low-throughput networks. The objective is to reduce the packet size while preserving the integrity and representativeness of the transmitted data, thereby optimizing the UAV communication process.

Delaying Transmission

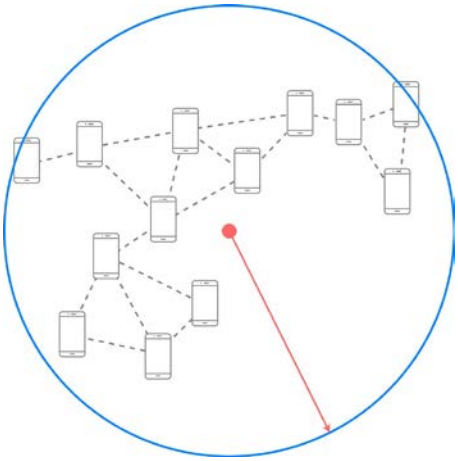
Whenever topology information is collected by a monitoring UAV, the question arises at which time this topology information can or should be transmitted to the base station. Intuitively, received information should directly be forwarded to minimize its Age-of-Information (AoI) on reception. This comes especially in mind, in case that information about the entire cluster is shared directly by the disaster network, such as all nodes and their locations within (Zobel et al., 2022). But whenever the cluster changes during the overflight, sending another message would be necessary. The optimal time to send the message is when the overflight of the cluster ends. At that point, the UAV cannot receive any more updates from the cluster, the information is most accurate, and no redundant messages are sent. However, pinpointing this exact time may be impossible. For individual node detection, furthermore, a UAV cannot know when all nodes in a cluster are detected — if that is even possible due to its flight path. Starting with a single node, each measurement must be grouped correctly together with other nodes, that are estimated to be in the same cluster. If a node changes position and the cluster splits as a result, this must also be considered in the process. Directly sending every measurement or every update of a possibly detected cluster or of singular nodes may impose a high load on the communication channel. Waiting for changes for a certain time before sending only the most up-to-date information could, therefore, be highly beneficial.

To address this, a delay λ is introduced, measured for every cluster. Whenever information for a cluster is received at the UAV, this delay is reset. Only when no change in information for that cluster has happened for that time, the cluster information is sent to the base station. In general, a small value for λ reduces the AoI at the base station, but may increase channel utilization due to redundant update messages. A larger delay, on the other hand, reduces information quality due to a larger AoI, but may optimize channel utilization.



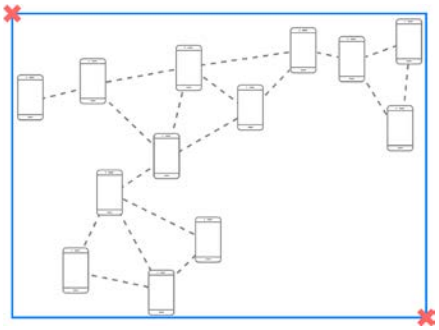
The specific value of λ could, for example, depend on the beacon send interval of the ground-based network. It determines at which rate information can be expected, usually in the range of a few seconds (Á lvarez et al., 2018). Whenever nothing is received after a multiple of that interval, information can be sent to the base. When this rate is unknown or cannot be determined by the UAVs, a static λ can be employed. Since typical smaller UAVs fly between 10 m/s to 30 m/s, λ must be chosen accordingly. As an example, $\lambda = 1s$ could be too low to overfly gaps in an oddly-shaped cluster and would lead to several necessary message transmissions, while $\lambda = 10s$ would result in possibly long-left clusters before sending the information. In general, λ must be chosen wisely due to the additional delay that worsens information quality.

The size of λ and its implications are addressed later-on. At this point, however, we note that the impact of λ on the age-of-information of monitoring data is tremendously smaller compared to a solution without a wireless data channel. A physical return for delivery can take a long time, as a single traversal of a monitored disaster area may take 30 minutes or more. Thus, any sensible choice of λ should perform better than a physical data delivery.

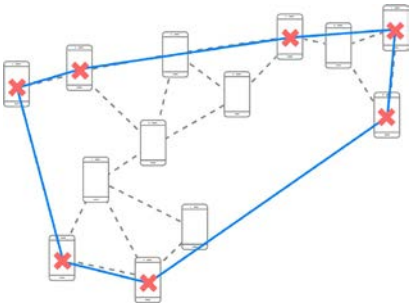


Aggregating Topology Information

To enable the utilization of low-throughput channels for topology information transmission, not only the number of messages must be reduced, but also their size. Within the scope of this paper, we are interested in monitoring the clustered network topology in the disaster area. Thus, the exact location of every individual node is not as important as the larger cluster topology they are part of. Furthermore, historic information is not as important as the most current topology. Therefore, only the most recent location of each node is interesting for the cluster topology.



Instead of transmitting every monitored node location as a set of locations representing a cluster, we propose to aggregate the collected monitoring information directly on the UAV before sending. The goal is to reduce the size of the transmitted content as much as possible, while maintaining a suitable cluster representation. To address this, we specifically propose four simple geometric representations with different levels of aggregation: Point, Circle, Bounding Box, and Convex Hull. Figure 3 sketches out each representation with an exemplary disaster network cluster of mobile devices. Each approach provides a different accuracy in terms of representation of the actual cluster and different messages sizes for transmission to the base station. The aggregates are constructed based on the most recent information available to the UAV directly before transmission, i.e., only after the delay λ has expired, as described in the previous section.



(a) **Point** — The center of the smallest enclosing circle is used as a single point to represent the cluster.

(b) **Circle** — The smallest enclosing circle, indicated by a location and a radius, is used to represent a cluster.

(c) **Bounding Box** — The bounding box, i.e., the smallest enclosing rectangle constructed by only two opposing corner vertices, is used as cluster representation.

(d) **Convex Hull** — The convex hull, i.e., the smallest convex shape enclosing the cluster, is used as representation. The number of required vertices depends on the cluster's shape.

Figure 3. Different cluster representation methods to aggregate topology information and to decrease its transmission size. Blue denotes the representing geometrical shape, red the required information that is transmitted for its representation. The exemplary cluster consists of mobile devices forming an ad hoc disaster network.

Point The Point representation aggregates all cluster information, visualized in Figure 3a by a disaster network cluster of mobile devices, into a single location. This point is calculated as the center of a smallest enclosing circle of all known cluster nodes. Point has the most reduced transmission size with a single location, e.g., being 8 Bytes in size. But this approach also provides the most inaccurate representation.

Circle The Circle representation (Figure 3b) extends Point by the radius of the smallest enclosing circle of the cluster. While increasing the transmission size, assuming 8 Bytes for the center location and another 4 Bytes for the circle radius, this provides a better representation of the cluster and its extents than a single point.

Bounding Box The Bounding Box representation (Figure 3c) uses two vertices to define the diagonally opposed corners of the smallest rectangle, in which all cluster nodes are contained. We align the bounding box in cardinal direction, thus, the horizontal edges are aligned West/East while the vertical edges are aligned North/South, respectively. This representation requires two locations, e.g., each 8 Bytes in size.

Convex Hull The Convex Hull approach, shown in Figure 3d, provides the most accurate cluster representation. Nevertheless, the transmission size can vary greatly, depending on the shape of the convex hull defined by its vertices, each being an 8-Byte location. More complex shapes require more vertices to form the convex hull, thus, also increasing the transmission size significantly.

Increasing Descriptiveness

The proposed approaches can tremendously reduce the transmission size compared to sending all information as individual measurements, especially for large clusters. Nevertheless, the descriptiveness of such detailed information is also lost by reducing it to geometric shapes: information on how many or which nodes are in a cluster, or how old a measured datum is not included in the aggregation from the beginning. We propose to include a single timestamp as minimal information for each aggregate, representing the oldest measurement in the aggregated data set. With this, the receiving base station is, at least, provided with a rough estimate of the data quality and can also differentiate information received at different times or from different sources more easily.

Furthermore, in case that a sufficient data channel is available, the aggregated cluster representations could again be enriched with additional information in exchange for a larger transmission size. As a first option, we can include the number of nodes represented by an aggregate. This only adds a simple and small integer value, but provides a clearer notion of the cluster size, which is valuable information, e.g., for disaster relief efforts to assess the importance of a cluster. However, a requesting service of our Aerial Monitoring System could require individual node information. In such cases, the network IDs of the enclosed nodes in the aggregated representations can be included as a second alternative. Although a valid option, this significantly increases the transmission size again, contrasting our initial goal of reducing it to enable usage of low-throughput networks. Nevertheless, this approach could be a reasonable tradeoff whenever network conditions are just slightly below the requirements for transmitting the entire topology in detail, but adequate with minor reductions.

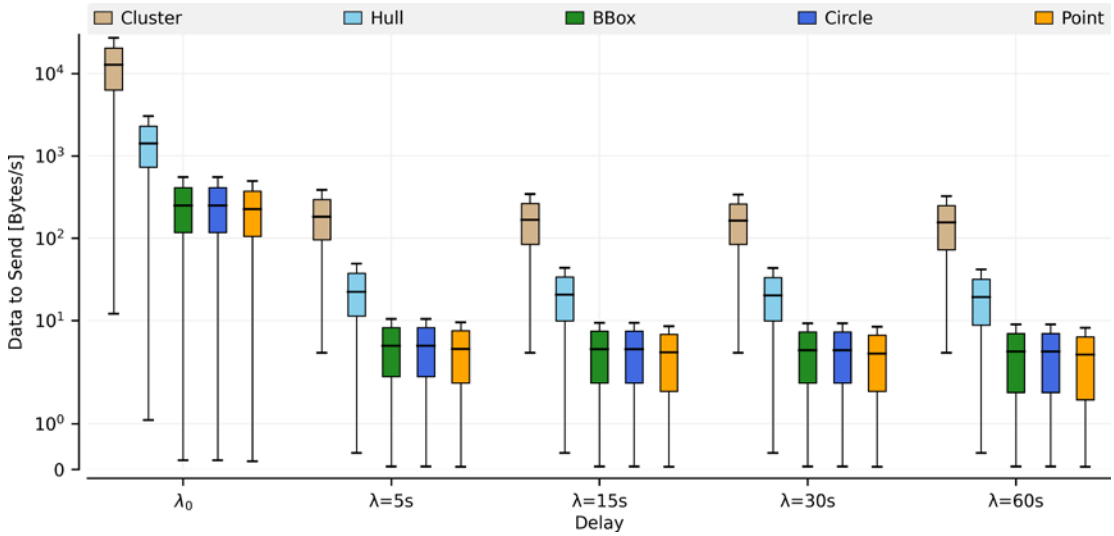
EVALUATION

The evaluation is conducted in the Simonstrator (Richerzhagen et al., 2015) simulation framework, operating in the extended simulation environment designed for Unmanned Aerial Systems and ground-based Delay-Tolerant Networks (DTNs), as detailed in Lieser et al., 2019. This paper puts special emphasis on the less-researched communication between monitoring UAVs and base station. Thus, we utilize an available implementation of an Aerial Monitoring System from prior work (Zobel et al., 2022), which already includes monitoring UAVs and data collection of a disaster network. The existing implementation is extended by a LoRa channel with configurable data rate. Furthermore, the proposed topology information aggregation approaches and message additions discussed in the previous section are integrated.

Table 1. Simulation Environmental Settings.

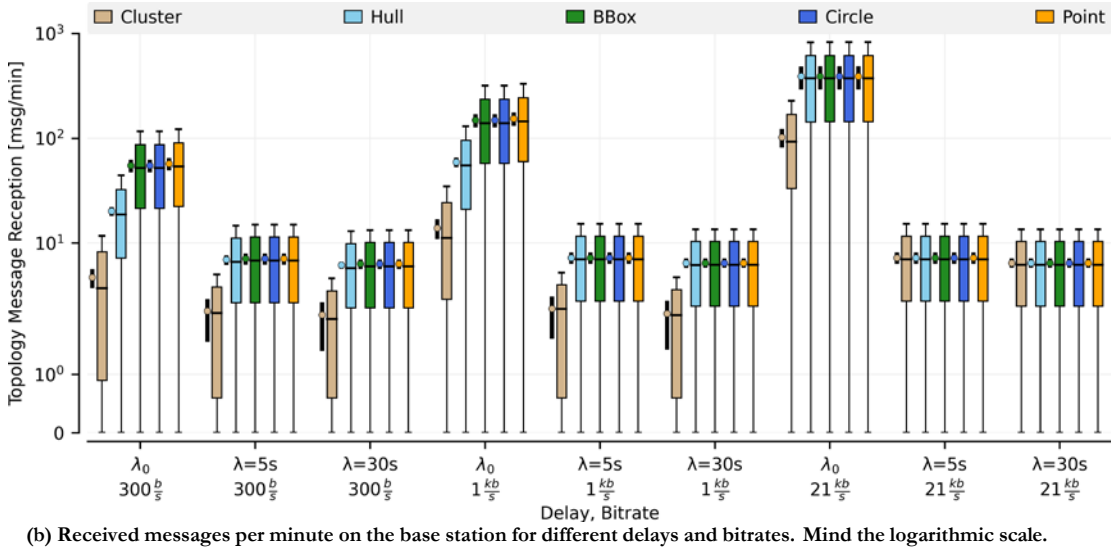
Scenario	Map	Inner City, Post-Disaster
	Size	2000 m x 2000 m;
	Node Movement	Civilian Disaster Mobility [a]
	Points of Interest	5, random distribution
	Duration	3 h, 10 random seeds each
Disaster Network	Size	100 Nodes
	PHY	WiFi, IEEE 802.11g
	Range	approx. 75 m
	Data Rate	5 Mbit/s
Aerial Monitoring System	UAV	Quadrotor [b]
	Coverage Path Planning	Lawnmower
	Network Interaction	Cooperative Data Collection [c]
	Monitoring Mission Time	approx. 36 minutes
Monitoring Data Transmission	Aggregation	[None (Cluster), Point, Circle, Bounding Box (BBox), Convex Hull (Hull)]
	Additional Information	[∅, #Nodes, IDs]
	Transmission Delay λ	[None (λ_0), 5s, 15s, 30s, 60s]
	Channel Data Rate	[300 bps, 1 kbps, 21 kbps, 1 Mbps]

[a] cf. Zobel et al., 2021, [b] cf. Zobel et al., 2019, [c] cf. Zobel et al., 2022



The simulation environment settings, listed in detail in Table 1, encompass 100 mobile devices moving in groups within an inner-city disaster area of 2x2 km^2 (Á lvarez et al., 2018; Zobel et al., 2021). For each simulation run of three hours, five points of interest like shelters and first aid stations are randomly selected, with the constraint that they must not overlap and must maintain a minimum distance of at least 300 m from each other. Devices predominantly gather around these points of interest and move in-between them. The mobility model relies on available Open Street Map (OSM) data, limiting device movement to streets and pedestrian walkways mapped in the OSM dataset. Each combination of simulation parameters is repeated ten times with different random seeds.

The entire area is monitored by a single UAV, completely traversing the monitoring area before returning to its base station. Traversal route planning uses a Boustrophedon-style coverage path planning approach (Choset & Pignon, 1998; Zobel et al., 2022), resulting in a total flight time of around 36 minutes from takeoff to landing. Topology aggregation can be switched between the four proposed aggregation methods Point, Circle, Bounding Box, and Convex Hull. Furthermore, the entire cluster information can be send without any aggregation (Cluster). Optional information in aggregates can be omitted (∅), include the number of nodes (#Nodes), or contain a list of all nodes' network IDs (IDs). The transmission delay λ, as described in the previous section, is investigated for no delay (λ_0), reasonably small values of $\lambda = 5s$ and $\lambda = 15s$, and much larger values of $\lambda = 30s$ and $\lambda = 60s$, respectively. Most importantly, we adjust the data rate of the transmission channel towards the base station to investigate requirements on it depending on the used aggregation methods and included detail of information in topology messages. Specifically, we test three settings that represent a data rate similarly achievable by using LoRa: A data rate of 300 bps constitutes the lower bound of possible data rates, 1 kbps a median tradeoff between throughput and signal robustness, and 21 kbps constitutes an upper bound. An additional data rate of 1 Mbps was evaluated as reference comparison for a generic cellular network connection.



Sender Demands and Actual Throughput

At first, we take a look at the requirements of a monitoring UAV on the channel capacity for sending its information w.r.t. the transmission delay and the aggregation approach. When considering the entire monitoring mission time, the UAV queues between 2.9 and 13.8 messages per second when using direct transmission (λ_0) for around 75% of the time, which is independent of the aggregation approach. When using a transmission delay, however, this significantly reduces to a median of around 0.12 messages per second and to a maximum of 0.25 messages per second. With that, we have a first clue on the expected impact of using a transmission delay and not directly relaying all information received. Additionally, this clearly impacts the amount of data a monitoring UAV wants to send, as visualized in Figure 4a. For direct transmission, sending all information without aggregation would require a median of 13.4 $\frac{kByte}{s}$ but, e.g., only 194 $\frac{Byte}{s}$ with $\lambda = 5s$. At the same time, using aggregation with λ_0 already reduces the amount of data significantly, to around 1.5 $\frac{kByte}{s}$ using convex hulls and even further to around 250 $\frac{Byte}{s}$ for the other approaches. The differences between the transmission intervals, on the other hand, are only in the range of a few bytes per second, slightly decreasing with a higher interval. This suggests that only a few retransmissions were necessary, due to seen topology updates after sending the initial packet. The slight differences between the intervals also suggest that the shorter intervals are already sufficient to track a cluster's topology without requiring multiple topology messages to send during an overflight. Overall, the reduction in both the transmission delay and the aggregation approaches clearly highlights that information can be reduced on the sending side, which tremendously reduces the requirements for the data channel.

Next, we take a closer look at message reception. This clearly depends on the throughput of the channel: with a smaller channel, less messages can be sent and received per time unit. This bottleneck brings several problems, that are (i) an increase of the probability that messages are waiting longer in a sending queue, (ii) that messages are dropped from the queues due to expired waiting times, or (iii) that the queues are already full and new messages are dropped instantly. In the end, these problems are recognized on the receiver, as fewer messages are received than queued to send. Figure 4b visualizes the measured message reception in messages per minute on the base station. As expected from the reduction of sent messages seen in Figure 4a, using a transmission delay obviously decreases the number of messages on the receiving side. However, a larger transmission delay does not impact that number in a more significant way than a smaller delay. In contrary, — especially for the slower bitrate settings on the channel — the number of messages for Cluster and Convex Hull are *lower*, despite a higher number of messages queued on the sender. This already suggests that messages are dropped. With an increase in bitrate, on the other hand, the number of received messages increases for λ_0 for all approaches, while leveling up for Cluster with the other aggregated approaches for a bitrate of 21 $\frac{kBit}{s}$ using a transmission delay. Thus, the number of message drops reduces generally with a higher bitrate, as expected. More importantly, a bitrate of 1 $\frac{kBit}{s}$, which is achievable by state-of-the-art LoRa modules, shows to be sufficient to transmit the aggregated topology information without perceivable message drops.

(a) Throughput demands for sending packets on an unlimited monitoring UAV with different delays. Mind the logarithmic scale. While we perceive a drastic decrease in demand between sending without and with delay, the influence of different delays is minimal.

(b) Received messages per minute on the base station for different delays and bitrates. Mind the logarithmic scale.

Figure 4. Throughput demands for an unlimited sender compared to the received messages on the base station with limited bitrates.

The loss of messages between sender and receiver is further investigated considering Figure 5. As before, a clear decrease in dropped messages with increasing bitrate and with using topology aggregation is perceived. In comparison to direct transmission, only a fraction of messages are dropped due to the smaller number and size of messages, even with a bitrate of only 300 $\frac{Bit}{s}$. These results also support the findings that a data rate of 1 $\frac{kBit}{s}$ is already sufficient for the transmission of aggregated topology information without perceivable losses due to channel capacity. For the Cluster approach, however, this still constitutes for a message loss of around 70%. In addition to the other figures, Figure 5 exemplary visualizes the results for 1 $\frac{MBit}{s}$ data rate to highlight that this is sufficient to send all information without aggregation and loss over the data channel.

Message Size and Optional Message Content

As depicted in Figure 6a, the size of messages is an important factor for their transmission in low-throughput channels. Especially for very large Cluster messages, but also seen in detail for larger Convex Hull messages, these are not received on the base station due to the channel limitations. First with a data rate of 21 $\frac{kBit}{s}$, and supported by the measurements at 1 $\frac{MBit}{s}$ when all messages are received without problems, very bulky messages can be transmitted. The large number of dropped Cluster messages highlights that they are too large in size to be

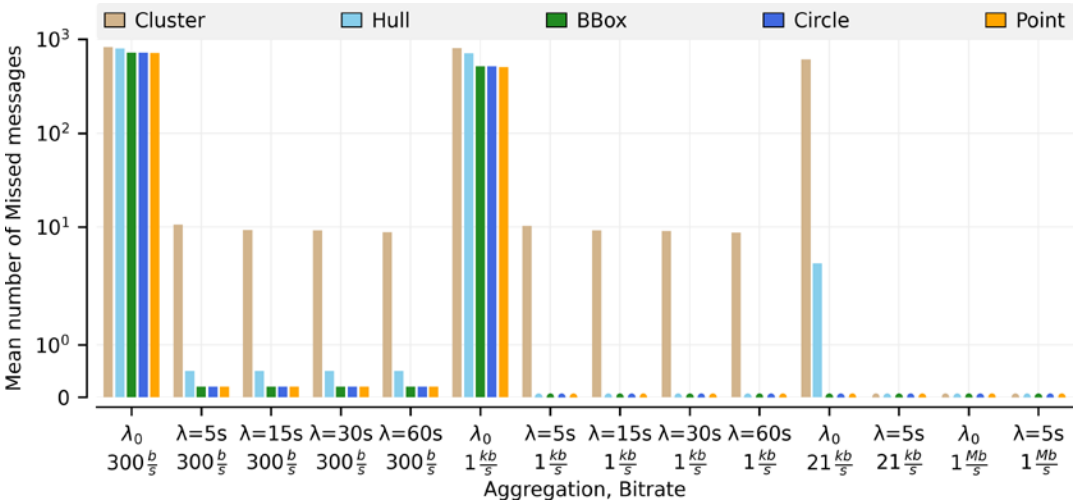


Figure 5. Mean number of missed messages, aggregated over all simulation runs. Mind the logarithmic scale. Round caps indicate zero values. With increasing bitrate and by using topology aggregation, the rate of dropped messages decreases significantly. For aggregated topology information, a data rate of 1 $\frac{kBit}{s}$ is already sufficient for transmission.

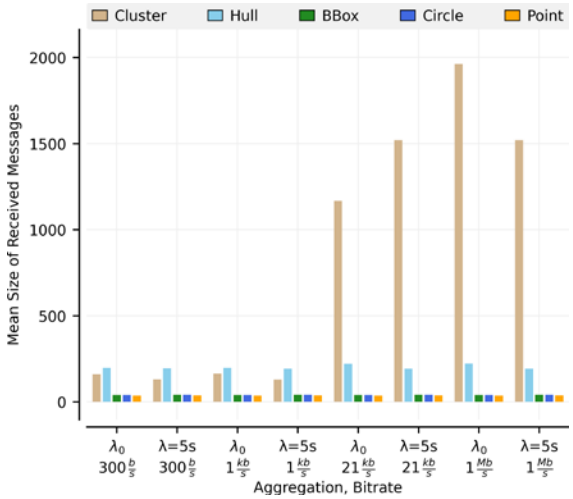
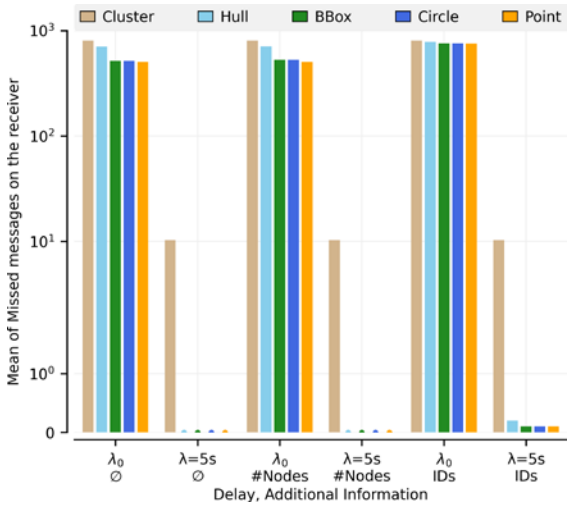


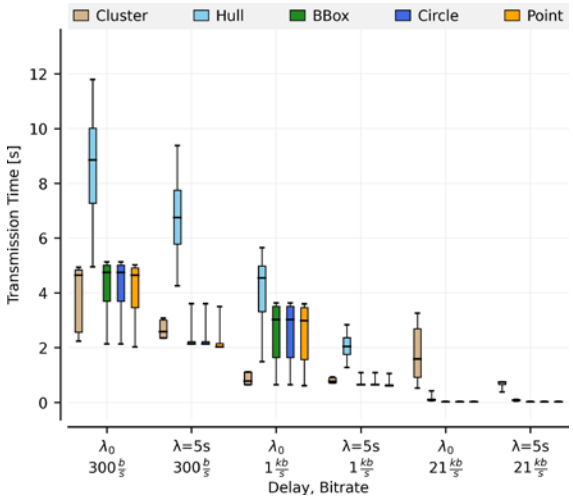
transmitted successfully in low-throughput networks. Thus, the proposed aggregation of information and reduction in size is clearly necessary to allow data transmission for larger clusters in the first place.

In the previous section, we also introduced optional message content in the information aggregates, to increase their expressiveness towards the receiving base station. But we also discussed that, especially including a list of all node IDs, significantly increases the message size, contradicting the intended size reduction. Therefore, Figure 6b takes a closer look of the influence of the optional message content in aggregate messages, on the example of 1 $\frac{kBit}{s}$ bitrate. Clearly, there is no impact by adding a simple integer value for the number of represented nodes in the aggregates, which is also true for a bitrate of 300 $\frac{Bit}{s}$ and the higher bitrates, respectively. For the list of IDs, however, an increase of messages drops is perceivable due to the comparably extreme message size of aggregates. They can increase to more than ten times the size of the same message without these IDs. This increase is especially problematic for the lower bitrate channels, since message drops re-appear for aggregated topology messages with a formerly sufficient bitrate of 1 $\frac{kBit}{s}$ and strongly increase for a bitrate of 300 $\frac{Bit}{s}$. This supports our statement that the list of message IDs should only be added when absolutely necessary and with a sufficiently scaled channel throughput. Preventing message loss and sending the aggregated topology information to the base station is more important than this optional information.



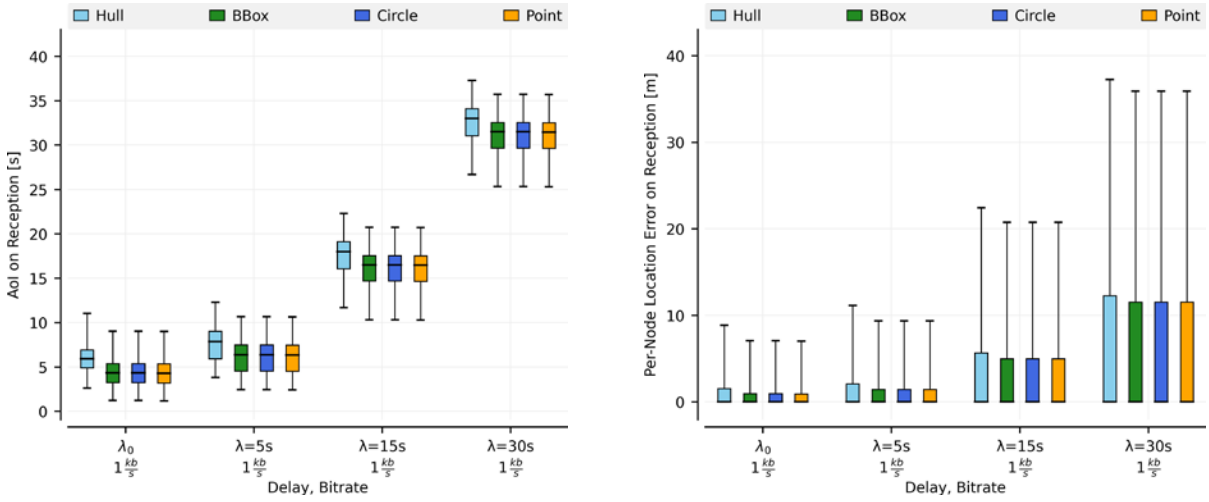
Transmission Time

Another problem with limited channel throughput is the additional delay introduced by filled sending queues. In addition to the actual airtime of a packages, i.e., the time to send the entire package from start to end on the wireless medium, this results in a certain transmission time per packet. To assess this transmission time, we traced the time difference between putting a packet in the network interface's queue on the monitoring UAV and receiving it at the network interface on the base station. This transmission time is visualized in Figure 6c.



Directly perceivable is that transmission times are generally higher for direct transmission than for a delayed transmission. This comes as a direct result of longer sending queues, which increases the delay for all messages. Furthermore, messages for Convex Hull are clearly more delayed than other types. This can be attributed to their significantly larger size compared to the other aggregation approaches. Therefore, they take longer to transmit and extend the waiting time in the queue for all messages. For the other aggregation approaches, only slight differences can be seen from the results. Curiously, transmission times for Cluster messages are much lower for 300 $\frac{Bit}{s}$ and 1 $\frac{kBit}{s}$ bitrate. Nevertheless, Figure 6c only depicts the time for *received* messages — and, as seen before, these are only the small ones. Larger messages are only received for 21 $\frac{kBit}{s}$. With that bitrate, the transmission time increases again because most messages are now countable for the transmission time. Similarly, nearly no delay is introduced for the aggregated approaches by the queues, indicating empty queues and nearly instantaneous transmission.

(a) Average size of received messages per bitrate and delay transmission. With a higher bitrate, very large Cluster and Convex Hull messages can be transmitted.



(b) Missed Messages per optional message content, using a data rate of 1 kbps. Using aggregation, only Convex Hull results in a few message drops for ∅ and #Nodes. When sending a list of all node IDs, however, the number of message drops increases intensely for direct transmission, and slightly for $\lambda = 5s$.

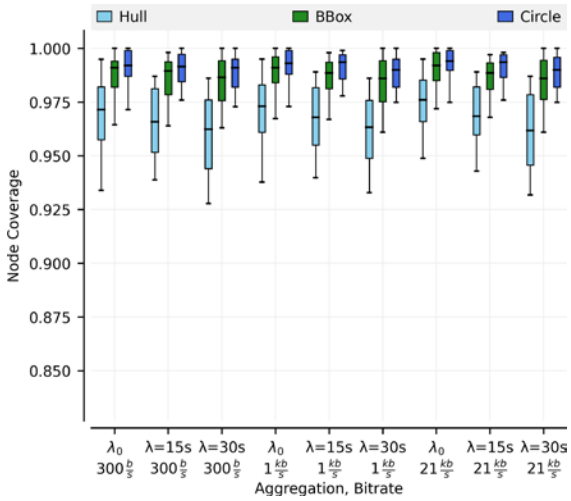
(c) Transmission time as difference between message insertion at the sending queue on the UAV and message reception at the base station. Only received messages can be counted with this metric, which must be considered when assessing this time difference especially for larger messages and smaller bitrates.

Figure 6. Received message size, missed messages on the receiver for optional message content, and transmission time. The results highlight that the proposed aggregation methods enable transmission via low-throughput data channels in contrast to sending all data.

(a) The age of monitored information when received on the base station, measured per node information aggregated on the monitoring UAV.

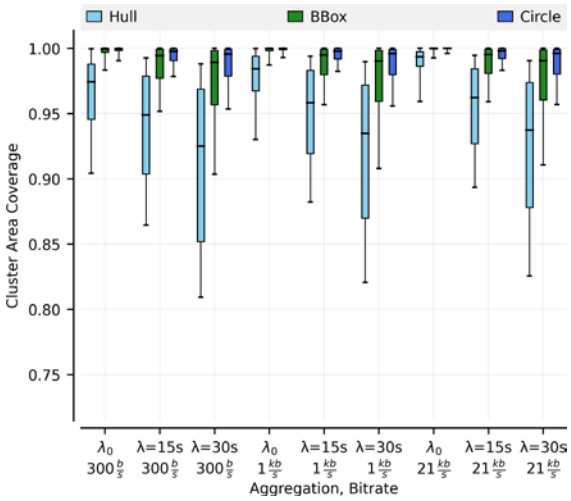
(b) The location error of information received on the base station, measured per node information aggregated on the monitoring UAV.

Figure 7. Per-node Age-of-Information and absolute location error on reception for a data rate of 1 $\frac{kbit}{s}$.



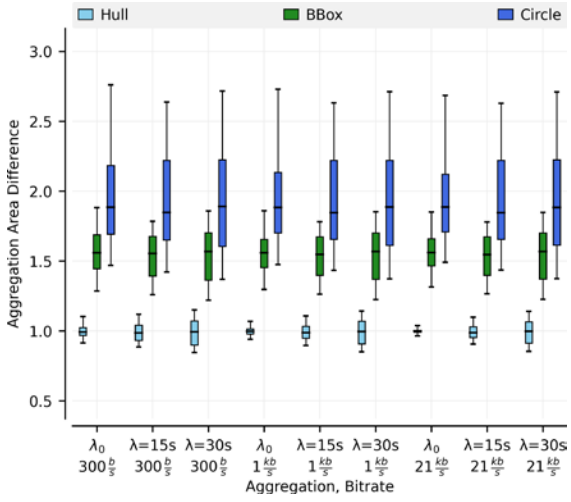
Topology Representation of Aggregations

The remaining question is, whether the aggregated information in the form of the proposed simple geometric shapes is suitable to represent the actual topology that was monitored by the UAV.

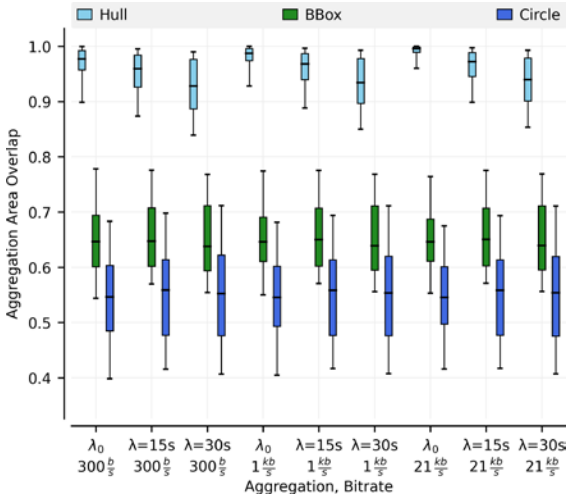


First, we look at the Age-of-Information (AoI) and the location error (LE) of the information. Both metrics encompass the difference from the initial measurement on the UAV until the final reception and assessment on the base station. Therefore, they provide a possibly expected error margin, introduced by a delayed transmission ($\lambda > 0$) and waiting times due to message queues and limited channel throughput. Figure 7 depicts results for both metrics on the example of a 1 $\frac{kbit}{s}$ bitrate. As expected, we see a direct correlation between the transmission delay λ and the AoI. However, we also see a generally larger AoI for the Convex Hull approach due to longer transmission time required as a result of the larger message sizes. Since the AoI can directly influence the location error, as it gives more time for the monitored devices on the ground to possibly relocate, the LE similarly increases with a higher delay. Nevertheless, the median LE is still zero, providing an acceptable information quality, at least within the simulated scenario. However, these results may change with other scenarios or simulated mobility models. In general, a low AoI and location error is preferable; the transmission delay should be kept as small as possible.

Second, we specifically regard the representation and accuracy of the aggregated topology information compared to the actual network topology. Figure 8 provides an overview of the used metrics. As geometric comparison baseline serves the convex hull of the network cluster at the time of receiving the aggregate at the base station. Since the Point approach does not provide an actual geometric area, no comparisons are possible.



Most importantly for our approaches is, that they cover the network clusters constructed from individual nodes to represent the actual network topology. As depicted in Figure 8a, the node coverage of Convex Hull, Bounding Box, and Circle aggregates is very good, with more than 92.5% of nodes always covered. Furthermore, the less exact approaches Bounding Box and Circle usually cover more nodes than Convex Hull. This results from their larger but less precise extents, allowing more node movement on the ground before losing coverage. On the other hand, there are no significant differences on node coverage for different transmission delays. Additionally, there are only slight performance increases with a higher data rate. For the coverage of the geometric cluster representation, however, the influences of mobility in the network are much clearer. Figure 8b highlights a decrease in cluster coverage with a higher transmission delay and better coverage with higher data rate. Similar to node coverage, the less-exact Bounding Box and Circle generally cover more of the clusters, even with mobility, than the more exact Convex Hull. The tradeoff, however, becomes clear when comparing the difference in size between the aggregation and the actual network cluster (cf. Figure 8c) as well as the overlap of the aggregation with the network cluster (cf. Figure 8d), respectively. The circular aggregation area is between 1.25 and 2.75 times bigger than the actual cluster, including only 40% to 70% of it. The bounding box representation performs better, but still depicts an area up to 1.8 times the size of the actual cluster. Only the Convex Hull approach is able to closely represent the network clusters. But with a higher susceptibility to node mobility, the transmission delay also has a much larger impact on its accuracy than on the other approaches.



(a) Node coverage.

(b) Cluster area coverage.

(c) Aggregation vs. actual cluster size.

(d) Part of aggregation overlapping with actual cluster.

Figure 8. Overview of comparing metrics for the representation of aggregated topology information and the actual network topology and network clusters on the ground. Note that the y-axes are not starting at zero. For comparisons with the actual cluster area, the convex hull of the network cluster is used.

CONCLUSION

The possible impact and the necessary requirements of a data channel between Unmanned Aerial Vehicles (UAVs) and their operating base station is one of the less-researched topics in the field of Unmanned Aerial Systems. Especially for low-cost off-the-shelf UAVs without proper network interfaces, such as for satellite or cellular networks, alternatives are required to allow their application in large-scale disaster areas, where a central ICT infrastructure may not be available.

This paper discusses the importance of such a data channel on the example of an Aerial Monitoring System, that searches and monitors mobile devices in a disaster scenario with UAVs. This information is highly valuable, for example, to rescue services, but may arrive only with severe delay without a proper data channel available to the monitoring UAVs. LoRa is one of the suitable wireless communication technologies that could be integrated and used on off-the-shelf UAVs and we are currently working on a possible hardware implementation. LoRa provides a very robust, but also very limited low-throughput communication channel. We have shown that the bitrates achieved by LoRa are not suitable to transfer typical topology information monitored by UAVs. Therefore, we propose to aggregate topology information as simple geometric shapes, which can be transmitted using only small, basic information like a few locations or numerical values. Our evaluation results demonstrate that theses aggregations significantly reduce the size of messages for transmission to the base station. At the same time, they maintain an adequate representation of the monitored clusters and the network topology. The aggregated monitoring information can be transferred with reasonable delay and reliability towards the base station even over low-throughput networks, tested in this paper with a bitrate as small as 300 $\frac{bit}{s}$. A higher throughput reduces transmission times and message drops, further increasing the usability of both our approach and the gathered monitoring information.

Future work must encompass more realistic representations of the data channels. In this work, we focused on the application of information aggregation and its usability within limited data channels, but neglected signal losses, packet collisions, and more. Furthermore, an increase of devices in the disaster network and multiple monitoring UAVs working in parallel may further burden the used data channel, reducing its usability and effective throughput. More sophisticated, possibly situation-adaptive aggregation approaches are, therefore, necessary in combination with larger and more complex network environments. Similarly, the reduction of transmission data could be approached as an optimization problem, where only the optimal subset of actual location measurements is sent to reduce channel utilization. Nevertheless, the work in this paper provides a foundation for future research in an important, but currently unattended and not well-researched subject of Unmanned Aerial Systems.

ABSTRACT

Disaster management is plagued by uncertainty and chaotic situations, often crossing boundaries and affecting multiple jurisdictions. Collaboration in these settings is complicated, especially when authorities face failure in the infrastructure available leading to facilities operating over capacity and/or vulnerable people left without support. There are records about those experiences globally. There is a broad literature on shelter location/allocation, but few articles consider the potential failure facilities and none of those contributions consider the collaboration between multiple jurisdictions. This article introduces a novel bi-objective formulation for shelter location-allocation considering backup facilities for operations involving multiple jurisdictions. This approach is applied to a set of numerical examples and a real case of volcanic eruptions in Mexico. The results show the influence of transboundary coordination on the support provided to disaster victims, the value of backup facilities and the capacity of the model design to provide relevant alternatives in practice.

Keywords

Shelter location-allocation; transboundary coordination; backup facilities; stochastic optimization.

INTRODUCTION

Just in 2022, disasters caused by natural hazards threatened over 185 million people and caused an estimated US $223.8 billion of economic losses (CRED, 2023). Humanitarian logistics has arisen as a critical field to develop solutions to handle the conditions created by disasters. It involves multiple stakeholders collaborating to deliver products and services to satisfy the needs of people affected by disasters (Gutjahr et al., 2020).

Evacuation and shelter selection influence the service experienced by people affected by disasters. Shelters are often prepared in advance, but emergency services and facilities can fail under disaster situations (Albareda-Sambola et al., 2015). Although there has been an increase of models incorporating backup facilities, there is limited information about the value of these facilities, especially when facility capacity is included in the formulations.

Humanitarian logistics is a multi-actor, multi-agency, and cross-jurisdictional activity involving private and public organizations (Oloruntoba, 2010). Despite the emphasis on the interaction between different stakeholders, coordination under disaster circumstances remains a key challenge (Balcik et al., 2010). This complexity is further

fueled by the need to conduct joint operations for crises across boundaries affecting different jurisdictions (Boin et al., 2014) because each jurisdiction has defined responsibility and attributions.

Disasters can transcend political, functional and temporal boundaries, which is translated into significant complications to handle them requiring extreme adaptation (Ansell et al., 2010). Recent research highlights the importance of incorporating the collaboration of agencies from different jurisdictions (Nurmala et al., 2017; Olsson, 2015). However, that has not been reflected in the development of cross-jurisdictional models for disaster response. This study answers two research questions: i) what is the effect of coordination for shelter selection between different jurisdictions in the service provided to people affected? and ii) what is the value of incorporating backup shelters for disaster response?

This research proposes a two-stage stochastic optimization model to support evacuation and shelter location decisions incorporating cross-jurisdictional collaboration. It is tested using a set of numerical examples and a case study. It contributes to the literature by proposing a model for operational collaboration in shelter management between stakeholders from different jurisdictions, acknowledging the possibility of failure of any facility using backup facilities, and investigating the impact of transboundary coordination on the experience of the people affected by the disaster.

LITERATURE REVIEW

Backup Shelters

Shelter location involves the selection of suitable safe points to provide protection to people affected by disasters (Kınay et al., 2018). The vulnerability of facilities inside the affected area has motivated studies looking into the use of backup facilities for distribution centers (Mohamadi et al., 2019; Rahmani et al., 2018; Yahyaei & Bozorgi-Amiri, 2019). The need for backup shelters to react to failures in sheltering, however, has been understudied, with many studies neglecting to consider shelter failure (Ma et al., 2016).

There is a stream of articles focused on selecting the location for building shelters in suitable areas (Aghaie & Karimi, 2022; Geng et al., 2021), thereby reducing the possibility of shelter failure. However, in many countries the policy is to use existing facilities as shelters (Liu et al., 2011), which are vulnerable to failure. The work of Gangwal et al. (2023) and Wang and Xu (2023) shows that it is important to look at the vulnerability of the shelter not only because of damage on the facility itself, but also because of road failure leading to isolated shelters.

Albareda-Sambola et al. (2015) introduce the use of the p-next center problem to select primary and backup facilities closer to the victims in case they reach their closest center and it is closed. Albareda-Sambola et al. (2019) extend that idea by considering different strata of people requiring different services whereas Hinojosa et al. (2023) use a hierarchical process where the planner sets service centers based on the worst-case behavior of the public and the beneficiaries select the center based on their preferences. Although this is a promising avenue of research, all the models disregard the capacity of the facilities, which is a very practical constraint in reality. An et al. (2013) propose a formulation assuming each facility is subject to independent probabilistic disruptions which are represented in a set of scenarios. Their formulation defines the allocation upon the realization of the corresponding scenario, which requires the government to notify and direct all the evacuees. Aiming to maximize network reliability and considering facility capacity, Babashahi et al. (2020) use reserve hub elements as backup components to prevent failure considering failure probabilities calculated based on incoming traffic. Nonetheless, these models consider a single jurisdiction affected by the disaster.

Coordination Across Jurisdictions

Disasters are often connected across different jurisdictions, with the outcome of one jurisdiction affecting the situation on another one (Ansell et al., 2010) and requiring to manage conflicting objectives (Rui et al., 2008). In these environments, deciding whose resources to use is a complex decision because of the inability to ensure fa ir allocation of joint operations (Schulz & Blecken, 2010), leading to concerns about fair distribution of shared workload (Schulz & Blecken, 2010). The combination of these problems can negatively influence the cost and service level provided.

Research has discussed the problems associated with formal structures in handling new and complex problems (Olsson, 2015) and underlines the importance of adopting cross-sector partnerships in humanitarian logistics (Nurmala et al., 2017). Ansell et al. (2010) argue the need for a transboundary authority structure that can be triggered in times of crisis and that will help minimize confusion and bureaucratic infighting. Collaboration between municipalities and different services, for instance, can enable more effective operations (Zikeloglou et

al., 2024). That is the reason the European Union has led the first European Disaster Response Exercise (Hollis, 2020) and some articles have considered the collaboration between different agencies using agent -based simulation (Lebcir & Roy, 2023; Valaei Sharif et al., 2023), game theory (Coskun et al., 2019; Ergün et al., 2023), and Industry 4.0 technologies (Kumar & Singh, 2022). Nonetheless, less effort has been invested into humanitarian logistics activities. Wojtalewicz et al. (2014) use the case of the Regional Hub Reception Center (RHRC) led by the Purdue Homeland Security Institute involving 17 jurisdictions to propose the use of simulation to efficiently assess the use of facilities to improve coordinated responses. Polese et al. (2024) propose an approach for cross-border multi-risk assessment as an answer for single-risk and independent assessments which neglect the cascading effects between jurisdictions. Wang et al. (2022) use a regional healthcare coalition to collaborate for stock pre-positioning and post-disaster procurement and transshipment to serve affected areas. However, current models are ill-equipped to consider the coordination of different jurisdictions for shelter management.

This paper designs and tests a novel optimization model to allow for the location and allocation of primary and backup shelters enabling the coordination and use of resources from different jurisdictions. The contributions of this article are threefold; i) provides a model allowing operational collaboration between stakeholders from different jurisdictions for shelter management, which is an area neglected in the literature; ii) proposes a capacitated formulation increasing the reliability of the response by acknowledging the possibility of failure of any facility, an approach understudied in the literature; and iii) shows the impact of transboundary coordination on the experience of the people affected by the disaster, which can foster the development of more contributions incorporating transboundary coordination.

METHODOLOGY

This study develops a two-stage optimization model to guide the selection of primary and backup shelters for people affected by disasters considering transboundary coordination. The aim is to find the best combination of the decisions that can lead to a good level of service for disaster beneficiaries.

Optimization is a commonly used method to determine the 'optimal' location of facilities because it allows investigating the different possibilities and define the most appropriate option based on the objective functions (Kınay et al., 2018). It has been selected for this research because it allows balancing the support provided to disaster victims and the resources available during disasters. There have been discussions in the literature about the best performance measures for humanitarian logistics. Although minimization of cost is often used to ensure efficiency in the operations, this research argues that the effectiveness of the operations (i.e. the support given to affected people) needs to be a priority. This research incorporates both objectives in a multi-objective formulation to guide decision-making. The use of two-stage optimization allows us to incorporate the uncertainty about the impact of the disaster and the state of the infrastructure (Rodríguez-Espíndola et al., 2020), where the first sta ge is at the imminent pre-disaster stage and the response stage uses information about the impact of the disaster to guide response decisions.

Context of the Situation

The model proposed promotes the coordination between different jurisdictions to make allocation decisions of primary and backup shelters. The allocation of people is guided by two objective functions. The first objective function minimizes the total distance travelled by the people affected to focus on effectiveness. With the possibility of transboundary coordination, people evacuated in a demand area can move to a different jurisdiction if it is beneficialfor them. To ensure that there is a level of fairness between authorities from different jurisdictions, especially looking at the expenses incurred, the second objective function of the model minimizes the maximum cost per person per jurisdiction. It balances the expected cost (i.e. the sum of facility cost and transportation cost) to avoid overburdening any one of the jurisdictions.

In the two-stage formulation, first stage decisions are focused on facility selection and the flow of people from demand areas to shelters right before the event. Given the range of time for the arrival of people, it is assumed people will get there by their own means. Second-stage decisions take place at the response stage. Considering uncertainty on the magnitude and impact of the disaster, a set of disaster scenarios can be used to guide decision-making. The model incorporates damage to shelters and to the road network to plan the transportation of people allocated to those facilities in buses provided by authorities. Hence, the second stage is focused on the decisions about transportation of people, defining the number of people to move to the same or different jurisdictions.

Notation

Sets

I	Set of demand areas
J	Set of potential shelter locations
L	Set of jurisdictions
D^l	Set of demand areas in jurisdiction l
L^l	Set of shelters in jurisdiction l
S	Set of scenarios

Parameters

TM	Capacity of the buses
TC	Transportation cost per km
$N1$	Percentage of population served by their own jurisdiction at stage 1
$Budget_l$	Operational budget at jurisdiction l
d_{ij}	Distance between demand area i and shelter j
e_{jk}	Distance between shelter j and shelter k
π_s	Probability of scenario s
Cap_j	Capacity of shelter j
Pop_i	Demand in area i
Bus_l	Number of buses available in jurisdiction l
G_j	Cost of locating facility j
H_{ks}	Availability shelter k in scenario s.
W_{jks}	Road connectivity between shelter j and shelter k in scenario s

Decision variables

x_{ij}	Number of people sent from demand area i to shelter j
y_{jks}	Number of people sent from shelter j to shelter k in scenario s
A_j	Use of shelter j
R_{jks}	Number of buses going from shelter j to shelter k in scenario s
M	Maximum operational cost per person

Model

$$Min\ z = \sum_{i\in I}\sum_{j\in J} d_{ij}\, x_{ij} + \sum_{j,k\in J: j\neq k}\ \sum_{s\in S} \pi_s\, e_{jk}\, y_{jks} \tag{1}$$

$$Min\ M \tag{2}$$

$$M \sum_{i\in D^l} Pop_i \geq \sum_{j\in L^l} G_j A_j + \sum_{j\in L^l k\in J: j\neq k}\ \sum_{s\in S} \pi_s TC\, e_{jk}\, R_{jks} \qquad \forall\ l \in L \tag{3}$$

$$\sum_{i\in I} x_{ij} + \sum_{k\in J: j\neq k} (1 - H_{ks}) y_{kjs} \leq Cap_j\, A_j \qquad \forall\ j \in J, s \in S, H_{js} = 1 \tag{4}$$

$$\sum_{j\in J} x_{ij} = Pop_i \qquad \forall\ i \in I \tag{5}$$

$$\sum_{i\in I} x_{ij} = \sum_{k\in J, j\neq k, H_{ks}=1} W_{jks} y_{jks} \qquad \forall\ j \in J, s \in S, H_{js} = 0 \tag{6}$$

$$y_{jks} \leq TM\, R_{jks} \qquad \forall\ j \in J, s \in S, H_{js} = 0 \tag{7}$$

$$\sum_{k\in J, j\neq k} R_{jks} \leq Bus_l \qquad \forall\ l \in L, j \in L^l, s \in S, H_{js} = 0 \tag{8}$$

$$y_{kjs} \leq Cap_k \qquad \forall\ j, k \in J, s \in S, H_{js} = 1, H_{ks} = 0 \tag{9}$$

$$\sum_{i\in D^l}\sum_{j\in L^l} x_{ij} \geq N1 \sum_{i\in D^l} Pop_i \qquad \forall\ l \in L \tag{10}$$

$$A_j \in \{0,1\};\ \ x_{ij}, y_{jks}, R_{jks} \in Z^+$$

Objective function (1) minimizes the total sum of the distance travelled to go to primary and backup shelters. Objective function (2) minimizes the maximum cost of the operations (M) per person per jurisdiction to balance the burden of the different jurisdictions. The cost is calculated in inequality (3) to incorporate the cost of opening facilities and transporting people from primary to backup shelters by the number of people originally residing in the area. Inequality (4) ensures the capacity of the shelters is not exceeded, whereas equation (5) forces the system to allocate all the people in the affected area to a shelter. Equation (6) defines the number of people allocated to a primary shelter that has been damaged to transfer them to the backup shelter. Inequality (7) defines the number of buses needed whilst inequality (8) ensures the number of buses allocated does not exceed the number of available vehicles. Inequality (9) sets a limit on the number of people who can move from a damaged shelter to the backup shelter Inequality (10) is activated if there is an agreement to ensure a percentage of the population of a jurisdiction is served by the same jurisdiction at the first stage tuning the parameter $N1$. Finally, variables are declared.

Solution Method

This research assumes that the overarching priority for authorities is to protect people. Considering the relative importance of objective function (1) over function (2), the model is solved using a lexicographic approach. The model is initially solved to minimize objective function (1) and using objective function (2) as a constraint. Then, the term LEX is introduced to fix the value of the total distance using the following equation:

$$LEX = DIS$$

A new inequality can be defined using the term LEX:

$$LEX \geq \sum_{i \in I} \sum_{j \in J} d_{ij}\, x_{ij} + \sum_{j,k \in J: j \neq k} \sum_{s \in S} \pi_s\, e_{jk}\, y_{jks} \qquad (11)$$

Equation (11) substitutes Equation (1) in the original formulation and it becomes a constraint. The model is then solved minimizing (2) to obtain a single value that can be presented to the decision-maker.

ANALYSIS OF RESULTS

This study is divided into two parts: one using numerical examples and the second one using information from a real case study. This study uses a set of numerical experiments in the first part to analyze the performance of the model, the importance of backup shelters and to explore the value of the stochastic solution in instances of different sizes. The second part is focused on the case of an eruption of the Popocatepetl volcano in Mexico to look at the impact of transboundary coordination under real conditions.

Numerical Instances

Model Results

The model was initially tested using a set of randomly generated numerical examples. The experiments were set based on three instances of different impact shown on Table 1.

Table 1. Characteristics of the numerical examples

Instance	Demand areas p/jurisdiction	Shelters p/jurisdiction	Jurisdictions	Scenarios	Demand
Low	50	50	3	5	51,310
Medium	75	75	4	15	68,991
High	100	100	5	30	86,152

Parameters for the numerical examples were generated using a random number generator based on the type of variables (e.g. binary, integer). The information was coded into GAMS 35.2.0 and solved using Cplex following a lexicographic approach. Each instance was solved allowing a maximum of 12 hours for solution time per model. The process followed was to minimize objective function (1) first, then fixing the objective value, and then minimizing objective function (2) to obtain the solution. A summary of the f indings is presented in Table 2. The optimality gap is defined as the distance between the objective value of the feasible solution found and its optimal value. The first two instances had a gap below 10% within the time limit of 43,200 seconds, whereas the gap of over 15% of the high instance is deemed acceptable because of its size. The results suggest that longer solution

times or heuristic algorithms might be required to close the gap in large-scale instances.

Table 2. Summary of the findings

Inst.	Total distance p/person (km)	Max buses p/1000 people	% of people across jurisdictions (Stage 1)	Max % of people across jurisdictions (Stage 2)	Max % people transferred to backup	Gap (%)	Solution time (s)
L	1.55	0.61	35.54	1.39	2.57	0.18	5.10
M	2.4	3.33	59.84	11.46	13.18	5.6	43,200
H	3.29	4.59	77.86	19.39	21.26	15.85	43,200

The results show a large percentage of people travelling across jurisdictions and requiring backup shelters. Additionally, the model was able to split the expenditure across the different jurisdictions successfully as shown in Table 3. That is also reflected in the number of shelters opened in different jurisdictions, trying to find the best combination of resources without burdening any jurisdiction.

Table 3. Analysis per jurisdiction

Instance	Cost/person/jurisdiction (MXN)		Shelters p/1000 people	
L	R1	62.06	R1	0.31
	R2	62.35	R2	0.35
	R3	61.21	R3	0.31
	R4	-	R4	-
	R5	-	R5	-
M	R1	71.35	R1	0.41
	R2	72.17	R2	0.48
	R3	71.75	R3	0.41
	R4	72.08	R4	0.42
	R5	-	R5	-
H	R1	73.89	R1	0.45
	R2	73.79	R2	0.45
	R3	73.82	R3	0.48
	R4	74.18	R4	0.45
	R5	73.87	R5	0.42

Value of the Stochastic Solutions

To investigate the value of the stochastic solution, we calculated two traditional measures: the expected value of perfect information (EVPI) and the value of the stochastic solution (VSS) shown on Table 4. EVPI is calculated using the value of the recourse problem (RP) and the wait-and-see solution (WS) using the formula: $EVPI = z^{RP} - z^{WS}$. VSS is calculated using the values of the expected value problem (EV) and the Expectation of the Expected Value Solution (EEV) with the formula: $VSS = z^{EEV} - z^{RP}$.

Table 4. Value of the stochastic solution

	EVPI		VSS (Relaxed A and C)	
Instance	Total distance travelled p/person (km)	Max Cost/person /jurisdiction (MXN)	Total distance travelled p/person (km)	Max Cost/person /jurisdiction (MXN)
Low	0.02	12.01	0.25	13.15
Medium	0.14	21.17	0.32	0.82
High	0.29	19.35	0.28	9.13

Figure 1 shows the different solutions obtained for the problem. For all iterations we found that the values obtained

in the RP solution were higher than the values from the wait-and-see problem ($EVPI \in R^+$). The high value of EVPI, particularly in the distance travelled, shows a significant difference between the RP and WS values, which means that the variability in the problem has a significant effect on the number of people served.

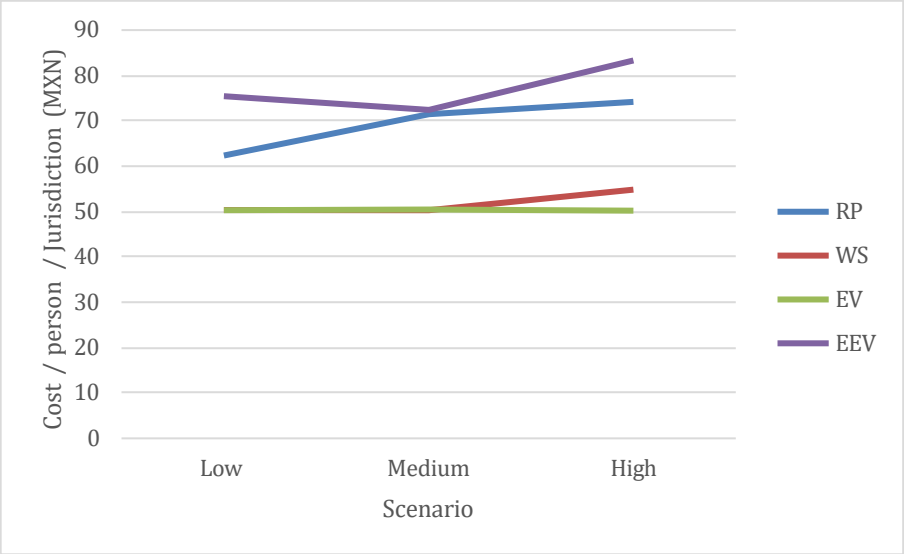

Figure 1. Results of the VSS and EVPI analysis.

The second part of the analysis looked at the cost of ignoring the uncertainty in decision-making. Initially, all the EEV problems were unfeasible when we fixed the variables from the EV solutions. That means that making decisions based on a unique expected value significantly increases the impact on people affected by the disaster. An alternative to obtain feasible EEV values is relaxing some of the first stage variables. After different tests, variable A_j was unfixed to obtain the values shown in the Table. From the practical perspective this result makes sense, given that the availability and capacity of the shelters affect the decisions about backup shelters.

Case Study

Context

The study used real information from a case study in México to investigate the impact of cross-jurisdictional coordination in disaster management. The characteristics of the case can be found in Table 5.

Table 5. Characteristics of the case study

Jurisdiction	Demand areas	Shelters	Demand (people)
EDOMEX	48	60	28,303
PUEBLA	168	141	25,495
MORELOS	107	8	4,998

The eruption of the Popocatépetl volcano in Mexico is used as a case study because of the potential impact on different States of the country. The volcano is located inside a very populated region close to Mexico city, with over 165,000 inhabitants living within 20 km from the crater and surrounded by critical infrastructure (García et al., 2023). It represents one of the latent hazards in the country (medium to high level alert) and it is surrounded by three different States: Estado de Mexico (EDOMEX) Puebla and Morelos, each one of them with response plans. The combination of latent danger of an eruption, a densely populated area and the presence of different jurisdictions make the case relevant to show the application of the model and to draw useful insights.

The purpose of this analysis was to look closer into response mechanisms considering the collaboration (or lack thereof) between the authorities of these States.

Data Collection and Gathering

The demand areas and people to evacuate were estimated using a radius of 30 km of the volcano based on

estimations from Mexican authorities. We used the census data (https://www.inegi.org.mx/programas/ccpv/2020/) and road networks (https://www.gob.mx/imt/acciones-y-programas/red-nacional-de-caminos) from Mexican authorities. The catalogues of facilities with their capacities were obtained from to the States of Mexico (https://cgproteccioncivil.edomex.gob.mx/refugios_temporales), Puebla (https://proteccioncivil.puebla.gob.mx/refugios-temporales) and Morelos (https://obraspublicas.morelos.gob.mx/pdf/rutas-de-evacuacion-y-refugios-temporales). Shelter costs were estimated using the capacities of the shelters and the requirements per person from Mexican authorities (https://www.dof.gob.mx/nota_detalle.php?codigo=5257322&fecha=03/07/2012#gsc.tab=0). The number of buses was assumed to be 1,250 per jurisdiction.

The digitized information was used to determine demand based on distances to the volcano. The distances were calculated using Transcad© after digitizing the facilities found in catalogues from authorities and using the centroids of each one of the AGEBS (Área Geoestadística Básica in Spanish – Basic Geostatistical Area). AGEBs are population units used in Mexico (similar to neighborhoods). Those distances were used to estimate transportation cost based on the consumption of diesel from Serrano-Guevara et al. (2022) and average Diesel cost in Mexico.

Two dimensions were used to generate scenarios: magnitude of the disaster and damage to the infrastructure. Using 4 levels (low, low-medium, medium-high, high), a total of $2^4 = 16$ scenarios were generated for the analysis. The probability of scenarios was generated assuming probabilities of 0.5 for low magnitude/damage, 0.25 for low-medium magnitude/damage, 0.15 for low-high magnitude/damage, and 0.1 for high magnitude/damage. The availability of facilities was defined using a random number generator [0,1].

Findings

The first part of the analysis was concentrated on coordination. The model proposed was compared with two similar models: one not allowing coordination (i.e., each State handles their own population) and another one with partial coordination (i.e., people is directed to shelters in their jurisdiction in the first instance but allowed to go to other jurisdictions for backup shelters). The results are shown in Table 6. Very small gaps show that the solutions obtained are very close to the optimal value in all the instances with solution times below 4 minutes in all cases.

Table 6. Comparison of coordination scenarios

	Total distance travelled (km)	Max cost/person/jurisdiction (MXN)	Gap	Time
Total coordination	1,298,902.38	1,828.76	0.01	204.04
Partial coordination	2,519,124.89	1,096.03	0.01	200.13
No coordination	2,547,299.96	769.18	0.00	180.74

The distance travelled by the affected people is significantly reduced by the mobility across jurisdictions, cutting the value nearly in half. An interesting aspect though is that the cost per person per jurisdiction is considerably lower when no coordination is permitted. To delve closer into that result, Table 7 is used to contrast the cost per person at each one of the jurisdictions, showing that a flow of people travels from EDOMEX and PUEBLA to MORELOS when coordination is allowed.

Table 7. Cost per person per jurisdiction

Cost/person/jurisdiction	EDOMEX	PUEBLA	MORELOS
Total coordination	715.28	891.11	1,828.76
Partial coordination	740.43	872.28	1,096.03
No coordination	713.93	659.92	769.18

We used a sensitivity analysis with partial coordination to see the behavior of the system. The results can be seen in Table 8. All the gaps were below 5%, which shows that the solutions obtained are very close to the optimal value in all the instances. Solution times are below one hour which is considered acceptable for the planning horizon of the model. The model is forcing a percentage of people (from 10% to 100%) to be served in their original State in the first stage, although there is flexibility to move to another jurisdiction in the second stage.

The results show consistent changes in distance and cost when the percentage of people is modified.

Table 8. Sensitivity analysis

Same jurisdiction	Total distance travelled (km)	Max cost/person/jurisdiction (MXN)	Time (s)	Gap
10%	1,320,293.53	1,790.93	253.60	0.17%
20%	1,364,022.34	1,753.10	464.71	4.60%
30%	1,417,004.34	1,734.19	711.82	1.40%
40%	1,490,484.15	1,647.18	962.45	0.69%
50%	1,586,394.40	1,584.34	1,218.67	0.00%
60%	1,710,150.91	1,722.72	1,481.07	0.00%
70%	1,860,978.08	1,402.67	1,736.04	2.80%
80%	2,050,855.03	1,311.74	1,991.38	4.20%
90%	2,280,056.95	1,152.80	2,239.88	0.14%
100%	2,519,124.89	1,096.04	2,478.48	0.91%

DISCUSSION

Numerical Examples

The number of people crossing boundaries to find safe places at stage one is noteworthy. The results show that nearly more than a third of the population evacuated is moving to a shelter in a neighboring jurisdiction in all three instances, with more than half of the population doing so in the medium and large instances. The number increases with the magnitude of the disaster, showing that coordination and collaboration among jurisdictions can be instrumental to protect affected people, especially for large-scale disasters.

Several articles in the literature neglect considering shelter failure and its impact on the population. Our results underscore that backup shelters are particularly important for the medium and high impact instances, although less common in the small instance. These results highlight the importance of backup shelters and transboundary coordination in disaster settings. The findings underscore the potential of the model proposed to balance the burden for the jurisdictions involved. The comparison of the dif ferent instances shows that the model mainta ined a similar level of expenses for all the jurisdictions involved, trying to push down the maximum cost per person per jurisdiction following the second objective function.

The analysis about the value of the stochastic solution derived large values of EVPI and VSS, showing the relevance of the two-stage stochastic formulation. Inadvertently, the unfeasibility of EEV points out a problem already identified in practice. When backup shelters are neglected, there is vulnerability in the system to have a shortage of capacity to shelter all the population needed. The VSS results confirm that neglecting to consider the uncertainty in the different instances has a significant negative effect on the ou tcome of the operations.

Case Study

The reason behind the lower distance traveled when cross-jurisdictional coordination is allowed compared to the instance with no coordination is because different communities from the three States are in close proximity, making it easier for them to move to some of them rather than going across their State.

It was noteworthy to find that the cost per jurisdiction was lower in the instance with no coordination compared to the instance allowing coordination. The closeness between some communities from different States and the lexicographic approach prioritizing distance travelled influence this result. When coordination is allowed people from EDOMEX and PUEBLA go to MORELOS, increasing the overall cost in that State. Once the minimum distance is fixed, the model is unable to find an answer that can balance the cost of the three States. That is an important consequence to have in mind given the importance of reducing the total distance travelled.

The sensitivity analysis shows how, the least flexibility is allowed for people to go to other States, the higher the distance they need to travel to reach a safe destination. That stresses the importance of coordination between different jurisdictions to improve the conditions faced by people affected by disasters. Maximum cost per person per jurisdiction is less clear because it depends on the results of the minimization of the total distance travelled

and the particular network in study.

Overall, the results from the numerical examples and the case study provide three main points: i) coordination and interoperability makes a significant difference in the service provided to people affected by disasters; ii) it is important to contemplate the possibility of failures in primary shelters and the need of secondary/backup shelters to successfully provide housing for people displaced by the disaster; and iii) ignoring the uncertainty in the event when making sheltering decisions has a significant negative effect in the performance of humanitarian operations.

CONCLUSIONS

This article introduces a two-stage stochastic model for the selection of primary and backup shelters for vulnerable population considering the collaboration between different jurisdictions. This study is the first one in the literature to incorporate transboundary coordination into primary and backup shelter location. The literature on transboundary coordina tion is still at a nascent stage, but the findings from this study show the impact of ignoring the interaction between authorities from different boundaries. Although jurisdictional and political issues can affect disaster planning, this article provides evidence that a well-coordinated joint response can be beneficial for the victims, and even for the authorities involved.

There are different opportunities for further research. The extension of policies such as the p -next center problem (Albareda-Sambola et al., 2015) can be valuable to advance similar models in the future. The experimentation with different objective functions could be useful to see the behavior of the model under different policies. Finally, the development of a heuristic to reduce solution times for larger instances would be beneficial for the application of the model in practice.

ABSTRACT

The increase of the global mean temperature likely leads to more frequent and prolonged fire weather periods, with hot and dry conditions. This would also lead to increased frequency and magnitude of wildfires, and increased risk of spatial and temporal co-occurrence. A key to control and suppress wildfires during fire weather is a strong initial response, for which aerial firefighting resources can be used. This paper investigates the potential of optimization modeling to support pre-wildfire location planning of aerial firefighting resources, by developing a binary integer programing model and test it on Swedish case data. The model produces useful results given considerably less amount of available input data to determine the locations, compared with the manual planning. With relatively short solution times, it shows potential to support fast relocation of resources during sudden changes of circumstances, and to facilitate implementation of a standard operating procedure, with less expert knowledge dependence.

Keywords

wildfire suppression, initial attack, fire weather, preparedness, planning.

INTRODUCTION

Due to increased amounts of greenhouse gases in the atmosphere, the global mean temperature has increased, and evidence suggest that the warming trend will continue (IPCC, 2021). The mean temperature change will affect temperature extremes, which are already observed in northern Europe (IPCC, 2021), and the warming trend will lead to increased frequencies of all kinds of hot extremes (Seneviratne et al., 2021). Due to strong correlation, increased frequencies of hot extremes will likely lead to more frequent and longer periods of dry conditions or droughts (Zscheischler & Seneviratne, 2017). For the reasons above, there will be more periods with fire weather, which is related to hot and dry conditions, and driven by high temperatures, and low soil moisture and humidity (Turco et al., 2017). More and longer periods of fire weather, will likely lead to increased frequency and magnitude of wildfires (Mueller et al., 2020), with increased risk that wildfires occur spatially and temporally close to each other. This increased risk will require improved preparedness for wildfires.

A key to control and suppress wildfires during periods of fire weather is a strong initial attack (Pierce 1970, via Greulich, 2003), which can be done using aerial firefighting resources (e.g., helicopters and scooping airplanes) (Plucinski et al., 2007). The effectiveness of initial attacks using aerial firefighting resources is restricted by the response times (McCarthy, 2003), which depends on the distance between fire ignition points and the resource locations. This calls for research on pre-wildfire locations of aerial firefighting resources as an effort to improve

the preparedness for future events. To date, this is a underdeveloped area of research (Belval et al., 2022).

The purpose of this paper is to investigate if optimization modelling of short-term pre-wildfire location of aerial firefighting resources can improve the preparedness for wildfires. This is done by developing an optimization model to determine where to locate the resources based on the current risk of wildfires. The results of the optimization model are then compared with a real case to determine its potential to enhance the preparedness for wildfires. The real case includes the historical locations of aerial firefighting resources in Sweden, as well as the historical incidents where the resources were used, during the high-risk wildfire season (June-August) of 2021.

Related Work

According to previous research, some factors are considered critical for the success and effectiveness of managing and suppressing wildfires. In a retrospect analysis of wildfires where aerial suppression was used, Plucinski et al. (2007) finds that the area burning on arrival, the fire danger index, the time to initial attack, and the fuel hazard score were all statistically significant factors to the success of the initial attack. In a similar analysis of aerial suppression effectiveness in Australia, McCarthy (2003) also finds the time to initial attack as a critical factor for the effectiveness, and argues that the earlier the resources can reach the fire, the more likely they will be able to contain it.

Regarding the time to initial attack, previous studies have used different quantitative methods to address it, from visualizations of retrospective analyses (Belval et al., 2022) to more advanced optimization models (Shahparvari et al., 2021). For example, Greulich (2003) developed a spread-sheet based procedure to determine locations of air bases to improve the preparedness for a given protection area. For a similar purpose, Fried et al. (2006) used stochastic simulation to, for instance, determine long-term locations for the stationing of firefighting resources. More recent studies chose to use the same method as presented in this paper, which is optimization modeling. Both Griffith et al. (2017) and Shahparvari et al. (2021) have developed models to address resource allocation to ongoing fires. The former developed a model to solve dynamic resource allocation problems to ongoing suppression efforts, based on the fire spread direction and environmental conditions (Griffith et al., 2017). The latter focused on resource coordination during suppression efforts requiring collaboration between aerial and ground firefighting resources, by optimizing the allocation of resources and the assignment of tasks required in the effort (Shahparvari et al., 2021).

An example of a study similar to the one presented in this paper is Maritano et al. (2016), who developed a model to determine a helipad network on Sicily, Italy. However, the network is not primarily used to increase the preparedness for wildfires, but a set of services performed by helicopter (e.g., transport, medical services, tourism services, civil protection). Also, the locations they suggest are long term implementations, and the location of helipads is not based on wildfire risk data. The only study found that is closely related to the study presented in this paper is Zeferino (2020), who developed a model to locate aerial firefighting resources in Portugal. The differences in this paper are that we consider tactical, short-term locations, that we have less resources available to locate, and that our locations are based on wildfire risk data.

One contribution of this paper is an optimization model to determine the best locations of a finite set of aerial firefighting resources, based on wildfire risk data. As far as we know, this kind of model has not been developed and validated before. Another contribution is that the model is tested and compared to the historical, manual planning, which is done by experts. The results show that the model manages to produce results that are close to what the experts achieve, by using only wildfire risk data, while the experts have access to much more information. This proves the usefulness of both the Fire Weather Index (FWI) that we use to estimate wildfire risk, and optimization modeling as a base for decision support. In wildfire suppression practices, the model could potentially be used as a support for day-to-day dynamic resource preparedness planning to increase the effectiveness of aerial firefighting resources used for initial attacks.

Method

In this paper, an operations research approach was used by applying optimization modeling to solve a set of instances to the aerial firefighting preparedness location (AFPL) problem. The input data were processed using the programming language R through the platform RStudio, while the model was formulated using the language AMPL through the platform AMPL IDE. Through AMPL IDE, the model and the specific input data for each instance of the problem were sent to the solver CPLEX. Through a case study, the results of the model were tested and compared with aerial firefighting preparedness locations from a real case.

A MODEL FOR THE AERIAL FIREFIGHTING PREPAREDNESS LOCATION PROBLEM

This section presents the problem studied and the assumptions made in our formulation. Furthermore, the mathematical formulation of the model is presented, including sets, parameters, variables, objective function, and constraints.

Problem Description and Assumptions

The problem to be solved in this paper is called the aerial firefighting preparedness location (AFPL) problem, here solved as a *p-median* problem (Daskin & Maass, 2015). The problem can be stated as

To determine a finite number of preparedness locations for aerial firefighting resources that minimizes the weighted distance between the locations and all risk points based on their wildfire risk value.

The goal is to minimize the total "risk distance", which is the sum of the products between the distance and the risk value. The following assumptions have been made:

- The risk value for each risk point is known
- There is a finite number of resource locations to be determined
- Since the resources are aerial, Euclidian distances between each pair of location and risk point can be used
- Although aerial firefighting resources might have different characteristics in reality (e.g., speed, capacity), the resources in the model all have the same characteristics

Model Formulation

The AFPL problem was formulated as a binary integer program (BIP). The notation used in the mathematical representation of the model is presented below.

Sets

$I = \{1,\ldots, n\}$, *the set over all risk forecast points*
$J = \{1,\ldots,m\}$, *the set over all possible resource location points*

Parameters

d_{ij} = *the Euclidean distance between risk point i and location point j*
h_i = *the risk value in risk forecast point i*
p = *the number of aerial resources to be located*

Variables

$$yy_{jj} = \begin{cases} 1, & \text{if a resource is located at point } jj \\ 0, & \text{otherwise} \end{cases}$$

$$xx_{iijj} = \begin{cases} 1, & \text{if risk point } ii \text{ is assigned to a resource located at point } jj \\ 0, & \text{otherwise} \end{cases}$$

Using the above notation, the objective function (1) and constraints (2)-(5) below were constructed.

Objective Function and Constraints

$$\text{Min} \sum_{ii=1}^{nn} \sum_{jj=1}^{mm} h_{ii} ss_{iijj} xx_{iijj} \tag{1}$$

$$\text{s.t.} \quad yy_{jj} \geq xx_{iijj} \qquad \forall ii \in II, jj \in JJ \tag{2}$$

$$\sum_{jj=1}^{mm} xx_{iijj} \geq 1 \qquad \forall ii \in II \tag{3}$$

$$\sum_{jj=1}^{mm} yy_{jj} = pp \tag{4}$$

$$xx_{iijj}, yy_{jj} \in \{0,1\} \qquad \forall ii \in II, jj \in JJ \tag{5}$$

The model is solved for a specific day and finds operational locations for the resources to match the risk values that day. The objective (1) is to minimize the distance between resource locations and risk points, based on their risk values. Hence, the goal is to minimize the total "risk distance", which is the product between h_i and d_{ij} for all risk points *i* covered by the closest resource location *j*. This corresponds to minimizing the total time spent on travelling to incidents, given that the number of incidents in a risk point, over time, is directly proportional to the risk value. The constraints in (2) ensure that a risk point *i* can only be covered by a selected resource location *j* if there is a resource located there. The constraints in (3) ensure that all risk points *i* are covered by at least one resource location *j*. The single constraint in (4) ensures that the total number of resource locations selected must be equal to a finite number *p*. In this paper, the value of *p* is determined by the historical number of resources located during each studied date.

CASE STUDY

To test and validate the potential of the model, a case study was performed for Sweden using data from the wildfire high-risk season (June-August) of 2021. Looking at days when the aerial resources were used at a wildfire effort, a comparison was made between the locations that were suggested by the model (BIP locations) and the historical locations (Real locations) determined by experts before the effort. For each wildfire location, the distance from the closest resource was calculated and compared.

The Swedish Decision-Making Process

In Sweden, the aerial firefighting preparedness locations are decided by the Directions and Priority Function (IPF), with representatives from different departments of the Swedish Civil Contingencies Agency (MSB). The IPF holds regular meetings twice a week during the fire season, with the possibility of increased frequency during periods with multiple ongoing missions or high fire risk and uncertainty.

Before the meeting, an analysis is performed and documented based on the weather and fire risk forecasts. A fire risk forecast is available on daily level for the coming six days, and on hourly level for the coming 48 hours. Beside the forecast data, the conducted analysis is based on the forecast uncertainty and reports from external actors in the Swedish emergency response system. To complement the nationwide analysis, critical and uncertain geographical areas may be studied further, especially concerning previous weather, extreme fire behavior, and the ability to manage a potential fire in the area.

After an IPF meeting, the preparedness location proposals are put forward to the deputy decision maker of the MSB, and if approved, a formal decision is signed and documented. The decision is formulated as the number of resources (helicopters and planes, respectively) that should be prepared to respond, together with their determined locations during the specified period. The decision is then forwarded as orders to the operational unit level.

Input Data

The main set of input data used covers the utilization of aerial firefighting resources, constituting scooping airplanes and helicopters, in wildfire suppression efforts during the case period. In total, the set consists of 54 suppression efforts where aerial resources were initiated, during 34 different dates. This means that the case included 34 instances of the AFPL problem to be solved. For each date where aerial resources were used, a set of wildfire risk data was provided by the Swedish Meteorological and Hydrological Institute. Each date included a set of 62 351 points with risk values based on the Fire Weather Index (FWI). The FWI is a compiled index accounting for the effects of soil moisture and wind on the fire's behavior in terms of build-up and spread (National Wildfire Coordinating Group, 2021). However, these points were aggregated into a network of 1 335 20x20 km zones, where the FWI value of each point included in each zone were added together.

The set of possible resource locations included 286 points, representing the center coordinates of the most densely populated cities in each municipality of Sweden. The reason for using this set is that the current selection of preparedness locations in Sweden is on municipal level. The number of resource locations is finite in each instance of the problem. Thus, the finite number denoted *p* in the formulation was set to the real number of resource

locations determined. This enables comparison between the model's solution and the locations used in the real case. In summary, each of the 34 case instances of the AFPL problem included:

- 286 possible resource locations
- 1335 risk points
- 1335 FWI values, one for each risk point
- A distance matrix with the distance between each pair of risk point and possible resource location.
- A finite number of selected resource locations (varies between 2 and 8)

COMPUTATIONAL RESULTS

Each of the 34 instances were solved to integer optimality using the solver CPLEX, with a relative MIP gap tolerance of 0.0001. The average solution time over the instances was 764 seconds, with the minimum and maximum time at 217 and 1162 seconds, respectively. The problems were solved on a PC with an Intel® Core™ i7-8565U CPU at 1.8-1.99 GHz, and with a RAM of 16 GB.

To investigate the potential of the developed model, a comparison was made with the real resource locations during the 34 days. The analysis compared the resource locations of the model and the real case over the distance to the 54 efforts where aerial firefighting resources were used. Aggregated results are presented in Table 1.

Table 1. Aggregated results for the BIP model and the real case locations, respectively, over 54 efforts during the high-risk wildfire season of 2021

	BIP Model	Real case
Average distance to effort	96 757 m	91 046 m
Minimum distance to effort	10 206 m	8 631 m
Maximum distance to effort	205 922 m	302 548 m
Occurrences, distance > 200 000 m	1	4
Number of times closest	18	32
Average difference when closest	66 025 m	46 776 m

As can be seen in Table 1, the experts on average manage to locate the resources closer to the efforts. However, looking at efforts where the closest resources are far away (more than 200 km), the model seems to be doing a better job of ensuring that all efforts can be reached within a reasonable time. The experts consider a risk point to be reached within an hour of travelling time if it is within 200 km from an aerial resource, which is why it was used in the comparison.

For the results in Table 1, it is assumed that the resource located closest to each effort point were used. Thus, we assume that if there are two or more efforts during the same date, the location point closest to the efforts will have enough resources to initiate an attack, even if the effort points share the same closest resource location. Since this is not always realistic, further comparative analyses were done for a set of cases with several efforts during the same date. One interesting date is the 7th of August 2021, during which 5 efforts with aerial firefighting resources were initiated. The FWI values, the resource locations, and the effort points for the model and the real case scenario are presented in the two plots in Figure 1.

The assumption that all effort points will use resources from the closest resource location point means that the real historical locations have a better preparedness for the scenario in Figure 1. However, if it instead is assumed that all resource points can only initiate an attack to one effort point, the situation is the opposite. An overview of the results with the respective assumption, using a greedy approach for the model and the real case, for all days with more than one effort initialized, is presented in Table 2. Here, greedy means that for all efforts, the one with the closest available resource gets a resource allocated to it. Then, the effort with the closest available resource, not counting the ones that have already been allocated, gets a resource, and so on.

The change in results when applying the two assumptions (Table 2), comes from the changes of maximal distances for the model and the real case. This change is more tangible for the real case, which means that the suggestion of locations by the model seems more stable during days with several efforts. Only looking at the current fire risk,

the model performs better in terms of being closest to the areas with high wildfire risk. However, the overall results suggest that the current preparedness planning performs better than the model in terms of the distance to efforts where aerial resources were initialized. In the following section, a discussion about possible causes for this will be made.

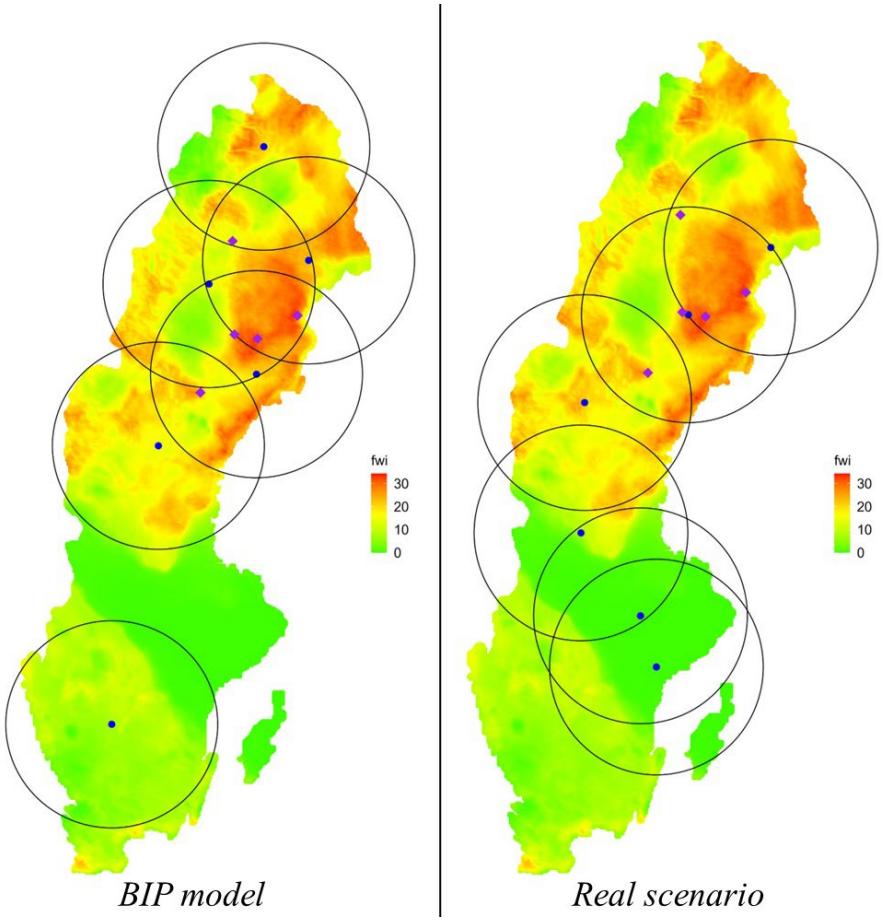

Figure 1. The FWI risk values (green-red), resource location points (blue points), and initiated effort points (purple diamonds) during the 7th of August 2021. The black circles represent the reach (200 km) within one hour from takeoff

Table 2. Aggregated results over the 11 days with more than one effort initialized, with a total of 31 efforts, for the BIP model and the real case scenario, respectively, while influenced by two different assumptions

	Closest resource location		**Closest available resource location**	
	BIP	**Real case**	**BIP**	**Real case**
Average effort distance	90 952 m	83 466 m	122 237 m	128 632 m
Minimal effort distance	10 206 m	8 631 m	10 206 m	8 631 m
Maximal effort distance	193 334 m	257 119 m	481 692 m	747 161 m
Distance > 200 000 m	0	1	4	5
Number of times closest	8	21	9	20

DISCUSSION

The first things to discuss are the situations where the real case locations are close to effort points with low or moderate fire risk. Such cases are extremely difficult, if not impossible, to include in a preparedness planning using optimization modeling, at least without including more aspects than the fire risk in the objective function. Now this is the sole factor determining the resource locations in our model. Figure 2 presents the locations and efforts from the 1st of June 2021, which is such a case.

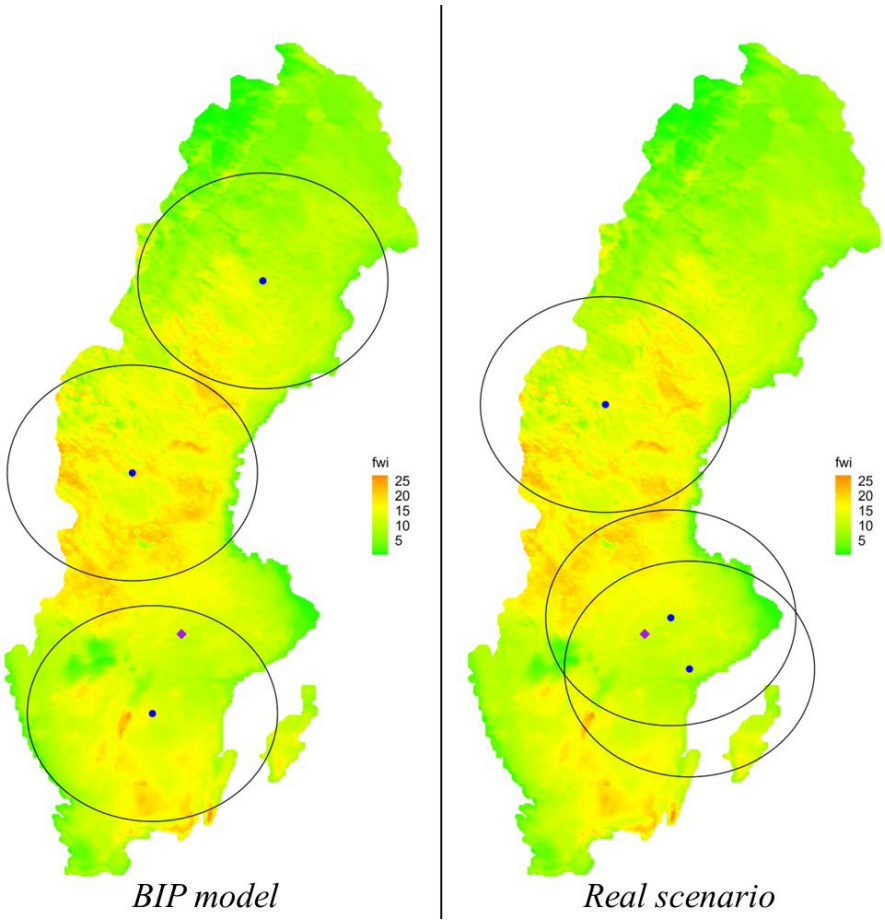

Figure 2. The FWI risk values (green-red), resource location points (blue points), and initiated effort points (purple diamonds) during the 1st of June 2021. The black circles represent the reach (200 km) within one hour from takeoff

In this case, the effort is a wildfire in Arboga, not far from Västerås, which is one of the fixed locations for firefighting helicopters currently used in Sweden. As can be seen in Figure 2, the resource locations are much closer to the initiated effort point in the real case scenario compared to the BIP model. Since the wildfire risk in the effort point is small compared to other areas in Sweden during this time, the BIP model would never suggest locating resources any closer to that point. However, it might be argued that the BIP model determines a more equal resource location regarding the actual fire risk, which is one of the critical factors for initial response success (Plucinski et al., 2007).

Although the comparative results show that the current resource preparedness locations are better on average, we argue that the BIP model shows potential for several reasons. Firstly, it determines the resource locations with considerably less amounts of information compared to the real case. Despite this, the difference in average distance to the effort points is only about 7 km. With information available in the real case, e.g., status of ongoing wildfire efforts, resource availability, and the ability to reach the effort point with ground resources, the BIP model might give even better results. The second reason is the solution time. For the instances of the AFPL problem tested, the solution time for the BIP model was on average 13 minutes (with minimum 4 and maximum 19 minutes). With the intended use as input and decision support during pre-planned IPF meetings, these solution times can be considered adequate. It may also enable optimized relocation of resources if the circumstances suddenly change, which is considerably more difficult, complex, and time-consuming without the model. However, of course there still exist improvement opportunities regarding the solution time. Thirdly, the BIP model

enables the implementation of a standard operating procedure in the location planning of aerial firefighting resources. Due to the complexity of the current planning procedure, it is dependent on the knowledge of a small group of experts. With a support tool including the BIP model, the planning procedure can become more standardized, hence, less dependent on individual knowledge and skill. Lastly, the model shows potential in minimizing the maximal distances to efforts during instances of the AFPL with several simultaneous effort initializations. This can be seen in Table 2, where the BIP model does have longer minimum distances, but considerably shorter maximum distances.

However, to fully investigate the potential of the BIP model as a support tool for resource location planning, more data is needed on the utilization of aerial firefighting resources during wildfire suppression efforts. Although the dataset used includes all aerial fire suppression efforts in the selected period, they count to 54 separate efforts on 34 different dates, which is too few to be certain about the model's potential. Also, to enable a fair and thorough comparison between the model and the real case scenario, their locations need to be based on the same risk data, which currently is not the case. Here, the real case locations are based on forecast data, while the model's locations are based on analyzed risk data. Therefore, this paper should be considered a first step to investigate the potential of optimization modeling for resource preparedness planning, which is identified as a research area with high potential (Belval et al., 2022).

CONCLUSIONS

With increased recognition of the interactions between climate change and the frequency and magnitude of wildfires, more attention is needed on how to improve the preparedness for wildfires in emergency response systems. In a first step to address this, we have investigated the potential of optimization modeling to support pre-wildfire location planning of aerial firefighting resources, utilizing available wildfire risk data based on the Fire Weather Index. This, by developing a BIP model for resource location planning and test it on a case which included 54 separate efforts utilizing aerial fire suppression on 34 different dates during the high-risk fire season 2021 in Sweden. The model's results were then compared with the real resource location planning during this period. Although the model did not outperform the real resource location planning in all cases, it showed potential concerning solution time and the implementation of a standard operating procedure. Additionally, given the considerably less amount of information the model results are based on, the overall results can be argued to be satisfying.

To fully investigate the potential of optimization modelling to support pre-wildfire resource location planning, more research is needed. The future research plan includes incorporating extended wildfire risk data which provides risk forecasts not only for the current day, but a few consecutive days. The plan also includes extensions in terms of other types of data besides the wildfire risk to include in the model, for example resource availability, wildfire reachability, population density, vulnerability, and critical infrastructure.

ACKNOWLEDGEMENTS

The authors would like to thank the Swedish Civil Contingencies Agency and the Swedish Meteorological and Hydrological Institute for providing data and information to this study. The project behind this study, Efficient management of multiple natural events (EMMUNE), is part of the Centre for Advanced Research in Emergency Response (CARER). This work was supported by the Swedish Civil Contingencies Agency and Formas, a Swedish research council for sustainable development [grant 2019-06052].

Towards a Repository for Datasets of Mass Casualty Incidents

ABSTRACT

Many mathematical models and algorithms addressing logistics around mass casualty incidents (MCI) have been proposed in the literature. However, hardly any data sets exist that can be used to analyse, validate, and evaluate approaches and solutions. As MCI are comparably rare, real-world data is scarce and often extremely sensitive, making it difficult for researchers to get access and build test datasets. In this paper, we therefore present the first steps towards a repository for the exchange of datasets to facilitate validation and comparison. We first provide an overview of potential stakeholders such as working groups, review disaster-related databases and existing repositories for other fields followed by a preliminary taxonomy to identify and structure the relevant entities and their characteristics within models for disaster management.

Keywords

Dataset, taxonomy, disaster management, operational research, decision support

INTRODUCTION

In 2022, 185 million people were injured, homeless or otherwise affected by disasters (Centre for Research on the Epidemiology of Disasters (CRED) et al. 2022). Providing help to such a high number of people combined with the short or complete lack of time to prepare for a disaster poses logistical challenges. With an increasing number of disasters over the past years, the field of disaster management has received more attention in the literature (Tippong et al. 2022), resulting in a steadily increasing number of published articles that propose models to solve (a subset of) the problems arising in disaster management.

An ongoing problem in developing, validating, and comparing these models is the lack of comprehensive publicly available datasets that include all the necessary information. One reason for the lack of those datasets is the unpredictability of disasters. In contrast to daily operations for which the data collection can be planned in advance, disasters usually occur at no or only short notice and lead to exceptional situations. As a consequence, collecting comprehensive data of good quality is difficult (Shi et al. 2023). Despite these difficulties, several statistics of disasters are publicly available, but these are often not detailed enough to test and validate models. Consequentially, researchers have to make assumptions and educated guesses for a varying range of parameters based on their knowledge of the on-site conditions. From an academic perspective, this approach leads to limited comparability of the models, unclear practical value, and the risk of "over-fitting" the model without the intention to do so.

To overcome this problem, one solution would be to collect, structure, and share existing datasets and add missing information based on expert knowledge. One approach to then provide access to these datasets could be a repository. Such a repository would have multiple advantages. First, it would facilitate access to existing datasets and reduce researchers' workload when testing their model. Second, such a collection of datasets would also facilitate the comparison of actual or assumed values for different parameters across datasets. On the one hand, such a comparison could support the analysis of differences between data sets (e.g. due to different local conditions or disaster types), and, based on this, the general validity of a proposed model. On the other hand, an overview of realistic values for parameters can also support researchers to create, derive, and verify new datasets.

To create a repository that shares the datasets in a structured way, the following steps are necessary (adapted from Leeftink and Hans 2018).

*corresponding author

- **Step 1** Search for existing databases and interest groups.
- **Step 2** Develop a taxonomy to categorise existing models and their datasets.
- **Step 3** Validate the taxonomy with researchers and experts from practice and link the existing datasets and the parameters used therein to the developed taxonomy.
- **Step 4** Derive standardised validation datasets based on existing datasets and discussions with experts.

In this paper, we present the first two steps, while the remaining steps will be part of future works. As the field of disaster management covers a broad spectrum of problems, we will first focus on the subarea of casualty management, which includes models related to managing the needs of casualties, such as treatment, transport, shelter, and relief supplies (Farahani et al. 2020). The remainder of the paper is structured as follows: The next section describes the current work performed for Step 1, followed by a description of Step 2 and a preliminary framework. We conclude the paper with an outlook of future steps and a summary.

STEP 1: WORKING GROUPS, DATABASES, AND REPOSITORIES

To assess whether repositories or validation sets exist, we conducted a literature search and identified and screened potential hosts of these repositories such as working groups, databases and other repositories as examples.

Working Groups in Humanitarian Logistics and Repositories

Worldwide, many different working groups in the area of humanitarian logistics exist. While we focus on Operational Research (OR) / Information system (IS) groups, it is worth noting that input for datasets can also come from medical or practice groups, e.g. the working group on disaster medicine of the German Society for Interdisciplinary Emergency and Acute Medicine (DGINA) (AG Katastrophnemedizin DGINA 2024).

Within the IS community, the Information Systems for Crisis Response and Management (ISCRAM) group is probably the most fitting for our endeavour. As stated on their website (ISCRAM 2024), "the ISCRAM Association's primary mission is to foster a community dedicated to promoting research and development, exchange of knowledge and deployment of information systems for crisis management, including the social, technical and practical aspects of all information and communication systems used in all phases of management of emergencies, disasters and crises." While OR/Management Science models represent a subset within this field, the scope of this working group is broader with respect to the applied methodologies. With yearly conferences and additional events, ISCRAM is one of the main conference outlets for crisis-related research. We also searched within the Association for Information Systems (AIS) and identified the Special Interest Group on IT in Healthcare, AIS SIGHealth, as potentially relevant as well (AIS SIGHealth 2024). In contrast to ISCRAM, the working group does not organise an individual conference, but offers healthcare tracks at the main IS conferences, e.g. ECIS. It seems less suited to host the repository but can still offer valuable access to existing data sets and the chance to advertise a repository, once it exists.

On the OR side, two working groups within the Association of European Operational Research Societies, EURO, are most promising: 1) HOpe, the EURO working group on Humanitarian Operations (EURO working group HOpe 2024), and 2) ORAHS, the EURO Working Group of Operational Research Applied to Health Services (EURO working group ORAHS 2024). The purpose of HOpe "is to create a platform that facilitates communication among the interested parties and forms an active group" (EURO HOpe mini conference 2024) while "Humanitarian Operations Research studies decision-making problems related to providing logistical assistance for humanitarian purposes, and in response to humanitarian crises" (EURO HOpe mini conference 2024). The College of Humanitarian Operations and Crisis Management (HO & CM) of POMS "seeks to create a focus group of researchers and practitioners to study how to manage operational systems under stress or severe resource constraints. A prime objective is to foster a creative environment among academics and practitioners to recognise how operations management plays a crucial role in dealing with the alleviation of human suffering under conditions triggered by cataclysmic acts of man and nature." Within the Institute for Operations Research and the Management Sciences (INFORMS), we also identified two potentially fitting working groups, namely the Health Applications Society (INFORMS Health Applications Society 2024) and the Military and Security Society (INFORMS Military and Security Society 2024), although it is not clear from their website whether they also focus on the humanitarian aspects. Moreover, we identified additional associations, mainly country-specific, that also include humanitarian logistics, e.g. during their yearly conferences. Examples include the Decision Science Institute (DSI), the German OR Society and the UK OR Society.

Based on our investigations we conclude that to the best of our knowledge, a repository for research does not exist on the websites of any of those working groups yet.

Existing Databases

Besides repositories provided by working groups, other sources for input data are existing databases. Within the field of disaster management, various databases exist. A widely cited database with global coverage is the Emergency Event Database (EM-DAT) (Jones et al. 2023) hosted by the Centre for Research on the Epidemiology of Disasters (EM-DAT et al. 2024). The database includes natural and technological disasters and provides information about a disaster's type, region, humanitarian, and economic impact. Data on disasters with a terrorist background is collected by the Global Terrorism Database (LaFree and Dugan 2007). For each recorded incident, the database provides information about the location, the attacker, the method, and the number of casualties. Datasets from various sources are made available on the Humanitarian Data Exchange (HDX, OCHA 2024) platform hosted by the United Nations Office for the Coordination of Humanitarian Affairs (OCHA). Unlike the other two databases, this platform does not only focus on disasters, and datasets are provided by various organisations, resulting in different data structures. Besides these databases, several databases on a national level exist, such as the Canadian Disaster Database (CDD 2024), for example. Although these databases can be useful for getting insights about the size of a disaster, they usually lack the detailed information required for validating models for disaster management, such as locations of included hospitals and shelters, their capacities, or the available fleet of vehicles.

Repositories and Benchmark Sets Outside of Humanitarian Logistics

While we could not identify any existing repositories for humanitarian logistics, there exist repositories or benchmark sets for other problems within the field of OR which can provide insights into the purposeful design of a repository and/or taxonomy. The VRP-REP (Mendoza et al. 2014) is a repository for instances of the Vehicle Routing Problem (VRP). It stores problem variants, references, datasets, and the best-known solution for each combination of problem variants and datasets. Instances for shift scheduling problems can be shared on www.schedulingbenchmarks.org (*Schedulingbenchmarks* 2024). The repository differentiates between instances for nurse rostering, multi-activity multi-day and other employee scheduling problems, and similar to VRP-REP links the different instances, references and best-known solutions. Instances for planning and scheduling of projects are collected and shared by Ringer and Fox (2024). The aim is to provide realistic instances to enhance the development of models with significant practical value. For problems related to operating room scheduling, Leeftink and Hans (2018) developed a benchmark generator to facilitate the access to realistic datasets. Moreover, for each of the different instances as identified by Leeftink and Hans (2018), 200 samples are provided to enhance comparison between different models and, if already found, provide the optimal solution.

These repositories can serve as a guideline for the development of a repository of humanitarian logistics. With the large variety of problems addressed within the literature on disaster management, the repository should provide an overview of existing variants, provide realistic values for the different characteristics, and allow scholars to create a dataset based on their needs.

STEP 2: TAXONOMY

After having identified relevant working groups, existing databases and repositories, the following step is to develop a taxonomy for classification. First, we review the literature for existing frameworks that could be applied to our purpose, before we present our developed taxonomy to describe the relationship between the attributes of different entities.

Previous Taxonomies

In the past years, several taxonomies have been presented within the field of disaster management. On a broader level Kuipers and Welsh (2017) provide a taxonomy to classify the literature. Based on frequent terms and keywords used they derive 19 umbrella terms, thereof ten for crisis types and nine for crisis themes. Wong et al. (2017) present a taxonomy that provides an overview of evaluation typologies. Therefore, they define three layers, the timeline of the disaster, the status, and the overarching theme of resilience, to which the different typologies are related. Rauner et al. (2018) propose a taxonomy that links tasks in disasters to responders. They identify eleven interventions in various phases of the response and three broad categories of responders, further refined for each category. Tatham and Spens (2011) develop a taxonomy to store explicit knowledge in humanitarian logistics. Combining two existing frameworks, the "Supply Chain Operations Reference" and the "Lines of Development", the authors adopt the five primary processes of the supply chain and eight force elements to create a taxonomy. Besides these taxonomies, several other taxonomies have been published. However, these focus on very specific aspects of disaster management, such as simulation tools (Barthe-Delanoë et al. 2015), volunteers (Betke et al. 2023), or IT support (Pottebaum et al. 2014), among others. Taxonomies have also been proposed in related areas like emergency

logistics (Reuter-Oppermann and Bernath 2016; Reuter-Oppermann and Rachuba 2017, for example), which might also provide some relevant insights.

Despite the variety of taxonomies within the literature, we could not find any taxonomy addressing humanitarian logistics on a sufficiently detailed level so that it could serve as a basis for the classification of datasets. Therefore, in the following, we present a preliminary taxonomy for the purpose of classifying datasets.

Preliminary Taxonomy

To develop the taxonomy, we follow the approach suggested by Nickerson et al. (2013) and Kundisch et al. (2022). The purpose of this taxonomy is to identify and structure the relevant entities and their characteristics within models for disaster management. This leads to the meta-characteristic of our taxonomy, namely, to enhance the classification of datasets and the therein included parameters. We set objective and subjective ending conditions and defined the objective ending conditions to be met once all papers of our sample have been examined, and the entities and characteristics have not been changed (i.e. no elements were added, deleted, or updated). For the subjective ending condition, we evaluated whether the proposed taxonomy is concise, robust, comprehensive, extendable, and explanatory. Eventually, as an evaluation goal, the taxonomy should support users to classify and analyse models and datasets within the field of disaster management. We chose an empirical-to-conceptual approach and analysed a selection of papers within the field of casualty management in disasters as presented in Farahani et al. (2020). We opted to use this literature review as a starting point, as it covers the relevant papers within the field until 2019. We acknowledge that by doing so we exclude more recently published papers. However, we believe that the selection of the papers is broad enough to develop a general taxonomy that should also be applicable to papers published after 2019, and if necessary, be extendable to incorporate new characteristics as a next step. From the selected papers, we collected the parameters and sets used in the mathematical models. For the first version of the taxonomy, we derived the entities based on the most common sets in the models and their characteristics based on the indexed parameters. For each entity, we then assessed whether *i)* the entity has unique characteristics or could be merged with another entity, and *ii)* the entity is common enough to be considered a general entity in the taxonomy. We then re-evaluated the attribution of the characteristics, in particular those characteristics that originate from parameters with multiple indices. For each characteristic, we assessed *i)* the dependency, both on entities and on other characteristics, and, similarly to entities, *ii)* their generality. We then used this first version for a (preliminary) validation and assessed the taxonomy's applicability. Based on the results, we modified the taxonomy and repeated the process until the ending conditions were met.

Eventually, we identified ten entities and clustered them into three subcategories, as depicted in Table 1.

Table 1. Entities

Overarching entities	Immobile entities	Mobile entities
Network	Incident sites	Casualties
Budget	Medical centres	Vehicles
	Distribution centres	Commodities
	Shelters	Staff

The characteristics of each of these entities are explained in more detail in the following subsections and are summarised in Table 2.

Network

The network, or graph, formalises the spatial relationship between entities. The locations of immobile entities can be represented as nodes, and the transportation network connecting these locations as arcs (Figure 1). Each node and arc can have several attributes. The attributes of nodes depend on the type of the entity and will be further explained in the respective section. Arcs can be characterised by two main attributes: the distance, i.e. the length of an arc, and the status. The status refers to the condition of an arc. Especially after natural disasters, arcs can be damaged or blocked, leading to a reduced capacity or (partial) unavailability for routing.

Table 2. Overview of characteristics

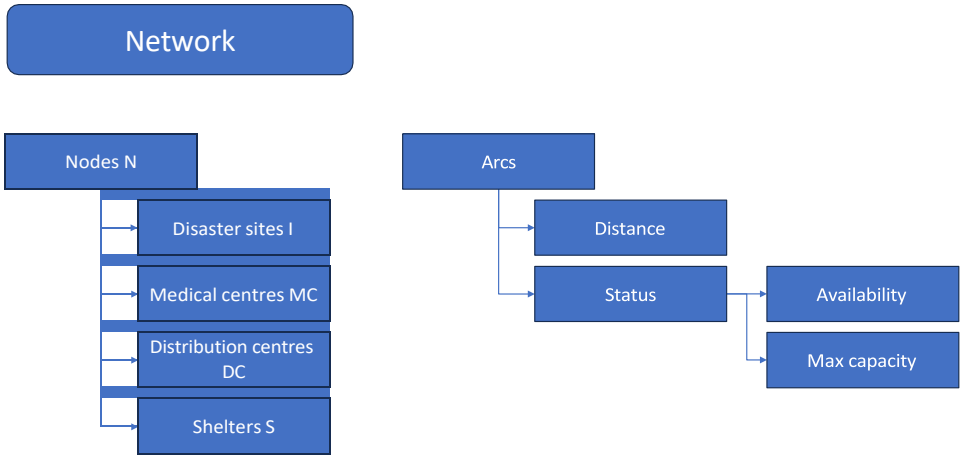

Figure 1. Network

Budget

The budget includes the financial funds to manage the disaster. It can be divided into designated and free budgets (Figure 2). Free budget can be used for any disaster response relief measure, while designated budget is reserved for specific measures, such as constructing shelters, medical centres or distribution centres or the purchase of commodities. Although usually not referred to as budget, a frequently used alternative is to define the number of potential distribution centres/medical centres/shelters to be located or commodities to be bought. This slightly different definition of budget by dividing the monetary budget by the costs for construction or purchase may facilitate the interpretation of these values.

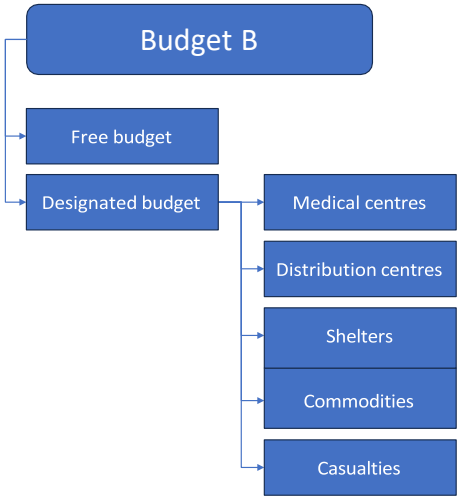

Figure 2. Budget

Incident Sites

The most important nodes in the network relevant to disaster management, although often not explicitly mentioned, are the incident sites (Figure 3). These incident sites are primarily defined by their geographical location, usually defined by a single pair of coordinates for a central point such as a point of registration. Each location can differ in terms of the disaster's onset and the resulting damage. Combined, these characteristics determine, among others, the number of casualties and affected people or the status of the close transportation network at a certain moment. To be able to respond to a disaster, each incident site may require different resources such as commodities and staff. While some of these resources depend on the number and type of casualties and are therefore linked to the entity of casualties, other resources depend mainly on the location of the disaster. Examples of such location-dependent

resources are staff required for general tasks as search and rescue or managing the disaster site and equipment or commodities not linked to specific entities.

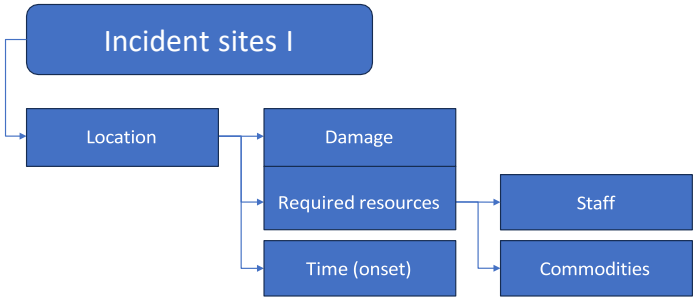

Figure 3. Incident sites

Medical Centres

A medical centre is an entity that provides treatment to casualties (Figure 4). The location of this entity can either be predefined or to be selected from a subset of potential locations. Medical centres can vary in their level, ranging from top-tier hospitals to temporary care units. A level is characterised by the capacity to treat casualties, which can be a fixed capacity or extendable as needed. Moreover, the level of a medical centre can impact the treatment times due to the equipment and the general experience of their staff. These treatment times may further depend on additional factors such as the casualty type or the skill of the treating staff. However, these factors are not explicitly mentioned in the overview to keep the taxonomy as general as possible. Beyond the level's impact on treatment-related attributes, the differences in size and equipment can also be reflected in the establishment and expansion costs.

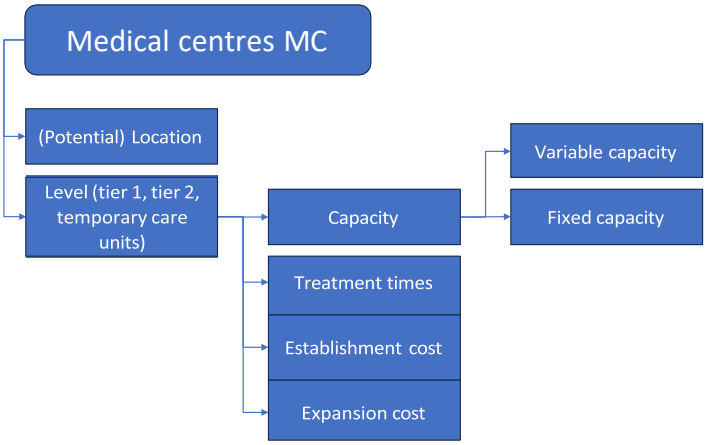

Figure 4. Medical centres

Distribution Centres

Distribution centres (DC) are entities that store and distribute commodities (Figure 5). Their location may be predetermined or selected by the disaster manager from a set of potential locations. DC can also differ in their level, ranging from national DC to temporary local DC, each level impacting various attributes. The most important attributes include the capacity to store and distribute commodities and the current stock. Similar to medical centres, the capacity can be fixed or extendable. While these attributes describing the capacity can be further specified, such as by commodity type, for the sake of generality, these extensions are not explicitly listed in the overview. To operate a DC of a certain level, staff is necessary, which can be further specified by the fixed staff requirement, e.g. for administrative tasks, and the capacity-dependent staff requirement. The differences among DC levels are also reflected in the associated establishment and extension costs.

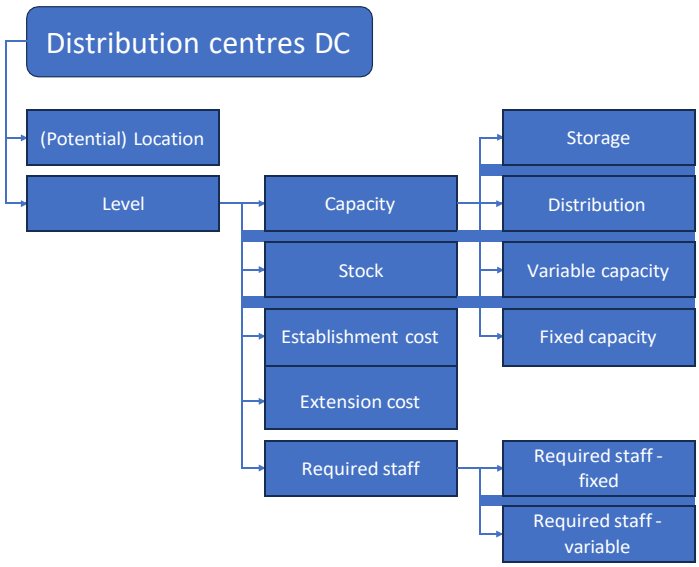

Figure 5. Distribution centres

Shelters

In the literature of disaster management, shelters are entities that can handle commodities and provide shelter to affected people. Hence, they share some characteristics with DC and medical centres (Figure 6). Their location is already predetermined or must be selected by the decision maker. Shelters can be characterised by their type, which may vary in terms of their capacity, stock, and the cost of building a new shelter. Similar to DC, capacity refers to the storage and distribution of commodities. Moreover, as shelters also provide a safe place for those affected, another characteristic of capacity is the number of people that can be accommodated in a shelter.

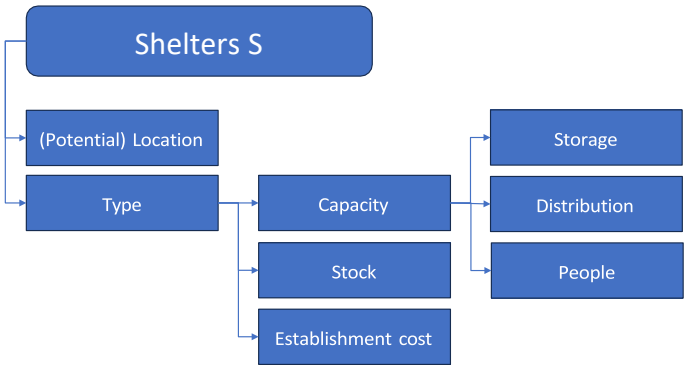

Figure 6. Shelters

Casualties

Casualties are the most important entity in casualty management (Figure 7). This entity usually has three main attributes, namely the type, e.g. the injury types or triage categories, the initial location, which is usually one or more incident sites, and the number of casualties, which is defined either by a fixed number or an arrival rate, e.g. to represent rescue/extrication. The type of casualty has an impact on several other attributes. First, it can determine the priority and the survival probability function or the transition probability from one type to another, the latter of which can be interpreted as a discrete form of the survival probability function. Regardless of the formulation, both can determine the maximum waiting time for a casualty. At the incident site, casualties may need treatment, and the treatment time depends on their type. Different types of casualties may also require different additional resources, resulting in different eligible medical centres or shelters, eligible vehicles, required commodities, such as water, food, or blankets, or required staff per time unit.

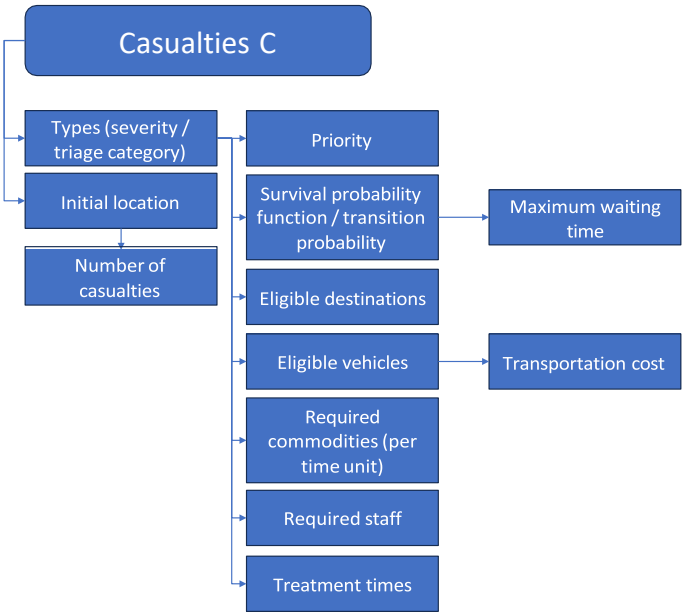

Figure 7. Casualties

Vehicles

Vehicles are entities for transporting casualties, commodities, and staff, and can be characterised by the location, the number of vehicles available and the type (Figure 8). Vehicle types can differ in their travelling speed and eligible arcs, which together with the distance of those arcs determine the travel time between two locations. In addition to the travel time, loading and unloading the casualties and commodities may require additional time or specific facilities. The quantity of commodities and people that can be transported is determined by the capacity of a vehicle type and can be defined by the eligible load, the weight, or the volume of commodities or casualties. Transport costs vary among vehicle types and may also be influenced by the specific load type. However, for the sake of generality, this detailed specification is not included in the overview.

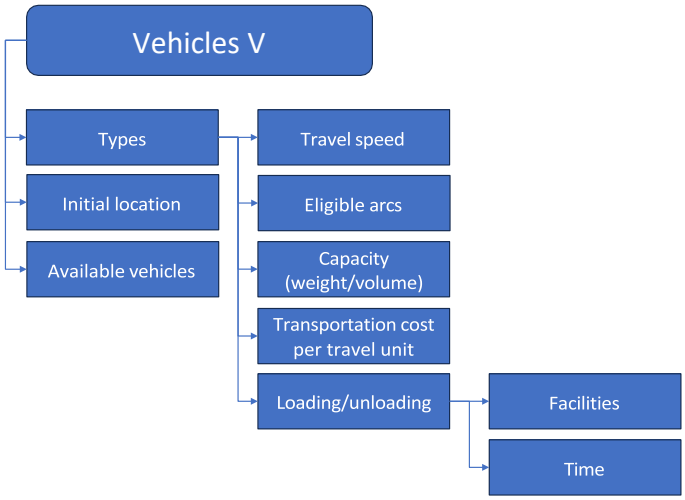

Figure 8. Vehicles

Commodities

To supply affected people and casualties, various types of commodities are required. These types can differ in their priority, dimensions, associated costs, and availability (Figure 9). Costs can include unit costs, holding costs and penalties for shortage (other potential cost types are not included in the taxonomy for reasons of generality). Availability can further be specified on a supplier level.

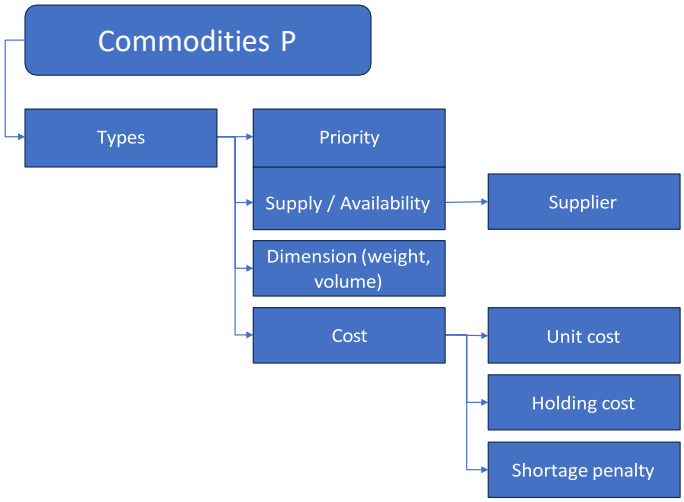

Figure 9. Commodities

Staff

Staff is an entity that treats patients, handles commodities, or fulfils other necessary tasks (Figure 10). It includes paid staff as well as (spontaneous) volunteers. Similar to casualties and vehicles, staff can be characterised by their type, location, and number. The number of staff can either be static or change over time due to availability and resulting shifts. The type of staff can affect the associated wages and can further be specified by the qualification. The qualification may determine the tasks staff members are allowed to perform and can be further refined by the skill level, which in turn may affect the quality and time required to complete a task.

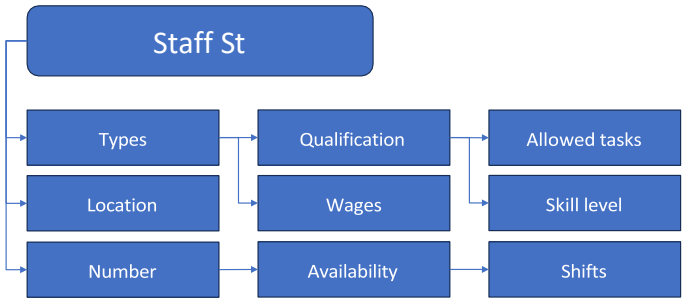

Figure 10. Staff

NEXT STEPS

The next step is to validate the presented taxonomy (Szopinski et al. 2019). For this process, we will invite academics and practitioners with strong expertise in disaster management to participate in discussion rounds, focus groups or interviews. We also aim to discuss the inclusion of entities and characteristics that are not or only implicitly mentioned in the literature and therefore are not (yet) included in the taxonomy. For instance, in practice, general circumstances such as the weather or the region might impact the characteristics of various entities. While they are generally not described in the literature, they could be added to the taxonomy as an additional overarching entity for completeness. Another point for discussion could be the definition of a disaster site. Currently, scholars define them as a set of single coordinates representing one specific point within a disaster area, such as a casualty collection point. However, depending on the disaster, single points may not be the best representation, and instead of defining a discrete set of locations, defining an area might be more representative. Furthermore, to facilitate the use of the repository, clear minimum requirements for the metadata should be defined. For instance, although certain disaster characteristics do not directly affect the model parameters (e.g. the specific cause of building damage) or are already implicitly included in the entity characteristics (e.g. the size of the affected area represented by the number of nodes and distances) and are therefore not included in the taxonomy, adding such information could be valuable for researchers to validate and compare their models.

After the evaluation with experts, we aim to map the published data (sets) and parameters to the taxonomy from both, articles used for taxonomy building, i.e. the articles selected by Farahani et al. (2020), and more recent articles. These two approaches should allow us to obtain an overview of available instances, which can be based on either real or hypothetical data. Based on this, we aim to create benchmark datasets in collaboration and discussion with experts and publish them in a repository to facilitate the comparison of existing and validation of future models in the field of disaster management.

CONCLUSION

In this paper, we proposed a road map for the creation of a repository for the sharing of humanitarian logistics datasets. We provided an overview of currently existing working groups and benchmark sets and presented a preliminary taxonomy for the field of casualty management. These two steps serve as a basis for the future set-up of a repository. Apart from the steps outlined in the previous subsection, future research could focus on extending the taxonomy to other areas of disaster management that are not yet covered to expand the usability of such a repository.

ABSTRACT

Critical infrastructures, which constitute the backbone of our modern society, are increasingly exposed to natural hazards. Loss of performance or failure of a critical infrastructure can lead to cascading effects that affect even more services and citizens. Floods, as one of the most prominent natural hazards, are prone to affect multiple critical infrastructures at once, making it even more difficult to assess combined effects of these (cascading) disruptions. Hospitals are especially vulnerable in a flood scenario, as they are reliant on multiple other infrastructures, such as power and water supply or the road network. In order to prepare for upcoming events, sophisticated analysis tools are required that are capable of modeling the spatial extent of flood induced disruptions and their impact on critical infrastructure services. In this work, we present a proof of concept that focuses on the impact of multiple disruptions on hospitals. We conducted a case study on an extreme flood scenario in the city of Cologne (Germany). Historically, Cologne has proven vulnerable to river-floods, as thousands of people were affected through floods in in 1993 and 1995. The approach is based on a combination of I) a geographic information system, which makes the extent of disruptions spatially explicit and II) a Bayesian network, which is used to assess the impact of one or multiple disruptions on a single hospital. We present a work-in-progress approach in this work. The results generated using this approach enable a first comparative overview of the expected level of services of the examined hospitals.

Keywords

Critical Infrastructure, Cascading Effects, Flood Risk Management, Bayesian Network, GIS.

INTRODUCTION

Growing interdependencies of critical infrastructures (CI) in combination with increasing exposure to natural hazards contribute to society's vulnerability to CI breakdowns (Nick et al., 2023). In addition, the functionality of one CI is most often reliant on the functionality of at least one other CI (Rinaldi et al., 2001), which poses a challenge for disaster resilience. The resulting highly interconnected networks can lead to severe cascading effects in case of a single disruptive event, such as a flood (Fekete, 2019). These interdependencies can cause impacts on a local CI that can have far-reaching effects on other CI. For this reason, it is important to have an in-depth understanding of disruptions and the resulting cascading effects to better prepare for upcoming challenges. This requires sophisticated CI analysis methods that look at exposure to natural hazards and also investigate CI interdependencies enabling a prediction of cascading effects and their impacts.

In this work, we study how the impact of multiple (cascading) flood-induced disruptions on different service levels of a CI can be analyzed for flood risk management. In terms of CI, we focus on hospitals as they are crucial for disaster response and especially vulnerable to floods and failure of other CI services (Melnychuk et al., 2022). We thus require a model that (1) makes the distribution of the considered disruptions spatially explicit, and (2) enables an estimation of the effect of one or multiple disruptions on predefined service levels of a hospital. A case study of an extreme flood scenario in the city of Cologne (Germany) is conducted as a proof of concept. The final goal of the approach is to create a map that provides a comparative overview of the expected level of services between the examined hospitals.

Here, we present an approach to address these goals. The main contribution of this work is an approach for assessing the impact of multiple flood-induced cascading effects (i.e. disruptions) on hospitals. The novelty of this approach is the consideration of individual as well as combined disruptions on hospitals in a flood scenario taking into account uncertainties. We argue that it is important to consider the uncertainties both of the disruptions as well as in their impact on a hospital. As a result, the approach generates a map which can be used to compare affected hospitals to one another serving as an information tool for emergency responders in flood risk management. Especially in emergency response, it is important to consider cascading sequences triggered by natural events (Ricci et al., 2024).

The approach is based on a combination of a geographic information system (GIS) and a Bayesian network (BN) - the GIS informs the BN (as e.g. outlined in Johnson et al., 2012). The GIS is used to model the spatial extent of the considered disruptions. Geographic information systems are used extensively in emergency and crisis management, including impact analysis of natural hazards (e.g. see Tzavella et al., 2018 or Geiß et al., 2022). The Bayesian network is used to model the impact of the disruption(s) on a single hospital under consideration of uncertainties. Bayesian networks, which are probabilistic graphical models (Pearl, 1988), are often used in the literature to model the effects of natural hazards on CI (e.g. see Kameshwar et al., 2019 or Ram´ırez-Agudelo et al., 2021).

The definition of a disruption in this work follows the proposal by Mentges et al., 2023: A disruption (e.g. a damaged road) is caused by a disruptive event (e.g. a flood) and lasts as long as the performance of the system is decreased as a consequence of the event. The disruption ends when the system has recovered and can thus last longer as the disruptive event, i.e. the flood is gone but the road is still damaged. The concrete disruptions considered in this work are: the flood itself - in terms of a rising water levels, the flooding of hospital access roads (a indirect, i.e. cascading, effect), and potential blackouts caused by the flood (a second cascading effect). We selected these disruptions as the starting point for our work-in-progress approach because they are significant in their impact and are likely to occur in a flood scenario.

The remainder of this paper is structured as followed: First, our work-in-progress approach is described, including the case study of a extreme flood scenario in Cologne, Germany. Subsequently, preliminary results are presented, followed by a discussion and conclusion.

APPROACH

The approach can be divided into three steps: (1) the considered disruptions (flooded area, access road availability, and blackout areas) are modeled in a GIS environment, (2) a Bayesian network model is developed that is used to infer the effect of a single or multiple disruptions on the service levels of a hospital, and (3) the GIS and BN are combined (GIS informs the BN) to estimate the expected level of service of each individual hospital in an automated manner. In the following, the case study is presented, followed by the GIS model and its method to estimate the spatial extent of the considered disruption. Subsequently, the BN is developed and the combination of the GIS and the BN outlined.

Case Study Description

Our approach is developed and tested in the case study area of Cologne, Germany. Cologne is Germany's fourth largest city with a population of about one million people. The city is divided by the Rhine river, which is the second largest river in Germany. There have been several devastating Rhine floods in the past, for example in 1993 and 1995 (Herget and Meurs, 2010), the latter affecting 33,000 people and causing damage of 35 million euros in Cologne alone (Fink et al., 1996). A five-hundred-year flood (extreme flood) hazard map is used as exposure data in this case study (see Figure 1). Three disruptions that can be expected in a flood scenario and affect a hospital are considered in this work-in-progress approach: (1) the flood itself in terms of the rising water level, (2) a potential flooding of access roads to a hospital, and (3) potential blackouts caused by flooded transformer stations or safety shutdowns.

Open Street Map (OSM) data is used to determine access roads of hospitals in Cologne, the location of transformer stations used to determine blackout areas, and the location of hospitals. This data represents example data which was not reviewed for actuality and accuracy. The data of the extreme flood scenario called HQ 500 is provided by official sources (geoportal.nrw, 2024; geoportal of the state of NRW: www.geoportal.nrw/). In this scenario, the effect of failed or overtopped dikes, mobile flood defenses, and intrusion of ground water into old river arms is included (Fekete, 2020).

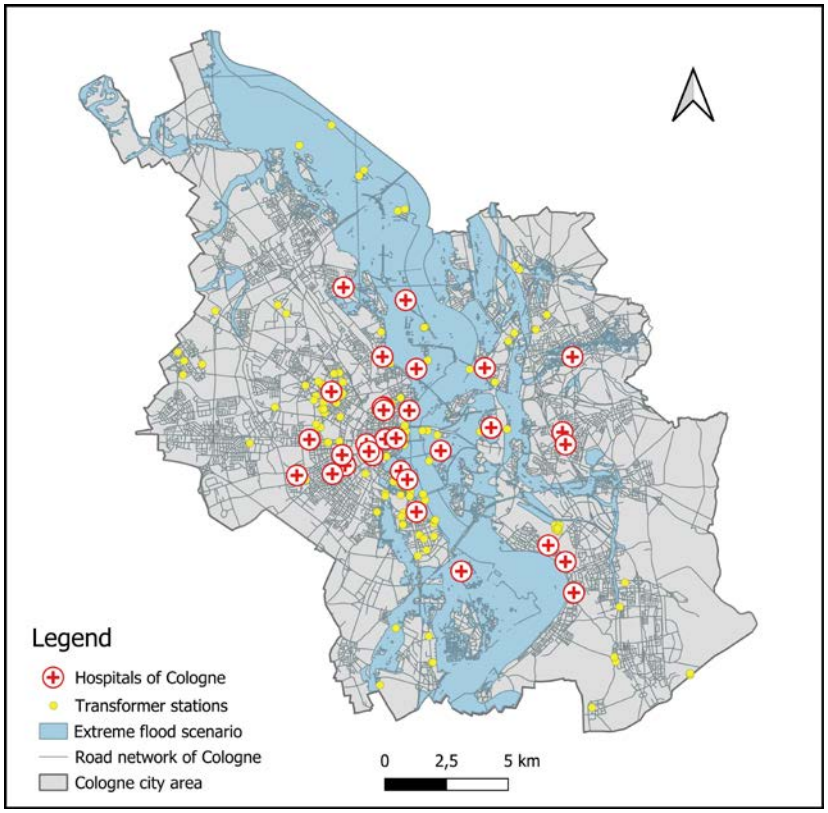

Figure 1. Map of Cologne including the extent of the assumed flood scenario, as well as the road network and locations of transformer stations and hospitals.

GIS Model

The spatial extent of the considered disruptions (flood, blackout, and road availability) is modeled in QGIS, which is an open source geographic information system. The approaches used to assess the spatial extent of these disruptions are work-in-progress in terms of their level of detail, but sufficient for a proof of concept of the approach. In the following, a brief description of the three individual approaches - one for each disruption - is presented.

The *flood* disruption is modeled by examining whether a hospital is located within the flood propagation layer in the GIS. It is analyzed, whether the flood propagation layer shows an overlap with a hospital building (compare Figure 1). In this work-in-progress approach, we conduct a binary assessment that omits the water level.

In order to determine the *access road availability* for each hospital, a ring buffer with a diameter of 100 meters is established around each center point of a hospital. Each access road within this buffer that does not show an overlap with the flood propagation layer is identified (see Figure 2). For each buffer, i.e. each hospital, it is determined if no access road, a single access road, or multiple access roads are available.

Figure 2. Example of a 100 meter buffer around a hospital showing multiple flooded access roads and one access road which can still be used.

The approach to determine blackout areas is based on a method presented by Pala et al., 2014. The method uses on Thiessen polygons (also called Voronoi diagram) without weights. In order to determine the Thiessen polgyons, an algorithm is used that grows cells (that constitute the polygons) in a raster format starting from each source point (Pala et al., 2014), which are the location points of the transformer stations in Cologne. In a next step, it is analyzed which transformer stations are within the flooded area and thus would potentially be damaged or shut down for safety reasons. The corresponding cells to these source points are considered as potential blackout areas (see Figure 3). Four different areas of different blackout probability are considered in the approach: (1) the area that shows an overlap with the flood propagation layer and the affected Voronoi cells is considered as area with highest the blackout probability (assuming a 90% probability), (2) the area that shows an overlap with the flood propagation layer but not with the affected Voronoi cells is considered as the area of medium blackout probability (70% probability), (3) the area that shows an overlap with the affected Voronoi cells, but not with the flood propagation layer is considered as an area of lower blackout probability (50%), and (4) the area that does not show an overlap with both the flood propagation layer and the affected Voronoi cells is considered as the area with zero blackout probability.

Bayesian Network

The Bayesian network (BN) is used in the proposed approach to estimate the impact of one or multiple disruptions on different service levels of each hospital. The BN is implemented in Python based on the pgmpy library (see Ankan and Panda, 2015), which is a versatile library for working with probabilistic graphical models. A BN, introduced by Pearl, 1988, is a directed acyclic graph composed of nodes representing system variables and edges representing conditional dependencies (for a brief introduction of BN see e.g. Puga et al., 2015). Nodes that interact, are connected by edges in the direction of influence. For example, an edge $X \rightarrow Y$ implies that X (the parent node) influences Y (the child node). Additionally, each node has a probability distribution attached to it that defines the chance of finding the node in a given state. Nodes that are not influenced by other nodes (no edge is pointing towards these nodes) are called marginal nodes. Nodes that are influenced by at least one other node (edge(s) pointing towards the node) are called conditional nodes. Conditional nodes have conditional probabilities that are used to infer the state of a child node given information on the states of one or multiple parent nodes.

In our approach, a variable describing the expected *Level of Service* of a hospital is the target child node of the BN. The states of this node constitute potential level of services of a hospital. At this point, it must be considered that the number of states enhances the complexity when defining conditional probabilities for this variable - for each combination of parent and child node states, one probability value must be determined. We selected a simple categorization of hospital service levels that is proposed in Witte et al., 2021: (1) *normal*, which describes the unimpaired operation of the hospital, (2) *emergency*, which describes that the hospital only performs the basic services, and (3) *failure*, which describes that the hospital should be evacuated.

The node *Level of Service* of a hospital is influenced by the considered disruptions. Thus, the three modeled disruptions (flood, road accessibility, and blackout) constitute the parent nodes of node *Level of Service* (see Figure 4). The dependencies between the disruptions are not modeled in the BN, but in the GIS model, thus all disruption

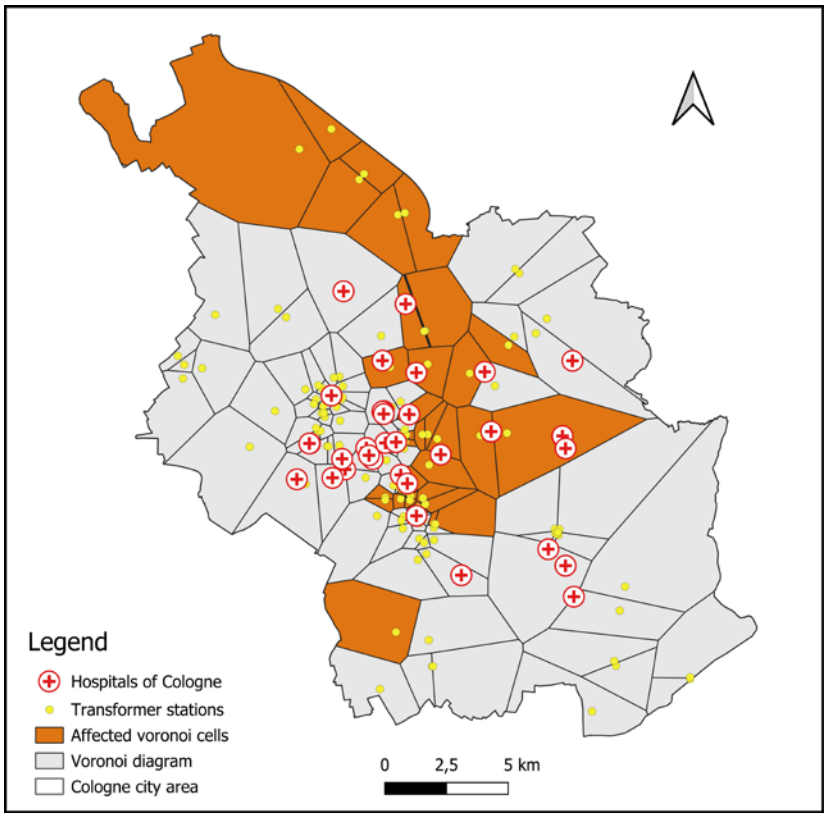

Figure 3. Map of Cologne including the transformer station-based Voronoi diagram including affected Voronoi cells that indicate areas prone to blackouts.

nodes are marginal nodes. The states of the disruption nodes are basic divisions. The nodes *Blackout* and *In Flooded Area* show binary states: *True* and *False*. The node *Road Accessibility* shows three states that describe if no access road is available, a single access road is available, or multiple access roads are available (all nodes and node states are listed in Table 1). The probability values quantifying the nodes of the BN were selected by the authors and reflect the basic dependencies between the variables - the more a hospital is exposed to disruption(s), the more likely it is to be in a state of *failure*. If a hospital is exposed to at least one disruption, the node *Level of Service* cannot be in state *normal*.

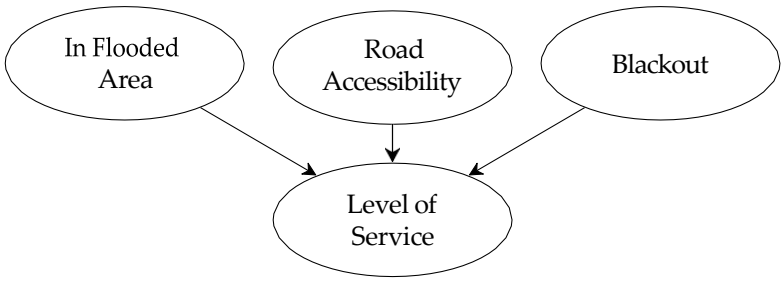

Figure 4. Bayesian network of the approach including the target node *Level of Service* and three parent nodes that describe the considered disruptions.

Table 1. All four considered variables of the Bayesian network shown in Figure 4 including their states.

Variable	**Level of Service**	**Road Accessibility**	**Blackout**	**In Flooded Area**
State 1	Normal	None	True	True
State 2	Emergency	Single Road	False	False
State 3	Failure	Multiple Roads		

In order to calculate the posterior probability of node *Level of Service*, i.e. the probability given evidence on the disruption nodes, the BN (see Figure 4) is duplicated and assigned to each hospital. The individual BNs are informed by the results of the GIS model, i.e. it is analyzed, if a hospital is within the flooded area, if it is in one of the four blackout zones (high, medium, low, and zero probability zone), and how many access roads are available.

Two types of evidence (information about node states) gained from the GIS must be distinguished. The evidence on variable *In Flooded Area* and *road Accessibility* is considered as hard evidence - which describes that we know the exact state of this variable (within the boundaries of the model). For node *Blackout*, we defined four areas with varying blackout probability, thus we do not have evidence with certainty, but evidence of a probability distribution. In order to consider this uncertainty evidence, soft evidence, introduced by Valtorta et al., 2002, is applied. In this way, the posterior probability of node *Blackout* being in state *True* follows the probability assigned to the individual blackout zones.

RESULTS

The results (see Figure 5) are illustrated using the geopandas library in Python that enables geospatial data analysis and visualization (Jordahl et al., 2020). The BN is duplicated and assigned to each of the 35 hospitals and spatially informed by the GIS model. This results in 35 probability distributions of node *Level of Service*. Thus, for each hospital, one probability value for each considered level of service (normal, emergency, and failure) is calculated, which sum up to one. Figure 5 shows the results on three maps. Each map shows the probability of one node state (normal, emergency, failure) for each hospital. Before going into detail on the results, it must be pointed out that these results have limitations due to assumptions within the model environment and cannot be used directly to estimate realistic effects of a flood. Nevertheless, the results allow an assessment of the suitability of the approach in regard to the research objective.

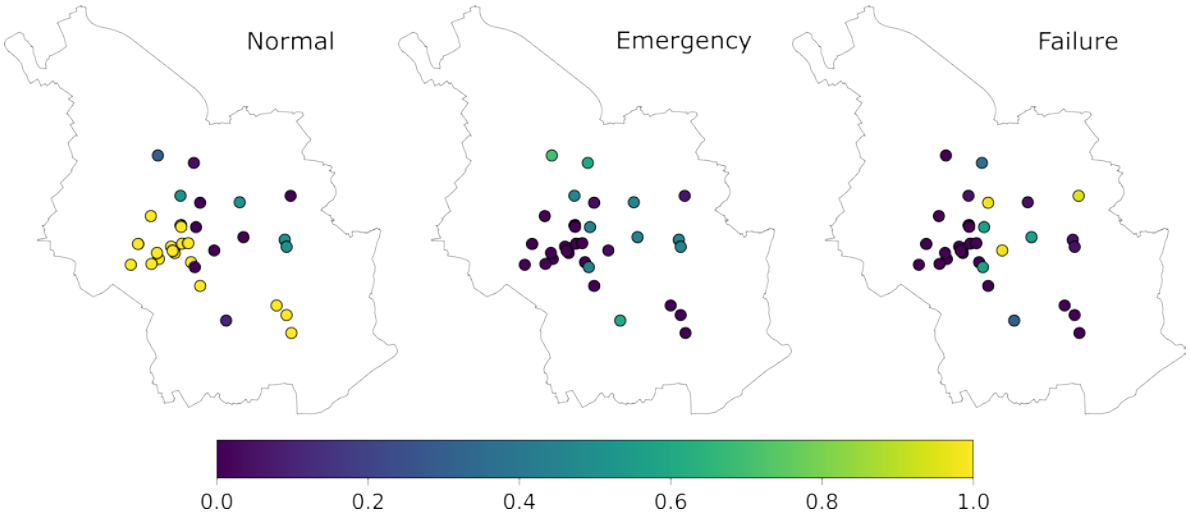

Figure 5. Preliminary results of the case study presented as three maps that illustrate the probability values of the three states of node *Level of Service*. The color of the dots (each representing one hospital) follow the colorbar at the bottom of the figure, thus, each color represents a certain probability value. Looking at one hospital on all three maps, the probability values sum up to one.

The preliminary results show that 20 hospitals are not affected by one of the three considered disruptions, i.e. $P(\mathit{Level\ of\ Service} = \mathit{Normal}) = 1$ (see bright yellow-colored circles in the left image in Figure 5). 17 hospitals are located west of the Rhine river and three hospitals are located in the south east of Cologne. Seven hospitals show a probability of 0% for state *Normal*, i.e. they are affected by at least one disruption. Two of these hospitals show the highest probability of state *Failure* with 97% (see bright yellow-colored circles on the right image in Figure 5). These hospitals are located close to the Rhine river and are within the flooded area as well as within a potential blackout area (leading to the highest probability of a blackout), and no access roads are available. One additional hospital shows a high probability of state *Failure* with 94%. This hospital is located near a tributary of the Rhine and is located within the flooded area and an affected Voronoi cell, but there is one access road still available.

DISCUSSION AND CONCLUSION

Cascading effects are of increasing interest in research, not only in the context of supply chains, but also with regard to the interconnection of natural hazards and related impact chains. However, concrete assessments, showcasing

how these interactions and cascading effects play out are still needed. The presented work-in-progress approach provides a first step to assess cascading effects and resulting multiple disruptions on hospitals in a flood scenario. By introducing a BN, the effect of a single or multiple combined disruptions is modeled including consideration of uncertainties in both the intensity of the disruption and the effect on different service levels of a hospital. Using a GIS model, the spatial extent of the disruptions is modeled. By combining both models (GIS informs BN), each considered hospital can be individually assessed with regard to its exposure to the considered disruptions. In this work, we presented a proof of concept of the approach. The preliminary results (see Figure 5) show that hospitals highly exposed to the considered disruptions can quickly be identified as well as hospitals that are not affected at all. Hospitals that are exposed to a subset of the considered disruptions can also be identified, but require a more detailed examination to assess the severity.

Nevertheless, in order to enable a more detailed and realistic assessment of hospitals exposed to flood-induced disruptions, several steps are required within future work to improve the approach. The resolution of the node *Level of Service* could be enhanced, thus considering a more detailed description of hospital services. These services can vary depending on the type and resulting capabilities of a hospital, i.e. some hospitals have specialized services such as fire burn status beds (Fekete et al., 2017). In addition, the resolution to assess the spatial extent of the disruptions can be improved. For example, in the presented work, only a binary assessment of whether a hospital is within the flooded area or not is conducted. Within future work, the height of the flood at each hospital building could be taking into account - data on the flood height is also made available by public services. The method to assess road accessibility could also be improved. In the presented approach, only a single ring buffer is used to determine access roads of a hospital. This analysis neglects the accessibility of these roads from a greater distance - a part of a road near a hospital might not be flooded, but the road might not be accessible from a greater distance. In addition, the type of access roads (e.g. a highway or a small road) could be considered as well as if the access roads to a hospital are passable. The method to assess potential blackout areas can also be improved to allow a higher resolution of blackout areas, e.g. by implementing the weighted Voronoi diagram method presented by Pala et al., 2014 or an analysis based on a reconstruction of the power grid (e.g. see Medjroubi et al., 2017).

When enhancing the complexity of the approach, more data is required to build the BN. Especially, the conditional probability table attached to node *Level of Service* requires extensively more data when considering a higher resolution of both the parent (disruption) nodes and the granularity of the description of hospital services (states of node *Level of Service*). As this data is likely to originate from expert surveys, supporting tools (e.g. see Morris et al., 2014) should be used to elicit probability distributions from experts. However, Bayesian networks also allow data from different sources, such as historical or simulated data, to be combined, which is a major advantage when modeling rare event scenarios, such as the extreme flood scenario of the case study.

To conclude, we presented our work-in-progress approach to assess the effects of multiple (cascading) disruptions on the services of hospitals in a flood scenario. The approach is based on a combination of two models (GIS and Bayesian network) allowing to spatially assess the impact of the considered disruptions on individual hospitals under consideration of uncertainties in disruption exposure and impact. In this work, we presented a proof of concept of the approach in a case study of an extreme flood scenario in the city of Cologne. The preliminary results are promising and enable a first comparative overview of the expected level of services of the examined hospitals. This can support decision-makers in emergency management, but also researchers of other disciplines to better visualize and understand the abstract concepts of cascading effects. It can also help to illustrate how different sectors, such as health, energy, and transport, can be analyzed using one model.

ABSTRACT

Understanding how to accurately inform the population about the risks of disasters is key for the well-functioning of our societies. Risk communication is also an essential feature of the disaster cycle, fundamentally contributing to preparedness but also to management. Here, we use an agent-based model (ABM) to investigate such an important problem. Specifically, we study the emergent behavior of a population of individuals who revise their opinion on the risk of a certain event, based on information received from an institution, processed through individual sensitivity, and discussed with peers. Such a complex process may include several biases, e.g., due to heterogeneous risk perception across the population, and homophily, i.e., tendency of individuals to interact with like-minded people. Our ABM, which encapsulates these crucial features, allows us to perform a campaign of numerical simulations towards gaining mathematically-grounded insights into their impact on the emergent behavior of the population and, ultimately, on how accurately institutional information is received and processed by a population. Such insights can be useful to design empirical studies to test them and, in case of empirical support, to use them to design recommendations for policy decision makers.

Agent-Based Model, Homophily, Opinion Dynamics, Risk Perception, Network

INTRODUCTION

Accurately informing the population about the risks connected to natural hazards, climate change, and men-made disasters is crucial. The importance of sharing accurate and useful information about risks is growing, together with the increase in the number of disaster events all over the world (*Global Assessment Report On Disaster Risk Reduction*, 2022). Effective risk communication means that citizens are correctly informed about what might happen, how they should prepare and what they should do to prevent, mitigate or adapt to the consequences. In a way, risk communication is crucial for response and management (Mamuji & Etkin, 2019), but its effects are present also in the recovery and mitigation phase. However, effective risk communication is extremely hard to achieve, and its effectiveness can depend on several factors (Bradley et al., 2014).

One major challenge comes from the fact that the same message can be interpreted in different ways, but also that the process of sharing information can lead to a final outcome, in terms of content and its spread, that is impossible

to predict. The social amplification of risk framework (SARF), first proposed by Kasperson et al., 1988, was intended as a way to explain how risks can be amplified in social interactions. Its purpose is to show the multiple interactions between psychological, social and cultural factors that can heighten or attenuate public perceptions of risk and related risk behaviours. The SARF has been applied to many different situations and hazards, ranging from wildfire risks (Brenkert-Smith et al., 2012) to chemical accidents (de Souza Porto & de Freitas, 1996), and to nuclear energy generation in Europe (Bearth & Siegrist, 2021). However, several decades after the introduction of the SARF, there are open issues that are still puzzling researchers and practitioners (Kasperson et al., 2022): social media, uncertainty, risk communication and integrated analysis. In this work, we focus on risk communication and systemic risk (which is referred to as integrated analysis by (Kasperson et al., 2022)) and we aim to contribute to understanding how collective risk perception emerges from artificial agents' beliefs, but also how it changes and evolves over time.

Agent-based modeling offers the opportunity to explore the factors impacting the spread of reassuring or worrying messages (Onggo et al., 2014)), then contributing to identify possible pathways for the social amplification of risk (Busby et al., 2016). A parallel but unrelated strand of research about the spread of beliefs in a population is opinion dynamics, a well-known sub-field of complex systems and agent-based modeling which aims to model the determinants of opinion spreading in a population, and predict its emergent behavior, which can span from the emergence of consensus among individuals, to steady disagreement andpolarization (Deffuant et al., 2000; Hegselmann & Krause, 2002; Proskurnikov & Tempo, 2017; Sen & Chakrabarti, 2014).

An early attempt to combine an opinion-dynamical model with a model of collective risk perception (Giardini & Vilone, 2021) has provided interesting insights about the impact of trust in institutional communication, trust in peers and varying level of agents' individual risk sensitivity. This model of collective risk perception based on opinion dynamics shows that, even if the agents receive the same initial information about the likelihood of the hazard, their perception of the actual risks is modified by individual traits and by the resulting social influence process. For different parameter configurations, overestimating risks (with regard to the initial state and the information received) is a likely outcome, but the system never reaches full consensus. This suggests that, regardless of the content of the message, individual risk perception and belief revision processes will lead the population to hold different beliefs about how risky a certain situation is. Even if the message has the same content, heterogeneous agents will perceive and transmit it according to their individual features, meaning that collective risk perception can be feebly linked to the original message. Another interesting but rather counter-intuitive result of that model is that different network structures (including regular structure, random topologies, and real-world structures) had negligible effects on the final opinion distribution, even on two empirically calibrated network topologies. This result is at odds with empirical studies (Becker et al., 2017) and simulation models of opinion spreading on networks (Flache et al., 2017), which suggest that network structure plays an important role in opinion formation and change. In order to better understand the interplay between network structure and collective risk perception, we designed a model in which information about risk is spread on the basis of the similarity across agents, i.e., their homophily. Homophily, *the observed tendency of like to associate with like* (Kossinets & Watts, 2009), is one of the most recurrent empirical regularities of social life (McPherson et al., 2001). Friends, romantic partners, colleagues, and other kinds of associates all tend to be more similar to each other than randomly chosen members of the same population with respect to a variety of dimensions (race, age, gender, socioeconomic status, habits, education, hobbies). Homophily can foster the spread of healthy behaviors in social networks (Nunner et al., 2022), but it can also contribute to the formation of echo chambers and polarization (Bessi et al., 2016). It is worth noting that, to the best of our knowledge, homophily in disaster risk perception has not been previously addressed. In the risk and decision making literature some attention has been devoted to risks related to different health treatments (Berry et al., 2018), and infectious disease outbreak (Kadelka & McCombs, 2021), but we are not aware of any work focusing on the relationship between homophily in risk perception and risk communication.

In order to fill in this gap, we explore the effect of homophily-based communication in an opinion dynamic model of collective risk perception. Building upon the work of (Giardini & Vilone, 2021), we designed an agent-based model (ABM) in which agents receive information about the likelihood of a disaster from an institutional source (broadcast), revise this information according to their own individual traits (risk perception), and then share the information with other agents (risk communication) on the basis of their homophily.In our model, agents interact in pairs, thus resembling an interpersonal discussion on risk, which is an important means through which individuals gather information and make sense of uncertain situations (Perlstein, 2023). Binder and colleagues in their study (Binder et al., 2010) using data from a public opinion survey on a new and potentially risky facility in the US found empirical support for the hypothesis that people are more likely to engage in interpersonal conversations with interaction partners who are expected to share their 'discussion valence', i.e., like minded individuals. This is in line with studies on political communication that reported that it is relatively common for people to find themselves in discussion networks with people sharing similar opinions (Huckfeldt & Sprague, 1987). Homophilous ties can

also be established on the basis of other characteristics, for instance shared political views or trust in institutions, but in this study we are interested in understanding whether and how preferentially interacting with others who have similar levels of risk perception might lead to consensus on risk perception in the population. In an extension of the model (in preparation) we plan to add homophily in trust in institutions and trust in the media as additional conditions to explore whether being homophilous in different dimensions has an effect on the final distribution of risk perception in the population.

Inspired by similar approaches in mathematical modeling of epidemic spreading (Frieswijk et al., 2023), we encapsulate homophily into the risk communication step of the ABM. Specifically, we include an additional parameter that captures the level of homophily of the population, which shapes the network formation process through which agents share information with others, favoring interactions among agents with the same risk sensitivity. Ultimately, our goal is to employ the ABM to understand whether homophily leads to highly clustered and polarized risk perceptions, and whether this varies depending on the levels of perceived risk.

MODEL DESCRIPTION

In our ABM, we consider a population of L agents, indexed by positive integer numbers $\mathrm{V} = \{1, \ldots, L\}$. Each agent $i \in \mathrm{V}$ is characterized by an opinion $O_i \in [0, 1]$, which represents their evaluation of the risk. We shall refer to this variable as the *opinion* of agent i, consistent with the opinion dynamics literature. Specifically, $O_i = 0$ represents the scenario in which agent i's evaluation is of minimum risk, whereas $O_i = 1$ means that i gives the maximum evaluation of the risk. For the sake of simplicity, we model opinions as the subjective probability that the disaster will actually take place, regardless of the magnitude of the possible consequences. We acknowledge that this is an important issue and we will tackle this in future work. Agents' opinions are updated on the bases of the interplay between internal characteristics of the agents and two different sources of influence: i) elaboration of institutional information, and ii) interaction among peers.

The elementary dynamics is set as follows: at the beginning of each discrete time step, the institution communicates to each and every agent the value of the risk I, which is a continuous value in the range $I \in [0, 1]$ with the same convention that $I = 0$ means minimum risk and $I = 1$ means maximum risk. Here, we assume that the institutional information I is kept constant throughout the iterations. The agents elaborate the information received. Then, they share their updated opinions among each other, and further elaborate their opinion on the base of such interaction with peers. The mathematical details of such opinion revision process are described in the following section.

Elaboration of Institutional Information

Once received the value I of risk assessment by the institution, each agent i modifies their opinion on risk o_i according to the Deffuant's model (Deffuant et al., 2000). Specifically, the current opinion (O_i^o) is revised to the new opinion (O_i) as

$$O_i^o \longrightarrow O_i = O_i^o + T_i (I - O_i^o) , \tag{1}$$

where $T_i \in [0, 1]$ is a parameter that captures individual's trust in the institution: the larger such parameter, the larger the impact of the information provided by the institution in agent's i opinion formation process.

Then, the updated opinion O_i is further processed according to internal characteristics of the agent. Specifically, we introduce a parameter $R_i \in \{-1, 0, +1\}$ that captures i's risk sensitivity. When $R_1 = -1$, agent i has low risk sensitivity, and is thus inclined to underestimate the risk; when $R_1 = +1$, agent i is highly sensitive to risk, tending to overestimate it; while $R_i = 0$ captures risk-neutral agents who do not distort the information received. Such a further process based on risk sensitivity is captured by the following update rule:

$$O_i \longrightarrow \begin{cases} \frac{1}{2}(1 + O_i) & \text{if} \quad R_i = +1 \\ O_i & \text{if} \quad R_i = 0 \\ \frac{1}{2} O_i & \text{if} \quad R_i = -1 . \end{cases} \tag{2}$$

In plain words, the presence of (positive or negative) risk sensitivity induces a bias affecting how individuals process the information received from the institution. This is consistent with what observed in the social psychology

literature (see, e.g., Popovic et al., 2020; Richard Eiser et al., 2012).

Table 1. Variables and Parameters of the Model

Symbol	*Values*	*Meaning*
L	Integer	Number of agents in the network
O_i	$[0, 1]$	Evaluation of the risk (opinion) of agent i
I	$[0, 1]$	Risk assessment communicated by the institution
T_i	$[0, 1]$	Trust in the institution of agent i
R_i	$\{-1, 0, +1\}$	Risk sensitivity of agent i
P_i	$[0, 1]$	Trust in peers of agent i
H	$[0, 1]$	Level of homophily in the network

Interaction Among Peers

Once the agents have received and processed the institutional information I, they exchange their opinions with peers on a social influence network, consistent with Scherer and Cho, 2003. More precisely, for each time step, we pick up L couples of agents (i, j), sampled uniformly at random. Each of these couples is a candidate interaction that can take place. Once the pair (i, j) is selected, we randomly assign an order to the two agents that form the edge, say i and j. Let us define j as the "speaker" and i as the "listener" (the symmetrical interaction where i is the speaker and j the listener will take place in the same way).

At this stage, we incorporate homophily in the model as the possibility that individuals may prefer to interact with akin peers than strangers. This assumption is based on the homophily principle, which means that we assume that agents with the same risk sensitivity interact more often (McPherson et al., 2001). Homophily is modeled as follows. For each one of the L couples of agents (i, j) sampled at random, i and j actually interact according to a probabilistic rule. Specifically, the interaction always takes place if the two agents i and j have the same risk sensitivity. Otherwise, the interactions takes place only with probability equal to $1 - H$, while with probability equal to H the "listener" refuses to receive information from the sender, and thus link (i, j) is discarded. In other words, if $H = 0$ there is no homophily in the population, and everyone interacts indifferently with everyone else; at the opposite of the spectrum, if $H = 1$, agents avoid completely interactions with peers not belonging to the same class. Clearly, such a mechanism ultimately generates a time-varying network of social contacts, whose pattern is shaped by homophily. In fact, for $H = 0$, at each discrete time step individuals interacts on an instance of an Erdos-Renyi random graph with L links (Newman, 2010); as H increases, the network starts displaying a clustered structure, which will ultimately impact the emergent behavior of the system, as we shall see in the following section.

Finally, if the interaction between a speaker j and a listener i takes place, then the listener revises their opinion. Specifically, let O_i and O_j be their opinions before such interaction takes place, respectively. Then, agent i will change their own opinion according to the Deffuant's rule described in Deffuant et al., 2000:

$$O_i \longrightarrow O_i' = O_i + P_i (O_j - O_i) , \tag{3}$$

where $P_i \in [0, 1]$ is a parameter that captures agent i's trust in peers. In this work, we set $P_i \equiv 1 - T_i$, which yields

$$O_i \longrightarrow O_i' = O_i + (1 - T_i)(O_j - O_i) . \tag{4}$$

On the other hand, the speaker does not revise their opinion. Finally, the listener elaborates again its opinion according to the rule in Eq. (2). All the variables and parameters of the model are summarized in Table 1.

Simulation Setting

In this work, we perform a campaign of numerical simulation on the model described in the above, in order to explore the role of homophily on the collective risk perception. To this aim, we generate Monte Carlo simulations of the ABM, and we estimate the quantity of interest (i.e., the final average opinion of the population), by averaging the result obtained over an ensemble of 2,000 independent realizations (*i.e., runs*).

In each run, we consider $L = 1,000$ agents and we initialize agents' initial opinions and trust in institution uniformly at random in the domain $[0, 1]$, each agent independently of the others. The risk sensitivity is assigned as follows: each agent has a probability $p = 0.5$ to have risk sensitivity equal to zero (neutral agent), a probability $\rho/2$ to have $R_i = +1$ (risk-averse agent) and $(1 - \rho)/2$ to have $R_i = -1$ (risk-prone agent), where $\rho \in [0, 1]$ captures the average bias of the population: $\rho < 0.5$ means that there are more risk-prone agent than risk-averse agent, while $\rho > 0.5$ represents the opposite scenario.

Every run is performed for a sufficiently large number of iterations in order to achieve a final steady state, *i.e.*, a configuration where the dynamics has become constant and the global configuration of the system is stable, that is, the state of the system does not change anymore.

RESULTS

In this section, we describe the results of our numerical simulations. Specifically, we perform two sets of numerical simulations. In the first one, we consider the scenario with no homophily ($H = 0$). In this scenario, we consider populations with different characteristics in terms of risk sensitivity (captured by the parameter ρ). Specifically, we consider a balanced scenario ($\rho = 0.5$), and two biased scenarios (with $\rho = 0.15$ and $\rho = 0.85$, respectively). In all scenarios, we consider different values of the risk assessment communicated by the institution I, and we study how the opinion revision process shapes the collective risk perception.

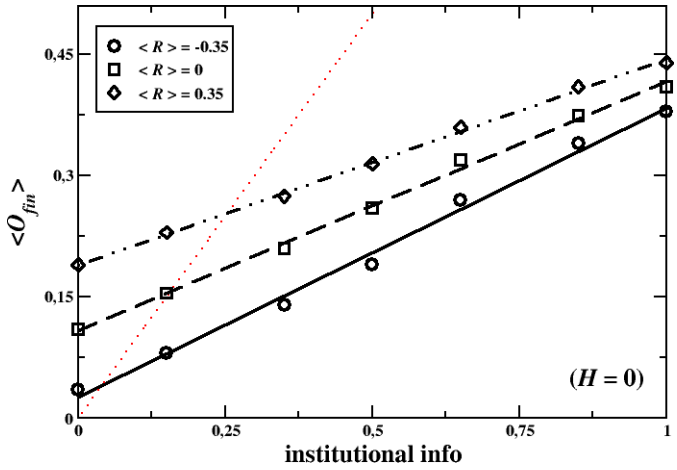

Figure 1. Monte Carlo estimation of the average final opinion $\langle O_{fin} \rangle$ as a function of the institutional information I for a system of $L = 1,000$ agents and a population with initial opinions and trust towards institution randomly assigned with uniform distributions, for different values of risk sensitivity. Lines represent linear fits of numerical data, red-dotted one is the bisector of the first orthant.

Specifically, Figure 1 shows the final average opinion, that is, the average evaluation of the risk in the population, in a completely balanced system, that is, when $\rho = 0.5$, yielding a balance between the number of agents with high and low risk sensitivity (on average). In general, our results are consistent with those described in Giardini and Vilone, 2021: the population tends on average to overestimate the risk for low-risk situations (that is, small values of I), and underestimate it in the opposite case. Interestingly, the value of I for which the population starts to underestimate the risk is lower than $I = 0.5$. The same study is reproduced also in the case of non-balanced populations, that is, for populations with lower and higher risk sensitivity. Overall, the emergent behavior is qualitatively similar. Unsurprisingly, the collective risk perception is higher for the population that is more sensitive to risk. However, it is worth noticing that even in the scenario in which $\rho = 0.85$ (yielding an average risk sensitivity of 0.35), the population starts underestimating the risk even for values of institutional information lower than $I = 0.5$. These observations are consistent with the conclusions of previous research, which highlighted how the nontrivial way through which people elaborate information received from the institution may lead to a biased collective risk perception; in particular, with an underestimation of severe risks (Giardini & Vilone, 2021).

In the second set of simulations, whose results are illustrated in Figure 2, we consider a scenario in which homophily is present. Specifically, we investigate how increasing the value of homophily shapes the final average opinion of the population. To this aim, we consider the basis balanced scenario presented in Figure 1 (with $\rho = 0$), and we estimate the average final opinion for different values on H. Our results suggest that increasing the homophily can lead to an overestimation of the risk, whereby the echo chambers formed by the network formation process seem to amplify the risk perception, with potentially harmful consequences to the society.

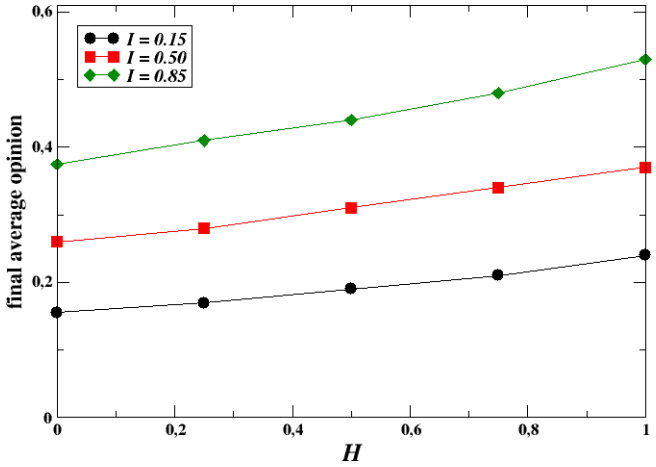

Figure 2. Monte Carlo estimation of the average final opinion $\langle O_{fin} \rangle$ as a function of the homophily H for different values of the institutional information. The system has $L = 1,000$ agents with fully balanced parameters: initial opinions, trust towards institution, and risk sensitivity randomly assigned with uniform distributions.

CONCLUSION AND ONGOING RESEARCH

In this work, we used agent-based modeling to explore the role of homophily on the collective risk perception in heterogeneous populations. Specifically, building on an ABM proposed in Giardini and Vilone, 2021, we have incorporated a mechanism that captures the tendency of individuals to interact more with like-minded people. Then, we have performed a campaigns of Monte Carlo simulations to unveil the impact of such behavioral mechanism on the emergent behavior of the system, showing how it could lead to biases in how institutional information is received and processed by a population.

The results discussed in the previous section offer us a preliminary understanding of the interplay between risk communication, individual biases and homophily in information spreading. When agents interact preferentially with similar agents this results in a widespread amplification of the risk perception, which can have several undesired outcomes. This finding is in line with research on homophily in the spreading of desirable and undesirable behaviors (Brechwald & Prinstein, 2011), paving the way for different lines of further research toward extending the existing findings, deriving analytical results to support them, and validating the model on real-worlds case studies. We are aware of the multiple limitations of this work in progress, including lack of validation of the model, limited exploration of the parameter space and a quite simplistic description of the homophily principle.

To address some of these limitations, we are currently working along three main avenues in order to further develop the model.

First, the numerical simulations presented in this paper are being extended along several directions. One relevant direction is to embed the model on a nontrivial network structure, restricting social interactions to those between neighbors on the network. This approach, already used in Giardini and Vilone, 2021 for the simpler model without homophily, can be readily extended to incorporate homophily toward investigating the interplay between such behavioral mechanisms and the complexity of real-world networks of social interactions. Moreover, more realistic implementations of homophily should be considered and incorporated into the model.

A second research direction that we are currently exploring is the possibility to establish rigorous analytical results for the model of collective risk perception formation described in this paper. Concerning this research direction, the key step consists in re-formulating the opinion formation process described in Eqs. (1)–(4) using the system-theoretic formalism of opinion dynamics models [See, e.g., Proskurnikov and Tempo, 2017] Using this formalism, under some assumptions, it is possible to gain analytical insights into the emergent behavior of the population, and derive closed-form expressions for the final average opinion, as function of the different parameters of interest. Some promising preliminary steps towards achieving such a goal can be found in Zino et al., 2024. This procedure will allow us to corroborate the findings of our numerical simulations with rigorous analytical observations.

Third, we are working towards validating the ABM in real-world scenarios, using survey and experimental data to calibrate the model. A recent review paper (Bradley et al., 2014) pointed out that natural disaster preparedness interventions, which authorities might wish to target at a whole population, mainly involved interpersonal communication, but their effectiveness is limited. The insights gathered thanks to ABM can be used to shape theories and data collection on the factors driving an heterogeneous population to form its collective risk perception about a certain event. This can be done starting from survey data, such as the study in Salvati et al., 2014, which collects data on risk perception concerning floods and landslides in different Italian regions, and how such collective opinion evolves over time. Using this data, we are currently working towards calibrating the model to provide an empirical validation that supports our ABM. We also plan to extend the model in order to design opinions about hazards differing in terms of impact.

ABSTRACT

Southwestern British Columbia is the most seismically active region in Canada because of its proximity to the Cascadia Subduction zone. To improve emergency preparedness for Vancouver Island, models have previously been developed to estimate the potential damage to infrastructure from a major earthquake, to consider community resilience while awaiting relief supplies, and to optimize procedures for repairing damaged roads and routing trucks from marine terminals to needy communities during the 72-hour emergency response phase. However there are large uncertainties in the disaster impacts, and numerous assumptions in the models' parameters, so this study serves to conduct sensitivity analysis on several of the factors to produce more robust recommendations from the model outcomes including: best depot location for road-clearing teams; most critical roads for supply distribution; most critical ports for supply distribution; and the effect of incorporating a community resilience measure. Effective display of results is an important consideration.

Keywords

Relief supplies distribution, road-clearing model, earthquake, sensitivity analyses.

INTRODUCTION

The Cascadia Subduction zone is the tectonic boundary between the Continental North American and the Oceanic Juan De Fuca plates in the Pacific Ocean. Southern British Columbia, Canada, lies on top of the Cascadia Subduction zone, making it the most seismically active region in all of Canada, with a 2-month sample shown in Figure 1 according to the (logarithmic) Moment Magnitude Scale (Rogers, 1998).

The closest densely populated regions to the subduction region, the communities on Vancouver Island (VI) and the smaller nearby Gulf Islands, are the most vulnerable places to large magnitude earthquakes. A Cascadia earthquake of magnitude M9, which recurs at intervals from 100 to 1000 years (Clague, 2002), can cause major infrastructure damage on these islands, impeding relief supply distribution during the immediate response phase following the shock, compounded by potential disruption in transportation modes which could have a significant impact on the flow of essential goods between and within the islands.

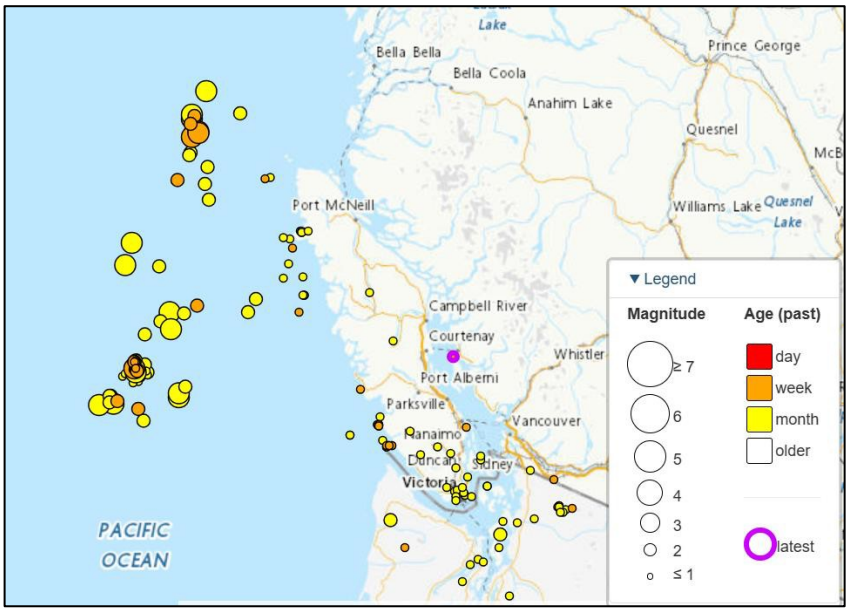

Figure 1. All earthquakes for May and June 2023 (source: Natural Resources Canada, 2010)

A significant contribution to emergency preparedness is to model the main components of the distribution network for relief supplies, how elements may be damaged by a natural disaster, and what mitigating strategies may be considered to minimize the disruption. Studies have been conducted to predict the damage a Cascadia Earthquake may induce on and around Vancouver Island (VI), as well as road network reconstruction and relief supplies distribution plans to deal with the aftermath (Chang et al., 2020). Other models for reconstruction of roads and routing of relief supplies were developed and executed on data available from past disasters (Souza Almeida et al., 2022a). However, little research is available on sensitivity analyses of such models, whether on existing case studies or simulated disaster data. This study deals with analyzing the results of one such model for a simulated Cascadia earthquake scenario on VI.

The relief supplies delivery problem involves boxes of essential goods, with one box per person in the affected region lasting one week. The mechanism is to have the boxes delivered to the islands via ship from the City of Vancouver on the mainland, while having road clearing teams repair roads on VI in the most effective way to reconnect communities whose links to the road network were severed by the earthquake. Delivery trucks pick up the boxes from marine delivery points, and use any undamaged roads or repaired roads to access the communities. However, the earthquake can also shut down ports on the islands temporarily due to damage, and/or halt some shipping routes due to interrupted navigation services. Barges can be used as surge capacity to get boxes to Vancouver Island as they can access many more suitable landing spots. Within the 72-hour emergency phase planning horizon, any unmet demand can be fulfilled by helicopter from mainland airports to an island community.

The post-earthquake optimal resupply plan relies on several foundational models. The Critical Infrastructure (CI) Analysis of Regional Disruption & Ferry Route Interruption model (Bell & Bristow, 2020) characterizes the damages to infrastructure, marine and road transport, and shipping routes given a Cascadia earthquake. Community demand for relief supply boxes is principally proportional to their respective populations, but this can also be weighted by a resilience index (Chang and Tanner, 2022) which captures the relative impact of the earthquake on each community based on multiple factors associated with their preparedness and vulnerability. The resulting community impact factor (CIF) is an integer measure of a community's resilience to the Cascadia earthquake with 1 being the most resilient value and 5 being the least resilient community to an earthquake.

Outputs from those two models concerning CI and CIF respectively produce inputs for relief supply distribution optimization, which comprises two models: a road clearing model on VI to reconnect isolated communities, and a multi-modal distribution model of relief supplies which takes advantage of these reconnected roads to reach affected communities. These two models are synchronised and referred to as the Road Clearing and Relief Supplies Distribution (RCRSD) model. The RCRSD is solved using a Greedy Randomised Adaptive Search Procedure (GRASP) heuristic to optimally satisfy the demand for relief supply boxes as shown in Figure 2. The RCRSD model generates a solution for damaged roads' reconstruction, while simultaneously finding the optimal way to distribute supplies via sea, land, and air to the affected communities.

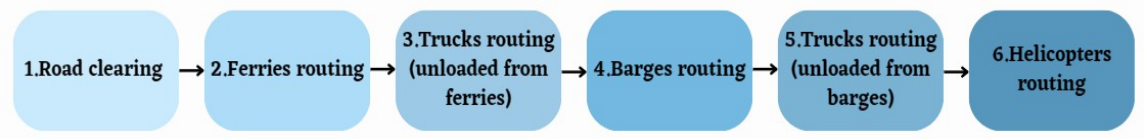

Figure 2. Working order of the RCRSD model

The combination of all of these models provides scenario results to help develop response plans by the relevant authorities, as well as industry and community stakeholders to improve the emergency preparedness for VI. However, there are large uncertainties and multiple assumptions in all stages of each of these models, so the outputs from a single run do not well represent the potential range of outcomes following an actual earthquake. But conversely, it is infeasible to run the models for all possible combinations of conditions, therefore a systematic sensitivity analysis process is needed to reflect the span of post-disaster circumstances and associated risk mitigation strategies to best prepare for the emergency response phase. Such a sensitivity analysis based on the RCRSD model, but also with some variations in outputs from the CI and CIF models, is the subject of this study.

The aim of this paper is to conduct sensitivity analyses on multiple input parameters to the RCRSD model to answer the following questions. The sensitivity analyses are primarily conducted given a situation where the earthquake damage to roads and ports is moderate (Case A: *Partial disconnection*), with an extension considering limited variations for the situation where damage is much greater (Case B: *Extensive disconnection*).

- Where are the best and worst locations to establish the depot on Vancouver Island where the road clearing teams are pre-positioned?
- Which damaged road segments are consistently cleared over multiple runs of the RCRSD model (as the solution method is heuristics based), and how does that affect communities supplied?
- For a given level of roads consistently cleared within the 72-hour window (i.e. in 25%, 50% and 70% of the runs respectively), if those road segments are then considered undamaged, what is the next priority set of roads to be cleared?
- Which ferry port and which barge port respectively supply the most relief boxes, and what is the impact of having one or the other unavailable?
- What is the impact of having the number of available ferries or barges from the mainland reduced?
- What is the effect on the relief box supply distribution if the communities' relative neediness (CIF – community impact factor) is omitted?
- How should the results of the above analyses be presented to be intelligible and useful?

METHODOLOGY

The methodology for conducting the sensitivity analysis is essentially these four major steps, each of which is expanded upon below:

a) Determine which variables will be considered to be altered for the sensitivity analysis;

b) Determine how to represent the results effectively, given the large number of outputs;

c) Determine a framework for altering combinations of the input variables for the sensitivity analysis;

d) From the plethora of results, synthesize recommendations for Emergency Management planners.

Input Variables

Over 50 input variables are used in the RCRSD model. Many of them are considered fixed, such as the road network on Vancouver Island, and the communities' populations. The sensitivity analyses focus on factors within the planners' control, such as where to pre-position road clearing teams, and anticipation of various state variables affected by the earthquake such as which ports will be opened or closed and the number of ferries or barges available.

Output Parameters

For each run of the RCRSD model, 17 output files are generated as shown in Table 1.

Table 1. List of all output files generated from a single run of the RCRSD model

	Output name	Output ID	Content details
1	Initial demand	ID	List of demands of every community on VI in terms of number of boxes of supplies
2	Road clearing edges	RCE	Objective value of road clearing sub-model and list of unblocked edges with the time taken and ID of the team that clears it
3	Road clearing routes	RCR	Route taken by each road clearing team
4	Ferries island delivery	FID	Demands delivered on ferries to each of the smaller islands in terms of number of trucks
5	Ferries demands	FD	Objective value of the ferries routing optimization model and the demands delivered to each port via ferries in terms of number of trucks
6	Ferries routes	FR	Routes details for every ferry
7	Ferries truck delivery	FTD	Demands delivered by trucks that arrived on VI via ferries to each community in terms of number of boxes
8	Ferries trucks routes	FTR	Routes details of trucks that arrived on VI via ferries
9	Barges island delivery	BID	Demands delivered on barges to each of the smaller islands in terms of number of trucks
10	Barges demands	BD	Objective value of the barges routing optimization model and the demands delivered to each port via barges in terms of number of trucks
11	Barges routes	BR	Routes details for every barge
12	Barges truck delivery	BTD	Demands delivered by trucks that arrived on VI via barges to each community in terms of number of boxes
13	Barges trucks routes	BTR	Routes details of trucks that arrived on VI via barges
14	Helicopter community demands	HD	Demands delivered by helicopters to communities on VI
15	Helicopter routes	HR	Routes details of helicopters
16	Communities with unsatisfied demands	UC	List of communities whose demands are not 100% met
17	Communities completely supplied	SC	List of communities whose demands are completely met

Regional Division of Vancouver Island

Given the large number of output variables (Table 1), coupled with the 109 communities on VI included in the model (Figure 3), it is ineffectual to provide the results solely in terms of distinct community supply satisfied, segments of roads fixed within the time horizon (out of 3707 possible), ports and barges and ships operating, etc. While all of these details are calculated and stored, they must be aggregated in effective ways to provide useful insights regarding the outputs.

Various techniques were used to aggregate the results and render them digestible. For some, percentages were applied such as the percent of damaged roads repaired within the specified time horizon, or the percent of total community demand for boxes met via water and land avenues (versus helicopter). To represent changes in supplied amounts under different run conditions, the levels of supplies are often aggregated by four different regions of VI namely North Island, Central Island, Pacific Rim, and South Island as shown in Figure 3. Sunshine Coast and Gulf Islands, although used in the RCRSD model, were excluded from the sensitivity analyses done in this study.

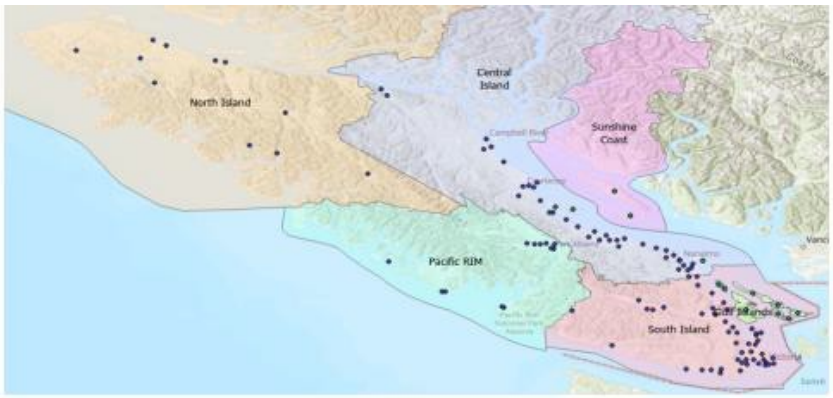

Figure 3. Communities and regional division of Vancouver Island used in the RCRSD model (Chang et al., 2020))

Framework for Altering Combinations of the Input Variables

Figure 4 illustrates the framework used to vary the models for the sensitivity analyses. Since there is an infinite number of possible infrastructure damage combinations arising from a Cascadia earthquake, the (CI) model (Bell & Bristow, 2020) was used to generate two scenarios: Case A of *Partial disconnection*, and Case B with *Extensive disconnection*. The sensitivity analyses were conducted primarily on Case A in this study, with a few runs run as an extension to examine how the more severe Case B might alter some key outcomes.

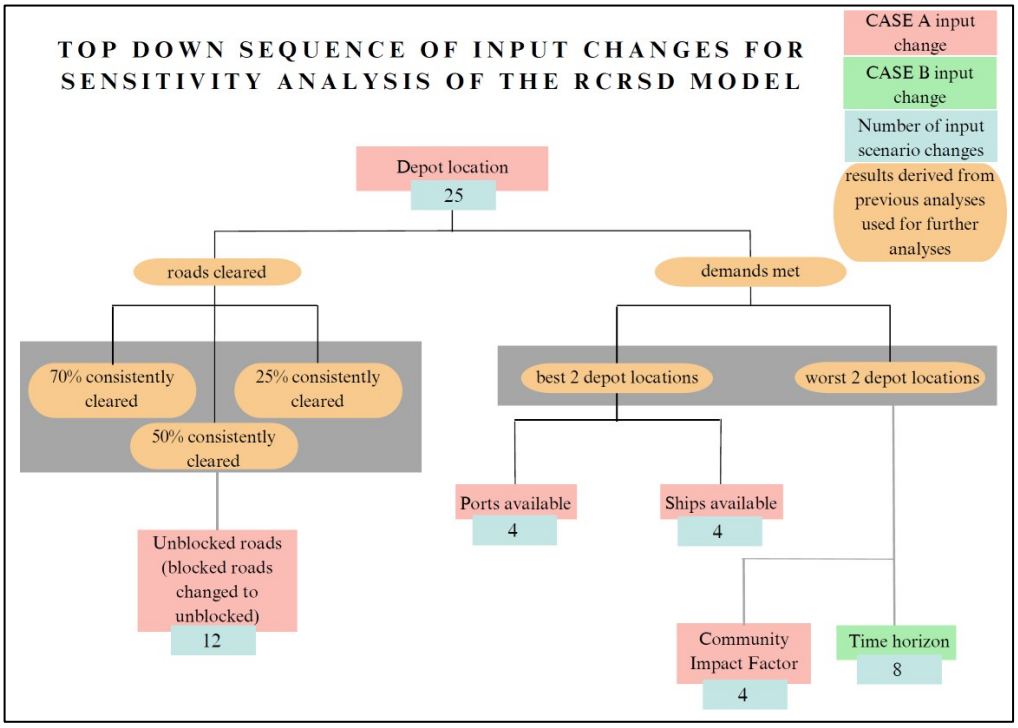

Figure 4. Sequence and number of input changes done for the sensitivity analyses

The depot location where the road clearing teams are co-located can have a significant effect on the efficiency of getting damaged roads reopened thus connecting more communities within the modelled time horizon, hence this variable is extensively studied in the sensitivity analysis, comparing 25 different base locations as noted in Figure 4. A previous study has shown that four road-clearing teams at one station is a reasonable limit, as there are greatly diminishing returns in having more (Souza Almeida et al., 2022b). One modelling outcome of particular interest is which road segments are most critical in quickly reestablishing connectivity between communities. Since the optimized set of cleared roads varies from run-to-run, one way to measure these priority roads is to observe which segments are consistently repaired across all of the computer runs. Since the concept of "consistently repaired" is subjective, three levels of consistency are defined, namely roads that are consistently cleared in at least 70% of the model runs, or 50% of the runs, or 25% of the runs respectively. Then, given each of these prescribed levels

of road repair, the models were then rerun assuming that those consistently repaired roads were not damaged to see what would be the next priority segments for repair (Figure 4).

Concurrently, the RCRSD runs were used to identify the two best depot locations, as well as the worst two depot locations (Figure 4, middle right). Even though only one depot is considered in practice in this model, comparing the best two depot locations allows the decision makers to consider choosing either of them based on other practical reasons, especially if their effectiveness is similar. Considering the worst two depot locations provides insights on how important depot location is on VI for effective goods supply (i.e. comparing the best vs the worst depot location), while also highlighting the deleterious impact of making a poor decision about this risk mitigation strategy.

For each of the best two depot locations, sensitivity was conducted on the base Case A conditions of which ports on the island are open or closed throughout the planning horizon, and which ships routes are operational or not during that period due to navigational constraints (Figure 4, bottom right). Finally, for the best and worst two depot locations respectively, the outcomes for the scenario with *Extensive disconnection* (Case B) are contrasted with those for *Partial Disconnection* (Case A). For case B, extensions in the 3-day time horizon are also examined, since very few roads are repaired within the 72-hour response window given the severe Case B conditions.

INPUT DATA

Inputs Related to Roads

The RCRSD model has a total of 2543 nodes and each node corresponds to a geographic location on or around Vancouver Island as shown in Table 2 (Souza Almeida et al., 2023).

Table 2. Types and locations of nodes used in the RCRSD model

Node range	Node type	Location
0 – 108	Community	VI
109 – 2414	Road intersection	VI
2415 – 2421	Ferry port	VI
2422 – 2428	Ferry/barge port	VI
2429 – 2457	Barge dock	VI
2458 – 2470	Community	Small islands
2471 – 2477	Ferry port	Mainland Vancouver
2478 – 2480	Ferry/barge port	Mainland Vancouver
2481 – 2515	Barge port	Mainland Vancouver
2516 – 2536	Airport/Heliport	Mainland Vancouver
2537 – 2542	Port community	VI

Port communities are the communities on VI that have a port nearby from which they can receive supplies directly via ship or barge (i.e. no road clearing required). Out of the 3707 road segments used in the RCRSD model, 1123 are assumed to be blocked in this study, with the available roads and the blocked roads for Case A shown in Figure 5. Assuming that the unblocking rate is constant for all the road-clearing teams, the unblocking time is calculated for each damaged road segment based on its length.

Inputs Related to Shipping

For the Case A Cascadia earthquake scenarios, the RCRSD model considers that there are 57 available ships, with 35 ferries and 22 barges. Each ship has its own capacity of truck containers with emergency supplies that it can carry from mainland Vancouver to Vancouver Island. Based on the structural damage model, each port is associated with an opening time, from 0 hours which indicates that it was not closed due to the earthquake, to 72 hours, which means that it is not open at all during the emergency response phase (i.e. the 3-day time horizon). For Case A, the ferry ports that are available are shown in Figure 6, while Figure 7 represents the barge docks. The barge docking locations are always available because it is assumed that barges do not require any particular infrastructure to unload supplies.

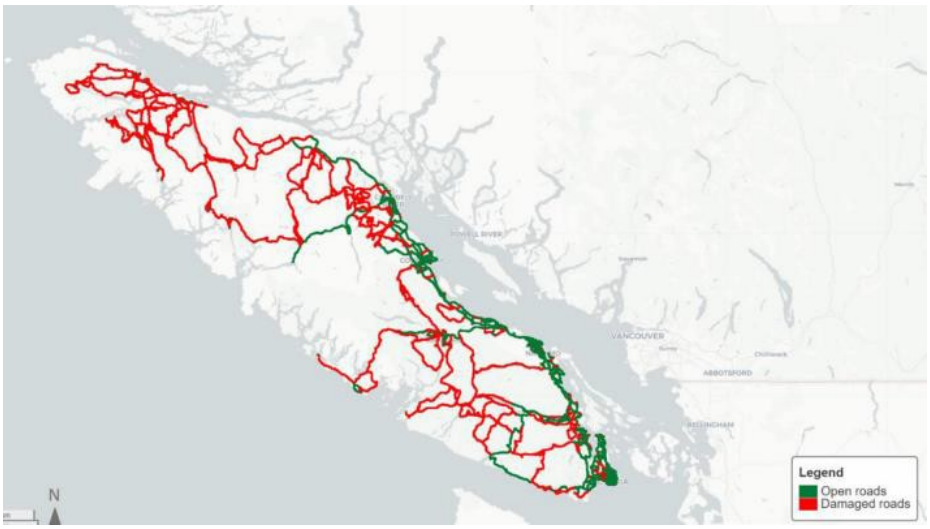

Figure 5. Open and blocked roads for Case A (source: Souza Almeida et al., 2023)

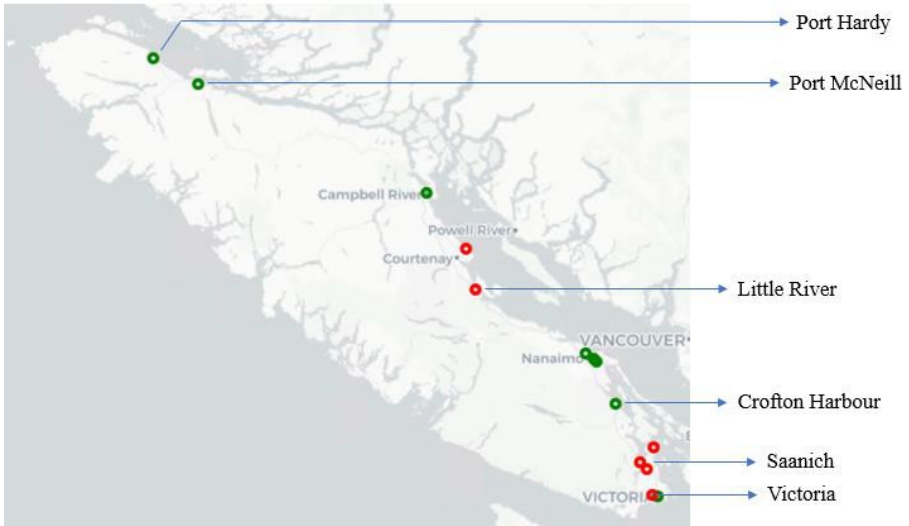

Figure 6. All ferry ports for Case A (red ones damaged)

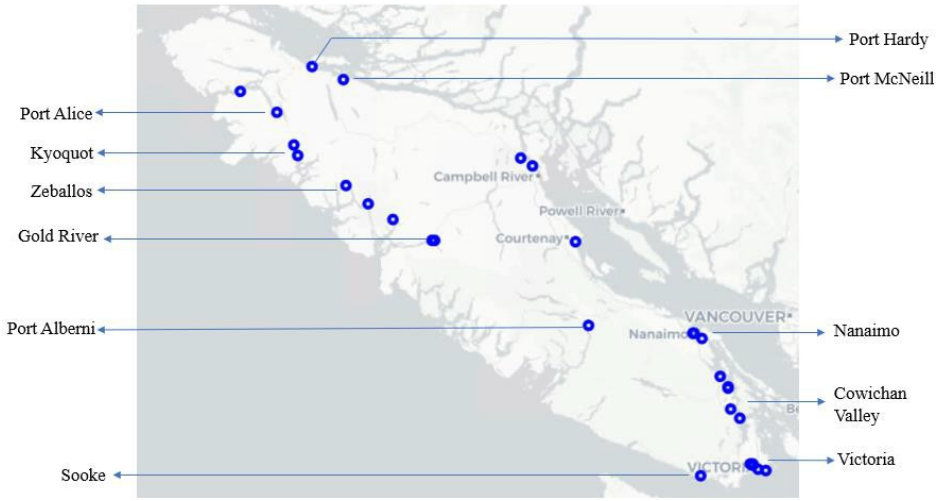

Figure 7. All barge docks for Case A

Inputs Related to Community Resilience

The resilience of communities is captured by assigning their respective nodes a value between 1 and 5. For the analysis that is done without accounting for the CIF (Community Impact Factor), all these values are changed to 5, thus giving the same priority for all communities. The CIF is used as a weight for each community in the optimization model, where the objective function is a combination of community population and CIF.

Case B Inputs

The structure of inputs for Case B is same as that of Case A, but given this more severe CI damage scenario, the roads that are considered blocked in Case B are shown in Figure 8 (Souza Almeida et al., 2023).

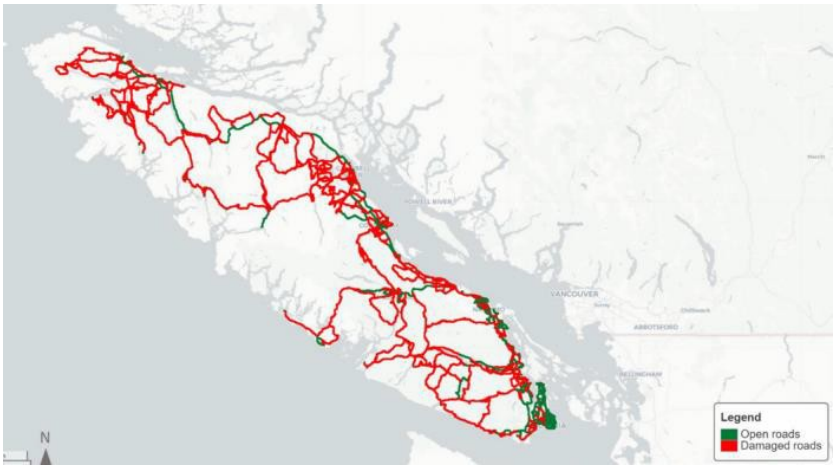

Figure 8. Open and blocked roads for Case B

RESULTS

Depot Changes Results

The first step in the sensitivity analysis for Case A was to change the location of the road clearing teams' depot. The different depot locations for which the RCRSD model was run are shown in Figure 9. For each scenario of input variation, the model was run three times to account for the changes in model results arising from the use of the GRASP heuristics method. The results of community demands supplied under every scenario (averaged between the three runs of same scenario) were tabulated as shown in Table 3. The total demand for each run is to deliver 777,646 boxes, equal to the total population on VI and the Gulf Islands.

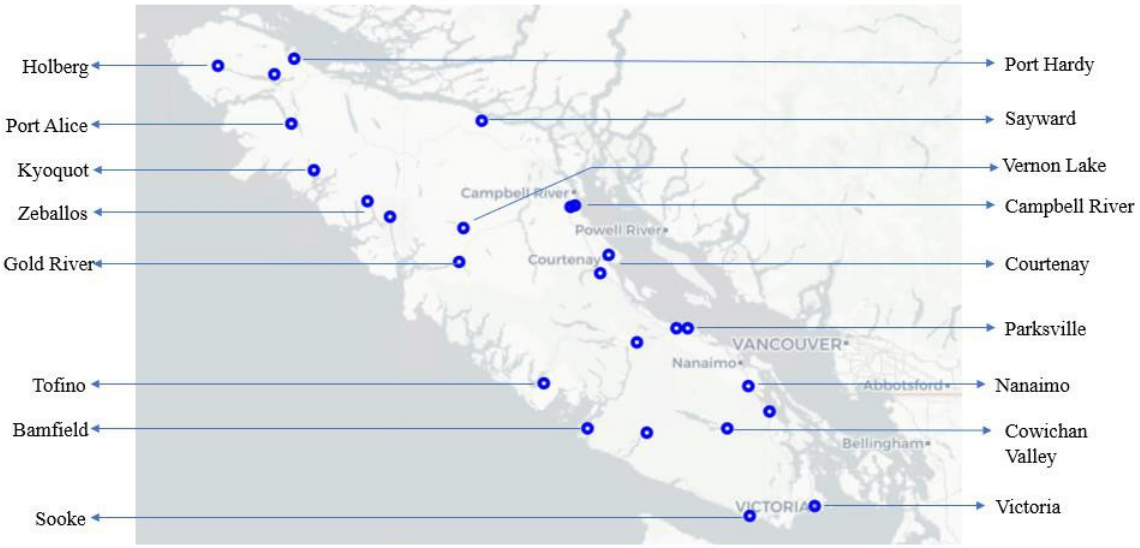

Figure 9. Alternative road clearing teams' depot locations for Case A

Table 3. Road clearing and demands supplied observations when depot location is changed (for Case A)

Scenario ID	Depot node ID	Depot location region	% Total demand supplied	% Supplied Communities
D1	42	Central Island	57.1	54.69
D2	46	North Island	63.8	60.68
D3	57	Central Island	49.9	51.04
D4	80	North Island	43.1	33.85
D5	219	Pacific Rim	42.9	33.85
D6	220	South Island	65.7	60.16
D7	742	South Island	62.6	58.85
D8	778	Central Island	61.1	57.55
D9	802	Central Island	47.8	48.70
D10	1075	Central Island	47.8	49.74
D11	1195	Central Island	65.6	61.98
D12	1544	South Island	41.6	35.16
D13	1579	Pacific Rim	63.6	58.07

D17	2069	North Island	43.5	36.46
D18	2165	North Island	43.0	34.64
D19	2227	North Island	43.0	35.16
D20	2313	Pacific Rim	43.3	35.94
D21	2324	Pacific Rim	44.5	38.28
D22	2343	South Island	31.6	24.74
D23	2375	South Island	63.8	60.16
D24	2395	South Island	59.3	53.65
D25	2431	Pacific Rim	53.4	51.82

From the results shown in Table 3, the best depot locations (Scenario IDs: D6, D11) and worst depot locations (Scenario IDs: D22, D15) were mapped (see Figure 10). The ranking is done based on the demands supplied and not the number of roads cleared because for certain depot locations, although there is a high degree of road clearing activity, the demands supplied and the reach to communities is very low. The demands met by the different modes of transport for the best depot location (Scenario ID: D6) and the worst depot location (Scenario ID: D22) are also shown in Figure 11 and Figure 12 respectively.

Figure 10. Best and worst depot locations

```
Total_truck_demand = 499672.0
Total_heli_demand = 8455.0
Total_ferries_demand = 1076.0
Total_barges_demand = 12342.0
Total_demand = 521545.0
Total_demand_without_heli = 513090.0
```

Figure 11. Demands met for D6 by different modes

```
Total_truck_demand = 198313.0
Total_heli_demand = 8518.0
Total_ferries_demand = 1076.0
Total_barges_demand = 1274.0
Total_demand = 209181.0
Total_demand_without_heli = 200663.0
```

Figure 12. Demands met for D22 by different modes

The results by regional division of VI are shown in Table 4, where it is seen that having the road clearing teams' depot located at either Central Island or South Island yields better results compared to having it located at Pacific Rim or North Island.

Table 4. Region-wise depot location details in terms of total demand met

Depot location region	Scenario IDs used for aggregation	Mean % demand met by region
Central Island	D1 D3 D8 D9 D10 D11	54.88
North Island	D2 D4 D15 D16 D17 D18 D19	45.74
South Island	D6 D7 D12 D22 D23 D24	54.08
Pacific Rim	D5 D13 D14 D20 D21 D25	48.53

At a higher level of aggregation, the demand results averaged for each region of VI (and the Island overall) are shown in a bar chart in Figure 13.

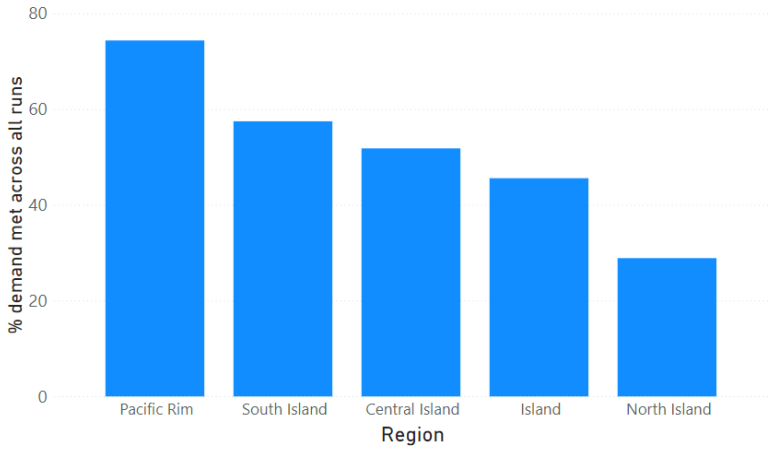

Figure 13. Regional demands satisfied across runs D1 to D25

Across the 25 input scenario variations, the communities on VI that received over 95% of their demands satisfied are shown in Figure 14. The communities that received under 5% of their demands met are shown in Figure 15. The communities in the Pacific Rim region of VI had most of their demands satisfied. The communities in the North Island region were the least likely to receive supplies.

Community	Region	Total_demand	Average_demand_met_across_all_runs_in_%
65	Pacific Rim	168	100.00
66	Pacific Rim	168	100.00
84	South Island	301	100.00
107	North Island	253	100.00
11	South Island	815	97.46
12	South Island	815	97.40
13	South Island	1113	96.00

83	North Island	2409	3.31

Figure 15. Communities that received under 5% of their demands

Roads Cleared and Subsequent Analyses

For the runs done by changing the depot locations of the road clearing teams as shown in Table 3, it was found that out of the 25 input scenarios there were no roads cleared for 5 scenarios (Scenario IDs: D4, D5, D12, D14, and D16). The reason why no roads were cleared was because the depot locations were too distant from any port or community to be reconnected within 72 hours. For example, the depot location for scenario D5 is shown in Figure 16, where the depot location is surrounded by only damaged roads, from which there is no completion of any connecting road clearing activity within the time window.

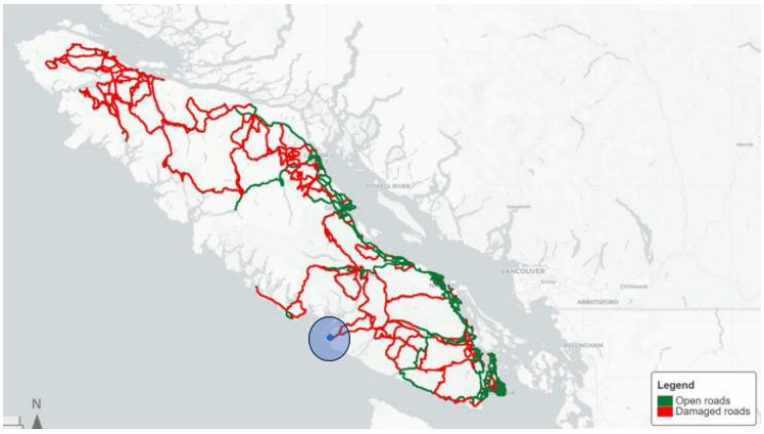

Figure 16. Map showing depot location of scenario D5 amidst blocked roads

The road segments that were cleared for each run were separately counted and for the runs with at least some road clearing activity, an average of 49 blocked road segments were cleared. The highest cleared was 81 road segments (out of 1123 damaged), associated with depot location at node 220. From all the runs, the outputs are then analyzed to find the road segments or edges that are frequently unblocked.

When all the runs are compared, it is seen that some of the blocked roads are cleared more frequently across the input scenario variations shown in Table 3 than other road segments. Figure 17 shows the road segments that were cleared for at least 70% of the original runs. This set of roads is referred to as RC1 in this study. The road segments that were most consistently cleared all lie in the South Island region. Similar results were generated for the situation with roads that were cleared for at least 50% of all the runs (referred to as RC2, see Figure 18), and for those cleared for at least 25% of all the runs (referred to as RC3, see Figure 19). For the last case, the map shows that there are significant road clearing activities happening in South Island and a few roads being fixed consistently in Central Island.

Figure 17. Roads cleared for at least 70% of the runs (RC1)

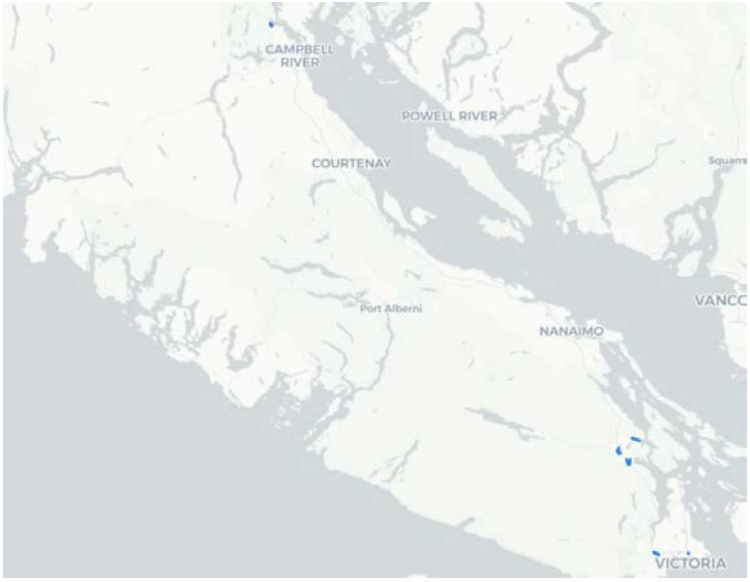

Figure 18. Roads cleared for at least 50% of the runs (RC2)

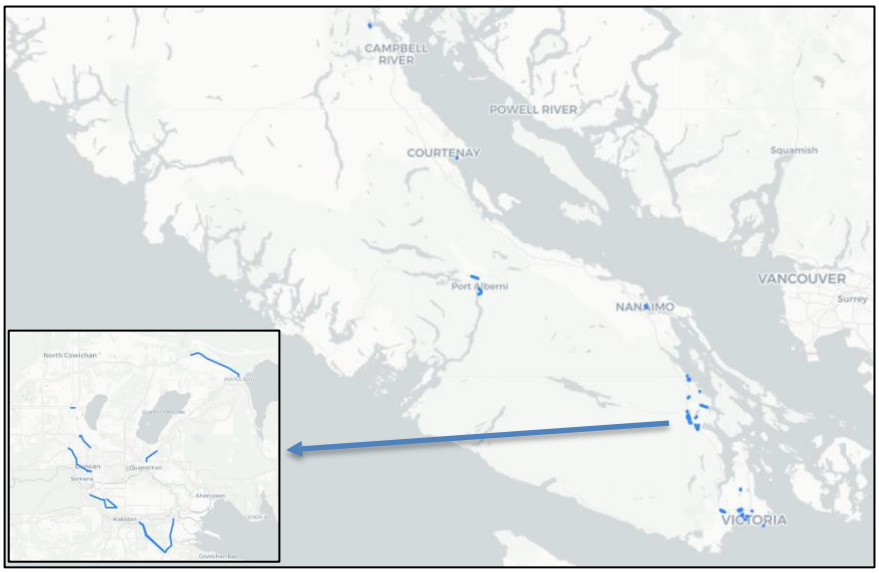

Figure 19. Roads cleared for at least 25% of the runs (RC3)

The consistently cleared roads shown in these three figures were then used as input changes for further analyses of the RCRSD model. For the 2 best depots (D6 and D11) and the two worst depots (D15 and D22), the blocked roads from the original dataset that are consistently cleared were considered to be unblocked as shown in Table 5 (at RC1, RC2 and RC3 levels respectively).

Table 5. Input variable scenario changes for consistently unblocked roads

	Input Variable chosen for analysis	
Run ID	**Depot location**	**Consistently unblocked roads**
D6RC1	220	RC1
D11RC1	1195	RC1
D15RC1	2002	RC1
D22RC1	2343	RC1
D6RC2	220	RC2
D11RC2	1195	RC2
D15RC2	2002	RC2
D22RC2	2343	RC2
D6RC3	220	RC3
D11RC3	1195	RC3
D15RC3	2002	RC3
D22RC3	2343	RC3

Table 6 shows the number of boxes that are supplied for each scenario, as well as the percentage of the total demand that is met, as the average of 3 runs done for each scenario. The total demand for all communities for each run is 777,646 boxes of supplies (i.e. the population of Vancouver Island and the Gulf Islands). The results can be contrasted with the original results reproduced in the final two columns. For the depots in the best locations (D6 and D11), there are no significant changes in the demands satisfied when the roads represented by RC1, RC2, and RC3 are considered undamaged. However, for the depot's worst locations, D15 and D22, that earlier showed demands satisfied as less than or around 40%, when the consistently cleared ones are considered unblocked, there are significant improvements in the demands satisfied as well as the number of communities that receive supplies.

Table 6. Results observed for changes in unblocked roads

				Original results	
Scenario ID	**Demand met in number of boxes**	**% Total demand met**	**% Communities supplied**	**Scenario ID**	**% Total demand met**
D6RC1	491645	63.22	61.33	D6	65.7
D11RC1	485185	62.39	58.98	D11	65.6
D15RC1	486428	62.55	57.42	D15	41.4
D22RC1	438715	56.42	52.01	D22	31.6

D15RC3	507548	65.27	60.94	D15	41.4
D22RC3	525983	67.64	62.89	D22	31.6

Critical Ports and Subsequent Analysis

The location of the most critical barge dock based on box supplies' origin is shown in Figure 20. For the communities serviced by trucks, 55% of the supplies went from this location. In comparison, the busiest ferry port, shown in Figure 21, contributed to only about 6% of the total supplies dispatched from the ports.

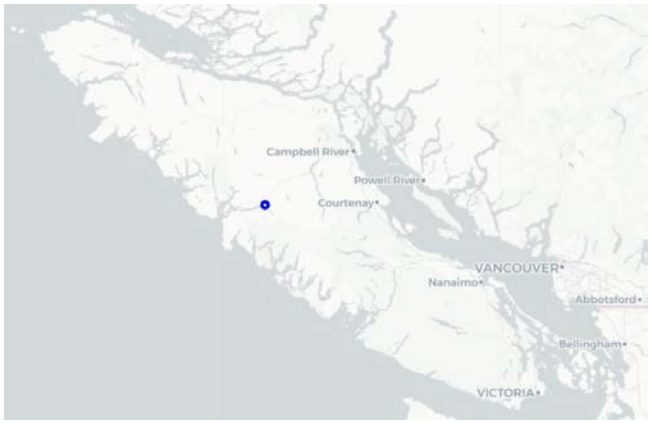

Figure 20. Location of critical barge dock

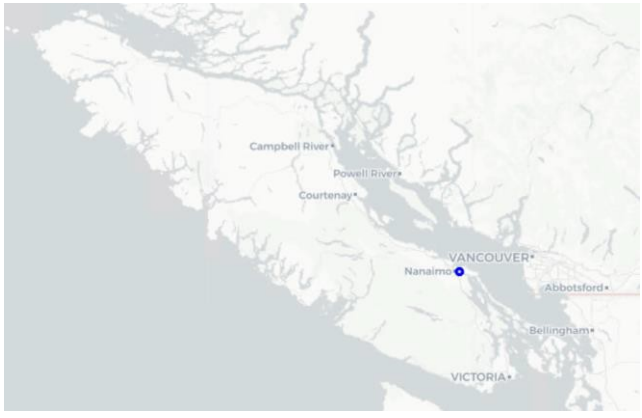

Figure 21. Location of critical ferry port

The next set of analyses were done by considering having either of the critical ports closed. The various input scenarios for which this analysis was done is shown in Table 7. For the two depots with the best locations (scenarios D6 and D11), combined with either the barge port closed (P1) or the ferry port closed (P2), the impact on deliveries are shown in Table 7, with the original results shown in the last two columns. For the scenarios where the barge port is considered closed (D6P1 and D11P1), the total demands satisfied are significantly less when compared to the scenarios where they are considered open (scenarios D6 and D11). The last two rows show that the impact of having the ferry port closed is much less, as it delivers a small proportion of the supply in the first place.

Table 7. Results observed for changes in ports availabilities

				Original results	
Scenario ID	**Demand met in number of boxes**	**% Total demand met**	**% Communities supplied**	**Scenario ID**	**% Total demand met**
D6P1	97075	12.48	21.61	D6	65.7
D11P1	26435	3.40	13.80	D11	65.6
D6P2	453662	58.34	53.91	D6	65.7
D11P2	464374	59.72	55.73	D11	65.6

Availability of Ships

Since the barge deliveries are greater than ferry deliveries, the RCRSD model is run by considering only 50% of the barges to be available, considering the two best depot locations. The case where all ferries are available and only 50% of barges are available is labelled as S1 in Table 8, while the case with all ferries unavailable and all barges operational is S2. When the barges are reduced by 50%, the total demand satisfied is reduced by a significant amount (comparing for example the original D6 result on the right, with the new D6S1), where the demand satisfied drops from 65.7% to only 12.1%. In contrast, for scenarios D6S2 and D11S2 where all ferries are assumed non-operational, the demands met are reduced by only about 10% from the runs D6 and D11 where all ferries are in use.

Table 8. Results observed for changes in ships' availabilities

				Original results	
Scenario ID	**Demand met in number of boxes**	**% Total demand met**	**% Communities supplied**	**Scenario ID**	**% Total demand met**
D6S1	94104	12.10	14.50	D6	65.7
D11S1	147291	18.90	21.58	D11	65.6
D6S2	435185	55.96	51.56	D6	65.7
D11S2	437010	56.20	51.82	D11	65.6

Community Impact Factor (CIF) Change

For the two best (D6 and D11) and two worst (D15 and D22) depot locations, new scenarios are run where the CIFs are neglected by making them all the same value, represented by C1 in Table 9. Comparing the results with the original outputs given in the two rightmost columns, there are no significant changes in the total demands met (greatest variation is 3%), except scenario D11C1 where total demand served dropped from about 65% to 47.68%. However, there is a decrease in the percentage of communities that receive supplies when the CIF is neglected in all scenarios.

Table 9. Results observed for changes in CIF

					Original results	
Scenario ID	**Demand met in number of boxes**	**% Total demand met**	**% Communities supplied**	**Scenario ID**	**Scenario ID**	**% Communities supplied**
D6C1	483812	62.22	53.51	D6	65.7	60.16
D11C1	370800	47.68	42.44	D11	65.6	61.98
D15C1	327414	42.10	34.47	D15	41.4	35.71
D22C1	261209	33.59	24.08	D22	31.6	24.74

Case B Findings

For the extensive disruption scenario (Case B, see Figure 4), the RCRSD model is run for only the two best and two worst depot locations from Case A analysis. All of the B scenario runs resulted in the same number of boxes being delivered. Changing the depot location does not make a difference in the results because there is no clearing activity completed in any in the B scenarios, so no communities are being reconnected to ports or barge docks within 72 hours. Out of the supplies that were dispatched, 5% was done by helicopters, 10% by barges directly, less than 1% by ferries directly, and about 84% by trucks of which 79% originated from the port in Victoria. When the time horizon was increased to 360 hours (15 days), although some road clearing happens, there is only about a 10% increase in the demands supplied when compared to the time horizon of 72 hours. Further details are provided in Vattoni (2023).

DISCUSSION

These sensitivity analyses on the distribution of relief supplies on Vancouver Island have explored the impacts of changes in some of the key factors affecting the outcome. While detailed outputs for each of the model runs are conserved, namely which roads are repaired and which communities receive supplies, better insights are provided through the use of regional aggregation of results, maps, and tables showing percentages of achievement. In response to the questions posed in the introduction section, select observations from these runs are presented in the following paragraph, while more extensive sensitivity analyses can be conducted eventually on a broader range of scenarios with varying degrees of earthquake damage.

The partial disconnection scenario (Case A) showed that the best location to have the depot would be the Central or the South Island regions of VI, but the latter is more likely to suffer damage from the earthquake. It was also shown that if the roads on South Island were reinforced so that they stayed unblocked, supplies are able to reach a larger percentage of the population. On changing the inputs related to shipping such as the ports that are open or the number of ships available, it was seen that over 50% of the supplies to communities went from a single barge dock halfway up the west coast. Additionally, when the critical roads were considered undamaged, it was found that the supplies to communities increased because the roads to this barge dock were cleared. These findings would help decision makers ensure to the degree possible the availability and strengthening of this infrastructure. Eliminating the Community Impact Factor (CIF) from the calculations does not affect the total supply significantly, but the number of communities that receive supplies are fewer. Preparedness experts can use these findings to help advocate for improved resilience (strengthening community infrastructure, maintaining more emergency supplies), particularly for certain towns which consistently receive less than 2% of their demand across all model runs (with those results housed in the detailed output files). The main findings from the more extreme Case B analysis is that 3 days is insufficient for conducting any appreciable road clearing, thus longer waits for deliveries are to be expected, or additional air response would be required.

ABSTRACT

The historical data on disasters serves various purposes, such as managing the risk of future disasters, assessing risk in the insurance sector, and formulating policies to reduce disaster risks, among others. To meet these objectives, there are databases, covering several types of disasters. However, in addition to differences in purposes, scope, access, and coverage, there are variations in the criteria for registering a disaster in the database and the information used for this register. Due to these differences, we have a scenario with discrepancies of information across existing databases. In this study, we propose a repository that combines the main advantages of some global databases, the data needs due to multilateral agreement, and the possibility of integrating regional or specific databases. The proposed Natural Disaster Data Repository (R2DN) contains a data schema and a data mapping process with two of the main global databases (EM-DAT and DesInventar) and S2ID.

INTRODUCTION

Natural disasters are phenomena that have been part of the Earth's dynamics for centuries, with recorded human casualties and material damages. When they occur in uninhabited areas, they are termed natural events. Earthquakes, floods, tsunamis, epidemics, and droughts are some of these phenomena with distinct characteristics and consequences. In some cases, an event may be associated with one or more of these phenomena, such as the earthquake that triggered the Indian Ocean tsunami in December 2004, affecting 13 countries in the region.

The Centre for Research on the Epidemiology of Disasters – (CRED, 2020b), at the Université Catholique de Louvain in Belgium, estimated that, in the last two decades (2000 to 2019), 7,348 disaster events (excluding biological and technological disasters) were recorded, resulting in approximately 1.23 million lives lost, affecting over 4 billion people, and causing economic losses of around $2.97 trillion. These figures represent a significant increase compared to the two previous decades (1980 to 1999), which recorded 4,212 events, 1.19 million deaths, over 3.2 billion people affected, and losses of approximately $1.63 trillion, as summarized in **Figure *1***.

In a scenario where various local databases provide information for the purposes of their regions, sharing information between databases is necessary for more comprehensive studies that include multiple regions. To ensure the agility, quality, and integrity of data, compatibility between the data is necessary, allowing for sharing between databases. However, as mentioned by (Panwar & Sen, 2020), existing major databases still exhibit disparities in disaster recording, making data exchange for comparison and analysis challenging. According to (Koç & Thieken, 2018), the lack of reliable, consistent, and comparable data is seen as a significant obstacle to effective long-term prevention of losses.

The Emergency Events Database (EM-DAT), developed by CRED in 1988, is widely recognized as a reference for the academic community, industry, and government entities in the disaster assessment phase. EM-DAT is maintained by the Université Catholique de Louvain with the support of the World Health Organization (WHO). It is available to non-commercial individuals and organizations upon registration on its website (CRED). A simple search in the Scopus database reveals that over a hundred articles, since 2012, reference EM-DAT in their abstracts. There are other databases, public and private, enabling comparisons between their characteristics.

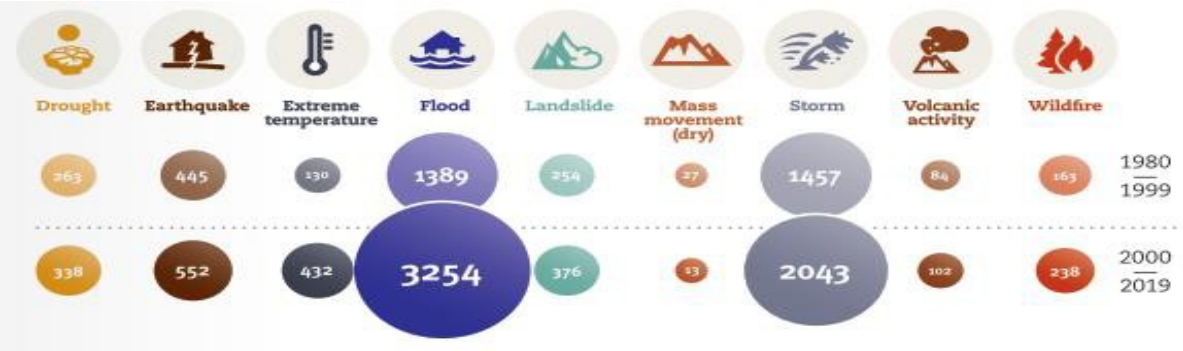

Figure 1. Impact of Disasters: 1980-1999 versus. 2000-2019 (CRED, 2020b)

The DesInventar, an initiative of UNDRR (United Nations Office for Disaster Risk Reduction), is a system designed for the acquisition, recovery, querying, and analysis of disaster records. This system is made available to countries in Latin America, the Caribbean, Asia, and Africa.

The S2ID is an Integrated Disaster Information System developed by CEPED/UFSC in 2011/2012 ("Ministério do Desenvolvimento Regional - S2ID"), serving as a support tool for states and municipalities affected by disasters that require federal assistance. The system enables these federative entities to exchange information with the federal government to obtain necessary resources to assist the affected population.

This work supports the proposal that each country or institution should have its own specific database of natural disasters to meet the specific needs of understanding natural phenomena occurring in its territory and their impacts on society. We share the proposals presented by (Wirtz, Kron, Löw, & Steuer, 2014) and (Khankeh, 2022). The purposes of creating and using disaster damage databases, according to (Khankeh, 2022), should include:

1. Promoting disaster relief, recovery, and reconstruction programs.
2. Assessing risks of future disasters.
3. Estimating the economic feasibility of investments made to reduce losses.
4. Monitoring disasters and their impacts to achieve international goals established for disaster risk reduction.
5. Conducting thematic analyses, such as differences in deaths by gender or age group in disasters.

However, we understand that the proliferation of specific databases should consider adhering to some standards already established by other institutions managing disaster databases. This approach can facilitate data sharing among them and enable the exchange and/or crossing of temporal and geographical information necessary for generating more effective analyses supporting governments and organizations in decision-making and the formulation of disaster risk reduction policies. The exchange and sharing of disaster information among countries are explicitly stated in Priority 4 of the Sendai Framework for Disaster Risk Reduction 2015-2030 (UN, 2015), and it is part of the commitment made by 187 UN member countries.

It is also important to emphasize the need to include data in the databases grounded on the demand for new attributes aligned with the disaster risk reduction indicators required by the Sendai Framework. Divergences between databases hinder data sharing and, consequently, limit the potential utilization of disaster databases. This is the main problem that will be addressed in this work.

What is the structure of a data repository that allows the assessment of natural disasters, is compatible with global databases, meets specific demands and complies with multilateral agreements in disaster management?

To answer this question, we established three goals that are described and discussed in this work. They are:

1. To develop a database structure that integrates disaster records from different databases.
2. To include the necessary information for the Sendai Framework indicators.
3. To enable the integration of specific databases aimed to support specific purposes from countries or institutions to assist their policies.

In the following sections, we will present the work context, the methodology employed to develop the study, the description of the three databases selected for the integration exercise, the criteria used for selection, the taxonomy and the R2DN data model, as well as an instance of the integration of the three described databases.

BACKGROUND AND METHODOLOGICAL APPROACH

The growing global demand for actions aimed at disaster risk reduction has driven the need for databases capable of storing and retrieving information related to these events. In response to this scenario, we observe a significant number of published articles addressing the use of disaster databases for various purposes, regardless of the authors' areas of expertise.

In Table 1, we present the results of a search conducted in the Scopus database. This research involved the inclusion of the keyword "database" along with terms representative of each phase of disaster management. We also provide the number of articles found since the year 2013, offering an overview of academic production in this field.

Table 1. Number of articles found from 2013 onwards, in the Scopus database, using the corresponding sentences Data retrieved on 10/31/2023

Search sentence	Number of articles
((“natural disaster” OR “natural hazard”) AND (“prevention” OR “risk reduction”) AND (“database”))	367
((“natural disaster” OR “natural hazard”) AND (“response”) AND (“database”))	347
((“natural disaster” OR “natural hazard”) AND (“assessment”) AND (“database”))	760

The Design Science Research (DSR), widely employed in Information Systems research and advocated by (Hevner, March, Park, & Ram, 2004), is the methodology we have chosen to conduct our research. Its guidelines, which include identifying a problem in society, creating an artifact capable of contributing to the solution of this problem, evaluating the contributions generated by the artifact, and disseminating the achieved results, have shown to be consistent with the planned strategies for the development of our study.

In our study, we identified a problem related to the difficulty of data sharing among existing disaster databases. Additionally, the solution to this problem must meet the requirements for emergency response in Brazil and be in compliance with international agreements in the field of disaster risk reduction. To address this issue, we designed a repository (artifact) that integrates disaster records from three existing databases. The challenges encountered during the integration process are analyzed, and based on these analyses, new requirements are formulated to enhance the repository's design, aiming to overcome the identified challenges.

In Figure 2, we present a diagram containing the stages and deliverables of our methodological approach, aligned with the guidelines of DSR.

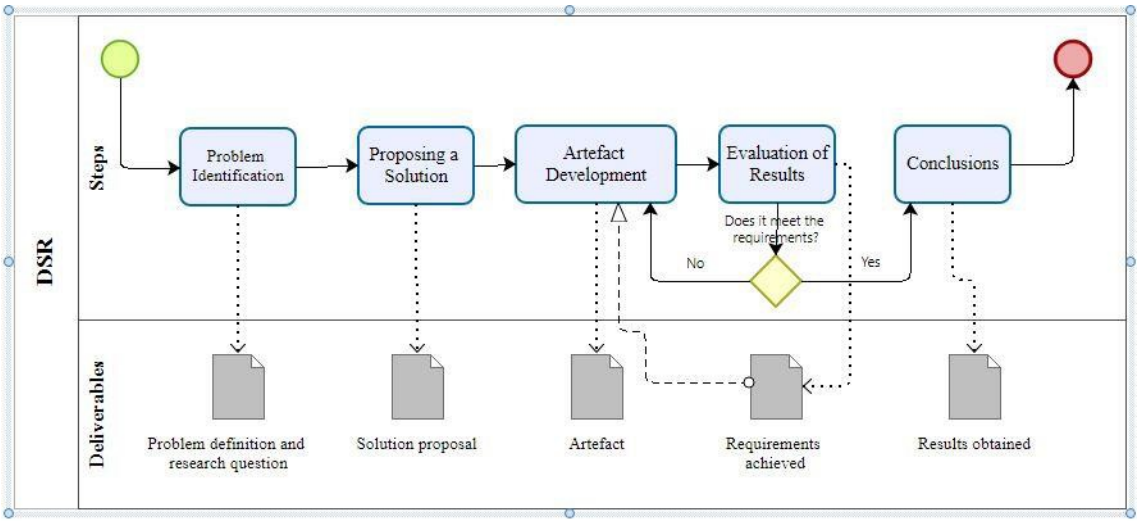

Figure 2. DSR steps and its deliverables

In the "Problem Identification" stage, where we identified a specific problem in society, it was described in this section along with the research question that contains the requirements for the desired solution. In the "Proposing a Solution" stage, we developed a model for a repository that meets the solution requirements, as presented in Section “The Proposed Model for R2DN”.

To demonstrate the feasibility of the proposed model, we implemented an instance in the "Artifact Development"

stage, as described in Section “Instantiating R2DN”. The repository development is divided into two parts. In the first part, actions necessary for the instantiation of the artifact are identified in the face of encountered difficulties, and in the second part, the implementation of R2DN is carried out, followed by an "Evaluation of the results". After each evaluation stage, the results are analyzed, and adjustments to the artifact are made as needed to achieve the expected outcomes.

DISASTER DATABASES

This work is based on three distinct disaster databases. Table 2~outlines the justification behind the selection of each one, as well as the criteria adopted for registering catastrophic events.

Table 2. Selected databases with motivation and event recording criteria

Database	Motivation	Registration Criteria
EM-DAT	Widely recognized by the disaster management community and accessible to the public.	10 or more human deaths / 100 or more affected people / Declaration of a state of emergency by the country and/or an appeal for international assistance.
S2ID	Aims to analyze emergencies in Brazilian states and municipalities.	Requesting financial assistance from the federal government.
DesInventar	Records disasters in all South American countries, except Brazil.	Each country using the system has the autonomy to establish its own criteria.

The use of different disaster databases allows for a more comprehensive understanding of disasters due to variations in criteria for recording in each database. However, these discrepancies lead to disparities between databases, making information sharing a challenge and consequently limiting the potential utilization of these disaster databases.

Despite EM-DAT being the globally recognized disaster database, we emphasize a significant discrepancy with the reality in Brazil (the country we chose to perform the data integration). The report on damages and losses resulting from natural disasters in Brazil (1995-2019), produced by CEPED (UFSC) and updated by FAPEU with support from the World Bank (FAPEU, 2020), indicates 64,429 disaster records with economic losses of R$ 333.36 billion (equivalent today to approximately US$60 billion) over these 25 years of the study. In the same period, EM-DAT recorded (query conducted on 07/20/2022) 136 disasters, totaling economic losses of approximately US$ 18 billion.

Several reasons can justify such a discrepancy, including different criteria for recording disasters and distinct purposes of the databases. While EM-DAT aims to register globally impactful disasters for humanitarian purposes, CEPED's database aims to register disasters that states and municipalities require some form of federal assistance.

The numbers presented above highlight the need for a specific disaster database for Brazil that aligns with our objectives and is compatible with major global databases. This would enable data sharing and comparative studies on the losses and damages caused by disasters across countries. We believe that recording losses from disasters is the first step in assessing resilience evolution in different regions.

According to (IRDR, 2014), most disaster databases record human and economic losses in some way, but they lack a standard set of indicators established from a common understanding. An initiative to address this issue is the set of indicators established in the Sendai Agreement.

To initiate the selection of disaster databases, we relied on the systematic review conducted by Khankeh (2022), which provided an analysis of these databases. Based on this review, we selected those with a global presence and a higher number of references on Google Scholar. Table 3 presents some of the characteristics collected from these databases' websites in June 2023. Note that not all information was completed in the websites. In addition, we included the S2ID to the table because it is the official system of the Brazilian government.

The process of selecting R2DN attributes was divided into three stages:

1. Analyzing the data structures of the three selected databases.
2. Analyzing the data needs of the Sendai Framework indicators.
3. Analyzing the data organization of the DaLA methodology.

Table 3. Comparison of the characteristics of disaster databases (the numbers on the website point to the URLs at the end of the table)

	EM-DAT	NatCatService	Sigma	DesInventar	GLIDEnumber	Dartmouth	S2ID

EM-DAT's data structure is accessible through its website (CRED). The available information covers various aspects of disasters, including identification, classification, location, and human and financial impacts. Among these attributes, five are related to disaster classification, covering nature, group, subgroup, type, and subtype of the event. Regarding the disaster's location, information about the continent and country is provided. However, there is only one attribute to describe the specific location within the country. Information related to financial impacts focuses on total reconstruction costs without providing specific details about the affected economic sectors.

DesInventar provides a document addressing the system's use, giving an overview of its data structure (UN Office for Disaster Risk Reduction (UNISDR), 2019). However, there is a lack of formalism in defining this data. The disaster classification is simplified into a single attribute called "event type" while financial impacts are detailed concerning the affected economic sectors.

S2ID metadata is accessible in the Digital Atlas of Disasters in Brazil (Ceped - Centro Universitário De Estudos E Pesquisas Sobre Desastres, n.d.). Disaster classification information resembles that of EM-DAT, as it served as the basis for S2ID disaster classification. The disaster's location is clearly defined, as municipalities where events occurred register these occurrences to request financial assistance from the federal government. As a result of this process, financial impacts, especially those related to the public sector, are thoroughly documented.

Sendai Framework

The Sendai Framework is a global initiative aimed at promoting disaster risk reduction policies worldwide. It aims to measure the progress of initiatives adopted by countries between 2020 and 2030, compared to the period from 2005 to 2015, through the establishment of seven global targets (UN, 2015). To achieve this goal, the framework seeks to prevent new disasters and reduce risks by implementing integrated and inclusive measures that aim to minimize exposure to risks and vulnerability to disasters. Additionally, it aims to enhance preparedness for disaster response and recovery to strengthen the resilience of affected communities.

These targets, to be achieved by 2030, are divided into:

a. Reduce global disaster mortality.
b. Reduce the number of affected people globally.
c. Reduce direct disaster economic loss in relation to global gross domestic product (GDP).
d. Reduce disaster damage to critical infrastructure and disruption of basic services.
e. Increase the number of countries with national and local disaster risk reduction strategies by 2020.
f. Enhance international cooperation to developing countries.
g. Increase the availability of and access to multi-hazard early warning systems and disaster risk information and assessments to people.

Targets a, b, c, and d require data from national disaster databases as evidence of progress in disaster risk reduction policies. Therefore, the attributes to be included in the R2DN data model must align with this need.

THE PROPOSED DATA MODEL FOR R2DN

In this section, we present the answer to our research question. The elements that supported the construction of the model include information sources from the metadata of the three databases, in addition to the indicators of the Sendai Framework.

Figure 3 illustrates the process of modeling the R2DN data schema. The first activity, "Identify disaster data categories" aims to organize the data into categories and subcategories. This approach, combined with the metadata, is crucial for a more precise understanding of the data and assists in defining responsibilities for collecting information about disasters.

Next, in the activity "Select R2DN attributes" we chose the data based on the attributes of the selected databases that will compose the disaster record in R2DN. In the subsequent activity, named "Allocate disaster attributes to their categories" we associate each attribute with its corresponding data category. For the data selected for R2DN, we check if there is a metadata description available in the source database. If it exists, this description is integrated into the R2DN model through the "Search metadata in the source database" activity. However, if it does not exist, in the "Define metadata" activity, metadata is generated for these data.

Finally, in the activity "Improve metadata with real examples" in the face of the absence or low quality of metadata in the source databases, we resort to real examples in the databases to enrich the corresponding metadata and improve its understanding.

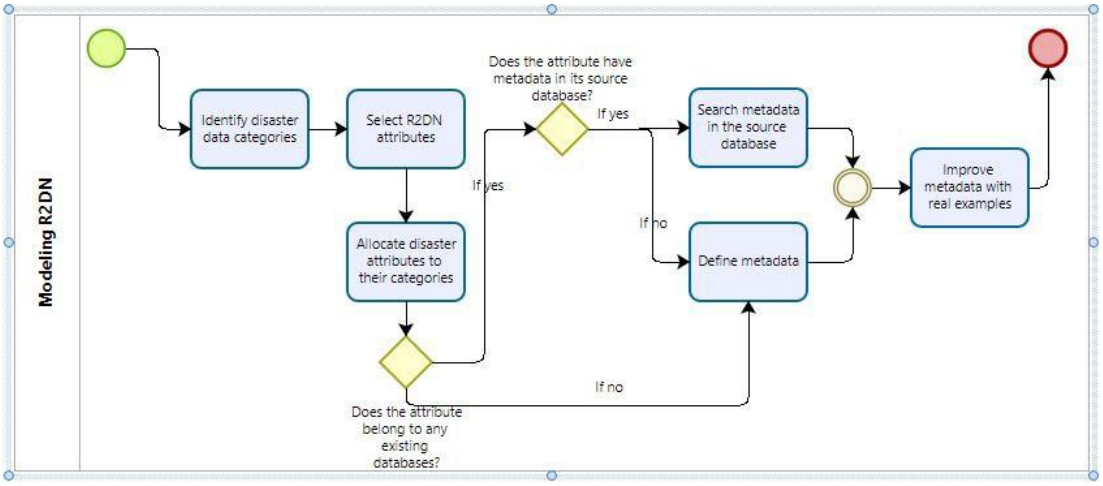

Figure 3. R2DN modeling process

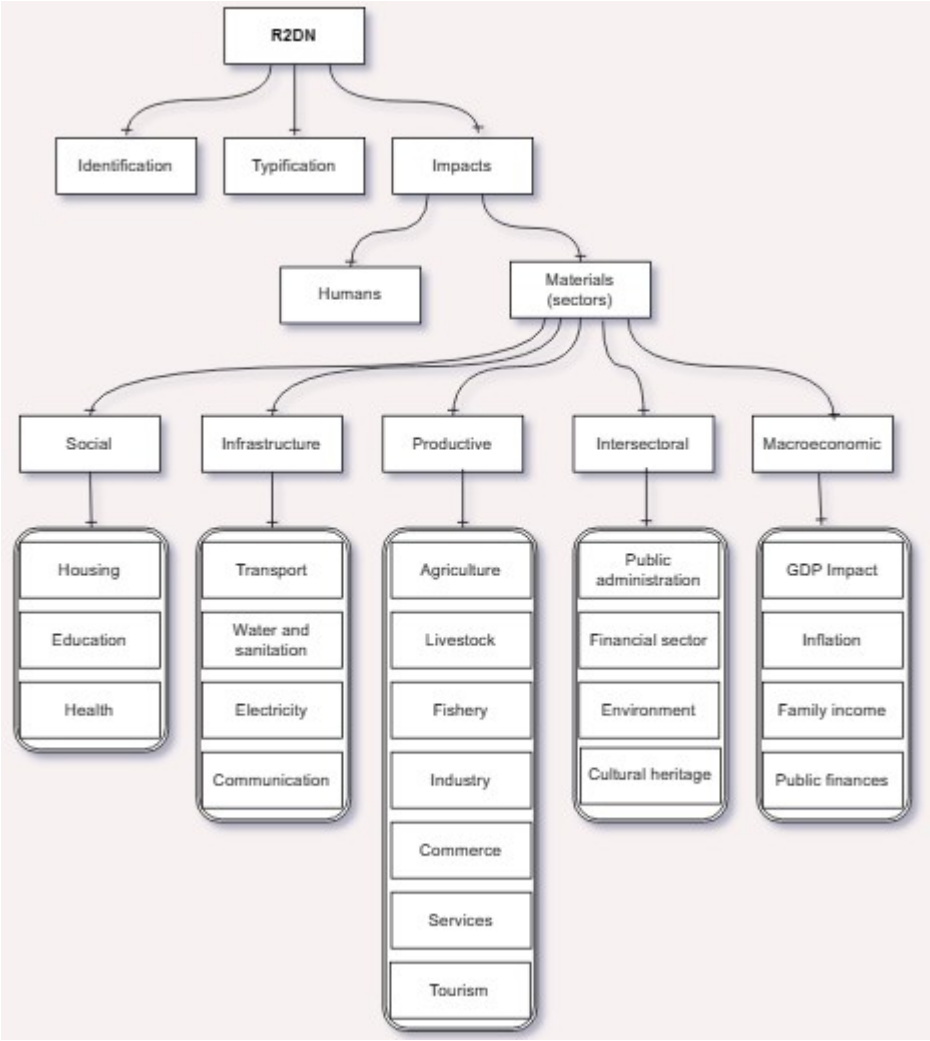

Figure 4. R2DN category and subcategory structure taxonomy

Taxonomy of R2DN Data

As a result of the "Identify disaster data categories" activity represented in Figure 3, we present in Figure 4 a

taxonomy with the structure of identified categories and their subcategories. To construct this taxonomy, we used the DaLA methodology as a reference, which is employed to analyze the impacts generated by disasters on the economy of a society. (World Bank, 2010). The purpose of this representation is to organize the data that will compose the R2DN disaster record, making its understanding and location more accessible. Below, we provide a description of these categories for a better understanding:

- Identification – group all information related to the disaster location, date and time, and event duration.
- Typification –group all information associated with the types and subtypes of the disaster (e.g., hydrological and flooding), disasters associated with the event, and triggering events of the disaster.
- Impacts – human and material impacts caused by the disaster.
- Human – contain the quantity of people directly impacted by the disaster (deaths, missing, injured, etc.).
- Material – group the sectors impacted by the disaster.
- Social – encompass data regarding the quantity of affected housing and educational and health units, whether by destruction or damage, along with associated values for their respective reconstructions.
- Infrastructure – consolidate data related to damages in transportation, water, sanitation, energy, and communication areas.
- Productive – cover damages in production sectors such as agriculture, livestock, fisheries, industry, commerce, and tourism.
- Intersectoral – group damages related to public administration, the financial sector, and the environment.
- Macroeconomic – will contain impacts on inflation, GDP, household income, and public finances.

Table 4. Categories and subcategories and their attributes

Category/subcategory	Attributes
Identification	continent, country, first and second administrative divisions, latitude, longitude, start date and time, duration, name, glide number, source and type of information.
Typification	category, group, subgroup, type, subtype, associated disaster, magnitude value and scale, triggering event, causes and effects.
Humans	dead, injured, sick, missing, displaced, homeless, other affected and people whose livelihoods are affected;
Material impact	description of public and private losses, total public and private losses, total securitized losses and total reconstruction cost;
Impact on housing	destroyed and damaged units, total number of people in destroyed and damaged units and loss value in housing units;
Impact on education	destroyed and damaged units, value to recover the units, value to reestablish teaching and number of days without teaching services;
Impact on health services	destroyed and damaged health units, cost of rebuilding health units, value of reestablishing emergency services, value of loss in vector control and number of days without health services;
Impact on infrastructure	amount of repair and reconstruction works, value of losses for repair and reconstruction, value of losses in public facilities and number of days of interruption in infrastructure services;
Transport	total cost required to restore transport services;
Water and sanitation	losses in the restoration of water supply and restoration of river and sanitary sewage;
Energy	total cost required to restore power generation and fuel distribution;
Communication	total cost to restore telecommunications services;
Agriculture	estimated value of loss of various types of crops;
Livestock	estimated value of losses in dead or sick animals;
Fishery	estimated value of loss in fishing activity;
Industry	estimated value of lost industrial production;
Commerce	estimated value of sales losses from commerce;
Services	estimated value of loss in the services sector;
Other sectors	estimated value of losses in other sectors not previously listed;
Public administration	estimated value to reestablish public safety and urban cleaning services;
Financial sector	estimated value of losses in the financial sector;
Environment	description of environmental damage, population affected by water, air and soil pollution, population affected by water depletion and area affected by fires in parks;
Cultural heritage	estimated value of losses in cultural heritage;

GDP	variation in percentage points of GDP;
Inflation	variation in percentage points in the inflation rate;
Family income	financial impact on family income;
Public finances	financial impact on public resource collection.

Selection of R2DN Attributes And Their Metadata

After analyzing the attributes of each database to address our research question, we adopted the following criteria for selecting the attributes that will be part of the R2DN.

1. **S2ID** – All attributes directly related to disaster events were selected. This selection is based on the R2DN's commitment to providing essential information to the Brazilian federal government to assist states and municipalities affected by a disaster.

2. **EM-DAT** – All attributes related to identification, typification, and impacts associated with the disaster event, as made available on the website, were selected.

3. **DesInventar** – All attributes related to the identification and typification of the disaster were selected. Additionally, among the attributes of human and material impacts, those containing information like S2ID were selected. Also included were those necessary for the indicators of the Sendai Framework.

To meet all the demands of our research question, 101 attributes were chosen, including those from the three selected databases and those necessary for the Sendai Framework indicators. These attributes are distributed across the categories and subcategories presented in Figure 4. In Table 4, we provide a summary of these attributes within their respective subcategories.

The context of this work is the registration of disasters in Brazil. An initiative in another country with the same objectives should encompass items 1 and 2 and adapt item 3 to the context of the new database.

INSTANTIATING R2DN

In this section, we will address the activities necessary to feed the R2DN repository with information about disasters from the selected databases throughout this work. Initially, it is essential to map the R2DN data schema in relation to the schemas of the three databases used in our research: EM-DAT, DesInventar, and S2ID. Integrating disaster records from different databases becomes a valuable tool for comparing different versions of the same disaster.

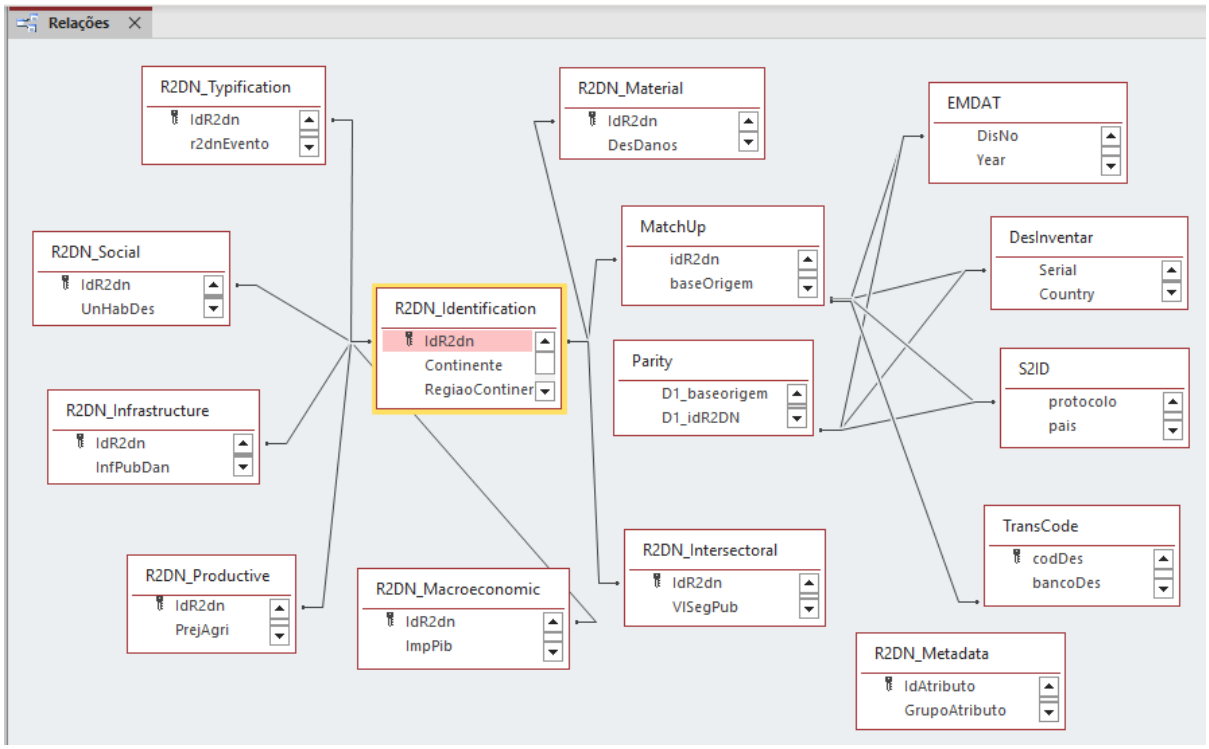

Figure 5. Implementing R2DN in Microsoft Access

Regarding the implementation of the R2DN tables, we decided to organize them based on the data categories established in our taxonomy, as illustrated in Figure 5. In addition to providing a clearer view of the model, this approach was adopted due to the low fill rate in disaster records (CRED, 2021). Therefore, each table will contain records of a disaster only if there is information in the respective data category. The "R2DN_Identification" and "R2DN_Typification" tables, as they contain basic disaster information, will always contain records related to the disaster. Opting for a single-table implementation would have resulted in significant disk space wastage.

The "R2DN_Metadata" table contains the mapping of the attributes of the selected databases with the R2DN attributes. This mapping is necessary to load data from the three databases chosen in R2DN. All other tables with the prefix "R2DN" have information about imported disasters. The additional tables, "MatchUp", "Parity" and "TransCode", play an auxiliary role in the "MatchUp" process, and will be detailed in the "Implementing R2DN" section.

Comparing disasters from different databases can be a challenge, especially when the classifications used are distinct among them. According to (Gall, 2015), it is necessary to establish technical standards for disaster loss databases to ensure comparability and compatibility between databases. The lack of standards hinders the ability to aggregate and consolidate losses over time, space, hazards, and loss metrics, being a critical need in the climate change community. Understanding local, regional, and global conditions is essential for the development of adaptation strategies.

In Table 5 we conducted a comparison of classifications of natural disasters recorded in the databases: EM-DAT (CRED, 2020a), DesInventar (UN Office for Disaster Risk Reduction (UNISDR), n.d.), and S2ID (SEDEC, n.d.). To simplify, we have listed only hydrological and meteorological events, which represent most events in Brazil. Additionally, we limited the presentation to three levels in the classification: Group, Subgroup, and Type.

Table 5. Disaster coding comparison

	EM-DAT		Brazilian disaster code		DesInventar
Group	**Subgroup**	**Type**	**Subgroup**	**Type**	**Type**
Hydrological	Flood	Coastal flood	Flooding		Alluvion
		Riverine flood			Avalanche
		Flash flood			Flood

	Landslide	Avalanche, landslide, mudslide, rockfall and subsidence	Flash flood		Landslide
			Flooding		Rain
Meteorological	Storm	Tropical Cyclone	Large-scale/regional-scale systems	Cyclones	Frost
		Extra-tropical storm		Cold fronts / Convergence zones	Eletricstorm
		Convective storm	Storms	Local / Convective	Snowstorm
	Extreme temperature	Heat wave	Extreme temperature	Heat wave	Heatwave
		Cold wave		Cold wave	Strongwind Tornado
		Severe winter conditions			Hailstorm

Challenges For Data Integration

The challenge in integrating disaster records from different databases lies in identifying similar events across distinct sources. The benefits of identifying similar disasters include:

1. Avoiding distortions in statistical analyses, as some records may refer to the same disaster.

2. Enriching information about a disaster since the three databases contain complementary data.

3. Enabling the comparison of discrepancies in disaster information across various databases.

To identify similarities between disaster records in different databases, three pieces of information are essential: the type of disaster, the location, and the date of the event. The following details how each of these pieces of information will be handled during the R2DN setup process.

As presented in the Table 5, discrepancies in disaster classification among the three databases are noticeable. The difference between S2ID and EM-DAT is relatively smaller, given that the latter based its classification on the former. However, in DesInventar, classification is done by countries, making it more challenging to compare types of disasters. As this work does not aim to exhaust this topic, we choose to restrict the scope to the types of disasters we will address. Thus, we will focus on hydrological, meteorological, and climatological disasters. These categories represent 95.2% of the disasters downloaded from S2ID for the period 1991 to 2022.

Regarding the location of the disaster, greater discrepancies are observed in the information between databases. S2ID considers the location as a discrete domain of states and municipalities, eliminating the possibility of identical locations with distinct spellings. DesInventar also treats the location as a discrete domain, distinguishing administrative divisions by country. For example, in Argentina, it considers province and department, while in Chile, it considers region and province. In EM-DAT, however, the location is a free-text field where various administrative divisions of the country are mixed.

Regarding the date of the disaster, it is necessary to consider a tolerance margin for dates from databases, as there may be a difference of days between dates related to the same disaster in different records. For example, a disaster occurring on 31/12/2013 may be considered the same event in another database but with a date recorded as 01/01/2014. In S2ID, municipalities have a ten-day period to register the disaster in the system from the date of occurrence (UFSC, 2012).

The first activity to instantiate the R2DN involves mapping the proposed data for the R2DN and the data from the selected databases. As the R2DN will be fed with disaster records from the three external databases, it is necessary to identify the source database. From this information, we will use the mapping to find the correspondence between the attributes of the R2DN and the attributes of the source database.

The next step involves generating the files that will contain the disaster records from the three selected databases (CRED, n.d.), (UN Office for Disaster Risk Reduction (UNISDR), n.d.) e (Integração, n.d.), which will be imported into the R2DN. The next section will address the challenges faced when comparing disasters in the R2DN using data from the three databases.

IMPLEMENTING R2DN

The goal of this section is to demonstrate the feasibility of implementing the R2DN through the construction of an artifact, which includes the data structures of the R2DN, the data structures of the three selected databases, and the data structures that will assist in mapping the attributes of each database to the attributes of the R2DN. The main challenge associated with transferring disaster information from other disaster databases to the R2DN is identifying the duplication of disasters. Detecting cases where two or more records from different databases refer to the same disaster is the primary challenge of our experiment, given the disparate ways in which information such as disaster type and disaster location is handled in different databases. This is the challenge we will address during the development of our project.

Since EM-DAT contains disaster records from all countries, DesInventar covers countries in Latin America, excluding Brazil, and S2ID only records events that occurred in Brazil, our goal is to identify duplicate disasters between EM-DAT and DesInventar, as well as between EM-DAT and S2ID. Therefore, it is not expected to find information about an event in all three databases simultaneously.

Regarding the location of the disaster, we note that EM-DAT addresses this information less formally, resulting in a combination of various locations. In the case of Brazil, this may include states and municipalities. On the other hand, S2ID and DesInventar divide the disaster location information into first and second administrative regions, which are pre-registered by countries. Based on this, we conclude that comparing the location in EM-DAT with the other databases should consider both administrative divisions to verify the possibility of similarity of disasters.

Concerning the classification of types of disasters, we observe a significant similarity between the Brazilian disaster code used by S2ID and the disaster classification employed by EM-DAT, as indicated in Table 6. However, the classification used in DesInventar is determined by the country representative when registering the disaster, making it more challenging to find similarities between events. Additionally, we found several instances where the same disaster was registered with different types across databases. For example, as a flood and landslide or a forest fire and drought.

To simplify our observations, we decided to focus exclusively on hydrological, meteorological, and climatological disasters. These categories comprise 95.2% of the disasters recorded in Brazil, as documented in the S2ID Atlas (Integração, n.d.) from 1991 to 2022. Based on our findings, we chose to establish a coding, as illustrated in **Table *6***, for the R2DN. This coding will be used in the comparison between disasters.

Table 6. Disaster Coding Conversion to R2DN

Database	Events	codR2DN
S2ID	Flood, Flash flood, Flooding	1
EMDAT	Flood, Landslide	
DesInventar	Alluvion, Avalanche, Spate	
S2ID	Large scale system, Storm	2
EMDAT	Storm	
DesInventar	Electricstorm, Hailstorm, Snowstorm	
S2ID	Extreme temperature	3
EMDAT	Extreme temperature	
DesInventar	Frost, Heatwave	
S2ID	Seca (Drought)	4
EMDAT	Drought, Wildfire	
DesInventar	Forestfire	

In Figure 6, we present the diagram of the R2DN instantiation process. In the "Load disasters from selected databases" activity, data extracted from the respective databases' websites is imported into auxiliary tables of the R2DN. In the subsequent activity, "Extract data for MatchUp" the "MatchUp" file is generated, containing the data from the three databases necessary for the analysis of similarities between disasters.

The "Analyze similarities between disasters" activity uses the "MatchUp" file to conduct the analysis of disasters. When it identifies one or more similar disasters, it instantiates the "Parity" file with information related to these two disasters. Finally, the "Instantiate R2DN" activity writes the disasters from the three databases into the R2DN.

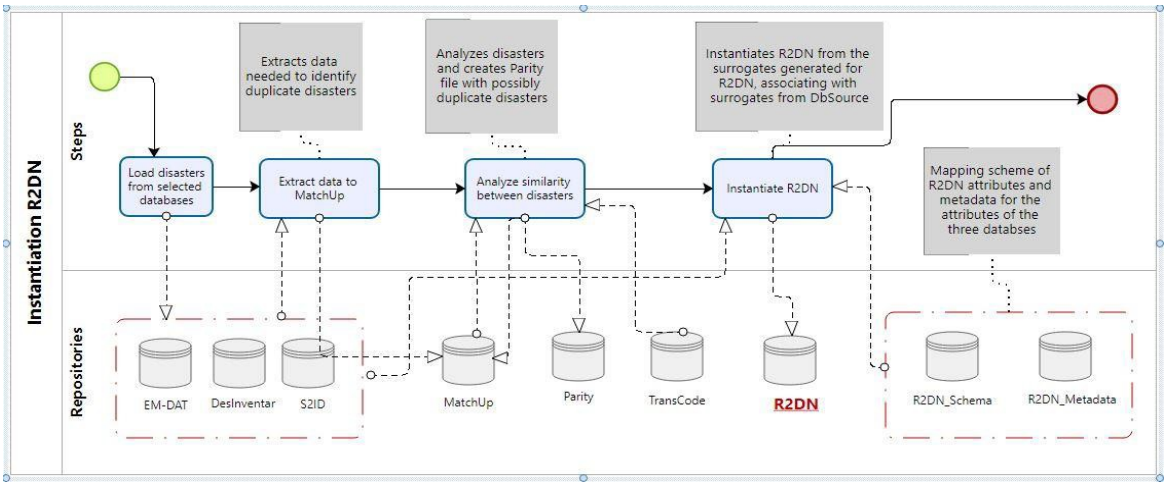

Figure 6. R2DN instantiation process

The "MatchUp" activity, which generates the "Parity" file containing the data of both considered similar disasters, is executed through an SQL command, as illustrated in Figure 7. It is important to note that the "MatchUp" table is invoked twice to enable the comparison of each disaster with all others in search of similarities.

ExecMatch X

```
SELECT d1.baseorigem, d1.idMatch, d1.idbaseorigem, d2.baseorigem, d2.idMatch, d2.idbaseorigem, d1.primDivPais, d2.primDivPais, d1.segDivPais, d2.segDivPais,
d1.data, d2.data, d1.evento, d2.evento, d1.mortos, d2.mortos, d1.feridos, d2.feridos INTO Parity
FROM MatchUp AS D1, MatchUp AS D2
WHERE (D1.pais = D2.pais) AND
    (D1.codEvento = D2.codEvento) AND
    (D1.baseorigem <> D2.baseorigem) AND
    ((D1.contadias - D2.contadias) < 10) AND ((D1.contadias - D2.contadias) > -10) AND
    (((D2.PrimDivPais LIKE '*' & D1.PrimDivPais & '*') OR (D2.SegDivPais LIKE '*' & D1.SegDivPais & '*')) OR
     ((D1.PrimDivPais LIKE '*' & D2.PrimDivPais & '*') OR (D1.SegDivPais LIKE '*' & D2.SegDivPais & '*')));
```

Figure 7. SQL command executed to pinpoint similar disasters

The conditions for identifying similarities, as can be observed in the "WHERE" clause, include: the same country, the same event code, different databases, a date difference of less than ten days, and similarity in the administrative divisions of the disaster locations. Lastly, the " Instantiate R2DN " activity creates disaster records in R2DN from the "MatchUp" file, incorporating the remaining data from the disasters coming from the auxiliary tables of the three selected databases.

The criteria adopted for selecting disasters to be imported from the three selected databases were as follows:

1. Disasters of hydrological, meteorological, and climatological nature.

2. Occurrence in the period from 2010 to 2015.

3. In EM-DAT, only disasters recorded in Brazil, Argentina, and Chile were considered.

4. In DesInventar, only disasters that occurred in Argentina and Chile were included.

The main consideration guiding all the criteria is the quantity of records available in the Brazilian Disaster Atlas Database, accessible through the website http://atlasdigital.mdr.gov.br/paginas/downloads.xhtml (accessed on 10/11/2023). This database covers disasters in Brazil between 1990 and 2022, with a total of 62,273 disaster records. Among these, disasters that fall under the first criterion represent 95.2% of the total.

The disaster records in the DesInventar database for South American countries mostly covered disasters that occurred until 2015. Therefore, we used the criterion of the occurrence period of disasters between 2010 and 2015. The application of this criterion reduced the disasters from the S2ID to 13,143 disaster records.

The choice of Argentina and Chile in South America is due to their presenting similar development indices to Brazil in the region, making the comparison of the impacts of disasters between these countries more equitable. Based on these criteria, the total number of disaster events imported into the auxiliary tables of R2DN was 14,760, as detailed in Table 7.

Table 7. Number of records imported into R2DN

Number of imported disasters in the period 2010-2015	
S2ID	13,143
EM-DAT – Brazil	33
EM-DAT – Argentina	15
EM-DAT – Chile	13
DesInventar – Argentina	1,345
DesInventar – Chile	211
Total	14,760

When considering the criteria for inserting EM-DAT disaster records, which include more than 9 deaths, more than 99 people affected, or the need for international assistance, see Table 8, we assume that all EM-DAT records should be found in the other databases. With this assumption, we face the challenge of locating the 33 EM-DAT disasters that occurred in Brazil in the S2ID, as well as the 28 EM-DAT disasters that occurred in Argentina and Chile in DesInventar.

Table 8. Final result of the MatchUp process

Numbers after running the MatchUp process	
Total records in the Parity file	1,746
Number of similar disasters	873
Similar disasters between EM-DAT and S2ID	686
Similar disasters between EM-DAT and DesInventar	187
Number of disasters not found in S2ID (spelling problem)	3
Number of disasters not found in S2ID	1
Percentage of disasters located in S2ID (except spelling error)	90.63%
Number of disasters not found in DesInventar (spelling problem)	5
Number of disasters not located in DesInventar	7

Percentage of disasters located in DesInventar (except spelling errors)	69.56%

Regarding the 33 Brazilian disasters registered in EM-DAT, one was not identified in our search in S2ID, three were not located due to differences in the spelling of locations, and the remaining 29 show similarities with 686 disasters in S2ID. The way disasters are recorded in S2ID, by municipality, creates situations where, for example, a disaster in the Serrana Region of Rio de Janeiro in 2011, resulting in 900 fatalities, has a single record in EM-DAT, while in S2ID, it is recorded in 19 municipalities.

In another example, the floods that occurred in Rio Grande do Sul in July 2014, due to the overflowing of the Uruguay River, impacted 117 cities, as reported in the media. (G1 - O Globo, 2014). This disaster has only one record in EM-DAT, and our process identified 98 similar disasters in S2ID. This highlights that the information from EM-DAT complements that of S2ID, providing a broader view of disasters, while the latter offers a more detailed perspective on disasters.

Another noteworthy result is that when applying EM-DAT criteria - more than nine fatalities or more than ninety-nine people impacted - for including disasters in its database, we note that, of the 13,143 disaster records in S2ID, 1,924 meet these criteria. According to these parameters, these disasters should be included in the EM-DAT database, which only contains 33 disasters, as shown in **Table *7***. Even considering that one EM-DAT disaster can represent dozens of disasters in S2ID, a considerable disproportion is evident. This reinforces the need for countries to develop regional databases suitable for their realities and demands.

The "MatchUp" process found 90.63% of Brazilian disasters from EM-DAT in S2ID, excluding cases with different spellings. In the case of DesInventar, this percentage was 69.56%. After a preliminary analysis, we were unable to explain the discrepancy between the percentages in the two databases. However, we believe that the greater formality in the use of S2ID may, in part, explain this difference in percentages.

CONCLUSIONS

This study introduced the R2DN data repository model as a response to the research question, which was designed to meet the established requirements. These requirements include the ability to assess disasters, compatibility with major global disaster databases, compliance with multilateral agreements aimed at reducing disaster risks, and meeting the specific needs of a country or organization to support its disaster management policies.

The strategy adopted to achieve the research objectives was as follows:

1. Define a methodological approach for the research.
2. Investigate the characteristics of major global databases, considering citations in academic works.
3. Understand the needs of the Brazilian disaster system, S2ID.
4. Analyze data requirements to meet the demands of the Sendai Framework.
5. Select EM-DAT, DesInventar, and S2ID as reference databases for the study.
6. Identify data needs to meet the requirements of the Sendai Framework.
7. Develop a taxonomy, based on the DaLA methodology, to classify the data selected for the proposed repository model.
8. Implement an artifact to demonstrate the feasibility of the proposed solution.
9. Evaluate the obtained results and generated contributions.
10. Indicate possible directions for future research within the scope of this study.

The **first contribution** of this study lies in the data taxonomy, the data model, and the metadata of R2DN. Our initial encounters with the files of some of the studied databases proved to be quite challenging in understanding the information contained in the data. All databases, without exception, provide their information in a disconnected list of data, significantly complicating its comprehension. Additionally, the available metadata did not offer adequate assistance. We believe that this work will be of great help to those wishing to delve into this subject. The classification of data through the developed taxonomy, coupled with the model that exposes the relationships between the data and the associated metadata, will facilitate the work of anyone dealing with this topic.

The **second contribution** we highlight comes from the development of the artifact that implements an instance of R2DN in a commercial database system. The steps in the development, such as mapping attributes from a database to R2DN, describing data import, unifying disaster type codes, and the procedures necessary to identify similar disasters, facilitate the inclusion of disaster records from other databases into R2DN. We believe we have opened a door for anyone interested in the topic, allowing them to expand R2DN with records from other disaster databases.

Regarding the limitations of this work, we acknowledge that using the three databases restricts the scope of the problem, as the comparison between their data is binary in nature. To elaborate, EM-DAT records need to be compared either with S2ID disasters or with those from DesInventar, given the specificity that S2ID exclusively contains records related to Brazilian disasters, while DesInventar has no records of disasters in Brazil. To overcome this limitation, we intend to include a fourth and perhaps a fifth database in a future version of the work.

Future Work Perspectives

The set of categories does not cover all types of disasters, but it can be easily extended to include disasters such as earthquakes, common in certain parts of the world. As we wanted to examine the occurrence of duplicate events, we left out types of events that are rare in Brazil and therefore are not part of the S2ID database. The taxonomy can also be extended or even replaced by a more complete one.

We believe that handling the location information of the disaster is the aspect that needs the most improvement. The way EM-DAT describes the same disaster occurring in various locations in a single record, with only one attribute for this representation, poses challenges. Furthermore, the spelling of locations in this attribute often contains inaccuracies. Since EM-DAT is the most widely referenced disaster database globally, any initiative to integrate disaster data must include it. In our work, whenever we needed to precisely locate an EM-DAT disaster, we resorted to internet searches using information such as country, date, and type of disaster, and were successful in most cases. Automating this search process represents an opportunity for future work.

Disaster management encompasses three basic phases: prevention, response, and recovery. Our work focused on databases that support the response phase, aiming to restore essential activities, and the recovery phase, to return to pre-event normality in the society affected by the incident. We consider that our proposed disaster data is comprehensive regarding the human and material impacts caused by these events. However, it lacks information on risks in the affected locations, as none of the selected databases in the study address this aspect. Therefore, we believe that integrating a database that includes information on disaster risk into the R2DN represents an opportunity.

Finally, to evaluate our solution, it should be used by researchers and professionals in the field of disasters to demonstrate its efficiency and effectiveness. In our initial attempt to produce such evaluation we didn´t get enough returns to produce a relevant analysis. We intend to pursue this evaluation soon.

ACKNOWLEDGMENTS

The work of Marcos R. S. Borges was partially supported by the Rio de Janeiro Research Foundation (FAPERJ) under grant # E-26/202.876/2018.

reinhard.bernsteiner@mci.edu

ABSTRACT

The COVID-19 pandemic strained global supply chains, and companies faced numerous production, logistics, or material management problems. It is claimed that the digitalization of supply chains can have the potential to make supply chains more resilient to interruptions and disruptions. This article focuses on describing the experiences of three large Austrian family-owned business during the supply chain disruptions caused by the pandemic and the Russia -Ukraine war. This assessment is done from the perspective of the supply chain leaders in the organization. We provide insights on what worked and what did not for these firms and what lessons we can take away from their experiences.

Keywords

Digitalization; Supply Chain Disruptions; Digital Supply Chain; Sustainability; Resilience; Best Practices.

INTRODUCTION

> "*The supply chain mantra is changing from efficiency and low-cost country sourcing, to supply chain resilience and visibility to reduce complexity and uncertainty. The acceleration of digital transformation is key to that new way forward.*" Henry Brunekreef, Director, Operations Advisory and National Leader, Supply Chain Management, KPMG in Australia

The ILO (International Labor Organization) has defined "Global Supply Chains (GSCs)" as the cross-border organization of the activities required to produce goods or services and bringing them to consumers through inputs and various phases of development, production, and delivery. Global supply chains are complex, diverse, fragmented, dynamic, and evolving organizational structures with cross-border production and trade as a critical element (https://www.ilo.org/global/topics/dw4sd/themes/supply-chains/lang--en/index.htm#44).

Established in 2015 by the United Nations, the Sustainable Development Goals (SDGs) are a collection of 17 interlinked goals designed to be a "blueprint to achieve a better and more sustainable future for all". According to (Chauhan et al., 2022; Gunasekaran et al., 2015) the SDG's serve as guidelines for the attainment of sustainable business development and focus on cross-sector as well as cross-country partnerships and cooperation for sustainability. These authors assert that the "efforts to drive businesses towards SDGs are grounded in the equitable sharing of risks and benefits and require actions such as collaborative planning and product development, exchange of information and coordination at various levels among different actors within an GSC" (Chauhan et al., 2022; Mehdikhani & Valmohammadi, 2019). According to the ILO and Pohlmann et al (Pohlmann et al., 2020) to achieve a sustainable future, businesses will need to align their goals with the SDGs at the strategic as well as operational (Chauhan et al., 2022). In fact, Golroudbary et al. (Golroudbary et al., 2019)

have shown in their research that an equal weighting of economic, environmental, and social elements is essential to developing, implementing, and executing sustainable policies and practices. These conclusions are also supported by a study by Haroon et al (Haroon et al., 2021) who explored the perceived significance of sustainability indicators, specifically economic, environmental, and social, among supply chain practitioners in the implementation of sustainable supply chain practices. They discovered that these practitioners consider all three sustainability dimensions as equally important. The SDGs are also well connected with the three pillars of corporate sustainability, ecological, social, and economic, also called the Triple Bottom Line (TBL) (Calabrese et al., 2021). The TBL is frequently employed to translate sustainable development into tangible and actionable decisions (Singh & Rahman, 2021).

Caiado et al. (Caiado et al., 2022) have investigated the integration of SDGs in global supply chain management and report that companies that align their operations and supply chain management activities with the SDGs can positively contribute to:

- ensure reliable and modern energy services, facilitating access to research and technology in clean energy, including renewables, energy efficiency, and advanced and cleaner fossil fuel technology (SDG#7).
- promote sustainable economic growth through the support of productive activities and the creation of decent jobs (SDG#8).
- encourage inclusive and sustainable industrialization by promoting innovation through improved resource-use efficiency and increased adoption of clean and environmentally sound technologies and industrial processes (SDG#9).
- diminish inequality by empowering and fostering the socioeconomic inclusion of everyone while ensuring equal opportunities (SDG#10).
- create more inclusive, safe, resilient, and sustainable cities by establishing accessible, sustainable, and intelligent transport systems (SDG#11).
- enhance technological capacity to transition towards more sustainable consumption and production patterns by minimizing waste generation through prevention, reduction, recycling, and reuse (SDG#12).
- Promote partnerships involving multiple stakeholders to mobilize and share knowledge, expertise, technology, and financial resources (SDG#17).

Supply Chain Disruptions

With the advent of modern digitalization in all its forms, speed, flexibility, scalability, just -in-time inventory, cost-effectiveness, eco-friendliness, or global connectivity are only a few of the many features linked to a global supply chain today. Family-owned businesses that are innovative otherwise often struggle with modernization though digitalization (Baskins, 2023). The COVID-19 pandemic and the Russia -Ukraine war caused supply cha in interruptions and disruptions that demonstrated the vulnerability of an interconnected global economy. Formally, according to Macdonald et al. (Macdonald & Corsi, 2013), supply chain disruptions are defined as "unplanned and unanticipated events that disrupt the normal flow of goods and materials within a supply chain" (Craighead et al., 2007), 132). With COVID-19 (Paul et al., 2021), the Russia-Ukraine war (Dyson et al., 2023), and the recent wildfires across the world (Galizia et al., 2021), it is certain that unanticipated global events will continue to have a significant disruptive impact on global supply chains and, in fact, occur regardless of risk planning (Ivanov & Dolgui, 2021). As a result, supply chain executives continue to face the critical challenge of recovering from disruptions while minimizing their impact.

The COVID-19 pandemic strained global supply chains, and companies faced numerous production, logistics, or material management problems. It is claimed that the digitalization of supply chains can have the potential to make supply chains more resilient to interruptions and disruptions. Some authors have conduced systematic analysis of the academic literature to theoretically discover themes, strategies, and challenges associated with global supply chain disruptions (Hald & Coslugeanu, 2022; Ivanov & Dolgui, 2021; Katsaliaki et al., 2022; Moosavi et al., 2022); there have been no studies that describe lessons and insights from the perspective of large family-owned business and their experiences during the COVID-19 pandemic and other disruptions. There are several researchers who argue that family-owned businesses need to transform particularly during turbulent times (e.g., Davis, 2022), but very little is known about what has worked for them during the disruptions in the past couple of years.

To address the above gap in our understanding, *this paper addresses the following question: What was the impact of digitalization on family-owned businesses during crisis such as Covid-19 and the Ukraine war? This question is explored from the perspective of supply chain leaders in the organization via semi-structured interviews. A descriptive analysis of the interviews is used to elicit the* ***lessons learned*** *relating to the impact of digitalization during supply chain disruptions*.

The remaining paper is organized as follows. Section 2 provides an explanation of our research method followed by a detailed analysis of results in section 3 and a discussion of "lessons learnt" in section 4.

RESEARCH APPROACH

To develop insights into how family-owned firms handled the supply chain disruptions due to the COVID-19 pandemic and the Russia -Ukraine war, we conducted semi-structured interviews over Zoom of senior supply cha in executives from three family-owned Austrian manufacturing firms in Spring 2022. The executives interviewed were the key leaders (SVP or VP level) of the supply chain for each firm and their digitalization efforts. The choice of firms was primarily due to the authors' ability to gain convenient access to the firm and key executives responsible for the digitalization efforts in each firm's supply chain. Although our sample size for this research is a limitation in terms of the generalizability of its conclusions, it is generally challenging, costly and time consuming to obtain access to senior leadership and firms for interviews of the kind reported in this research paper. Furthermore, we concluded that adequate data saturation was achieved with the three firms studied for the research goal of our study. Additional data collection would not produce any value-added insights with regard to the research goal of this research (Adams, 2015b; Saunders et al., 2018). The external validity and generalizability of our conclusions from this sample will of course be limited and applicable to firms that are like those studied. In this context, it is worth reiterating the argument made by Crouch and McKenzie (Crouch & McKenzie, 2006) about the "the logic of small samples…": "in the social world, to discover what features there are in them and to account, however partially, for those features being as they are… a research project scrutinizes the dynamic qualities of a situation (rather than elucidating the proportionate relationships among its constituents), the issue of sample size - as well as representativeness - has little bearing on the project's basic logic."

Expert interviews aim to give further insights about a topic that literature cannot answer entirely (Mayring, 2015b). Although methodological purists raise objections to expert interviews to the expert interview1 on grounds of it being a "dirty" *method,* the value of an expert interview is the individual's viewpoint and experience which can influence the researcher's investigation (Mayring, 2015a; Trinczek, 2009). The open ended semi-structured interviews provided an ideal setting for the free conversational speech of the interviewee combined with guidance from the interviewer (Adams, 2015a, 2015b). To minimize fatigue for both interviewer and respondent, according to (Adams, 2015a, 2015b), about one hour is considered a reasonable maximum length for semi-structured interviews. Our interviews generally lasted 1-1.5 hours with a blend of closed- and open-ended questions, and some follow-up "why" and "how" questions as needed (Adams, 2015a, 2015b).

After each interview, the content was transcribed and anonymized by the authors and coded according to Mayring's scheme for qualitative content analysis (Mayring, 2015a). The authors reviewed each transcript to develop categories or themes from them that address the primary research question of what worked and did not work during the disruptions due to the COVID-19 pandemic and the Russia -Ukraine war and the lessons learnt thereof (Mayring, 2015a).

Table 1: Open ended Semi-Structured Interview Guiding Questions

Q1. Please describe your role and your firm.
Q2. How much digitalization and/or automation exists with respect to the firm's supply chain?
Q3. In the context of the Covid-19 pandemic and the Russia-Ukraine war, how is digitalization and/or digital transformation allowing companies to overcome supply chain disruptions and/or become more resilient?
Q4. What have been the challenges relating to supply chain disruptions in your firm? How is digital transformation helping ("helped")? What are the risks of digitalization?
Q5. How do you (and your firm) think about the resiliency of your global supply chain? What does the future look like for you?

RESULTS

In this section we provide a concise description of the data organized around thematic categories identified using interview evidence and prior research. The three firms studied are characterized in Table 2.

Table 2. Attributes of Firms in this study

Family businesses	Size	Primary Products
Company 1	Employees: 770 Turnover: $730 million. Wholly owned subsidiary of a global company	Manufactures ground-based gardening tools, such as lawn mowers, robotic mowers, ride-on mowers, and garden shredders.
Company 2	Employees: 11,000 Turnover: $2 billion	Truck equipment manufacturer. Makes cranes, hook lifts, cable hoists, forklifts, liftgates, service bodies and platforms. Has 200 suppliers worldwide.
Company 3	Turnover: $1.67 billion Employees: 2,400 worldwide 14 plants; 8 branches in Europe & USA Products available in 100 countries	Business to business provider of beverages including fruit juice production, semi-manufactured products such as concentrates, and branded packaging for business customers.

Qualitative Findings from Interview Data

Nature of Supply Chain Disruptions

The COVID-19 pandemic, Russia-Ukraine war, the cascading impact of China's reaction to COVID-19, transportation bottlenecks, and general geopolitical factors severely impacted global supply chains and to some extent continue to disrupt them. The primary lessons learnt from these challenges to the supply chain are summarized below (Hald & Coslugeanu, 2022; Katsaliaki et al., 2022; Moosavi et al., 2022). These findings combine the information gleaned from prior research and echoed by executives from the three firms studied in this research.

Logistics Disruptions

The global logistics disruptions stemming from the COVID-19 pandemic impacted businesses and consumers as the flow of consumer goods into key markets such as North America and Europe, Southeast Asia and India was restricted by the continued shutdowns of ma jor global ports and airports, largely in China, South Korea, and the USA. According to a supply chain disruptions survey reported by the magazine Logistics Management, as of December 2022, nearly 72% of respondents were still handling global supply chain disruptions and 54% expected this pressure on global supply chains to continue (Bridget McCrea, 2022). The companies we studied faced logistics disruptions relating to semi-conductors or chip bottlenecks from Taiwan. According to the Economist, Taiwan produces over 60% of the world's semiconductors and over 90% of the most advanced ones. This became a limiting factor that intensified competition for chip components in short supply and had a ripple effect on manufacturing during COVID-19 and because of the ongoing the Russia -Ukraine war. All three subject firms faced disruptions due to the Russia -Ukraine war, particularly with respect to semi-conductors or chip bottlenecks impacting firms like Company 1. There was intense competition for chips between the large consumers such as BMW and others in Europe for chip supply). Additionally, the Russia -Ukraine war caused pressure on supply of raw materials such as Aluminum and Wooden Pallets which impacted "Company 1" in particular. Finally, all three subject firms faced transportation and logistics bottlenecks due to lack of shipping containers, time to transport form China/Taiwan to Europe of certain raw materials, and other similar constraints.

Production delays due to lack of components or materials

Production delays during COVID-19 become headline news. Manufactures were competing for limited supply of key commodities and logistical capacity, leading to consumers experiencing empty shelves and long purchase

lead times. This capacity constraint has not completely been ameliorated in many critical sectors. In the technology industry for example, even in 2023, the COVID-19 pandemic, increased demand for consumer electronics, and supply chain disruptions have all contributed to the shortage, which is affecting production, innovation, and prices (Versa Electronics, 2023). The ongoing Russia-Ukraine war has exacerbated the post-COVID recovery by disrupting global supply chains for some basic foods, fertilizers, chemicals, metals, and other minerals as well as oil and gas from Russia (Dyson et al., 2023). As the executive from Company 3 explained: "Out of stock situation are rarely seen in the food industry. However, if the supply chain is disrupted – we know that there are missing materials. Prices go up (supplies, financing, storage, and logistics/transportation) are significant cost factors. If we are out of stock due to bottlenecks – finished goods can be covered for a day or two, but it will ultimately impact production planning. This means we need to be agile while being economically. However, this continues to be a challenge to manage demand planning." For example, even materials that cost a few cents can have a major impact on delivery of materials. Company 3 had to stop production in their brewery p lant due to lack of CO_2 for one week; the cost is a few cents, but it is a critical component and was hard to predict that it would be in short supply. Similarly, Company 3 faced a water shortage due to high temperatures in Hungary being 40C or more; no one imagined such a shortage before. When the Russia -Ukraine war started, Company 3 had to stop receiving nails since steel was restricted from sanctioned countries such as Belarus. A very small item in terms of materia ls needed for the production line, but the intended impact was that palettes to ship goods could not be assembled and their cost tripled.

Over Reliance on limited and remote third parties causing supply chain disruptions

COVID-19 and the Russia-Ukraine war have demonstrated the inherent risk associated with focusing on one major trading partner(s) and/or cheaper remote vendors [(Allam et al., 2022). Many businesses had strong relationships with one major supplier, one large customer and/or one major supply chain partner. Researchers have found that buyers face a tradeoff between the benefits of close relationships with their suppliers, the countries they are located in, and the risk of excessive concentration (Polyviou et al., 2023). For example, according to one study (Oxford Analytica, 2023), Austria had to sharply cut Russia's share of gas imports in the wake of the February 2022 invasion of Ukraine but has already returned to pre-war levels due to challenges associated with contracts, energy diversification, domestic politics and foreign policy. The dependence on China as a manufacturing hub for the world caused server disruptions in the global supply chain during the pandemic and continues to do so even now. In fact it has been reported that nearly 51,000 global companies had one or more tier-1 suppliers, and five million have one or more tier-2 suppliers in the Wuhan region ((Ivanov, 2020); (Jim Kilpatrick, 2020)).

To compensate for the supply chain disruptions brought on by the pandemic and the Russia -Ukraine war, many companies have been moving their manufacturing and/or sourcing closer to home. According to the Logistics Management survey cited previously (Bridget McCrea, 2022), more than half (52.3%) of respondents have attempted to nearshoring and/or reshoring approach over the last two years while 36.4% have not.

In the case of Company 1 and 2 in our study, the reliance on Taiwan for wafers during COVID-19 was a massive limiting factor – demand for chips was high and transportation/logistics bottlenecks were endemic causing delays in production. Furthermore, both were trying to bring some manufacturing of components back to the Eastern Europe where labor was still a bit cheaper. Company 1 was also exploring alternative suppliers for their critical components by trying to just understand which components are critical so that they can move to demand planning better with global standards for suppliers in the value chain. This was driven by worries about not having adequate data transparency for the whole supply chain.

Company 3 being in the food sector had the challenge of understanding the quantity and type of goods that are needed and whether raw materials would be available, particularly since lead time was critical for perishable goods in the food industry. Additionally, dependence on 1000+ farm-based suppliers in Europe was particularly challenging for this organization since many of the farmers have no computers – contracts are manual and individually customized and vary from country to country even within the EU. However, interestingly, billing is electronic while farmers get paper payments.

Technology and Digitalization

The need to improve the resiliency of supply chains has become even more critical post -pandemic. Digita l transformation in supply chain management could enable organizational flexibility, business process automation, cost-effectiveness, visibility, and accelerate innovation in supply chain management itself ((Baryannis et al., 2019), (Hamidu et al., 2023), (Nasiri et al., 2020)). Using digital transformation to this end is a laudable goal but requires financial investment and strategic planning. Absence of planning and collaboration, wrong demand forecast, lack of inventory sharing, incorrect assumptions, lack of knowledge, agility, and flexibility, high volatility, over-reliance on the suppliers, and lack of integration between digital and non -digital management are

some reasons why digital transformation of supply chain may fail ((Baryannis et al., 2019), (Nasiri et al., 2020)). Additionally, there is some argument that digitalization is not a panacea for achieving resilience of global supply chains; the degree and sophistication of the digitalization needed may vary depending upon the nature of the business, size, and concentration of suppliers ((Zavala-Alcívar et al., 2020), (Yin & Ran, 2022), (Shashi et al., 2020), (Casalino et al., 2019)). In fact, Shashi et al. [22] found that "…technology appears as a necessary but not-sufficient enabling factor for ASC ("agile supply chain") deployment."

All the three firms in our study reported varying degrees of success with digitalization before and after COVID - 19 and throughout the disruptions caused by COVID-19 and the ongoing Russia-Ukraine war. At the time of our interview, Company 1 was in the early stages of digital transformation since they had very little plant level automation and used manual processes to handle raw material supplies. They were in the process of implementation of SAP HANA at the plant level with varying adoption across its plant s globally. Even though production planning was automated. Bottleneck handling was mostly annual (prior to COVID-19 through post-COVID timeframe). This was because of lack of data visibility across the supply chain, and it was difficult to get a "clear picture across multiple suppliers." In the words of our interview subject at Company 1, digitalization did not provide any immediate advantage to overcome disruptions, particularly of chips. In fact, Company 1 worked manually first to address manufacturing ba sed on supply of materials – that is adjust what would be manufactured based on what is available from suppliers. They were making decisions about which products to manufacture, for example based on which ones would provide the highest revenue. Limited qua ntity of certain components can impact how to distribute them to the right products in plants. Needed digitalization at the plant level to have all the information relevant for a decision in place, in time and fast.

Company 2 was also in the early stages of digital transformation and was strategically thinking about ways to approach it for its whole supply chain. Their supply chain had different digitalization maturity levels with some plants being the most advanced in terms of VMI, supply relationship management software that connected 200+ suppliers across the globe that also included integration with loading planning and transportation tools. According to our interview subject, Company 1 managed some disruptions in supplies of materials better by using supply relationship management software to get a holistic view of the supply chain. They also used VMI to plan better for inventory. Company 2 also used SAP HANA but for limited functions and was in the process of implementing it across the supply chain.

Company 3 was a contrast to the other two firms since they are in the food services industry and had rarely faced out-of-stock situations until the pandemic. They had implemented EDI (Electronic Data Interchange) with most of their major suppliers. However, they also have 1000+ farmers as fresh commodity suppliers from around Europe who did not have any automation. They had some visibility because of EDI and used demand planning and maintained safety stick when possible. Their mantra was to "be agile while being economical" in what is provided as finished goods. However, demand planning continued to be a challenge. Our interview commented that we because of the way economies are highly interconnected globally, they must use "agile JIT" and not focus on 100% availability of items, which is not always possible as illustrated by the supply chain disruptions during the pandemic and the ongoing Ukraine conflict. They also considered the notion of having more buffers in all parts of the supply chain with reasonable demand planning.

Workforce Issues

Uncertainties in workforce due to shortages of skilled labor and the impact of technology causes challenges for digital transformation of supply chains. To cope with a progressively digitalized and automated supply chain, workers must acquire fresh skills, and advancements in technology will significantly transform their current roles. A considerable portion of employees' routine tasks will be automated, necessitating greater emphasis on innovation, creativity, collaboration, and leadership in their jobs ((Berg et al., 2020), (Foroughi, 2021), (Wahab et al., 2021)). None of the subject companies had workforce concerns at the time of interviews. However, the partners in the supply chain of these firms were globally dispersed and workforce concerns were different in each part of the world. As suggested earlier about the implication of the SDGs on GSCs, there was limited consideration given for the workforce located at supply chain partners in terms of their economic uncertainty created by the pandemic and the impact on the sustainability of their viability. However, Company 3 was particularly concerned about the economic and social impact of the pandemic on the 100s of individual farmers who were their suppliers.

Lack of Transparency/Visibility

Supply chain end-to-end visibility can potentially mitigate the risks of supply chain disruptions (Brandon-Jones et al., 2015; Paul et al., 2021; Roy et al., 2019). Lack of visibility of the supply chain occurs due to inaccurate data, inability to track supplier performance, late updates, and incomplete information. Lack of visibility and transparency can also make decision making challenging in terms of which produ cts and how much to schedule

for manufacturing. Company 1 was in the early stages of digital transformation across the supply chain and lacked an integrated and holistic view of the whole supply chain from sales forecasting to component demand to production planning. In contrast Compa ny 2 used its supply relationship management platform with its 200+ suppliers to gain visibility on information flows and used that to optimize the supplier network particularly during the COVID-19 pandemic Finally, Company 3 was severely challenged with demand planning due to the lack of visibility of the smaller players in their supply chain and due to the unpredictable delays in transportation via containers.

DISCUSSION and LESSONS LEARNED

Based on our analysis of the supply chain disruptions faced by the subject firms and their approaches to addressing them, the following lessons/strategies, and implications for sustainability can be gleaned.

- **Digitalization must be strategically fit(ted)** and it is not a panacea for poor processes or strategic vision. This includes assessing the state of the global supply chain partners in terms of maturity level of digitalization. Strategic digital transformation of GSCs will need huge technology investments and commitment from top management. The implication here is that in terms of sustainability as described in SDG#12 and SDG#8, digitalization across the GSC will involve support for partners to upgrade their infrastructure, train employees, and integrate systems across the supply chain network. For example, Company 1 described the need to responsibly make sure perishable goods are protected and to allow for longer lead times by keeping greater buffer such as an extra truck of supplies. This would need more real-time supply chain optimization.
- Digitalization can result in benefits if the **supply chain automation** includes **much more than just eliminating manual tasks through automation**. It involves process and payment automation, improving resource efficiency, delivering valuable insights, and integrating transportation logistics across the GSC. To reap outstanding rewards, companies need to apply supply chain technology directly within the operations including plant automation and across its whole global supply chain. This insight aligns well with SDG#9 which encourages inclusive and sustainable industrialization by promoting innovation through improved resource-use efficiency and increased adoption of clean and environmentally sound technologies and industrial processes. Company 2 is a great example of how this was taking shape: they had implemented tactical network optimization process and system along with network optimization across their network. They used simulations of their network to conduct scenario analysis. The interview subject commented that "Simulating the network was game changing; the technology was a big advantage." This firm also used their supplier relationship managem ent digital platform to be more resilient by providing clear information flows and had implemented a relationship management software for all its 200 suppliers across globe and were also integrating transportation in the SRM process.
- Digitalization must address the issue of **supply chain transparency and visibility** head on. This not only means clear information flows but also clarification of processes, roles, and responsibilities. This will help with resiliency and adaptability and be in line with SDG#17. The implication of SDG#17 is that true collaboration including sharing of knowledge and information with global supply chain partners is critical for sustainability. We need to work in collaboration with suppliers. As the executive from "Company 2" in our study commented: "… (we) need to change – collaboration with the whole supply chain is essential…. including the internal supply chain – supply chain collaboration in engineering, suppliers, is now needed in the future to be successful".
- Consider **reconfiguring supply chains** to avoid disruption so that there is less dependence on just a few sources of raw materials and/or locations. Need to explore the idea of bringing some critical component manufacturing closer to plant operations. In doing so, the economic and social impac t on supply chain partners across the globe in terms of sustainable practices will need to be addressed per SDG#8 and SDG#17.
- **Adaptability (agility/responsiveness)** of the supply chain through backward integration is essential with digitalization. The idea is that truly resilient companies need to continue processes and make decisions by quickly reacting to dealers, partners, and customers. This means using tools and processes for better demand planning and agility to respond or react to changing demand in collaboration with supply chain partners (SDG#17; SDG#9).
- **Supply chain collaborations** are even more critical for sustainability and resiliency during disruptions (SDG#17; SDG#9). This is particularly important that this happens between large and small suppliers and buyers – VMI by itself cannot address this challenge.
- **Don't forget the human component**; Transparency also means educating the workforce for the next generation of digitalization and process transformations. It also implies that working conditions and

decent work practices be adopted and supported across the GSC network (SDG#8).

Limitations and Implications for Future Research

This research has inherent limitations due to the nature of the qualitative research method and narrow sample of firms participating in the interviews. However, in addition to the lessons learn ed described previously, there are interesting issues that could be further explored using mixed research or survey research designs. For example, research is needed to address the relationship between the extent of digital transformation in a global supply cha in and its impact on reducing supply chain disruptions – this could mean also looking at opportunity costs of not fully digitalizing a supply chain. Additionally, there is still research that needs to be done on how supply chains can be optimally reconfigured to become more resilient through digitalization during disruptions. One of the issues raised by our interviewees was adaptability of the supply chain to disruptions – how can we intentionally design adaptability and responsiveness? Another facet of GSCs that came out in our research that needs further study has to do with engendering effective collaboration across the network due to the large investments needed for a coherent and effective digital transformation strategy. How can firms accomplish this with a shared vision, smart financial investment, governance, and appropriate policies? Finally, a research issue that is often ignored in global supply chains is the study of challenges and best practices of applying decent work principles to labor across the GSC network.

ABSTRACT

Effective disaster preparedness, including the strategic stockpiling of resources, is crucial to respond quickly and efficiently to unforeseen crises. Therefore, we contribute to understanding effective disaster preparedness by examining the national food stockpiling practices in Germany and Switzerland, nations renowned for their proactive disaster management and high levels of preparedness. Using comparative content analysis, we thoroughly investigate the strategies, stakeholder involvement, and economic aspects these nations employ to ensure food supply. Insights are gained through in-depth interviews with experts in disaster management, food production, and food supply. The analysis reveals significant differences in the approaches, highlighting benefits and drawbacks for policymakers and practitioners. Our research underscores the importance of different strategies to suit national contexts and provides insights into best practices for enhancing food security and supply in the face of disasters.

Keywords

Preparedness, Expert interview, Disaster management, Decision-support

INTRODUCTION AND MOTIVATION

In today's ever-changing world, crises like the 2021 century flood in Germany, the COVID-19 pandemic, and military conflicts consistently impact global supply chains, particularly in the food sector. Given its intricate nature and essential role, food supply chains face an extensive risk landscape due to several factors. Notably, supply chain disruptions are increasing due to the growing frequency of crises and natural disasters, accompanied by changing climate patterns (WEF, 2023). Furthermore, the expanding global population drives increased demand for food, placing significant pressure on supply chains to ensure efficient and timely delivery (Rejeb et al., 2022). Additionally, risks arise from global food supply networks, technological dependencies, regulatory complexities, and growing interconnectedness (Kumar et al., 2022). The COVID-19 pandemic highlighted these vulnerabilities and significantly impacted and disrupted food supply chains. Bottlenecks in production and transport led to a mismatch between demand and supply. They impacted the availability and access to certain food products as described by Mor et al. (2021) and Weersink et al. (2021). The food supply chain relies on a complex and highly

*corresponding author

interconnected structure across various industries. Disruption or failure in any part of this chain can lead to systemic collapse. Dependencies within the food supply chain extend to critical sectors such as energy, water, transport or communication (Brem, 2015). These interdependencies increase the vulnerability of the food sector, with the extent of their impact varying based on the crisis.

As a result, governments, organizations, and private actors are urged to invest in strengthening food production capacities and establishing contingency plans that decision-makers can swiftly activate in times of crisis. One strategy in this regard is the pre-positioning of emergency reserves. For example, Germany and Switzerland have adopted measures to stockpile strategic food reserves and promote collaboration among stakeholders (BMEL, 2023). It is essential to note that both countries' disaster preparedness extends beyond food supplies, acknowledging that crises impact multiple sectors and require diverse relief materials such as energy and healthcare resources (BMWK, 2024; FONES, 2023). Despite their interconnectedness, sectors are usually managed independently, emphasizing unique stockpiling requirements. Notably, storing food presents distinct challenges, including meeting nutrition needs and changing population demands depending on the type of crisis.

Therefore, our paper examines the crucial significance and approaches of food stockpiling. It investigates emergency preparedness and storage strategies in Germany and Switzerland through four expert interviews, gathering valuable insights from professionals with expertise in the field. Based on the focus group interviews, this work provides insights into the following research questions:

- RQ1: What are the distinctions in stockpiling strategies between Germany and Switzerland, considering factors such as stakeholder involvement and economic aspects?
- RQ2: What insights can be derived from the national strategies to enhance preparedness and optimize the efficient distribution of resources in disaster preparedness?

By answering these research questions, our study provides the following contributions: First, by conducting and analyzing four expert interviews, we aim to identify the strategies, motivations, and decision-making processes involved in implementing food reserves in disaster preparedness. This approach allows us to gain valuable insights from experts with practical experience in different sectors and countries. Second, we thoroughly examine the advantages and challenges of the presented food stockpiling strategies, providing a comprehensive perspective on the efficiency and feasibility. Third, utilizing the insights gained from the expert interviews and the analysis of stockpiling strategies, we aim to provide stakeholders with a comprehensive understanding of different approaches to food emergency preparedness, aiding stakeholders in making well-informed and resilient decisions that can shape policies and actions. Fourth, in the discussion section, we highlight the critical importance of adapting to different crises to ensure the effectiveness of systems in diverse settings. These considerations enable decision-makers to tailor their strategies and responses accordingly. Furthermore, we offer recommendations for future work, focusing on understanding the nuances of different crises and leveraging tools such as information systems to manage the resulting complexities and enhance overall crisis resilience by taking on an integrated view.

This study is structured as follows. Initially, a comprehensive overview of the theoretical background is provided, setting the foundation for the subsequent discussion. Next, the research methodology is outlined, detailing the approach for gathering and analyzing data. Subsequently, the research outcomes are presented along with the critical findings. Finally, the study discusses the results and explores potential opportunities for further research.

THEORETICAL BACKGROUND

Pre-Positioning of Relief Supplies and National Stockpiles

Pre-positioning relief supplies is critical in disaster management to strengthen resilience and response operations. It involves strategically placing relief supplies such as food, water, medical supplies, and other essential commodities before a crisis occurs (Sabbaghtorkan et al., 2020).

Numerous studies, including those by Arnette and Zobel (2019), Condeixa et al. (2017), Ni et al. (2018), Rawls and Turnquist (2010), and Verma and Gaukler (2015) have explored the importance and implementation of strategies for stockpiling critical goods. Ongoing research in food emergency preparedness focuses on assessing the unique advantages of collaborative efforts in food supply during emergencies (Edge & Meyer, 2019). These works include studies aiming to enhance the efficiency of logistical processes and ensure the timely distribution of food resources (Ö zdamar et al., 2004). Furthermore, regulatory frameworks (Manzoor et al., 2014) and technological collaborations (Shrivastav & Bag, 2023) are investigated.

Several countries maintain national stockpiles, incorporating critical goods and food items in line with these considerations. The objective is to safeguard the food supply during crises, encompassing scenarios like natural disasters, wars, or other supply disruptions. The composition and scale of strategic national food stockpiles vary between countries depending on the country's emergency strategy and factors such as self-sufficiency, population size, geographical location, and vulnerability (Caballero et al., 2015). For example, Germany and Switzerland stockpile food for crises, while other countries, such as France or Italy, forego strategic national food reserves (Gerhold et al., 2019).

While the stockpiling of supplies in humanitarian relief operations is a subject of intense discussion, there remains a notable knowledge gap in comprehending how specific strategies can enhance pre-positioning and logistical activities, especially in the context of food-related crises at the national level.

Stockpiling Policies in Germany and Switzerland

German law mandates state emergency food provisions as part of the broader obligation to safeguard every human life (BVerfG, 1977). The Federal Ministry of Food and Agriculture (BMEL) is the primary entity responsible for emergency food provision in Germany. It is mandated to enact sovereign food management during a crisis (BMEL, 2023). Acting on behalf of the BMEL, the Federal Agency for Agriculture and Food (BLE) maintains about 150 warehouses known as the Civil Emergency Reserve and the Federal Grain Reserve, storing essential items such as rice, lentils, condensed milk, wheat, rye, and oats (BLE, 2023b). These stored provisions are intended to ensure a consistent supply of flour and bread and sustain the overall population's needs in urban areas (BMEL, 2023). Over the years, Germany has significantly transformed its approach to food security. The country incorporated military provisions into the constitutional framework in 1956, laying the groundwork for emergency food supply (Menski, 2016). Motivated by Cold War tensions, Germany instituted the Food Security Act (ESG) in 1965 and, in response to the Chornobyl disaster in 1986, introduced the Food Precaution Act (EVG) in 1990 (BLE, 2023a; Menski, 2016). These acts ensure essential provisions for the civilian population and the armed forces during war and other crises. In 2017, these acts were consolidated into the Food Supply and Preparedness Act (ESVG), providing a unified approach to defense and non-defense crises (BLE, 2023a).

In Switzerland, the national economic supply provides the country with essential goods and services in times of shortages (FONES, 2023). The National Economic Supply System (NES) is based on cooperation between businesses and the state. Representatives from the key economic sectors take on management responsibility and contribute their experience (FONES, 2021). Companies that import, manufacture, process, or introduce essential goods for the first time into the market must maintain reserves (Re´servesuisse, 2023). Storage requirements for food and feed, including items like sugar, rice, edible oils and fats, coffee, and grains for human consumption, as well as energy and protein carriers for feed purposes, totaling 711,294 tons (FONES, 2022, 2023). The Federal Office for Economic National Supply (FONES), which is subordinate to the Federal Department of Economic Affairs, Education and Research (EAER), is responsible for supervising the process (FONES, 2021). The supply strategy generally consists of two main phases: the preparatory phase and the intervention phase during severe shortages (FONES, 2018). In the preparatory phase, resilience is strengthened through training and collaboration with stakeholders, businesses, and industry associations to develop measures for improving resilience and interventions. According to the FONES (2018), the intervention phase comprises three stages:

1. Stage A (severe shortage less than one year): Stock releases, import promotions, and export restrictions.
2. Stage B (severe shortage up to one year): Stock releases and supply restrictions to distribute the scarce goods evenly to the population.
3. Stage C (severe shortage lasting over a year): Switch to domestic production to ensure a supply of 2,300 calories per person per day.

As the severity of the shortage situation improves, interventions are gradually withdrawn, aiming to return to normal conditions as soon as possible (FONES, 2022). Switzerland's supply policy historically transformed from state interventionism to market-driven approaches in response to changing global dynamics (FONES, 2011). During the First World War, the Swiss Federal Council slowly recognized the importance of food security and strategically intervened in the market to supply the population in crisis (Re´servesuisse, 2023). From 1929, companies were first obligated to store grain as part of the non-monopoly grain supply system, a hybrid of free-market economy and state-controlled areas (Willisegger, 2015). In 1955, the mandatory storage of these reserves was more comprehensively regulated by the Federal Act on Economic Preparedness for Wartime (FONES, 2011). 1982 the legal basis was established, allowing the state to intervene subsidiarily even in severe shortages outside of war

(Willisegger, 2015). This shift was prompted by the realization that supply threats could extend beyond wartime scenarios, as demonstrated by events such as the Suez Crisis and OPEC's actions in 1973 (Rickenbacher, 2021; SWI, 2022). This gradual transition led to the Federal Act on National Economic Supply (NESA), which expanded the scope of economic national defense (SE, 1982). Under this act, the federal government can implement state supply measures during war, power-political threats, and scarcity. On March 30, 2022, the Federal Council strengthened further supply measures in response to new requirements influenced by the energy crisis (SE, 2023). The detailed historical development of both stockpiling policies is depicted in Figure 1.

Figure 1. Historical development of stockpiling policies in Germany and Switzerland

METHODOLOGY

Case Description

We selected Germany and Switzerland as case-study countries for food emergency preparedness to further analyze the importance of pre-positioning and the connection between the public and private sectors. The approach offers a comprehensive perspective on various aspects of food security, ranging from economic significance and different governance models to internal and external collaboration.

Germany and Switzerland have established measures for national food stockpiling to prepare for potential crises. However, the approaches differ significantly. While Germany pursues a state-focused approach, Switzerland delegates significant portions of the responsibility to the private sector. Given the notable differences in the approaches of these neighboring nations, it is interesting to highlight their distinct development and strategies and present their advantages and disadvantages, along with the varying viewpoints.

Study Design

A qualitative study was conducted based on in-depth semi-structured interviews with experts in Germany and Switzerland. Expert interviews were chosen as they provide valuable perspectives from professionals specializing in food stockpiling, encompassing food security, logistics, and disaster management. The semi-structured interview method allows interviewees to freely articulate their thoughts on the subject matter, facilitating an open dialogue that can yield important insights beyond the constraints of a predefined question format.

Data Collection

A purposive sampling approach was employed to ensure the inclusion of experts actively engaged in the food supply chain. The sample criteria involved reaching out to individuals from governmental organizations and private companies with institutional and practical knowledge of emergency procedures, strategies, and agencies within the food supply chain. Initial contact was made via email or phone, introducing the research objectives and inviting

them to participate. Participants from Germany and Switzerland were explicitly addressed in the study to ensure comparability between the food emergency systems. However, finding participants proved to be highly challenging due to the sensitive nature of the topic and the limited engagement of the private sector in Germany.

In total, four interviews were conducted during July and August 2023. The selected experts are widely acknowledged for their extensive understanding of the topic within their respective countries, and their expertise is derived from their specific roles and responsibilities, as described in Table 1. The Semi-structured interviews were conducted via MS Teams, using separate interview guides for two stakeholder groups: i) Public authorities (policymakers) and ii) Private companies in the food industry (retailers and producers). The interviews, conducted in German, lasted between 60 to 90 minutes. All interviews were recorded with participant consent and transcribed verbatim for analysis.

Code	Role	Type of Organization		Country	
		Public	Private	DE	CH
DE1	Federal Agency for Agriculture and Food (BLE)	X		X	
DE2	Branch manager of several supermarkets		X	X	
CH1	Federal Office for Economic National Supply (FONES)	X			X
CH2	Head of procurement of a milling company		X		X

Table 1. Overview of expert interviews on food emergency stockpiling

Data Analysis

For thematic data analysis, we employed a qualitative content analysis approach based on Mayring and Gahleitner (2010). The statements obtained from the interviews were systematically structured into categories and coded to identify emerging themes and sub-themes. These provided valuable information about various aspects such as strategies, stakeholders, economic processes, and perceived advantages and disadvantages. To ensure the reliability of findings, different researchers coded the contents independently. After that, the results were compared and discussed until a consensus on the themes and sub-themes was achieved. This collaborative process resulted in a comprehensive coding framework that served as a basis for further interpretation and understanding of the data, as shown in Table 2.

RESULTS: COMPARATIVE ANALYSIS OF FOOD RESERVES IN GERMANY AND SWITZERLAND

Stockpiling Strategy

Germany and Switzerland adopt distinct approaches in implementing their food emergency preparedness systems, although some similarities exist. Both nations prioritize accumulating essential foods like grains due to their convenient storage and prolonged shelf life compared to processed products. Nevertheless, a direct comparison highlights that Switzerland also includes edible oils and coffee in its reserves. The duration for which the state's reserves can sustain the German population during a crisis remains to be determined as no legal supply period is specified. In contrast, stock levels in Switzerland are closely integrated into the regular economic production process and are set at three to four months. Calculations are grounded in import statistics and domestic production over a four-year cycle, automatically adapting to shifts such as immigration or population growth.

According to the expert *DE1*, Germany maintains emergency food reserves and other national reserves to reduce dependence on the food retail sector and fulfill the government's mission to supply the population during crises (DE1,

p. 20, lines 39-45). This state-centric strategy aims to strengthen the national emergency food supply, consistently maintain predetermined quantities of specific food items, and release them in crises. The reserves are allocated across several storage facilities, including the Federal Grain Reserve and the Civil Emergency Reserve, strategically positioned at confidential sites to prevent looting (DE1, p. 4, lines 16-18). The warehouses are contracted to private companies through tenders for storage and related activities, while ownership of the goods and control remains with the government (DE1, p. 20, lines 8-9). In a supply crisis, the federal states can apply for access to goods from the warehouses. The processing, transportation, and distribution of these goods are then the responsibility of the requesting federal state (DE1, p. 15, lines 1-5).

DE1 underscores that initially, the government aimed to avoid entrusting the protective role of food supply to private entities (DE1, p. 20, lines 39-44). This foundational position shifted during the 1990s with a broader reconsideration of the necessity of stockpiling and the government's role. Consequently, by 1995, private entities were operating the warehouses on behalf of the state (DE1, p. 15, lines 39-42). According to *DE1*, this shift is connected to the growing perception that stockpiling is no longer essential, a sentiment that gained momentum during that period (DE1, p. 20, lines 3-15). The overall attitude towards stockpiling has undergone multiple transformations since the conclusion of both World Wars. *DE1* emphasizes that *"there used to be a seriousness"*, backed by the organizational structure (DE1, p. 6, lines 9-10). Formerly, three departments oversaw food stockpiling, whereas today, only one remains (DE1, p. 6, lines 10-15). The peak of the contrasting attitude towards stockpiling occurred in 2016 when the Federal Minister of Agriculture contemplated the complete abolition of emergency food supply (DE1, p. 4, lines 38-44). However, according to *DE1*'s observations, the general attitude has shifted in the opposite direction in recent years. The Ukraine-Russia war has strengthened the current stance where the department overseeing stockpiling is directed to take all necessary measures to enhance supply security (DE1, p. 4, lines 42-44). This change is also emphasized by *DE2*, who deems preparatory measures crucial to mitigate the impact of unforeseen crises (DE2, p. 7, lines 6-14). Despite the significance, *DE1* contends that *"stockpiling has been overlooked in the past"* (DE1, p. 21, line 10), and the awareness of the topic is influenced by global market dynamics and worldwide crises (DE1, p. 21, lines 6-11).

In Switzerland, the State mandates the stockpiling of essential goods, imposing mandatory reserves, the so-called National Economic Supply System (NES). According to *CH1*, specific market players are legally obligated to maintain reserves for three to four months of their typical product processing or importing (CH1, p. 3, lines 42-45). Thereby, the EAER determines the duration for which these mandatory reserves must cover the average demand of the Swiss population (CH1, p. 17, lines 14-16). These mandatory reserves, integrated into companies' production sites, aim for efficient turnover during crises. Approximately 60 companies manage mandatory stocks of essential goods, such as sugar, wheat, rice, oils, fats, yeast, and coffee (CH1, p. 3, lines 45-52 & p. 6, lines 24-25).

According to *CH2*, the organization Re`servesuisse calculates mandatory stock levels for each company on behalf of the FONES based on import volumes and domestic production (CH2, p. 7, lines 39-45). A comprehensive review is conducted every four years, adjusting compulsory stock quantities for all products as needed (CH2, p. 8, lines 3-7). Notably, the stocked quantities remain private and not state-owned. In severe shortages, these stocks can be released to prevent or mitigate disruptions in the supply of essential goods (CH1, p. 14, lines 9-10). *CH2* clarifies that Switzerland's stockpiling strategy is not a response to individual planning failures of specific market participants but rather a macroeconomic assessment to identify and address market-wide crises, determining the need for stock releases (CH2, p. 5, lines 40-49).

In the early stages of the Swiss emergency food system, expert *CH1* notes that the State exclusively managed grain storage from the First World War to the 1970s and 1980s. The Swiss government collected harvested grain at designated points and oversaw its administration (CH1, p. 15, lines 21-23). A shift in the 1980s, driven by economic changes and a decline in self-sufficiency, led to increased imports and a transfer of food supply responsibility to the private sector under state supervision (CH1, p. 15, lines 31-45).

CH1 notes a significant change in Switzerland's perspective on emergency food stockpiling in recent years. Five years ago, many politicians and the population considered the provision system outdated and old-fashioned (CH1, p. 25, lines 49-52). However, the mentality changed with the outbreak of the COVID-19 pandemic in 2020:

> *"It was not necessarily the pandemic itself, but the disruptions that occurred in high-risk supply chains that led to a rethink of the need for reliable emergency food stockpiling."*
> (CH1, p. 16, lines 1-3)

This rethink was further reinforced when the Ukraine-Russia war highlighted the fragility of global supply chains. Today, the focus is no longer on abolishing emergency food preparedness but on analyzing where additional measures and resources are needed (CH1, p. 16, lines 1-13).

Regarding the historical evolution of food emergency preparedness, Germany and Switzerland initially shared common approaches but diverged significantly over time. Both nations maintained complete state control over warehouses and crisis supplies during the World Wars. In the 1980s, Switzerland shifted responsibility to the private sector due to a declining farming population and increased import dependence. Germany underwent a similar change in the 1990s, privatizing warehouses as the perceived necessity of state-controlled food storage diminished.

Today, Germany's strategy still centers mainly on the state's provision of food reserves, aligning with constitutional responsibilities for meeting basic needs. In comparison, Switzerland adopts a collaborative approach between the federal government and businesses. According to the law, companies are primarily responsible for supplying the population and must maintain mandatory stockpiles covering three to four months. The organization Re`servesuisse manages quantity calculations and stock allocations, with private companies owning warehouses and stored goods. In Germany, private companies secure storage spaces through tenders, while the state retains ownership of the stored goods. The quantities stored lack a legal foundation but are based on a 2011 decree that has yet to undergo fundamental adjustments in response to societal changes. Hence, in contrast to Switzerland, quantity requirements are determined by a range rather than a timeframe for supply.

In summary, the two countries exhibit different approaches in their current strategies, diverging from their earlier similarities. Germany emphasizes state control and provision, while Switzerland increasingly relies on collaboration with the private sector. Both nations respond to global events, demonstrating heightened awareness of the importance of food emergency preparedness.

Stakeholder

In Germany, the key public entities regarding emergency food supply are the BMEL and the BLE. According to *DE1*, the BLE is responsible for monitoring food emergency preparedness under the jurisdiction of the BMEL. This responsibility encompasses procuring and managing national crisis reserves (DE1, p. 2, lines 29-33). These reserves are maintained through contracts with private companies responsible for storage services (DE1, p. 20, lines 8-9). However, *DE2* indicates that preparatory measures do not involve private companies from the food retail sector (DE2, p. 7, line 28). During crises, the BLE facilitates the retrieval of stored goods by the federal states. Based on *DE1*, the distribution to grain or hulling mills and the population falls under the jurisdiction of the federal states. *DE1* describes the BLE's role as a facilitator and notes that during wartime, confiscations and government orders are altering the dynamics of private ownership:

> *"In principle, we open the doors and say: 'Now here [...] we have this quantity. You can come by with trucks and pick it up'. [...] At that moment, private ownership ceases to exist. Everyone must be aware of that."*
> (DE1, p. 4, line 53 & p. 9, lines 26-29)

In Switzerland, the relevant public entities are the EAER and the FONES. *CH1* states that the FONES, associated with the EAER, oversees the execution, monitoring, and potential release of mandatory reserves maintained by private companies (CH1, p. 3, lines 22-23). Consequently, according to *CH1*, the FONES assesses whether an inventory release is warranted during a shortage scenario. This assessment includes determining whether the shortage applies to the entire industry or is limited to a specific company that may have miscalculated (CH1, p. 12, lines 15-27). After that, the FONES can release 20% of stocks in the first phase (Stage A) without Federal Council consultation, enabling quick intervention to stabilize the market (CH1, p. 12, lines 28-34). If a severe and prolonged shortage necessitates releasing more than 20% of mandatory stocks, EAER approval through an ordinance is required (CH1, p. 12, lines 16-24). Therefore, as per *CH1*, the FONES collaborates closely with approximately 60 food industry experts within the private-sector cooperative Re´servesuisse to influence legislative processes for crisis response. The FONES has delegated the calculation and allocation of storage amounts in the food sector to this cooperative (CH1, p. 18, line 44 – p. 19, line 1). The members include all companies obligated to store mandatory reserves for national economic supply. On behalf of EAER, Re´servesuisse issues general import authorizations, monitors mandatory reserve stocks, and acts as an intermediary between the private sector and authorities (CH2, p. 7, line 31-43). The cooperative manages guarantee funds provided by the federal government for financing mandatory reserve storage, compensating members for storage costs, and addressing price fluctuations (CH2, p. 11, lines 41-51). Oversight of guarantee fund use and procurement falls under the responsibility of the FONES (CH1, p. 3, lines 21-23). The concept and interrelationships of the different actors in Germany and Switzerland are shown in detail in Figure 2.

In summary, Germany and Switzerland manage emergency food supply systems through key public entities with lean administrative structures. Despite prior personnel reductions, both nations are recruiting new staff, emphasizing the

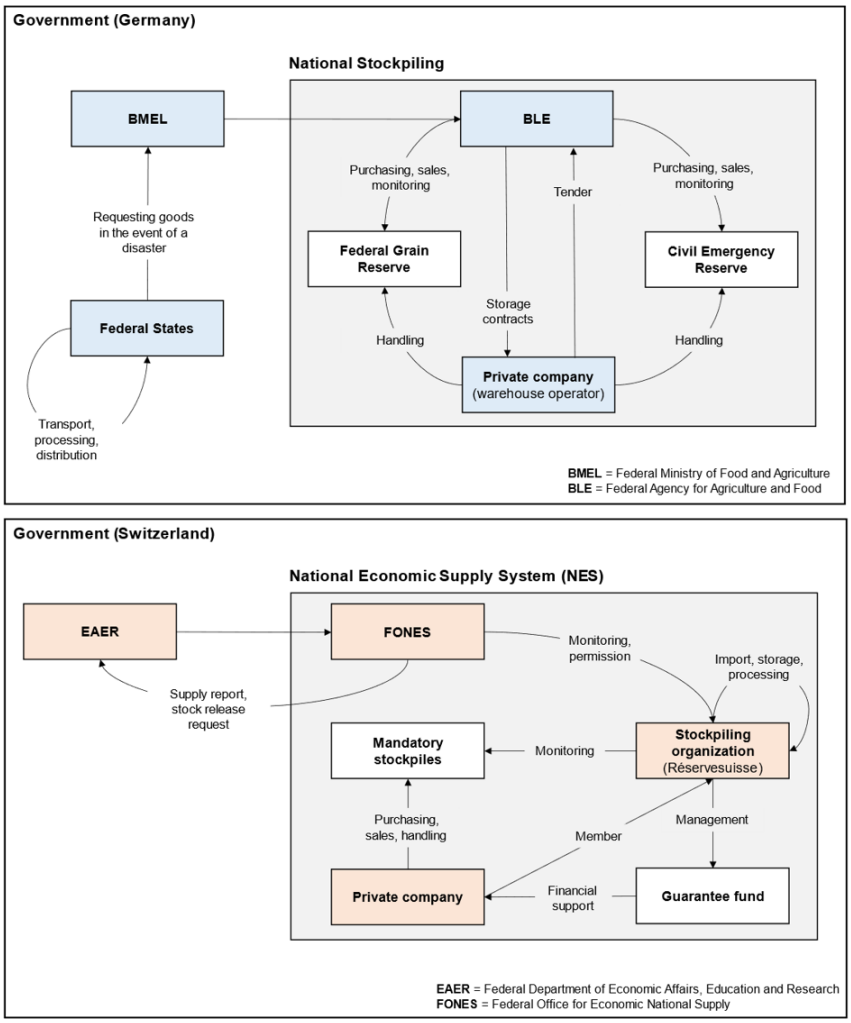

Figure 2. Organizational structure of stockpiling systems in Germany and Switzerland

increasing significance of the topic. In Germany, the BMEL and the BLE play central roles, with private companies responsible for storage services. In case of need, seizing companies' private property is also possible. There is no preventive involvement of logistics companies in this process.

On the other hand, Switzerland's EAER and FONES manage mandatory reserves maintained by private companies, mainly through the cooperative Re´servesuisse. Decisions and assessments are coordinated with representatives from the private sector, shaping mandatory storage in alignment with companies' current needs. The objective during a crisis is to maintain operations within the supply chains for as long as possible without government intervention, facilitated by the utilization of mandatory stocks.

While both countries aim to ensure a stable food supply during emergencies, the structures and mechanisms differ, reflecting the variations of governmental and private sector collaboration. Understanding these distinctions is crucial for comprehending the resilience and responsiveness of each nation's emergency food supply system.

Economic Aspects

Based on *DE1*, the federal government covers the costs of Germany's emergency food supply, focusing on crisis preparedness rather than profit generation (DE1, p. 11, lines 4-7). The storage costs, approximately =C0.33 per capita, amount to around =C27 million for Germany's population of 82 million (DE1, p. 22, lines 28-29). Funding comes from the federal budget, enabling the BLE to cover storage expenses and potential sales losses (DE1, p. 12, lines 24-26). These expenses include storing goods with private companies over an agreed period. The BLE procures and sells the stored goods in a ten-year cycle, with the expenses financed through loans (DE1, p. 10, lines 39-42).

CH1 estimates the Swiss system costs around CHF 20 million, translating to approximately CHF 6 per person per year for the country's nearly nine million inhabitants. The primary cost driver is storage expenses, including

mandatory capacities and administrative efforts, with storage costs being the exclusive expense for companies and the main factor influencing overall system costs (CH1, p. 6, lines 38-39 & p. 8, lines 35-36). As per *CH1*, only some private companies within a sector maintain mandatory stocks due to the considerable administrative burden involved. However, fair competition is ensured, as all companies must pay taxes on goods they import, and those holding compulsory stocks are reimbursed for their associated costs (CH1, p. 16, lines 13-19). *CH2* indicates that this storage method should be *"cost-neutral for mandatory reserve holders"* (CH2, p. 12, line 15). Achieving cost neutrality is crucial for encouraging companies to participate in emergency preparedness. By accessing federally guaranteed bank loans, companies can finance mandatory reserve quantities with reduced interest costs and benefit from higher tax deductions on reserve goods (CH1, p. 8, line 50 – p. 9, line 4). Moreover, *CH2* states that the funding for the system relies on robust border protection safeguarding agricultural prices. When the global market price drops below a specified threshold, customs duties are imposed at the border on imported goods, aligning the import price with the domestic price and increasing the cost of the final product. A portion of import levies, averaging CHF 40 per tonne, contributes to the guarantee fund of Re`servesuisse. This fund reimburses compulsory stockpilers for their incurred costs (CH2, p. 11, line 40- 50 & p. 12, line 6 - 7).

In economic terms, Germany and Switzerland exhibit distinct approaches to funding their emergency food supply systems. In Germany, the federal government assumes financial responsibility, allocating funds from the federal budget to cover the storage costs. A four-year budget plan is created, and the final funding amount is politically determined, influenced by global events affecting potential disposal losses. In addition, the BLE manages procurement and sales in a ten-year cycle, with expenses financed through loans. The emphasis is on crisis preparedness rather than profit generation.

In contrast, Switzerland's system costs are far surpassing Germany's costs. Storage expenses, including mandatory capacities and administrative efforts, constitute the primary cost driver. Financing involves import duties and tax benefits, focusing on cost neutrality and encouraging companies to participate in emergency preparedness. These divergent funding models reflect the unique economic strategies employed by Germany and Switzerland.

System Comparison: Perceived Benefits and Drawbacks

Germany and Switzerland implement fundamentally different approaches to ensure food supply. In Germany, the current strategy prioritizes state-supplied food within the Basic Law's framework of public welfare responsibility without specifying a definite period. In contrast, Switzerland pursues a collaborative approach between the federal government and businesses. According to the law, businesses are primarily responsible for supplying the population and maintaining mandatory stockpiles equivalent to three to four months. The two countries diverge in their current strategies, moving away from their early similarities. Recently, both countries have demonstrated an increased recognition of the significance of emergency food preparedness. Table 3 presents an overview of the comparative analysis of both systems regarding their perceived benefits and drawbacks.

The food emergency system in Germany features a robust infrastructure, ensuring affordable storage quantities to safeguard food security in disaster scenarios supported by transparent legal regulations and a streamlined administrative process. Furthermore, the system clearly defines applicability and decision-making authority while keeping storage locations confidential to mitigate the risk of looting or unfair distribution. The control over the strategy lies with the state, providing centralized oversight. In the view of *DE1*, the food reserves function as insurance for events like the COVID-19 pandemic or an event such as the Ukraine-Russia war, underscoring the rapid emergence of crises with unpredictable magnitudes (DE1, p. 22, line 14-31).

However, Germany's system has challenges. A significant drawback lies in the lack of regular adjustments and the detachment from market dynamics, unlike Switzerland, where quantities are adjusted every four years. *DE1* clarifies that in Germany, there are no regular adjustments in this regard.

> *"The most recent development in 2011 involved receiving a directive from the ministry specifying the quantities to be maintained in the reserves. This directive serves as our basis, and we must implement it annually."*
> (DE1, p. 4, lines 1-13)

Moreover, the reserves are only activated when the market ceases to function. This strategy renders using reserves for market support impractical and may complicate processing and distribution. In addition, the restricted involvement of the private sector and the minimal collaboration with other stakeholders raise questions about the effectiveness of distributing goods in an emergency and the timely availability of adequate human and transport resources. From the perspective of *DE1*, the issue arising from this system is that the BLE can *"only ever draw on the capacities that the*

Country	Category	Benefits	Drawbacks
Germany	Strategy	Food security for crises Low administrative effort Regulation of fair allocation	Lack of regular adjustments Application only in case of market failure Requirement of additional crisis processes Away from the market
	Stakeholder	Control lies with the state Clear responsibilities	Limited private sector collaboration Potential shortage of resources Federalism requires extensive coordination
	Economic	Warehousing at low cost	Strong dependence on state budget Risk of sales losses and quality problems Resource acquisition through confiscations
Switzerland	Strategy	Food security for crises Integration into the supply chain High product variety	High administrative effort Risk of looting and unequal distribution
	Stakeholder	Close collaboration Market participants offer expertise Market situation is known	Moral Hazard
	Economic	Market is protected from collapse Compensation for private sector	Strict controls and sanctions required High costs Entrepreneurial risk and competitive disadvantage

Table 3. Overview of perceived benefits and drawbacks

private sector offers" (DE1, p. 16, lines 41-42). The BLE is solely responsible for facilitating transport to potential production sites, while the actual distribution to the population falls under the jurisdiction of the federal states. In Germany, this decentralized approach presents a significant issue, as federal state jurisdiction hinders direct federal government intervention in state matters. As *DE1* points out, this federalism results in a substantial coordination requirement, which has been historically underestimated and exists only to a partial extent (DE1, p. 21, lines 41-45). Furthermore, *DE2* highlights the significance of a clearly outlined plan for distributing relief items during crises, noting that this information has yet to be communicated to the private sector. The approach entails predetermined contact points, defined responsibilities, and efficient coordination to ensure swift assistance, prioritizing essential food items and hygiene products (DE2, p. 8, lines 20-43). Aside from coordination issues, there is also the matter of whether the state possesses the necessary resources compared to private companies for efficiently managing goods and maintaining quality. While Germany benefits from low-cost warehousing, it faces challenges due to a strong dependence on the state budget and potential sales losses.

On the other hand, Switzerland adopted a decentralized approach to its food emergency system by integrating the stockpiles into the regular supply chain and offering a high product variety. It collaborates with federal and private stakeholders, allowing tailored responses to regional and unique nutrition needs like gluten intolerance. Furthermore, the close collaboration and coordination among stakeholders provide benefits, including transparency, market knowledge, logistical resources, and consideration of the interests of all stakeholders.

CH1 claims that a significant advantage lies in the strategic placement of stocks directly within the producing companies along the value chain rather than in remote locations:

> *"The warehouses are seamlessly integrated into regular production processes, not tucked away in a corner. This integration eliminates issues related to handling, such as spoilage. [...] The benefit of this approach is that all mandatory stockpiles are seamlessly integrated into the established channels. In the event of a shortage, for instance, if a particular type of bread is unavailable, the producer with compulsory stock can source from there and continue production. This process ensures that everything flows through the regular channels without needing modifications, which is a significant advantage."* (CH1, p. 4, lines 36-43 & p. 13, lines 45-51)

Consequently, questions regarding delivery destinations, responsible entities, and processing of goods become irrelevant, as the stocks are conveniently located within the companies engaged in activities like grain milling. *CH2* reinforces this claim by stating that market participants, in his perspective, clearly understand the demand for a product, including where, when, and in what quantity it is required. Moreover, they ensure delivery by established quality standards (CH2, p. 13, lines 21-25). In his view, the federal government faces the potential challenge of

accurately assessing market dynamics. It is possible to be right next to the market and not recognize it, which *CH2* identifies as the most significant risk associated with insufficient collaboration with the private sector (CH2, p. 13, lines 26-33). Furthermore, timely intervention can prevent a complete collapse and, according to *CH1*, also deter panic buying (CH1, p. 12, lines 16-20).

Nonetheless, Switzerland faces some drawbacks. The cost and administrative effort of maintaining strategic food stockpiles can be substantial, and the private nature of its system may lead to challenges like the risk of looting and unequal distribution. Moreover, while product diversity brings advantages, it also results in elevated administrative efforts and, consequently, higher expenses. As stated by *CH1*, the past was characterized by simplicity, with only a few grain variations available. However, numerous other varieties exist today, necessitating multiple silos to store each variety separately (CH1, p. 7, lines 34-52). Additionally, there is a moral hazard for companies to refrain from maintaining extra safety stocks, relying on the government to release reserves in times of scarcity. In this regard, *CH1* states that:

> *"Certain companies may have optimization considerations, questioning the need to maintain an additional month of free stock for their company. Some may argue that one week is sufficient, relying on compulsory stocks in case of emergencies. Evaluating the pain threshold in each case becomes a somewhat challenging task."*
> (CH1, p. 9, lines 46-51)

Thus, strict controls are crucial to prevent unauthorized stock releases during shortages. In 2018, as per *CH2*, his company faced a situation where low water levels on the Rhine prevented them from sourcing additional goods. Meanwhile, another company possessed sizable inventory reserves, leading the federal office to categorize it as non-crisis and refrain from releasing emergency stockpiles:

> *"We faced challenges in the past, especially when the Rhine nearly dried up, causing a prolonged halt in transportation for weeks or even months. The logistics chain was severely disrupted, and we still did not get the go-ahead because other players had larger stocks. Authorities must also establish clear criteria to determine when an economic crisis has occurred."*
> (CH2, p. 8 & 9, lines 50-52, 1-27)

According to *CH2*, the regulation lacks clarity in such cases. The Swiss system, while safeguarding the market against collapse and providing compensation to the private sector, introduces a competitive disadvantage for domestic processing. This issue arises because warehousing costs are passed on to consumers through product pricing, whereas imported goods are subjected to import levies (CH2, p. 8, lines 35-50).

DISCUSSION AND CONCLUSION

In conclusion, examining food emergency preparedness in Germany and Switzerland has highlighted significant distinctions in incorporating public and private actors, particularly concerning their stockpiling strategy, structural frameworks, stakeholder engagement, and economic approach. Germany emphasizes centralized control by the state and cost efficiency, while Switzerland focuses on collaboration and integration into the supply chain. The simplicity of Germany's approach contrasts with Switzerland's more complex and interconnected strategy involving various stakeholders. The strengths and weaknesses underscore the ongoing challenge of balancing efficiency, coordination, and adaptability in disaster management and preparedness.

Germany's system demonstrates a robust infrastructure with low administrative effort and costs. However, it raises the concern of whether ample resources and production capacity would be accessible for efficient processing and distribution during a crisis. On the contrary, Switzerland follows a decentralized approach that promotes adaptability but carries the risk of economic challenges and ambiguity regarding responsibilities. The ability to ensure equitable distribution of goods during a crisis remains to be determined.

In this comparative study, our exploration of Germany and Switzerland's diverse approaches to stockpiling critical goods and engaging with public and private stakeholders reveals valuable lessons for enhancing emergency food preparedness and addressing crisis-related challenges. While the private sector plays a crucial role in Switzerland, the interview with *DE2* sheds light on the opportunities for increased communication and awareness within the private sector in Germany. There is a clear interest in greater private sector involvement with well-defined guidelines and recognizing the benefits of integrating stored goods into the supply chain. However, *DE1* maintains that increased private sector involvement is not essential, emphasizing the state's primary role.

In Switzerland, both stakeholders are satisfied with their system but express minor requests for adjustments. These adjustments include more precise regulations during crises, fair compensation for warehouse keepers in light of rising costs, and a general preference for reduced administrative effort. Furthermore, during the interviews, when asking the experts about their "ideal vision" for food emergency preparedness, a unanimous emphasis was placed on the importance of stockpiling and maintaining national reserves. The statements highlighted the significance of close collaboration and underscored the necessity for increased investments in the underlying system and preparedness efforts. Notably, authorities in Germany and Switzerland advocate for expanding stored quantities and preparedness investments, with Switzerland proposing an extension of the potential supply period from four to six months. Furthermore, expert *CH1* suggested a hybrid approach that combines elements of both strategies, involving the private sector to use existing infrastructures and knowledge while having the government handle financing to address potential economic inequalities.

Nevertheless, it is essential to recognize the study's limitations. Most data is available in German, which could restrict the depth of our exploration. The study's scope, encompassing four interviews, might only partially capture the diverse spectrum of perspectives in both countries. Furthermore, Switzerland, less populated and smaller than Germany, operates with a unique system. Therefore, the transferability of structural elements, particularly legal aspects, might pose a challenge and necessitate further consideration in future analyses.

In addition, given the complex interconnections of critical sectors supporting food storage and supply, it is essential to consider specific crisis scenarios with greater depth, enabling the thorough identification of challenges and actionable strategies to enhance crisis management. For instance, a blackout scenario significantly affects various processes within the food supply chain, ranging from production to distribution and consumption. In Germany, logistical challenges may arise in extracting and distributing goods from storage facilities. Moreover, disruptions could occur in processing the goods at mills, bakeries, and communal facilities. Similarly, in Switzerland, it is necessary to assess how local supply chains and companies would navigate such a scenario and whether critical crisis resources like power generators are available to uphold production. Conversely, in the context of a pandemic, it is crucial to prioritize the mitigation of personnel shortages due to illness and implement suitable operational measures. Furthermore, diseases that affect digestion may influence the suitability of stored food. In other crisis scenarios like large-scale floods or earthquakes, decision-makers should focus on infrastructure functionality instead, considering potential blockages or destruction of roads and warehouses.

These diverse contexts underscore the imperative need for further detailed examination of the impact of different crisis scenarios on the systems and their performance. Moreover, investigating the integration of technology solutions or information systems for resource monitoring, enhancing communication, and fostering collaboration among various stakeholders present valuable approaches to mitigate risks and strengthen the resilience of food supply chains. Therefore, our study serves as a basis for future research and emphasizes the value of examining diverse strategic approaches and technologies in national food emergency preparedness.

ABSTRACT

Fire fighters operate in a dangerous, dynamic, and complex environment. Artificial Intelligence (AI) systems can contribute to improve fire fighters' situation awareness and decision-making. However, the introduction of AI systems needs to be done responsibly, taking (human) values into account, especially as the situation in which fire fighters operate is uncertain and decisions have a big impact. In this research, we investigate values that are affected by the introduction of AI systems for fire services by conducting several semi-structured focus group sessions with (operational) fire service personnel. The focus group outcomes are qualitatively analyzed and key values are identified and discussed. This research is a first step in an iterative process towards a generic framework of ethical aspects for the introduction of AI systems in first response, which will give insight into the relevant ethical aspects to take into account when developing AI systems for first responders.

Keywords

Values, Fire services, Value sensitive design, Responsible AI.

INTRODUCTION

First responders (FRs) operate in a dangerous, dynamic, and complex environment, in which they have to quickly understand the situation and how to mitigate danger, while keeping themselves and civilians safe. To improve effectiveness and safety, FR needs and corresponding capability gaps were identified by the International Forum to Advance First Responder Innovations (IFAFRI), e.g., the ability to create actionable intelligence based on data and information from multiple sources (Capability Gap 9) and the ability to conduct on-scene operations remotely without endangering responders (Capability Gap 7) (IFAFRI, 2019). Technology could enhance the safety, effectiveness, and efficiency of FRs and help closing these capability gaps.

One of the technologies which has a high potential for contributing to filling these capability gaps is artificial intelligence (AI). AI systems can play an important role in the future to, for example, improve shared situation awareness (e.g., (Mioch et al., 2021)) and contribute to advanced decision-making (Radianti et al., 2019). This leaves FR organizations with the challenge of integrating these AI systems in the decision-making processes in a responsible way by addressing (public) values and public function properly. In our view, AI systems in this domain are always part of a hybrid human-AI system, a socio-technical system, in which task allocation and task responsibility might change and new human-AI dependencies arise. This introduces the research challenge of developing hybrid human-AI systems in which AI technology and humans cooperate in a way that synergy is created (Akata et al., 2020; Seeber et al., 2020). In such a hybrid intelligence system, complex goals can be accomplished by combining

*corresponding author

humans and AI technology that collectively work on shared objectives with complementary capabilities that, when combined, augment each other (Dellermann et al., 2019).

The development and application of these hybrid human-AI systems need to be done responsibly (AI HLEG, 2018), e.g., regarding possible biases in (training) data sets and privacy aspects (e.g., (personal) data on FRs such as location, performance, stress). For some domains, the ethical aspects of AI systems and applications have received a lot of attention, e.g., the health domain (Blasimme & Vayena, 2020; Morley et al., 2020; Murphy et al., 2021) and the military domain (Galliott & Scholz, 2020; Wasilow & Thorpe, 2019). However, in the field of FR, it seems that ethics with regard to the application of AI has not yet been much addressed. To develop and apply AI systems responsibly, it is important that the AI systems support the stakeholders' values and that values of different relevant stakeholders are taken into account. The context in which an AI system is applied and choices in the (technical) development of the AI system determine the relevance and importance of the different values. In previous work in the FR domain, key ethical concerns have been identified for Search and Rescue robots to support development and deployment in a responsible way (e.g., see Harbers et al. (2017) for empirical research and Battistuzzi et al. (2021) for a scoping review). Following on this work, in this paper, we provide a qualitative empirical investigation of relevant values of relevant stakeholders of AI systems for fire services. This is a first step towards a generic framework of ethical aspects for AI in FR, which will give insight into the relevant ethical aspects to take into account when developing AI systems for FR. Subsequent steps for setting up the generic framework are differentiating between general values and instances of these values in specific use cases to take the specific context into account and linking and updating the framework with societal developments regarding ethical aspects such as norms and guidelines.

This research is inspired by the Value Sensitive Design (VSD) methodology, which accounts for human values throughout the design process (Friedman & Hendry, 2019). First, we identify relevant direct and indirect stakeholders of fire services. Second, we investigate relevant values of these stakeholders regarding the application of AI systems. To do this, we conducted three focus group sessions with fire service personnel in which we assess and analyze the stakeholders and their values. Using the focus group session results, we identify a first set of key values to take into account in the application of AI systems for fire services.

In the following, we first give background on ethical themes for AI systems and on values and value-sensitive design. We then describe the setup and execution of our focus group sessions and the results of these sessions, followed by the conclusion and discussion of the results.

BACKGROUND

In the last few years, a lot of attention has gone towards the responsible development of AI, amongst others by the EU High-level expert group on AI (AI HLEG, 2018)) and IEEE (IEEE, 2021). The AI HLEG was appointed to advise on a European AI strategy and identified key requirements, which each AI technology needs to fulfil before it is considered safe and trustworthy (AI HLEG, 2018). According to these guidelines, trustworthy AI systems should be lawful (i.e., respecting all applicable laws and regulations), ethical (i.e., respecting ethical principles and values), and robust (i.e., both from a technical perspective while taking into account its social environment). Four ethical principles are identified that AI systems should adhere to, namely respect for human autonomy, prevention of harm, fairness, explicability, and 7 key requirements, i.e., human agency and oversight, technical robustness and safety, privacy and data governance, transparency, diversity, non-discrimination and fairness, societal and environmental wellbeing, and accountability. These requirements are explicitly non-exhaustive. When applying these guidelines to specific AI applications, the ethical principles need to (1) be situated and considered in context to determine their relevance and supplement them with possible additional ethical requirements and (2) be translated into design requirements for the specific application and context. The AI HLEG does not give guidelines on how to do this and they have not been applied structurally to the FR domain.

Technology is not neutral but always manifests values (van de Poel, 2015). Values refer to what a person or group of people considers important in life (Friedman et al., 2013). Schwartz (2012) identified 10 basic universal values, i.e., power, achievement, hedonism, stimulation, self-direction, universalism, benevolence, tradition, conformity, and security. Some of these values conflict with each other (e.g., benevolence and power), whereas some are compatible with each other (e.g., conformity and security). A possible approach to support taking values into account in technology design is Value sensitive design (VSD). VSD is "a theoretically grounded approach to the design of technology that accounts for human values in a principled and comprehensive manner throughout the design process" (Friedman et al., 2013, p. 56). Values that are considered particularly important for technological design are Welfare, Ownership and Property, Privacy, Freedom from Bias, Universal Usability, Trust, Autonomy, Informed Consent, Accountability, Courtesy, Identity, Calmness and Environmental Sustainability. As we are

investigating values affected by AI systems for fire services and not general human values of stakeholders within the fire services, we use Friedman et al.'s account of values as a starting point in our investigation.

VSD is an iterative methodology that integrates three perspectives, namely conceptual, empirical, and technical investigations. These investigations are executed iteratively, though not necessarily in a set order. VSD contains a rich collection of different methods that help designers to investigate values in technology, such as direct and indirect stakeholder analysis and value scenarios (Friedman et al., 2017), and is thus particularly useful for our research. To be able to determine human values that should be taken into account, VSD asks system designers to establish a robust set of stakeholder groups and to justify those who likely are most strongly affected – that is, to provide an conceptual or empirical rationale for their inclusion in the design process. The same holds for values; the applicability and relevance of values should be investigated from the three different perspectives. In this research, we focus on one of VSD's perspectives, namely empirical investigation, by qualitatively identifying a set of stakeholders to include and key values to take into account when developing AI for fire services. In later steps, we will iteratively extend, refine, and test the results, also from a conceptual and technical perspective.

A tool that can help with creating an overview of the potential positive and negative impact of AI systems is the *Ethical matrix* (Mepham et al., 2003). The Ethical matrix is a conceptual tool designed to help decision makers deliberate about the ethical acceptability of existing or envisioned technology. It makes the impact of design choices on the different stakeholders explicit and provides structure and support in the design process. The cells of the matrix contain the impact, negative or positive, of the envisioned technology, on each of the stakeholder groups for specific ethical values.

METHOD

To determine relevant values for fire services regarding the application of AI, we conducted semi-structured interviews during focus group sessions with different subject-matter experts from the fire services. The goal of the focus group sessions was exploratory, to gain as much information as possible on expected impact of AI systems for fire services, and the results were qualitatively analysed.

The first focus group was conducted as an exploratory session with three incident commanders that are involved in innovation projects. The goal was twofold, first, to start exploring relevant stakeholders and expected impact of AI systems on these stakeholders, second, to test and evaluate the focus group setup. Two other focus group sessions with each 4 participants were conducted with fire fighters (carrying out day-to-day firefighting and fire safety work; 3 participants), dispatchers (managing emergency calls, ensuring that proper response teams are sent to the incident location; 2 participants), incident commanders (in charge of an incident; 2 participants), and an HR professional (1 participant). All participants (besides the HR professional) had experience in the field, ranging from limited experience (1-3 years experience) to very experienced (15+ years of experience). The focus group sessions lasted 2 hours.

The first, exploratory, focus group session consisted of several steps. To identify as many stakeholders as possible, the participants were asked to list all people that interact with an envisioned AI system (presented in a general scenario) and people that are affected by the system or who have a vested interest in its success or failure. To not have any influence effects on the process, the experts were asked to do this by themselves. After 5 minutes, the results were shared and discussed. Based on the combined list of stakeholders, a prioritization of stakeholders was made. After having selected the most relevant stakeholder, the participants determined which positive or negative impact of AI systems they could identify for these stakeholders. The participants went through the stakeholders (by themselves) and wrote identified impact on post-its. The results were plenary shared and discussed; as every participant shared their identified impact, participation of each of them was ensured. Additional impact was added during the discussion. After the focus group session, the identified (positive and negative) impact was analyzed regarding (possible) underlying values by a human-AI collaboration expert, mapped on an ethical matrix (van der Stappen & Steenbergen, 2020) and presented to the participants for validation. The discussion of this first version of the ethical matrix led to additional input regarding impact for stakeholders.

The other two focus group sessions consisted of the same steps as the first exploratory focus group, with slight adaptations, based on lessons-learned of the first focus group session: we realized that (1) a general knowledge of the working of AI systems is needed to identify impact of the systems and (2) example scenarios support the identification of impact. The participants of the first focus group were all involved in (AI) innovation projects and familiar with the possibilities of AI technology; for the other two focus groups, this was not the case. For that reason, we added a short overview over AI technology, its working, possibilities, and limitations. Also, two concrete scenarios (inspired by examples mentioned during the exploratory focus group session) were introduced as basis for the discussion on positive and negative impact of AI systems. These (descriptive) scenarios highlighted value

Table 1. Scenarios used during the second and third focus group.

	Scenario 1	*Scenario 2*
Situation	Large fire in storage tank; Fire brigade team is exploring the situation. Fire fighters wear sensors.	Tank truck with hazardous material collides with a tree within city limits. Hazardous substances spill.
Data	Measurement of physical properties of firefighters such as stress level, position, body temperature, presence of dangerous gases, body cam.	Video data from road cameras is processed automatically. Data from past incidents is available.
AI technology (first scenario version)	An AI system processes the data in real-time and combines the various data sources; it provides information to the incident commander about the current status of the firefighters in the field, monitors the situation and stress, and warns the incident commander in case of conspicuous things, e.g., if fire fighters come too close to a danger zone.	An AI system reports the incident to the dispatcher; it recognizes hazardous substances through ADR sign recognition and passes on this information. It also predicts the development of the situation based on similar incidents in the past and recommends to the dispatcher which resources should be sent. The dispatcher forwards reports and information to the fire house.
AI technology (second scenario version, extended autonomy of AI system)	Continuously monitors and predicts the (stress) status of the firefighters, also by means of stress-related data from the past. System advises the incident commander on employability (short-term and long-term)	The AI system reports the incident to the dispatcher, assesses who needs to be called, and puts the call through to the responsible fire house. It recognizes hazardous substances through ADR sign recognition and also passes on this information. It predicts situation development based on similar incidents in the past and forwards call for appropriate resources. The dispatcher monitors the report.

tensions. We described our scenarios as 'what if' scenarios, scenarios that are situated just a few years into the future and inviting the participants to assess ethical issues posed in the scenario (Wright et al., 2014), see Table 1. Each scenario consisted of two versions, with the second version extending the AI's autonomy to increase (possible) ethical issues.

The identified impact of AI systems was analyzed through thematic analysis and mapped onto affected underlying values. We coded inductively as a way to enter the data analysis with a more complete, unbiased look at the themes throughout the data. We categorized the resulting 28 codes into 13 themes, which will be described in the next section.

RESULTS

In this section, we describe the results of the focus group sessions. First, an overview is given of the most important stakeholder groups that were identified by the participants, together with the human values (as identified by Friedman et al. (2013) that are affected by the identified impact. Subsequently, the identified impact on the human values is described in more detail and in context of fire services, followed by other, more AI-related values that participants mentioned regarding the introduction of AI systems for fire services.

Stakeholders and Values

During the focus groups, participants identified the following stakeholders as most relevant to take into account during the introduction of AI systems: fire fighters, incident commanders, special operations fire fighters (e.g., for hazardous materials and digital exploration), dispatchers, company doctors, incident researchers, citizens, and the surroundings. For these stakeholders, the participants identified possible positive and negative impact of AI applications. Most impact was identified for three stakeholder groups, namely fire fighters, incident commanders, and dispatchers. This is not surprising, as the scenarios involved these stakeholder groups explicitly, and these stakeholder groups were (mostly) represented by the participants during the focus groups. Table 2 provides an overview of the (most relevant) stakeholders as identified during the focus group sessions together with the human values (as specified by Friedman et al. (2013)) which the identified impact affects.

Table 2. Most relevant stakeholders as identified during the focus group sessions and values (as specified by Friedman et al. (2013)) that the identified impact affects.

Stakeholders	*Values*
Incident commanders	Autonomy, identity, physical well-being
Fire fighters	Autonomy, identity, informed consent, privacy, physical well-being, psychological well-being, trust
Dispatchers	Autonomy, identity, privacy, physical well-being, psychological well-being
Citizens	Privacy, physical well-being, psychological well-being, trust
Surroundings	Physical well-being
Special operations fire fighters	Physical well-being
Incident researchers	Physical well-being
Company doctors	Physical well-being, psychological well-being

Human values

In this section, we describe in more detail which impact participants mentioned and the different human values that are implicated, based on the human values as described and identified by Friedman et al. (2013). For an overview of the impact mapped on stakeholders and affected human values, see Figure 1.

Autonomy Autonomy refers to people's ability to decide, plan, and act in ways that they believe will help them to achieve their goals (Friedman et al., 2013). Regarding autonomy, in general, participants were concerned over their dependence on technology. If FRs become too dependent on the technology, their ability to operate will be substantially impaired when systems fail. In addition, a concern is staying in control of decisions.

Regarding dispatchers, three aspects were mentioned. AI might become more and more autonomous and take over several tasks of the dispatcher. This could (1) lead to less autonomy in their task execution, and (2) impact the decision-making power of the dispatcher, and (3) disproportional trust of the results or advise of AI systems, with dispatchers reflecting less on the situation and thus operating less autonomously.

Regarding fire fighters, it is expected that AI systems lead to new needs regarding capabilities and knowledge. This might (negatively) impact their ability to act and make decisions in their operations. Furthermore, AI systems will also have impact on their task decision-making power, depending on the level of autonomy of AI systems regarding decision-making. In addition, because possible access to historic data, AI systems can give advise on (long- and short-term) employability, which might impact fire fighters' control about own employability, with possibly others deciding on their performance and health. Participants are concerned that there will be less space to make decisions based on own insights, and that human aspects, context, and experience will be less taken into account when making decisions.

For incident commanders, participants mention that AI could lead to the feeling of not being in control of own decisions anymore. Participants were also worried regarding the influence of AI advise on the decisions of incident commanders. Also, they mentioned that the human aspects remain very relevant in decision-making; for example, optimal teams based on some objective measure are not always the best, as other goals of teams should be taken into account, such as that people can learn and grow.

No positive impact of AI systems on autonomy was mentioned.

Identity Identity refers to people's understanding of who they are over time, embracing both continuity and discontinuity over time (Friedman et al., 2013). Participants mentioned that AI systems will have impact on the capabilities, knowledge, and possibly level of education that is needed for the job (of incident commanders, fire fighters as well as dispatchers). For example, AI systems might become more and more autonomous and might take over decisions that at the moment are taken by dispatchers. The participants saw this as a threat for their understanding of their work. For fire fighters and incident commanders, participants also mentioned that a culture change is needed, as AI gives completely new possibilities, which means that operations will need to change (e.g., regarding gaining situation awareness first remotely by means of autonomous UGVs and UAVs, instead of through human operation). In addition, participants expect that new (commander) roles will be created, e.g., a role as specialist digital exploration.

	Autonomy	Identity	Informed consent	Privacy	Physical well-being	Psychological well-being	Trust
Incident commander	- Dependence on AI - Decision-making - Human aspects	- Culture change is needed			+ Can monitor safety of team + Better long-term employability + Safer incident response		
Fire fighter	- Ability to make decisions - Control on employability - Human aspects and experience - Dependence on AI	- Needed capabilities, knowledge, and level of education will change - Culture change is needed	- Unforeseen use of data	- Unforeseen use of data - Who has access to data? - Feeling of being closely monitored	+ Better insight in own health status + Less stress + Better health + Better long-term employability + Safer incident response - (Felt) unpredictability of UGVs - Physical impairment	+ Less stress - Less social environment	- Feeling of being closely monitored
Dispatcher	- Task execution - Decision making - Reflection	- Needed capabilities, knowledge, and level of education will change - Threat for work		- More access to sensitive data	+ Better insight in own health status + Safer incident response through faster alarming	+ Less PTSD + Less stress	
Citizen				- Personal data	+ More safety through better recognition of environmental effects	- Less personal contact	- Feeling of being monitored
Surroundings					+ More safety through better recognition of environmental effects		
Special ops					+ More safety through better insight in presence dangerous substances		
Incident researcher					+ More safety through better insight and analysis on prevention		
Company doctor					+ Better overview of health status + Better early detection	+ Better overview of stress and trauma	

Figure 1. Ethical matrix. Red cells denote negative impact on the corresponding value, green cells positive impact, and yellow cells positive as well as negative impact.

Informed consent Informed consent refers to "garnering people's agreement, encompassing criteria of disclosure and comprehension (for 'informed') and voluntariness, competence, and agreement (for 'consent')" (Friedman et al., 2013). The participants mentioned that the introduction of AI systems could have impact on informed consent. It might not be clear what exactly is being done with (personal) data that is collected of fire fighters and that, when available, this data could be used for purposes that were not foreseen. The participants mentioned that a possible solution is the introduction of personal data safes which are not generally accessible and that people can determine in which situations these data safes are accessible and to whom (e.g., in life-critical situations to their incident commanders).

Privacy Privacy refers to a "claim, an entitlement, or a right of an individual to determine what information about himself or herself can be communicated to others" (Friedman et al., 2013). Impact on privacy was mentioned for fire fighter, dispatchers as well as citizens. For fire fighters, impact on privacy is seen mostly regarding two aspects, i.e., that of proportionality and of surveillance. First, when collecting and analyzing (personal) data, it is not always clear what the goal is of doing so and what the data is actually used for. There must be clear agreements on what AI systems do with the data and who has access to it (and to the results of a possible analysis). In addition, participants mentioned that fire fighters in general resist having their data collected, as it gives them the feeling of being closely monitored.

Dispatchers will need to take privacy (even more) into account. They will have more access to, for example, cameras on roads during incidents, and can directly watch the situation to support their situation awareness. Also, they are in direct contact with other first response organizations, such as police, that have access (and share) information during incidents.

Regarding citizens, participants mentioned that with the introduction of AI systems, care needs to be taken with personal information of citizens, such as video pictures and gps data.

Physical well-being Physical well-being falls under the value *Welfare* as identified by Friedman et al. (2013); in this context, we understand it as physical health and safety. For all identified stakeholders, participants mentioned that AI systems could impact the value *physical well-being*. AI systems could have a positive impact on the physical safety and well-being of incident commanders, fire fighters, citizens, and the surroundings as it could lead to a better situation awareness because of additional relevant information (on the incident and on personnel). This information leads to a more effective task performance through faster, earlier, more stable, and more informed decision-making of all professional stakeholders. For fire fighters, dispatchers, and incident commanders, having more information on one's own situation and being able to monitor and analyse one's physical status (e.g., regarding stress) and

acting on the status could make the job healthier and lead to better long-term employability. This holds also for the company doctor, in addition to possible early detection of (work-related) illness. For special ops and incident researchers, AI systems might lead to better insight and analysis of dangerous effects or situations, which in turn might lead to a safer incident response for all stakeholders. Also, deploying drones increases the feeling of safety.

However, physical well-being could also be impacted negatively. For fire fighters, carrying sensors or AI systems might impair movement and mobility, leading to less safe performance. In addition, being with UGVs in the same environment can increase a feeling of unsafety.

Psychological well-being Psychological well-being also falls under the value *Welfare* as identified by Friedman et al. (2013). According to the participants, for dispatchers as well as for fire fighters, AI systems can lead to improved psychological well-being. The participants mentioned that stress and PTSD (for dispatchers) could occur less because of more effective operations and because of being able to monitor one's (stress) situation.

As possible negative impacts, participants mentioned that the fire service organisation is a very social environment. A concern is that this will change with the introduction of AI systems, as human aspects might become less important, which might lead to less (psychological) well-being of fire fighters. In addition, AI systems might lead to less contact between citizens and dispatchers (due to for example automatic alarming); however, personal contact is important for citizens, to be heard and supported in a stressful situation.

Trust Trust refers to expectations that exist between people who can experience good will, extend good will toward others, feel vulnerable, and experience betrayal (Friedman et al., 2013). The human value trust is mentioned by participants to be impacted by AI for two stakeholder groups, namely fire fighters and citizens, with respect to trust in the first response organization.

For fire fighters, to effectively use AI, more data will be collected, also from fire fighters. Participants mentioned that fire fighters generally distrust the collection of (personal) data and feel closely monitored. They worry that the data is used against them (e.g., proving that a performance is not up to par). In addition, no context is present in the data, which is important to explain, for example, deviation from protocol. For citizens, trust in first response can be decreased for the same reasons. For example, the position of emergency callers is available for dispatchers, as well as of other people at the incident location. Monitoring and following these citizens (through AI systems) might enable a more effective operation; however, it could decrease trust in first response organisations due to a feeling of being monitored.

AI-related values

The participants of the focus group sessions mentioned several other values regarding the introduction of AI for fire services that are not part of the human values that are often implicated by ICT systems as identified and described by Friedman et al. (2013). This is not surprising, as Friedman's list of values relates to ICT systems in general and not AI systems in particular. The other values mentioned are *Accountability*, *Reliability*, *Trust in AI systems*, *Security*, *Transparency*, and *Appropriate training*. These values were mentioned in the context of what AI systems should adhere to, or how AI systems should function and were mostly mentioned independent of stakeholders, but as general aspects that should be taken into account during the design, development, and deployment of AI.

Accountability Accountability is seen in the context of liability (legal responsibility) as well as social responsibility. Participants are concerned that the legal responsibility is not clearly specified; aspects as liability when (wrong) decisions are taken (by the AI system as well as by the FR when being advised differently by an AI system) need to be taken into account when introducing AI systems. Also, for FRs, it is very important to be accountable for the decisions taken during operations, e.g., to be able to explain decisions after the operation. This also needs to be the case when AI systems are integrated into the operation.

Reliability Participants mentioned that it is important that AI systems are reliable, both in the results they present (e.g., in all situations, they should present working results) as well as in availability of the systems (e.g., they should not fail in high-stress or dangerous situations). This corresponds to the key requirement *Technical robustness and safety* of the HLEG (AI HLEG, 2018).

Trust in AI systems Participants mentioned that (appropriate) trust in AI systems is important. Topics that were mentioned regarding trust in AI systems were (1) understanding of system as the basis for trust, (2) *appropriate* trust, (3) dependence on systems. Regarding understanding of the system, participants mentioned that it is important to understand what the system is doing (e.g., predicting the next actions of a UGV), how the AI got to a result or advise, and how certain the advise is. Regarding appropriate trust, participants said that there is a danger of too much trust (e.g., being influenced in decision-making too much, not evaluating and reflecting enough on the advise of the AI) or of too little trust (and not taking the advise of the AI sufficiently into account). Participants were also concerned that if the AI system has some kind of autonomy (e.g., when recognizing incidents and sending relevant information about the incident when alarming first response), the FRs have no choice other than to trust the system, and thus depend on the system, as there is no time to validate all information before acting.

The participants also stressed that an incremental introduction of AI is necessary to learn about the capabilities of the AI system and how to integrate it into work processes and build up trust. This also is important because often, AI systems in practise do not work as well as in theory, which leads to distrust and less support.

Security Regarding security, participants mentioned that it is very important that data is kept at a secure place and that access control is in place. Misuse of data needs to be avoided; cybercrime is a danger.

Transparency Regarding transparency, participants mentioned several important aspects. First of all, it is important to have an understanding of the results of the AI system (e.g., advice) and the reasons why the AI system comes to these results. In addition, it is important to have an idea on the certainty of the results. Also, explanations of the advise are important, ideally taking the context into account (e.g., which context factors improve the certainty). Regarding UGVs, participants mentioned that it is important to have insight into the plan/goal of the robot, to be able to predict behaviour.

Appropriate training Regarding appropriate training, participants mentioned two topics: (1) it is of utmost importance that FRs learn how to work with AI systems, as most do not currently have sufficient IT knowledge, and (2) that it is important that FRs explicitly keep training on how to work effectively without AI systems, so that they are able to operate if the system fails and are able to evaluate advise from AI systems regarding applicability.

IMPLICATIONS ON DESIGN OF AI SYSTEMS FOR FR

In this section, we describe the implications of the results as described in the previous section on the design of responsible AI for fire services. As shown in Figure 1, positive as well as negative impact has been identified during the focus group sessions for the different human values. According to the participants, several human values are impacted (mostly) positively for the different stakeholders (although there is no human value that is only affected positively), i.e., *physical well-being* and *psychological well-being*. Several human values are impacted only negatively for the different stakeholders, i.e., *autonomy*, *identity*, *informed consent*, *privacy*, and *trust*. Particular attention should go to these values in the design-, development-, and deployment process of AI systems; AI systems should (explicitly) support the possible positive impact that they could have whereas the negative impact should either be reduced or avoided altogether, e.g., by specifying design requirements that explicitly take these human values into account. To do this, the AI-related values that have been identified can help; these were values that the participants said that AI systems should adhere to. For example, having design requirements regarding the values *accountability*, *transparency*, and *appropriate training* could help to reduce the expected negative impact on *autonomy*. Regarding *accountability*, understanding the responsibility distribution between an AI system and human would help a FR's ability to act and make decisions; regarding *transparency*, understanding advise of an AI system in the current context and being able to interpret its reliability lessens dependence on the results of the AI system; the same holds for being *trained* in how to work with and without the AI system. The translation from human values to design requirements is not straightforward (Aldewereld & Mioch, 2021). However, the values form a good basis to take into account in the design and development process of specific AI applications. For each specific AI application, the values should be re-evaluated for applicability and, together with stakeholders, value-based design requirements should be specified that promote positive impact and limit negative impact on these values. For our current research, design requirements can only be very abstract as we have not identified a specific AI system that is the subject of this research, but AI systems in general. As a proof of concept, we give an example of a translation of the value *Autonomy* into possible general design requirements, see Table 3.

Table 3. Examples of design requirements for a selection of the identified impact of AI systems on the value *Autonomy*.

Impact of AI system on Autonomy	*Design Requirements*
Dependence on AI	Personnel will[1] be extensively trained on how the AI system works and how to interact with the system during operations Personnel will be extensively trained on how to work. effectively without the AI system in case of failure and to be able to evaluate advise from the AI system. The AI system will be able to explain why a particular result or advise is given. This explanation will take the context into account and be adapted towards the particular task and role of the FR.
Decision-making	The human will stay in control of (operational) decisions. The role of the AI system in the task execution will be clear and integrated into procedures. Accountability and responsibility will be explicitly discussed and set for each AI system that is introduced.
Human aspects and experience	Protocols will be specified carefully regarding decision-making with AI systems, to make sure that human aspects and experience can be taken into account. The AI system will be able to learn from human experts.

[1] We use 'will' in the design requirements specification instead of 'shall' or 'should', as the latter imply a normative load.

CONCLUSION AND DISCUSSION

In this paper, we have made a first step towards a generic framework of ethical aspects of AI systems for FR. We held three focus group sessions with different stakeholders, discussing several value-sensitive scenarios and the expected impact of the described AI systems on different stakeholders. Based on the results of the sessions, we identified relevant stakeholders and values that could be impacted by the introduction of AI systems. Mapping the expected impact onto the ethical matrix gave a visual help to show clearly which values are supported by AI technology and which might be negatively affected. We have also given an example of how these values van be translated into design requirements.

The number of participants in the focus group sessions was relatively limited. Nonetheless, the participants were diverse in the function they hold in the fire organisation, which leads us to believe that the analyses give good insights into relevant values and expected impact of AI applications for fire services.

During the first focus group session we realized that to be able to identify possible impact of AI systems, a general knowledge of AI systems is needed. For that reason, we added an introduction into AI systems to the subsequent sessions. In addition, we learned that example scenarios support participants in their identification of impact. During the subsequent focus group sessions, we used scenarios to identify stakeholders and human values for fire services. The scenarios were well grounded as they were based on input from domain experts from the first focus group session, AI experts (prediction of possible technology), and literature (relevant expected values). We introduced two scenarios with different AI applications and different direct stakeholders to broaden results. The goal of the scenarios was to support the participants in thinking about AI technology and its possibilities, without limiting it to a specific implementation. The choice of these specific scenarios led to a first inventory of relevant human values, which we expect for future scenarios will be refined, extended, and if necessary amended. The chosen scenarios led mostly to the identification of impact on stakeholders within the fire services; this was intentional. In future work, we would also like to hold focus group sessions with other FR organizations (e.g., police, ambulance services) and citizens to also take their perspectives into account, as we expect that additional impact will be identified, leading to different affected values.

In the FR domain, previous research has identified relevant stakeholders and core ethically relevant themes and values for the application of rescue robots. For example, in Harbers et al.'s selection of most relevant stakeholders included victims, local authorities, electrical company, press, and observers (next to fire fighters, police, and ambulance) (Harbers et al., 2017). These stakeholders were also identified during our focus group sessions, but not prioritized for AI applications and our scenarios. For rescue robots, Harbers et al. (2017) identified the values personal safety, safety of others, access to information, well-being, effectiveness, ease of use, authority for fire fighters. Although these values do not directly correspond to the values that resulted from our sessions as we based our value definition on Friedman et al. (2013), most of them relate to them. Ease of use has not been

mentioned during our sessions. Battistuzzi et al. (2021) identified core ethically relevant themes by means of a scoping review, namely fairness and discrimination, false or excessive expectations, labor replacement, privacy, responsibility, safety, and trust. Most of these topics were mentioned during our focus group sessions; however, fairness and discrimination and labor replacement were not mentioned. During our focus groups, impact on the values *autonomy* and *identity* were mentioned clearly and were seen as very important. These values have not been identified by (Harbers et al., 2017) and (Battistuzzi et al., 2021). These values might be (more) affected by AI systems for decision support than by rescue robots, as building situation awareness and decision making are core tasks for FRs. Several human values that were identified in this research were impacted only negatively for the different stakeholders; in future research, it should be further investigated why this was the case.

In our research, some values that were mentioned by the participants correspond (partly) to some of the key requirements as promoted, for example, by the EU HLEG for AI (e.g., transparency) (AI HLEG, 2018). When comparing the values that were mentioned by the participants at the focus group sessions with the EU HLEG ethical principles and key requirements, it becomes clear that several requirements particularly relevant for AI systems were not mentioned by the participants, e.g., diversity, non-discrimination, and fairness, or environmental well-being.

There is a general consensus that AI technology raises ethical issues that are not raised by more conventional ICT technology (Floridi et al., 2018). For that reason, the original VSD list of values does not suffice for AI (Umbrello & Van de Poel, 2021) but should be supplemented by ethical principles that ensure that typical AI ethical issues are addressed. Additional to individual values, organizational and societal values and corresponding norms need to be taken into account to build socially responsible AI systems. The results of our bottom-up, empirical approach of identifying context-specific values should be supplemented by two other normative sources of values i.e., (1) values promoted by the design, such as by deriving from the UN's Sustainable Development Goals (Guterres, 2020) or from AI for Social Good principles; (2) values respected by the design, particularly values identified in relation to AI (e.g., ethical principles identified by the EU HLEG for AI (AI HLEG, 2018)).

We foresee that AI technology will not only impact the stakeholders that the participants identified as most relevant during the focus group sessions, but that AI will have impact on the first response organizations in their totality, changing roles and responsibilities, but also the way resources are allocated, how training will take place, and what is considered expertise (as is argued also for other domains, such as health care (Van Wynsberghe & Li, 2019)). Some of the impact identified by the participants supports this (e.g., expected impact on training needs, needed capabilities for first response work, and the need for a culture change). This makes it even more important to introduce AI systems responsibly, decreasing negative impact of the introduction of AI systems explicitly during the design and development process, evaluating AI systems not only in the direct interaction with the direct stakeholders, but also evaluating effects on the organizations.

The values identified in this research function as a basis for a general value set and will be iteratively built up during future research, together with a related requirements list, as well as the (related) specific values and (instantiated) requirements for critical scenarios. We started applying this research to a particular AI application for fire services (an AI-based decision-support system) (Mioch et al., 2024), to further specify values for this particular AI application, map these values onto design requirements, and operationalize them for the AI application to investigate practicability and applicability of the general framework. In addition, we will also continue with conceptual investigations by integrating values found from normative sources (such as AI for Social Good) into the results of this research, in addition to doing a scoping literature review on ethical aspects of AI systems applied to emergency response and integrating these findings into the ethical framework.

ACKNOWLEDGMENTS

We would like to thank the first responders of *Gezamenlijke Brandweer Rotterdam*, *Veiligheidsregio Rotterdam-Rijnmond*, and *Veiligheidsregio Zuid-Holland-Zuid* for their participation in this research. This research was supported by the University of Applied Sciences Utrecht (HU) through a '*promotievoucher*'.

ABSTRACT

The crisis management cycle contains the step *Preparedness*, in which the development of disaster plans takes place. Run plans for fire fighters are a well-established means for enhancing preparedness in public buildings. A wide array of plans is available, serving to aid firefighters in swiftly orienting themselves during emergency situations on-site. These plans may also include detailed information as needed, providing tactical insights into critical elements within the building. In this practitioner paper, we present the adaptation of run plans to the realm of cultural heritage preservation. We utilize the existing format for the communication of information about the safe handling of cultural heritage to the command staff and the fire fighters. These *cultural heritage escape plans* offer guidance on the safe handling, evacuation procedures, and the prioritization of cultural heritage items in the case of an emergency and can be added to the existing tactical firefighting plans in public cultural heritage institutions. The evacuation plan format has been developed by the Munich County Fire Fighters and was manually implemented for all cultural heritage objects of the Bavarian Palace Department. The format has proven beneficial. With this format, we aim to enhance the preparedness of cultural heritage sites against natural disasters. Given the inherent sensitivity of cultural heritage objects, which require careful handling, these escape plans encompass instructions for the secure dismantling and evacuation of these items to designated safe areas. Furthermore, we introduce the software WALKER, a specialized tool designed for the creation of evacuation plans tailored to cultural heritage contexts. WALKER has been deployed for test usage for cultural heritage institutions for testing and evaluation of its potential. Both evacuation maps and WALKER are part of an integrated crisis management for cultural heritage and can be classified as part of the *Preparedness* step in the crisis management cycle. Furthermore, when the plans are implemented during the response, they can also be considered part of the phase *Response.*

Keywords

Evacuation Run Maps, Cultural Heritage, Software for Cultural Heritage Protection.

INTRODUCTION

Museums and historical buildings can be hit by natural disasters, just as any other building. Yet, in various workshops of the KERES project it was found, that museums and heritage preservation authorities often fail to prepare against potential natural hazards. Research in Bavaria showed 38% of cultural heritage is in natural hazardous zones and more than 400 cultural heritage objects are endangered by more than one natural hazard. All in all 136 cultural heritages in Bavaria alone were struck by natural disasters (Japelj et al. 2019). A meta study conducted by the STORM project found that a general risk strategy for cultural heritage against natural hazards in European countries is still far from reality (STORM 2018). A low-threshold measure for the establishment of a more resilient cultural heritage landscape is the creation of evacuation run maps for firefighters: evacuation maps represent an appropriate tool to enhance the safeguarding of museums and cultural heritage against threats and are a crucial component of an effective protection plan. In this paper we present the creation of run maps for the evacuation of cultural heritage objects from buildings as well as a software to manage and create this evacuation run maps. The run maps can be addended to fire brigade operation plans and form the basis of an appropriate and efficient evacuation in the case of an emergency.

TACTICAL FIREFIGHTING PLANS

The approach of emergency responders is largely standardized when there are no indications necessitating special protective measures. If firefighting needs to be conducted differently than the trained standard procedures, this information must be conveyed to the firefighters. If they lack essential information about the incident or location, their response may be less effective. Therefore, effective communication and preparation of information play a paramount role. This information must be conveyed in a standardized manner and can complement standardized firefighting procedures.

In emergency situations, it is crucial for first responders to possess a comprehensive understanding of their surroundings. The primary means of conveying vital information to firefighters is through tactical firefighting plans. These plans are customized for specific sites and serve as a communication tool between building owners and the responding firefighting teams. Typically, a firefighting plan encompasses a general overview of the building and on-site infrastructure details, including hazardous areas and water sources for firefighting. Furthermore, it incorporates tactical information, such as the requisite extinguishing agents, with the flexibility to add supplementary details as needed.

In Europe, various standards exist that delineate and specify maps for firefighters. The German standard is documented in DIN ISO 23601, which outlines the common requirements for such plans (DIN 2020). This standard is established to create a foundation in Germany and is, when necessary, elaborated upon by the regional forces. The German standard DIN 14095 delineates operation plans for firefighting and other measures on specific sites and contains information about hazards, specific characteristics and risks (DIN 2022). If additional tactical information is given, the plan is called tactical firefighting plan. The plan contains necessary information for the head of operations, such as building information, site plans or story plans or so-called *special plans*. These special plans are predestinated to hold specific information for the evacuation of cultural heritage.

Particularly in the case of water-sensitive cultural heritage items, appropriate information about the extinguishing agent are essential. The necessary containment of fire and smoke may, in some cases, not allow for the omission of water suppression. However, in these cases targeted protective measures, such as the usage of fire blankets for the covering of cultural heritage items or their evacuation, before water usage, can be initiated. The timely and targeted evacuation of cultural heritage items holds particular significance. Depending on the urgency, required personnel, and potentially necessary protective gear, evacuation measures will mostly be achievable only by firefighting personnel. However, this process cannot succeed without the support and cooperation of the facility operator: cultural heritage might be secured by protective measures, about which the firefighters need to be informed. For the purpose of planning the systematic evacuation of art and cultural assets, an initial categorization of the artworks is necessary. In this regard, the facility operator determines the order in which the cultural heritage is to be removed from the danger zone. The operator must consider the art-historical significance and the intrinsic value of the art objects. As measure to foster preparedness, the creation of tactical firefighting plans is part of emergency management for cultural heritage and can be placed in the crisis management cycle. The cycle itself discussed in the community and several definitions exist (Moßgraber 2012), yet a common definition is the subdivision into the four parts *Preparedness, Response, Recovery, Mitigation* (FEMA 2022).

Evacuation Maps for Cultural Heritage Objects

The information named in the previous chapter must be provided to the firefighters in a standardized way, so it conveys information in the right format. To address the demand for evacuation plans for cultural heritage, the Munich County Fire Department has devised a route card format, serving as an interface between firefighters and cultural heritage managers. These maps enable managers to apprise firefighters of the specifics pertaining their cultural heritage objects, thus assisting in the prevention of collateral damages. The responsibility for creating run maps is held by the managers of cultural heritage; after creating the maps these can be added to the tactical firefighting plan, as described in the previous chapter. Especially in the context of hazards due to climate change to cultural heritage, the creation of evacuation maps fosters preparedness and prevents cultural heritage loss (Kotova et al. 2023).

The Bavarian Palace Department (Bayerische Schlösserverwaltung, BSV) is a public institution entrusted with the management and preservation of cultural heritage in Bavaria, which encompasses palaces, castles, and parks. This heritage encompasses both mobile and immobile cultural items, such as historical timepieces and Neuschwanstein Castle, which houses mobile cultural heritage items. To bolster preparedness for emergencies and safeguard mobile cultural heritage, the BSV has developed evacuation maps specifically tailored to their cultural heritage objects.

WALKER – A Novel Tool for The Creation Of Run Maps

Fraunhofer IOSB developed the concepts for WALKER during the KERES project, with a primary focus on safeguarding cultural heritage against the impacts of climate change. During the project a demonstrator for WALKER has been developed. The target users for this software are cultural heritage managers trying to foster their preparedness against potential disasters endangering their cultural heritage objects. WALKER allows the creation of run maps in the format devised by the Munich County Fire Department. It simplifies the creation and updating of run maps and includes a library of predefined icons commonly used by fire departments. This ensures that the generated evacuation maps adhere to recognized standards, making them practical for real-life applications. Furthermore, WALKER offers the evaluation of stored data, to allow the quick retrieval cultural heritage objects fitting a specific criterion, such as priority or the number of personal required for the transport.

WALKER has been developed in the context of the KERES project, which was accompanied by an expert panel. Members of the panel were cultural heritage institutions, as well as authorities and organizations with civil security tasks, such as fire fighters or the federal technical aid organizations. WALKER was developed together with the expert panel, who reviewed the application and requested or suggested new features. As the development took place during the COVID19 pandemic, the feedback sessions were held online in which the application was demonstrated. For interested users a testing environment was setup, which they could access for testing purposes. Suggestions and functions were defined in use cases, from which the most promising were chosen to be integrated into the prototype application. The development process followed the waterfall project management paradigm in four phases. Together with the experts a specification document for the software was developed. The specifications were solved with a draft, that offered (to that point hypothetical) functions, which were mapped to the requirements from the first phase. The third phase comprised the implementation of the developed functions. Quality assurance formed the last phase, in which software and end users tests were conducted.

The application allows the creation of evacuation maps through forms. Figure 1 shows the view used to create and update the evacuation maps. Information, such as position, priority or inventory numbers can be entered; images can be uploaded additionally.

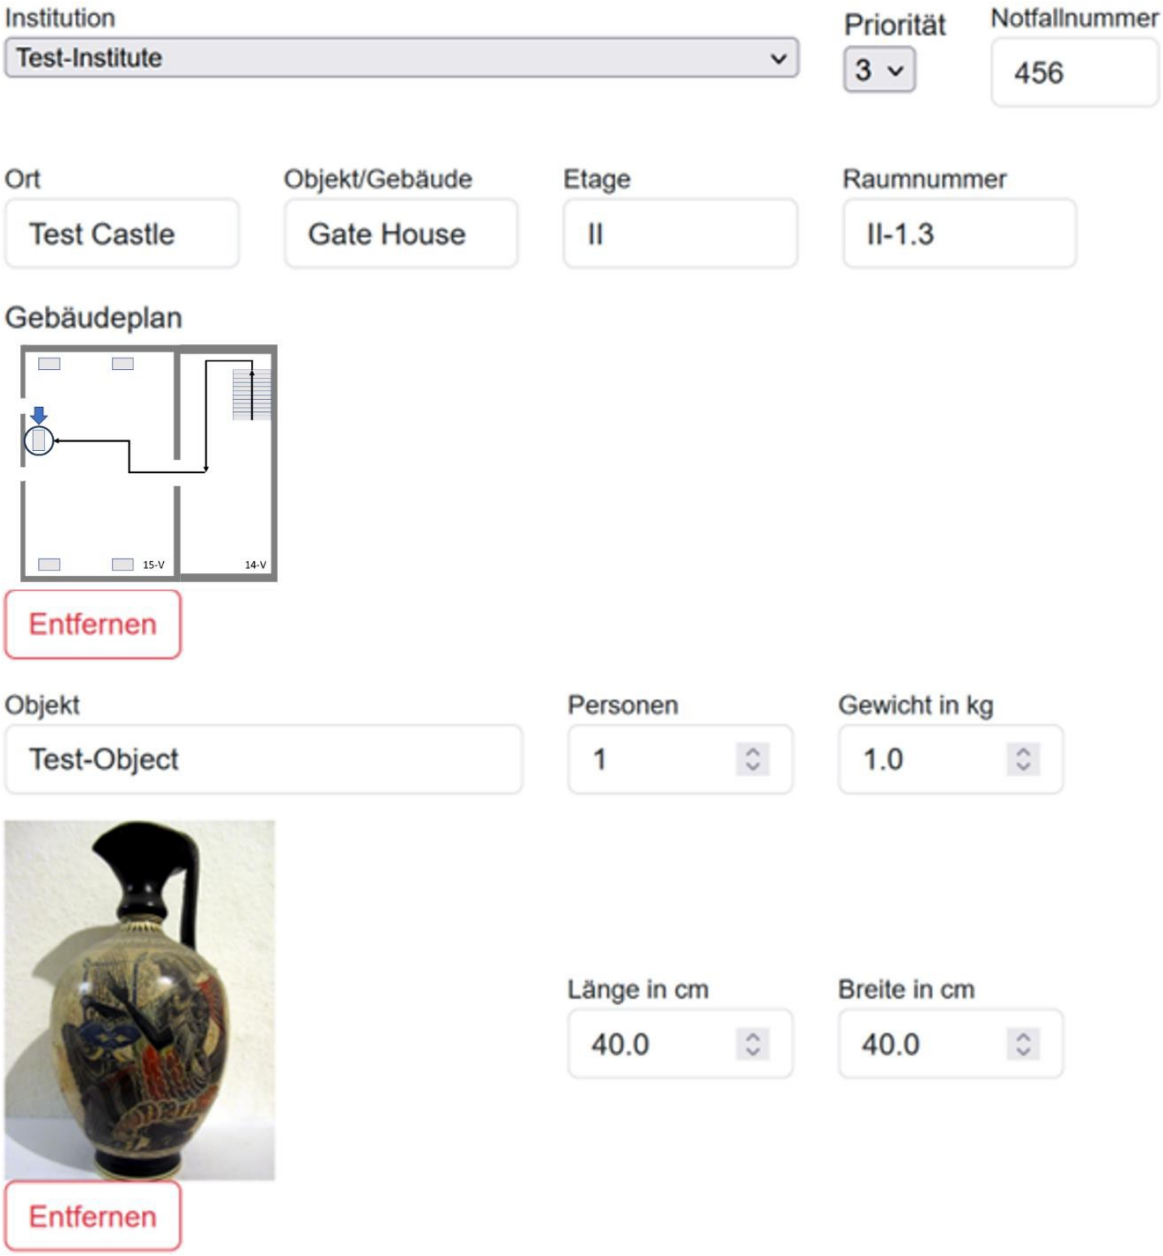

Figure 1. An excerpt from the WALKER form for data input

After entering the data, users can trigger the generation of the corresponding PDF-files which are offered as download. A created evacuation map is shown in Figure 2. It shows a hypothetical cultural heritage object managed by an institute called Test-Institute. The map was created on 09/08/2023 by a user called Walker. It has the priority level 3. The position of the object is shown in the map with an arrow; an image is shown as well. The object weighs one kilogram and measures 40 x 40 x 70 cm. A single person is required to transport the object. An image (broken vase) signalizes the object needs to be handled with care. This route card could be added to the tactical firefighting plan, thus supplementing the existing information for the firefighters.

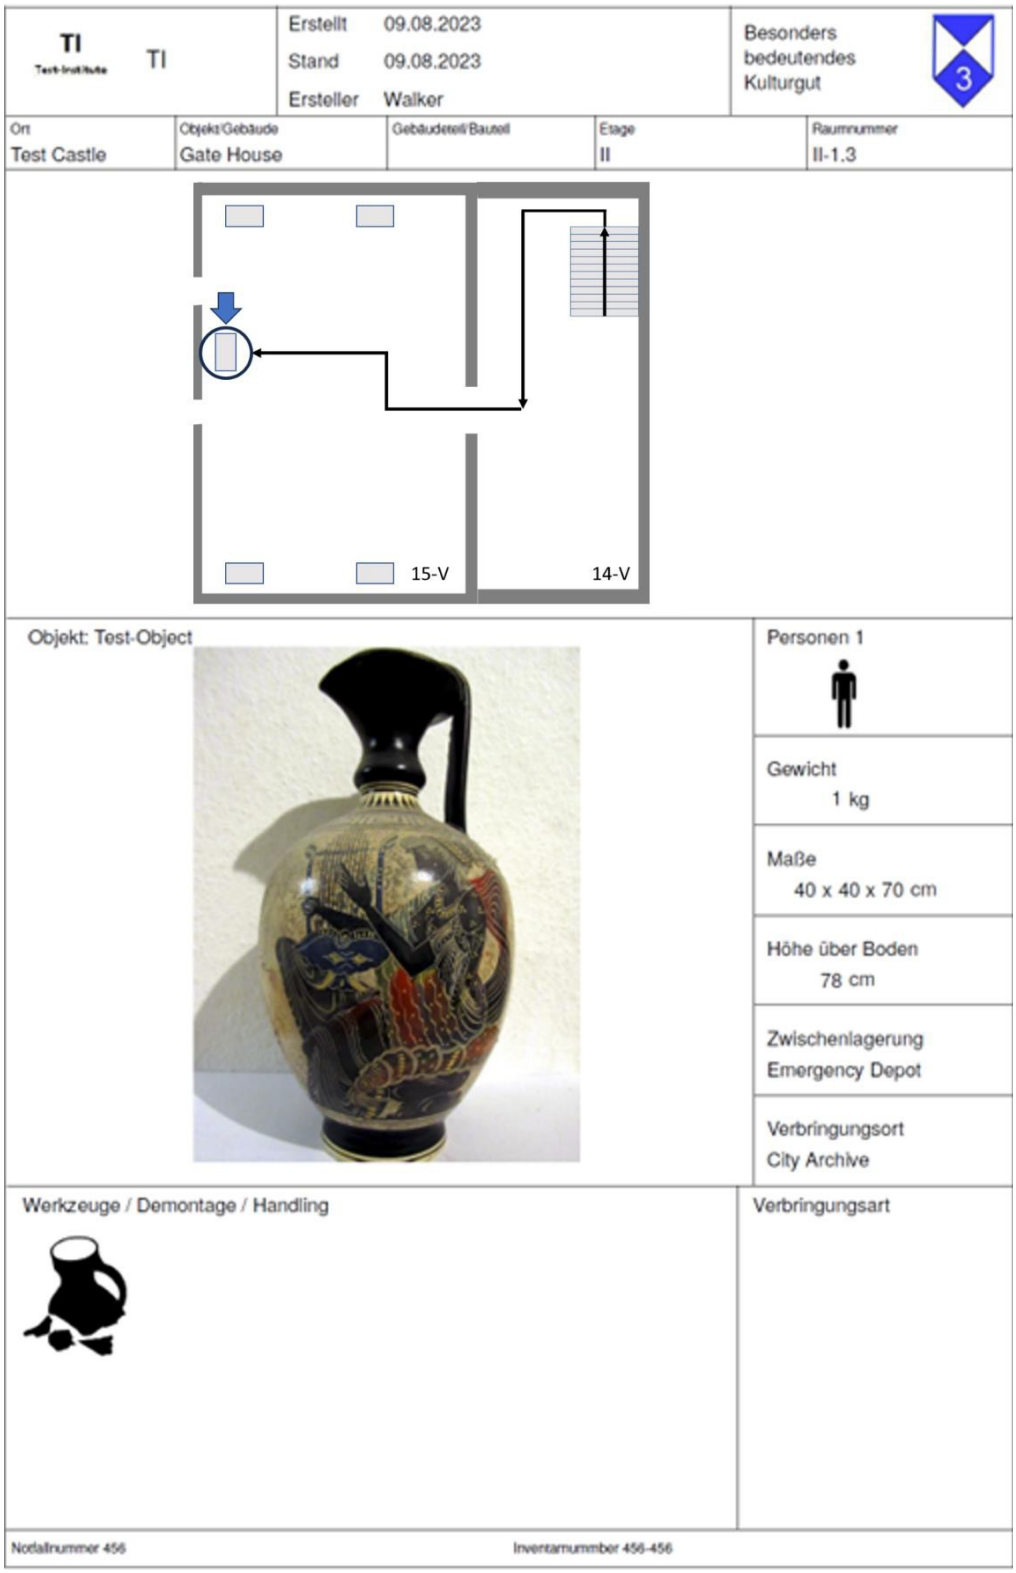

Figure 2. The WALKER generated route card

In the workshops, further beneficial features were pointed, such as the ability to filter evacuation maps by priority level and the required resources for its evacuation to be able to prioritize the evacuation of objects in case of an emergency. Yet, features like these face the contrary demand of availability of these maps in a printed form by authorities and organizations with civil security tasks. This aspect could be overcome by utilizing WALKER in the crisis operations center as application: the head of operations could, for example, request route maps with the highest priority or query objects that need only the firefighter personal he has available.

WALKER – ARCHITECTURE

WALKER is a web application built on Java 17. It is built on a backend developed on the Spring Boot framework and a front-end implemented as a Vue 3 single-page application, with Bootstrap used for layout purposes. Communication between the front-end and backend takes place through an HTTP programming interface. Structured data in WALKER is stored in a PostgreSQL database, although it can potentially work with any SQL-based database. Unstructured data, such as images, is stored within the file system. The file hierarchy is designed in a way that files from different institutions are stored in different locations if the file system. The database maintains records of file locations to ensure the unique identification of all necessary objects. Creating or updating data in WALKER can be accomplished in two ways: Users have the option to input all the necessary data for creating a route card through web forms. These forms also facilitate data updates, so the user uses the same forms for creating and updating data. The backend offers a REST-API, allowing for the (semi-)automatic creation of maps by uploading datasets. REST outlines principles for services without specifying implementation details. The first principle is the Client-Server Architecture, as seen in the World-Wide-Web, where a server provides a service that clients can request. Utilizing the widely adopted HTTP protocol (Internet Engineering Task Force 1999), REST client implementations are accessible across various programming languages. The second key characteristic is statelessness, requiring every message sent to a REST service to include all necessary information for processing. The common HTTP-methods are used to interact with the interface, whereas GET is used to retrieve entities, POST creates new entities, PUT and PATCH update entities and DELETE finally deletes entities (Roy Thomas Fielding 2000). WALKER employs LaTeX for map generation, which is triggered through the Java backend. The maps are made available as Portable Document Format files (PDF). Parameters, including required images and textual information, are stored in a configuration file. This file is then passed to as command line parameter to LaTeX, which, in turn, generates the map in PDF format. Passing the file as parameter should prevent command line injections. Assessment for potential publication on well-known open-source repository management platforms, such as GitHub, is ongoing.

EVALUATION

For further usability testing, WALKER has been deployed for BSV, as well as for Leibniz-Institut für Biodiversitätsforschung and will be deployed for Staatliche Schlösser und Gärten Baden-Württemberg. For deeper insights, we aim to evaluate both the practicability of WALKER and the user experience. An important aspect is the alignment of requirements due to different standardized operations in the federal states in Germany: differences in law and operations might have an influence on the usage of WALKER and its integration into the common workflows of a cultural heritage institution. WALKER has generated curiosity in the cultural heritage community, as it offers a low-threshold solution for the creation of evacuation maps and to enhance the preparedness of cultural heritage institutions. All test-users assess the software regarding its applicability, most importantly the question is, whether WALKER can provide benefit in a real-world context. For this, WALKER needs to undergo usability tests and most importantly expert reviews, with experts from the firefighting domain, as well as cultural heritage managers to find potential shortcomings. The created route cards could also be assessed through simulations and expert reviews, but as they are designed by fire fighters, their usability should be promising. In a dedicated upcoming project, we envisage to continue test and develop WALKER. The run maps have been evaluated during a test with fire fighters at Castle Schleißheim: before the drill, the handling and evacuation for all 400 objects within the castle have been documented with run maps in the described format (Bachhuber 2017). Feedback had been implemented in the route card format, which again was incorporated into the WALKER software.

CONCLUSION

In this paper we presented the transferal of run maps to the domain of cultural heritage for the evacuation of cultural heritage objects in the case of an emergency. By utilizing a well-known format of maps, we lower the acceptance threshold and foster practicability and the ability to integrate these maps into the common operational procedures. The format was developed by the Munich County Fire Fighters and was made publicly available for fire fighters and the managers of cultural heritage. The format has been adopted by the Bavarian Palace Department, who manually created evacuation maps for all relevant objects in their collections and assets. The maps have been tested in an evacuation drill with 400 objects in Castle Schleißheim. In the run of the KERES project, Fraunhofer IOSB developed a prototype software for the software-supported creation of maps in the named format. The software was deployed for several expert users. Further development and testing is envisaged in an upcoming project. The tests should evaluate the software and its application itself, but also its integration into the security framework of the using institutions.

ABSTRACT

Online violence is a complex issue transcending national borders with digital and real-world consequences. It is a consequence of hate, fueled by real and perceived injustices. Communities must be able to adapt - improving citizens' social and material conditions to prevent hate from taking root or spreading. Community resilience research focuses on assessing a community's ability to adapt and how well it copes with disruptions both known and unknown. Therefore, community resilience models and methods should be adopted by those working to prevent online violence both to investigate new means of preventing hate speech and to test existing community resilience theory in a new context. This paper will review online violence and community resilience, explain their connection, review community resilience models that may be of interest for violence prevention work, and describe how those models are being used in a project that is currently in progress.

Keywords

Community Resilience, Hate Speech, Online Violence, Violence Prevention, Sustained Adaptability.

INTRODUCTION

Communities of people are complex adaptive systems comprising individuals, social networks, technologies, and the environment. To thrive over time, all complex systems must adapt, changing their underlying architecture to meet their goals as the external environment exposes them to new disruptions. For a community, this means maintaining citizens' quality of life, accommodating new peoples and technologies, and preserving the natural environment. The capability to continually adjust over time has been labeled Resilience (Hollnagel et al., 2006). Resilience is an emergent property fostered by the interaction of components and subsystems such that the whole system is poised to adapt and continues to function as conditions change over time (Woods, 2015). Communities therefore constantly engage in work to make sense of the world, plan for the future, and coordinate resources to maintain a high quality of life for citizens. Taking steps to foster resilience will allow communities to perform this work while dealing with the shocks and threats of the world.

One of the most urgent threats of the present day is the proliferation of hate speech online. Hate speech is an example of online violence - a continuum of behavior from subtle discrimination to violent crime (Gagliardone et al., 2015; Kim, 2021.; Lupu et al., 2023). Though hate speech is not new, the internet - because of its transnational reach, accessibility, and the anonymity it permits provides an excellent medium through which hate speech may spread (Gagliardone et al., 2015; Kim, 2021). Research has shown that hate speech creates real tangible threats of violence to citizens, particularly the most vulnerable members of a community. Though online and offline phenomena are substantively related their relationship is complex and still not well understood (Lupu et al., 2023). While the need to address hate speech online is clear, the practice of addressing it proves complicated. It requires

communities to navigate fundamental tradeoffs between protecting individual liberties and the safety of citizens (Gagliardone et al., 2015). Limitations on speech must be specified in law, proportionate, and targeted to be justifiable. Victims are heterogeneous – people may become targets based on race, ethnicity, sexual orientation, gender identity or expression, religion, or disability. Furthermore, these behaviors have structural, interpersonal, and individual pre-determinants and impacts; effective prevention of violence-inducing behaviors requires an in-depth understanding of those pre-determinants. In other words, an understanding of the material and social characteristics of a community (its underlying architectural properties), how they interact to enable the spread of hate speech, and how they are affected by its spread and consequences. These principles are precisely the same as those central to research on community resilience.

The purpose of this paper is to elucidate the relevance of community resilience research to work preventing online violence such as hate speech. In section II we will elaborate on the concepts of online violence, hate speech, and community resilience and the links between them. In section III several models from the community resilience literature will be compared. In section IV we will discuss how these models could be applied to online violence prevention work and will recommend the most promising candidates for this application.

This work is ongoing and is part of the SOCYTI project - an in-progress, transdisciplinary initiative dedicated to developing new strategies and tools for the prevention of hate speech online. The work described in this paper represents the initial stages of our efforts to carry out this integration of community resilience research into online violence prevention. The project aims to develop a cloud-based, real-time detection system capable of evaluating text and images from social media posts for hateful content on a larger scale than ever previously possible. It is the hope of the research team that such tools can enable proactive interventions rather than just being used to reactively police hate speech online. Community Resilience research is integral to realizing this hope. In the future we will directly connect community resilience indicators to specific types of hate speech. These connections may reveal new means of preventing different kinds of hate speech from propagating.

LITERATURE REVIEW

Online Violence and Hate Speech

Hate speech is a product of hatred - a feeling of intense hostility and aversion, usually deriving from fear, anger, or a sense of injury. It relies on underlying tensions in society, which it seeks to re-produce and amplify. It is the expression of conflicts between different groups (Gagliardone et al., 2015; The Rabat Plan of Action, 2012). It is intended divide citizens into groups of 'us' and 'them' and then blame 'them' for the struggles of 'us'. Such scapegoating obfuscates the real sources of threats to communities. It degrades the community's capacity to monitor, anticipate, and respond to real threats, which are key cornerstones of system resilience (Hollnagel, 2009). This systemic resilience extends beyond just hate speech, dealing with how complex systems cope with all kinds of disruptions including natural and man-made disasters. As such, hate speech represents a legitimate compounding threat for myriad crises and disasters. In addition, such events in and of themselves can contribute to and exacerbate the aforementioned social and economic tensions which feed into the propagation of xenophobic ideology and sentiment.

Hatred can be constructed along several axes including race, ethnicity, language, gender identity or expression, religion, sexuality, or nationality. It may stem from political polarization – 'having an enemy to oppose provides people with a sense of identity, and the possibility of victory in the face of issues that seem too large to hold' (The Rabat Plan of Action, 2012). Economic issues such as unemployment, declining income, or increased living costs (especially during recessions) often contribute to anti-migrant sentiments. Groups that are excluded and/or discriminated against can become radicalized, which diminishes the possibility of establishing cohesion and cultural dialogue (Eminoğlu, 2020). Any combination of these factors, along with the absence of free and secure civic space, online disinhibition, and more may drive radicalization and the hate speech that results from it (The Rabat Plan of Action, 2012; UNOCT PVE Reference Guide, 2016) hence we label them *drivers*. The above list is not exhaustive. The structure and context of a community determine which drivers are present and how they combine to foster online violence.

Not all hate speech is illegal. 'Only the most egregious forms of hate speech, namely those constituting incitement to discrimination, hostility, and violence, are generally considered unlawful (Gagliardone et al., 2015). While legal responses such as protections for migrant workers and diaspora communities are important, legislation is only one of many tools. legislation must be complemented by initiatives from various sectors of society geared towards the deeper structural issues that foster radicalization, hatred, and hate speech – the drivers. Addressing such issues will require a plurality of policies, practices, and measures nurturing social consciousness, tolerance, and understanding (Kim, 2021; UNOCT PVE Reference Guide, 2016). Strong community building initiatives,

education and training programs, and intercultural dialogue foster acceptance and cultural literacy through interaction. Improving socio-economic parity, ensuring equitable access to basic and specialized services, and dedicating resources towards anti-radicalization plans assuage tensions on which hate speech depends (Eminoğlu, 2020). Healthy cooperation between local actors, civil organizations, and government is important to ensure that such changes are well supported and spread throughout society.

Community Resilience and Models

The word 'community' can describe groups united by common interest, geography, or socioeconomic, cultural, political, or ethnic makeup. Community resilience describes the capability of a community, enabled by an interconnected network of systems, to continuously meet its primary goals to keep citizens healthy, happy, and safe (Fitzpatrick, 2016). These systems comprise socioeconomic, ecological, and built aspects. A community is resilient when: '… the population are connected to one another and work together, … to function and sustain critical systems, even under stress; adapt to changes in the physical, social, or economic environment; be self-reliant if external resources are limited or cut off; and learn from experience to improve over time' (Fitzpatrick, 2016). We have identified research investigating these underlying concepts from many sources using the labels 'community resilience', 'societal resilience', and 'social resilience' and will treat each label as synonymous in this review.

Synthesizing existing strands of community resilience literature, the first from social-ecological systems and the second from psychology, yields the following set of core principles: People–place connections; values and beliefs; knowledge, skills, and lea rning; social networks; engaged governance; diverse and innovative economy; Community infrastructure; leadership; and readiness to accept change (Berkes & Ross, 2013). The agency of actors in the community and the process of self-organization both emerge from the state and combination of these principles. *Fostering agency in people* and *allowing for self-organization* are thus important foci for efforts to build community resilience.

Societal resilience literature suggests that 'societal resilience lies in techno-political macrostructures that actively shape societies and risks at a global level as well as in the skills of professionals' (Haavik, 2020). Techno-political macrostructures refer to critical infrastructures (power, telecoms, water, etc.) and critical societal institutions (health, political, family, etc.). This perspective contrasts with traditional safety science, which focuses wholly on infra structure robustness and restricts the ability to explore the nature of risks that transcend infrastructures and national borders such as the proliferation of hate speech online. 'If we accept critical infrastructures as the central risk object, we indirectly consolidate the politics, the technologies, and the practices that admit these structures their criticality' (Haavik, 2020). Adopting the new perspective creates space to investigate the adaptive capacity of a society by centering the socio-ecological production of risks.

Some social resilience literature argues that social resilience builds on the general concept of resilience, rooted in ecological systems thinking, and departs from it by incorporating an actor-oriented perspective recognizing the importance of power, politics, and participation. This conception of social resilience comprises three dimensions: Coping Capacities - the ability of social actors to cope with and overcome adversities, Adaptive Capacities - their ability to learn from past experiences and adjust to future challenges, and Transformative Capacities - their ability to craft sets of institutions that foster individual welfare and sustainable societal robustness towards future crises (Keck & Sakdapolrak, 2013).

A community resilience model must incorporate sociological, ecological, and infrastructural elements, an inherently complex task leading to many different model forms. Models can be qualitative, quantitative, or hybrid. Qualitative models create theoretica l frameworks, highlighting key components of resilience and their schematic connections. Quantitative models generally seek to make resilience comparable between entities and locations, and trackable across time (Scherzer et al., 2019). A common modeling strategy is to deconstruct a community into 'domains.' Domains represent functional areas inherent to a standard community that can be assessed for resilience. Sometimes these are called 'dimensions,' or 'subdomains.' Qualitative or qua ntitative indicators are then organized into domains. Several domains reappear across models and others are functionally identical while being labeled slightly differently. Some models include unique domains or are not organized into domains at all. In the following section, we will inspect several models and frameworks from the literature. This paper will cover five models, two frameworks, one toolkit, and one strategy for combatting cyber-racism. We will group them according to how their indicators are structured. A summary of these sources is shown in Table 1.

Table 1. Overview of Sources from Community Resilience Literature

Name	Type
Resiloc Resilience Indicators	Model
Disaster Resilience Indicators for Benchmarking Baseline Conditions (BRIC)	Model
Community Resilience Index for Norway (CRIN)	Model
City Resilience Index (CRI)	Model
Communities Advancing Resilience Toolkit (CART)	Toolkit
Community Disaster Resilience	Framework
Cyber Racism and Community Resilience	Strategy
The Community Capitals Framework	Framework
Intercultural Cities: Intercultural Dialogue as a Tool for Social Cohesion	Model

COMPARATIVE ANALYSIS

The RESILOC Model, The Disaster Resilience Indicators for Benchmarking Baseline Conditions (BRIC) Model, and the Community Resilience Index for Norway (CRIN) model are highly similar structurally. We label this shared structure Domain Set 1 and visualize it in Figure 1. All three contain *Social*, *Infrastructure*, and *Economy* domains. The *Social* domain captures general demographic characteristics of a population that enhance their ability to deal with adverse events. It includes relationships between people and groups, social networks, and culture (Scherzer et al., 2019; Cutter et al., 2010; Akerkar et al., 2022). The *Infrastructure* domain relates to physical structures, technical facilities, and systems essential to community functioning. These include transportation, electricity, gas, water, communications systems, food distribution chains, health facilities, municipal services, and public administration services. The *Economy* domain intends to portray overall economic health and thus focuses on indicators such as variability and diversity of income sources, range and types of local businesses, assessments of existing wealth, and the income generating skills-base of citizens (Scherzer et al., 2019; Cutter et al., 2010; Akerkar et al., 2022).

RESILOC uniquely contains a domain for *Government* and *Disaster Risk Reduction*. BRIC and CRIN both contain a domain for *Institutions* and *Community Capital*. RESILOC and CRIN both contain an *Environment* doma in. The *Government* domain and the *Institutional* domain are both concerned with institutional efficacy and transparency, and citizen engagement in political processes. Because the indicators present in each are so similar, we treat the two domains as synonymous. Thus, we visualize them as a single domain as shown in figure 1.

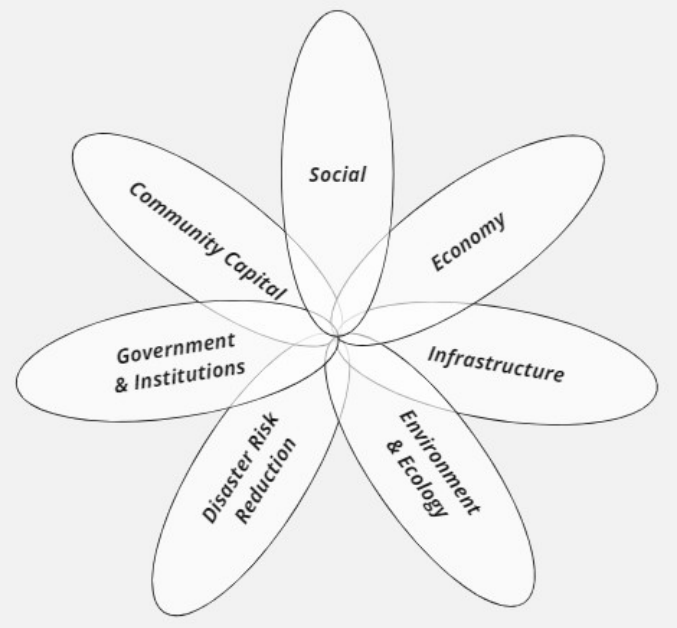

Figure 1: Domain Set 1

The indicators of the *Government/Institutions* domain often overlap with other domains because institutions play an important role in organizing and regulating social, political, and economic activities (Akerkar et al., 2022). Indicators within the *Infrastructure* domain also often overlap with other domains because physical infrastructures can serve purposes specific to the other domains (Akerkar et al., 2022). We keep the *Infrastructure* domain distinct to maintain space for assessing the purely physical attributes of infrastructure such as infrastructure quality, or the proximity of citizens to important infrastructure (Scherzer et al., 2019; Cutter et al., 2010).

The *Community Capital* domain is highly related to the *Social* domain but is unique in seeking to capture capacities such as the strength of community organizations and citizen knowledge, skills, and resources rather than social relationships and connection between people (Scherzer et al., 2019; Cutter et al., 2010). Across reviewed models there is considerable indicator overlap and potential misplacement between the *Social* and *Community Capital* domains. Despite this, a conceptual distinction between indicators that point towards social relationships and community capital is important, so we keep these domains distinct.

The *Disaster Risk and Reduction* domain describes frameworks, processes, and resources dedicated to risk reduction and emergency management. This includes equipment, temporary housing, statutory and voluntary organizations, etc. (Akerkar et al., 2022). Though many such indicators are intrinsically linked to the government of a community this domain is kept distinct to accentuate a focus on processes and capacities specifically for crisis situations.

The *Environment* domain has two focuses. First, assessment of the natural environment that intersects and envelopes a community (i.e., hazard and exposure mapping of local topography, geography, geology, vegetation, and biodiversity). Second, assessment of a community's exposure and resilience to natural hazards (Akerkar et al., 2022). Such indicators are sometimes organized as the *Ecology* domain. Because the indicators of both these domains are environmentally focused, we treat them as synonymous. Conversely, while there is also considerable overlap between *Environment/Ecology* domain and *Disaster Risk Reduction* domain indicators, we keep these domains distinct to recognize that communities must prepare for man-made as well as natural disasters and to maintain space for environmental indicators not directly related to crises.

Some models group indicators into an *Individuals*, or *Physical*, or other similarly narrow domain (Nguyen & Akerkar, 2020). This review is interested in models which consider resilience as a systems-level property, not as something that resides in individual citizens alone. To prevent losing the value of these indicators we recommend that these domains be disregarded, and their indicators reorganized into another domain present in that model as appropriate. For example, the community domain (human capital/knowledge, skills & resources) or the infrastructure domain (physical structures).

The City Resilience Index (CRI) and the Communities Advancing Resilience Toolkit (CART) represent other forms of organization. The CRI comprises four dimensions split into twelve goals into which indicators are grouped (City Resilience Index, 2015). We label this structure Domain Set 2 and present a visualization in Figure 2.

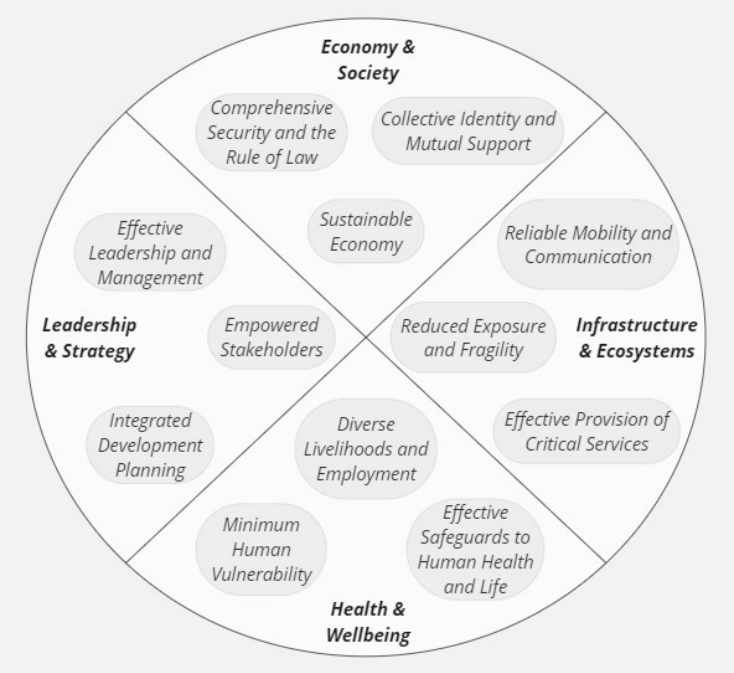

Figure 2: Domain Set 2

The *Leadership and Strategy* dimension includes indicators that would be found in the *Government/Institutions*, *Community Capitals*, and *Disaster Risk Reduction* domains of domain set 1. The *Infrastructure and Ecosystems* dimension includes indicators that would be found in the *Infrastructure*, *Environment/Ecology*, *Government/ Institutions*, and *Disaster Risk Reduction* domains. The *Economy and Society* dimension contains indicators that would be found in the *Economy*, *Social*, *Community Capitals*, and *Government/Institutions* domains. The *Health and Wellbeing* dimension contains indicators that would be found in the *Disaster Risk Reduction*, *Economy*, and *Infrastructure* domains. A summary of the comparison of domain set 1 and domain set 2 is shown in Table 2. Domain set 1 is shown in the first column. The presence of an X in a table cell indicates that the domains listed in that column and row contain analogous indicators as described above.

Table 2. Comparison Between Domain Sets 1 and 2

Domain (Set 1)	**Leadership & Strategy**	**Economy & Society**	**Infrastructure & Ecosystems**	**Health & Wellbeing**
Government & Institutions	X	X	X	
Community Capitals	X	X		
Social		X		
Economy		X		X
Infrastructure			X	X
Environment & Ecology			X	
Disaster Risk Reduction	X		X	X

CART does not contain specific indicators and only describes four overlapping domains of resilience. These are *Connection and Caring*, *Resources*, *Transformative Potential*, and *Disaster Management* (Pfefferbaum et al., 2013). We label this organizational structure Domain Set 3 and present a visualization in figure 3.

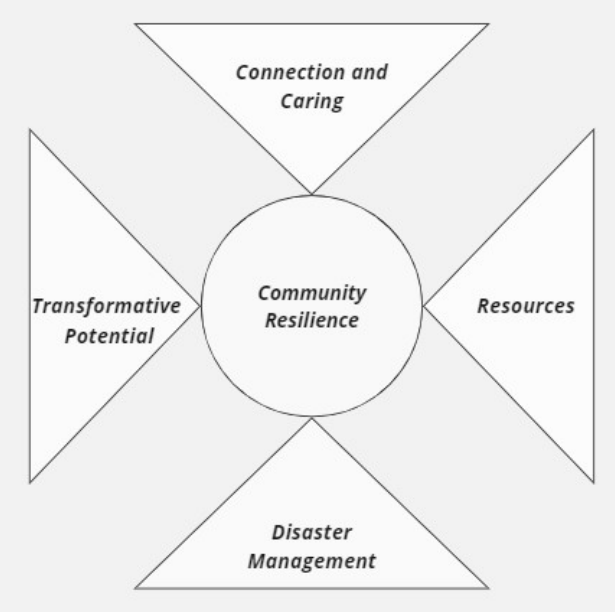

Figure 3: Domain Set 3

Connection and Caring focuses on social relationships, support systems, and the connection between people, which would be found in the *Social* domain. Resources includes natural, physical, information, human, socia l, and financial resources, which encompasses the *Environment*, *Community Capital*, *Economy*, and *Infrastructure* domains. *Disaster Management* concerns everything related to prevention, mitigation, preparedness, response, and recovery for crises. These indicators are closest to the *Disaster Risk Reduction*, *Environment/Ecology*, and *Government/Institutions* domains of the previous models. Finally, *Transformative Potential* is the model's most unique domain. It describes the ability to identify and frame collective experiences, examine successes and failures, and engage in critical analysis. Such indicators would be found in the *Government/Institutions*, *Community Capitals*, *Social*, and *Environment/Ecology* domains. A summary of the comparison of Domain Set 1 and Domain Set 3 is shown in Table 3 and a comparison between Domain Sets 2 and 3 is shown in Table 4.

Table 3. Comparison Between Domain Sets 1 and 3

Infrastructure & Ecosystems	X		X	X
Health & Wellbeing			X	X

Several sources do not organize their insights into a structured model. The *Community Disaster Resilience* (Fitzpatrick, 2016) framework provides a broad set of principles that explain why some communities cope with disaster events better than others. The paper on *Cyber Racism and Community Resilience* (Jakubowicz et al., 2017) positions racism and other forms of hate speech online as one of many challenges that undermine social cohesion and break down social capital. It also identifies resilience as the most critical element in resisting and overcoming hate speech. The *Community Capitals Framework* (Pigg et al., 2013) describes seven types of capital present in communities on which development efforts can focus. *Intercultural Cities: Intercultural Dialogue as a Tool for Social Cohesion* (Eminoğlu, 2020) explores a new model for social cohesion – interculturalism – and reports key aspects. These sources also show considerable overlap in their indicators.

All these sources contain indicators that relate to government, social networks and relationships, and community capital. Many of these indicators are written differently but point towards the same phenomena such as existing policies, civil engagement in political processes and community organizations, social cohesion and mutual care, and the skills of individuals. Indicators focused on the economy and the natural environment are present in the *Community Capitals Framework* and the paper on *Community Disaster Resilience*. Indicators focused on infrastructure are present in the *Community Capitals Framework* as well as the papers on *Cyber Racism and Community Resilience* and *Intercultural Cities*. Indicators focused on disaster risk reduction are present in the papers on *Community Disaster Resilience* and *Cyber Racism and Community Resilience*. A summary of the comparison of Domain Set 1 and these individual sources is shown in Table 4. A comparison between Doma in set 2 and these sources can be inferred by referencing table 2. A comparison between Domain Set 3 and the unorganized sources is shown in table 5. Both *Community Disaster Resilience* and *Cyber Racism and Community Resilience* provide indicators that fit into each domain of set 3. *Intercultural Cities* presents indicators that are related to connection and caring and resources. Interestingly, *The Community Capitals Framework* only provides indicators that are categorizable as resources.

DISCUSSION

Regardless of form and organization, all the models shown exhibit commonalities. The health and well-being of citizens is paramount. Attention is repeatedly paid to the extent to which all people can meet their basic needs, particularly in times of crisis. The community must be able to provide for the health and well-being of citizens and safeguard it through normal and emergency situations. This capacity may be captured via healthcare facilities, public health initiatives, economic structure, governmental policy, environmental health, etc. Attention is also paid to the organization of communities. Indicators cover culture and social structure as well as the makeup of the built and natural environment. Assessment of the quality of that environment is also seen across models. A comprehensive resilience perspective requires each element because social structures inform the kinds of infrastructure that is prioritized, and the existing built and natural environment shapes social organization, in addition, different kinds of infrastructure and ecosystems provide protection from some disasters and create vulnerability to others. The models are also concerned with the continuity of natural and infrastructural resources when faced with shock. Finally, the models capture knowledge and skills across layers in the community network. Resilient communities learn from the past and take steps to anticipate the future by making sense of the world around them. The knowledge that enables this is held by governmental bodies and institutions, as well as by citizens themselves, perhaps clustered into civil society organizations. What knowledge and skills exists, who holds that knowledge and those skills, and how to ensure those holders are included in decision making, is all critical for building the resilience of a community.

The relationship between violence inducing behaviors such as online hate speech and community resilience is a positive feedback loop. People are taught to hate. Communities with low resilience struggle to maintain their critical functions of keeping citizens happy, healthy, and safe. This creates tensions that can drive the spread of hatred. The exact combination of drivers that are present in one community changes according to what functions are failing or vulnerable. Hatred can spread through online platf orms rapidly, causing some groups to be ostracized and discriminated against. Discriminated people are dissuaded from participating in civic life which robs the whole of their perspective and skills and reduces their access to important resources needed to maintain their health and preparedness for emergencies. The separation of different groups degrades social cohesion making it more difficult for knowledge to transfer throughout the system, and inequitably exposes certain groups to dangers while reducing their means to cope with that danger. Resilience relies on initiative and reciprocity (Woods, 2019). People who are antagonistic to others will not engage in reciprocity and those who are discriminated against will have reduced initiative. Thus, new tensions emerge, and existing ones worsen, fostering more hate speech and other violence inducing behaviors as actors in the community stoke tensions for personal, political, or monetary gain. The spread of these behaviors weakens the community further, and sometimes results directly in violence. This makes it even more difficult for the community as a unit to adapt over time, i.e., degrading the resilience of the community, which provides more and more fuel for violence inducing behaviors.

We have compiled a series of focal topics to direct our future research and recommendations for others. First, we recommend that within community resilience research future work focus on better defining and separating the *Social* and *Community Capital* domains and their indicators. We also recommend that the models highlighted in this review be further analyzed and synthesized into a single comprehensive model. Our project will attempt this synthesis as part of our work. Finally, we recommend work be done to better consolidate research on community resilience, social resilience, societal resilience, community disaster resilience, and all other related threads. Research under each of these titles overlaps considerably and is aligned in their focus on sustained adaptability in

complex systems. Specific inquiry into sustained adaptability and other underlying principles of resilience is currently being carried out by researchers in Resilience Engineering along with several other fields (Woods, 2019; Yu et al., 2020 ; Engle, 2011), which may provide relevant frameworks for such a task. Within online violence prevention and related work, including ours, we recommend that future work directly integrate community resilience models. We will provide a few ideas for how this could be achieved.

Of the models examined in this paper, RESILOC resilience indicators, BRIC, CRIN, the CRI, and CART show the most potential for immediate practical application. The first three (Scherzer et al., 2019; Cutter et al., 2010; Akerkar et al., 2022; City Resilience Index, 2015) provide quantitative measurable proxies for their indicators alongside a comprehensive qualitative structure. These are essentially measures for potential drivers of online violence. Quantifiable measurements could be collected by automated tools and synt hesized in different ways to establish a clear baseline level of community functioning. The resulting information could be used to track the health of a community over time and potentially to prevent the spread of violence online by illuminating driving issues before they boil over. Monitoring only the presence of violent behavior online is inherently reactive. Monitoring the drivers creates more opportunity for prevention and a better means of anticipating future occurrences. For example, it is already well understood that periods of economic difficulty (economic strength is a community resilience indicator) can contribute to anti-migrant sentiment (directly related to multiple kinds of hate speech). Efforts to alleviate economic stress on groups of citizens may prevent the spread of hateful rhetoric by directly addressing the tension it aims to co-opt. These measures also provide a means of evaluating interventions. Because these indicators are agnostic to individual instances of online violence, they can be used repeatedly as the community changes and new sources of tension rise and fall. CRI and CART c an be used to generate complimentary data sourced directly from community members. This data can be used to evaluate the fitness of the other indicators or to assess citizen awareness regarding vulnerabilities in their community. If it is determined that the measurable proxies are insufficient or poorly tailored to a community, the comprehensive qualitative domains of all these models provide a structure that locally specific indicators could fit into. BRIC and CRIN provide a clear example of this. CRIN is an adaptation of the BRIC model to the context of Norway, though the two models share the same structure, their indicators are noticeably different.

CONCLUSION AND FUTURE WORK

Community Resilience is a nascent area of research with the potential to prepare groups of people to better cope with the emergence of threats that transcend national borders. Online violence, as an urgent global issue, presents an opportunity for this research to be tested. The natural place to test this research is prevention work because community resilience models provide means to identify and measure where the underlying architect ure is weak and thus where the tensions on which online violence relies exist in some communities. Because hate speech begets real world violence and degrades the health and wellness of citizens and communities, it fits well into the described domain of interest of community resilience theory. Yet current research has not explored how well community resilience models map to this specific kind of societal disruption. Such an application would serve to strengthen community resilience models by testing them on a novel type of threat and thereby assessing how domain agnostic they are. The insights gained from adapting and revising existing models to address issues of online violence and hate may provide insights and indicators that are similarly useful for dealing with natural disasters and other man-made emergency events.

Future work is needed within community resilience research and highly related fields to synthesize their findings into a single comprehensive framework and in online violence prevention work to integrate community resilience models. We are currently working on synthesizing the models identified in this paper. We will then connect some of the community resilience indicators from our set to different kinds of hate speech. We hope to establish as many similar connections as possible. Once this work is finished, we will develop tools to collect the measurable proxy data for our resilience indicators and to identify multi-modal data as hate speech. Online violence is destructive and dangerous in and of itself and can lead to instances of horrible violence in the real world. It demands that our communities change to overcome it and create a more accepting, diverse, and safe world for all people.

ABSTRACT

Digitalisation has a significant impact on most aspects of society. State agencies with safety and security tasks have to develop effective strategies to manage the opportunities and risks associated with technological innovations and increased networking. Emerging digital technologies have the potential to affect work practices and thus the organisational culture of such agencies. To examine the extent to which scientific research has addressed the impact of digitalisation on organisational culture so far, a systematic scoping review was conducted. Preliminary results show that the overall research topic is still in an exploratory phase and studies are primarily from the global north. The analyses show that the majority of studies focuses on artefacts around information data leading to respective work practices around data work.

Keywords

Organisational Culture, Digitalisation, Artefacts, Work Practices

INTRODUCTION

Since the advent of digital technologies and computers, digitalization has been a much-discussed development. New information and communication technologies, technical infrastructures and systems, changes in computing power, possibilities and capacities for data collection, processing, analysis and interpretation, artificial intelligence (AI), etc. are combined with significantly expanded corridors of connectivity, networking and exchange in working and living environments. Processes of digital change target all levels: Society and social subsystems, organizations and individuals. In times of the COVID-19 pandemic, these conditions seemed to offer both solutions and options for retreating from the pandemic-influenced world of presence into digital spheres and virtual spaces. In addition to the above-mentioned developments in society as a whole and the relatively dynamic development of technology and services (e.g., IT, AI), the digital transformation has been on the political agenda in several nations for several years and is embedded in a formal framework, for example, in Germany with the constantly updated "Implementation Strategy of the Federal Government". It is therefore no surprise that the field of government agencies including those responsible for public safety and security (in Germany subsumed under the collective term 'authorities and organizations with security tasks' (in German "*Behörden und Organisationen mit Sicherheitsaufgaben*"; BOS) are also under the influence of digital transformation processes (Schütte & Kox, 2022). Recent security-related developments (e.g., cybercrime, digital networking of offender groups), BOS and their representatives, politics, media, and academia (see e.g., Epple & Ludewig, 2019; Hüttelmaier & Käser, 2020) act as 'drivers' with regard to the discussion about the importance of digitalization or the digital transformation of BOS. This is often accompanied by promises or even pledges: Modernity of the organization (and its external image) and achievement of a current 'state of the art', preservation and optimization of the ability of BOS to act under the requirements of digitality and the handling of digital media, (improved) implementation of the mission, various further development potentials, promotion of innovativeness and flexibility, (better and closer) networking

for example in inter-agency cooperation (bitkom, 2020). Over the last years, a lot has happened in the digital transformation of German BOS. A rough insight into different government websites (e.g., of state police forces) contain references to state-specific programmes and master plans for digitalization that clearly show the development stages of the past and coming years. These include the expansion of digital radio and IT infrastructures, the purchase of additional mobile devices (e.g., smartphones for the North Rhine-Westphalian police), the inclusion of digital analysis approaches (such as social media analytics, big data analysis) and the 'purchase' of online specialists who, as 'Intel Officers', provide the police with important real-time information from the social media and other internet sources in particular during ongoing operations (Ministerium Landes Nordrhein-Westfahlen, 2021; Niedersächsisches Ministerium für Inneres und Sport, n.d., 2019). Non-police BOS such as fire departments, aid organizations or the Federal Agency for Technical Relief (THW) are also actively working on their digital transformation. Virtual Operation Support Teams (VOST) have already been established since 2017 as support structures in operational situations and docked with the THW (Fathi et al., 2018). In addition, almost all BOS use social media and operate their own social media accounts (Deutsches Rotes Kreuz, 2018). Innovative efforts are being made to implement new technologies to deal more efficiently with information on future developments in acute operations. Despite these developments, the status of the digital transformation of BOS still leaves room for improvement. It seems that digital transformation is not discussed much together with BOS and infrastructures and equipment are presented as expandable. Overall, there is a certain dissatisfaction with the state of digitalisation in the German BOS with the use of social media as an exception that is now more or less a normal part of communication (blaulicht.digital, 2020). Bureaucratic principles such as written form, file knowledge and rule-boundness offer stable structures for docking digital approaches. However, they may also sometimes slow down decisions, which favour a rather incremental organisational development, which appears to be less compatible with a technology development that brings new offers to the market in a very short time, while previous versions of tools and systems have not yet passed the bureaucratic decision-making processes. The development of operational routines with new technologies takes time. As long as they are not yet a normal part of practice and preparation in calm times, they cannot become a natural tool for acute situation management in turbulent situations, as they increase uncertainty more than they reduce it. The lack of techniques to quickly deal with or practice dealing with new technologies in the organisation delays the utilisation of new technologies (Schütte & Kox, 2022).

OBJECTIVE

Against the background of these considerations, the question arises as to what extent digital technologies are already anchored in the BOS. This question can be theoretically embedded the investigation of organizational culture (e.g., Bellot, 2011; Berg & Wilderom, 2004; Schein, 2010). This approach is not always very clear and free of criticism. Nevertheless, it can be stated that organizational cultures exist, are inherently fuzzy and socially constructed, are a product of groups not individuals, relatively unique to each organisation and subject to continual change (Bellot, 2011).

Schein (2010) assumes that organizational culture emerges at three different levels of an organization. He refers to the top and most visible level as the *artefact level*. This level includes everything that is directly visible, audible and tangible, such as dress code, architecture, office design, technologies, stories and documents, but also behavior patterns. The second level refers to *espoused values*, i.e. the organisations' stated values and rules of behaviour. The values are based on fundamental shared *basic assumptions* that are subconscious or unconscious, barely visible or observable and are almost impossible to research. In addition, van den Berg and Wilderom (2004, p. 571) "*define organisational culture as shared perceptions of organizational work practices*". They see *work practices* as a better means of capturing organisational culture, as these differ significantly more between organisations than values. Adopted from Schein (2010) and van den Berg and Wilderom (2004) we distinguish hereinafter between artefacts and work practices, which are defined as follows:

- *Artefacts*: This category refers exclusively to the field of digital technologies. Artefacts include hardware and software, technical systems, data, means of communication, etc.
- *Work practices*: This refers to activities of organizations and individuals that involve action, execution of processes, individual routines and techniques, etc. related to or shaped by digital technologies.

In order to systematically map the research done in this area, a scoping review (Tricco et al., 2018) was conducted. The following research question was formulated: *How are digital aspects i.e., artefacts and practices included in studies of BOS cultures?*

METHODS

Eligibility Criteria

Against the background of the questions and assumptions outlined above, scientific papers were included in the review process that relate and examine aspects of digitality and levels of organizational culture (e.g., technologies as artefacts, practices, values) in BOS. The papers needed to be: published in scientific journals, peer reviewed, published between the period of 2010 and 2023, social-scientific studies on the topic of organisational culture, written in English, focused on BOS (i.e., police, firefighters, emergency response) as well as focused on artefacts, techniques, practices included in studies of BOS cultures.

Papers were excluded if they did not fit into the conceptual framework of the study: opinion papers, journalistic articles, reviews and comments, technical analytics and discussions (engineering, computer science, etc.), only deal with the specifics of cyber-crime and internet-security, pure presentation of technologies/tools for an abstract addressee in the security field, or papers that discuss organizational change only as part of simulation experiments. Also excluded were studies that deal with organizations that: either cannot be seen as BOS, like actors of pre-hospital care, hospital care and emergency units, or are composed of several organizations and transcend national borders, as is the case with international police organizations, or were 'born' in digital era and are naturally influenced by digital aspects, e.g. Virtual Operation Support Teams (VOSTs). As Cobb et al. (2014, p. 890) point out: "*Empirical research on historical disaster events shows response efforts taking four different organizational forms: established, extending, expanding, and emerging. Emerging organizations are ones that have no pre-existing structure and come together as individuals who begin to connect and coordinate their work*".

Information Sources

To find the relevant academic articles the reviewers searched in the open data bases *Web of Science*, *SCOPUS*, *EBSCO* and initially *Google Scholar* for texts published between January 2010 and August 2023. During the search process, *Google Scholar* was dismissed as a source because of the platform's character limit per search and inconsistency in the results displayed on the first ten pages. On the three remaining platforms, the results were chosen when they featured the words of the search string in the title or the abstract and were published by academic, peer-reviewed journals.

Search

The reviewers formulated the search string in three parts, covering the themes BOS, digitalization and workplace culture respectively. The parts that were connected with AND operators consisted of related words that were connected with OR operators. For the term BOS the reviewers differentiated between police organizations and non-police organizations as described above, resulting in two different search strings. The final search strings for police and non-police are shown in Table 1 using SCOPUS as an example. Please note that the original search also included the terms in German. As there were no additional results, the terms are not listed here for space considerations.

Table 1. SCOPUS Search Strings

Sub-Search	Database	Search String
Police	SCOPUS	police OR "law enforcement" AND "organizational culture" OR "work practice" OR "work routine" OR "value system" OR "behavioral norm*" AND digitali* OR technolog* OR "artificial intelligence" OR "machine learning" OR "virtual reality" OR "augmented reality" OR "social media" OR "ICT"
Non-Police	SCOPUS	"fire brigade" OR "fire department" OR "fire services" OR "firefighter" OR "emergency service" OR "emergency response" AND "organizational culture" OR "work practice" OR "work routine" OR "value system" OR "behavioral norm*" AND digitali* OR technolog* OR "artificial intelligence" OR "machine learning" OR "virtual reality" OR "augmented reality" OR "social media" OR "ICT"

Selection

After removing duplicates, the refined search on *SCOPUS*, *Web of Science* and *EBSCO* concluded in a selection of 94 academic peer-reviewed papers (identification phase) that were then screened for suitability by all four reviewers (see Figure 1).

The first screening each reviewer read all abstracts and marked them as either fitting (n= 27), unfitting (n= 43) or in need of further discussion (n= 24). During this process, inclusion and exclusion criteria were iteratively formulated in more detail to make them clear to all participants. After individual review, the results were contrasted and discussed in the team. The 51 papers that were not unanimously excluded after their discussion were included in the next screening process that consisted of parsing the entire text for suitability. During the collection of said literature, 9 research papers of the 51 research papers were not openly available nor accessible through institutional affiliations. These papers were excluded from the investigation. In similar fashion to the first screening, the remaining 42 papers were read by each reviewer and marked as either fitting or unfitting (screening 2). After reading the entire text, two of the previously fitting papers were excluded and 14 of the papers that still needed discussion were excluded as well. Of the 26 remaining papers, 6 were still in need of further discussion, as the reviewers were in disagreement about their inclusion. After this process three more texts were excluded, leaving n=23 as the total amount of papers to be fully analysed. In the fourth step (inclusion), each of the included full texts were assigned to at least two different reviewers who first read and evaluated each text individually before discussing with the second reviewer.

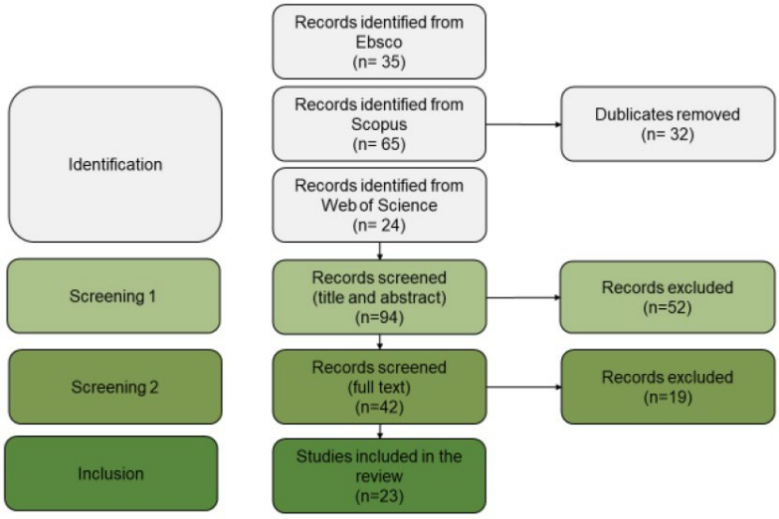

Figure 1. Visualization of the search process with information on excluded texts

Data Charting Process and Data Items

To ensure the most comprehensive data collection possible, an Excel table was developed during the screening steps which all reviewers filled in with categories or variables to be extracted. The categories which are also commonly used in other review procedures are: year of publication, author(s), country, topic (here: police or non-police), focus / aim of the study, study design / methodology, sample / setting / organization type, data collection, results, and limitations. The data in these categories is particularly suitable for text-related, descriptive and quantitative analyses. Some categories such as year of publication, author(s) or keywords are directly extractable from the texts. Other categories such as country or sample / setting can be derived using simple text analysis. The categories artefacts and work practices were derived by the reviewers based on the research question of the scoping review and the theoretical aspects of organization culture. To identify artefact categories, the reviewers assigned a potential artefact label to each text they read. Artefacts were relatively unambiguous in their identification and similar labels were assigned by both reviewers most of the time. In a next step, the reviewers created umbrella terms or overarching categories for all identified artefacts. As work practices are often discussed much less specifically in the texts, a consensus was reached between the reviewers through discussion. This is followed by a more in-depth interpretation of the relationship between the levels in relation to organizational cultural significance and an answer to the research question posed above.

RESULTS

Table 2 lists all 23 reviewed articles together with the listed keywords derived directly from the text. The table provides an initial overview of the different topics, contents and methodological approaches used. Some artefacts and working practices are also already sketched out. By further analysing the texts in depth, we identified 11 of the 23 papers as reporting solely on police organizations, 11 that reported on the various non-police organizations and one paper that focused on both police and non-police organization. A comparison of the geographical distribution of the study areas shows that the majority (seven) of the studies were conducted in the US, five in Sweden and three in the UK. The other study areas include the Netherlands (two), Canada, Italy, Denmark, Germany, Australia and India (one each). No studies that have been included in this review have been published on Africa or South America. In terms of the methods used, 18 studies can be categorised as qualitative approaches (10 of which were ethnographies) and six as quantitative approaches. Three of the 23 papers are a mix of both methods, while two can be described as conceptual papers. Themes, geographical distribution and methods show no noticeable trend over time, with no year having an extraordinary impact on the number of papers published. It should be noted, however, that as one could expect the two conceptual papers are among the first three papers published.

In the following we describe the results of the text analysis with regard to artefacts and working practices using the created umbrella terms or overarching categories: In total, nine overarching categories of artefacts have been identified by the reviewers, which are listed in Table 3 alongside the references. These include i) data storage and exchange technologies like cloud storage, ii) data visualisation and analysis technologies such as computer-generated diagrams, interactive maps or figures crafted on whiteboards, iii) information and communications technology (ICT) devices such as cell phones, computers or radio , iv) news and public information sources like news websites or other publicly available information, v) other social and infrastructure data like road traffic data, vi) social media, vii) surveillance technology such as Closed Circuit Television (CCTV) or body worn cameras, viii) various telemedicine technologies including electronic health records, and ix) virtual reality (VR) and augmented reality (AR) technology such as smart glasses or augmented bird tables.

With regard to work practices discussed, in total, six overarching categories of practices have been identified by the reviewers, which are listed in Table 4. These include i) administrative work including resource management and shift planning, ii) community engagement including public communication, iii) data work including information gathering, information processing and information sharing, iv) dispatch and control, v) inter- and intra-agency cooperation and collaboration, and vi) surveillance including investigations in hybrid environments.

Artefacts around information data could be summarised into a) information-gathering technologies, b) information analysis technologies and c) information visualisation and communication technologies leading to respective practices around data work. When looking at the multitude of work practices researched, data work stands out with more than half of the reviewed literature focusing on this practice. Many of the work practices identified are direct communication processes, either within the agency, between agencies or with/to third parties. There are also work practices that can be categorised as (computer-aided) information processing in the broadest sense, which can be summarised under the umbrella term computer supported cooperative work (CSCW). Finally, it should be emphasised that the categories listed in Table 3 and Table 4 are work in progress and represents preliminary evaluations. There is not always a clear distinction between the categories as they are themselves still under evaluation.

CONCLUSION

After presenting the main steps of the scoping review and addressing some initial findings, this paper draws the following conclusions. We give initial answers to the research question by giving a first descriptive assessment of the literature included in the review and provide an outlook on the next research steps.

The articles examined show that digital aspects have found their way into studies dealing with BOS and their work cultures. The analyses show that the majority of the reviewed studies are qualitative approaches including especially ethnographic studies. This could indicate that the overall research topic is still in an exploratory phase, i.e. there are many blind spots that require an open approach. It is also striking that the reviewed studies are primarily from the global north. The in-depth text analysis show that the majority of studies focuses on artefacts around information data leading to respective work practices around data work.

The team of reviewers assume that digital technologies have arrived in organizations as artefacts, but to a lesser extent in practices, espoused values or even basic assumptions. In other words, in seams that compared to analogue technologies such as pen and paper, axes, guns or water hoses, digital technologies have not yet become fully culturally embedded. Yet, our preliminary analysis has so far only focused on the categories of artefacts and practices, while other categories related to organizational culture have not yet been investigated and are the subject of the next steps.

ACKNOWLEDGMENTS

The contribution of Thomas Kox, Sebastian Rohwedder and Till Büser was part of the joint project "Weizenbaum Institute for the Networked Society" (FKZ 16DII131), funded by the German Federal Ministry of Education and Research.

ABSTRACT

Artificial Intelligence systems are more and more being introduced into first response; however, this introduction needs to be done responsibly. While generic claims on what this entails already exist, more details are required to understand the exact nature of responsible application of AI within the first response domain. The context in which AI systems are applied largely determines the ethical, legal, and societal impact and how to deal with this impact responsibly. For that reason, we empirically investigate relevant human values that are affected by the introduction of a specific AI-based Decision Aid (AIDA), a decision support system under development for Fire Services in the Netherlands. We held 10 expert group sessions and discussed the impact of AIDA on different stakeholders. This paper presents the design and implementation of the study and, as we are still in process of analyzing the sessions in detail, summarizes preliminary insights and steps forward.

Keywords

Values, Fire Services, Responsible AI, Decision-Support.

INTRODUCTION

In the last years, AI and data-driven systems are more and more being introduced into first response. Examples are real-time detection, monitoring, and analysis of threats and hazards (e.g., fire detection by means of machine learning algorithms (Talaat & ZainEldin, 2023)), real-time, continuous surveillance of the incident scene by means of drones or ground robots (e.g., by means of a machine-learning-based object detection system (Martinez-Alpiste et al., 2021)), and monitoring and analyzing physiological data of first responders (FRs) to detect (health) threats (e.g., by monitoring heart rate variability to determine current stress levels (Meina et al., 2020)). The development and deployment of AI systems raises new ethical issues (Stahl, 2021) and should be done responsibly, taking ethical, legal, and societal aspects into account. In the last years, many research programs have been started to further research how AI systems can be designed and built responsibly, both by industry (e.g., Google[1] and IBM[2]) and academics (e.g., Harvard[3]); also, law and regulations on responsible AI are planned (e.g., the EU Act (European Commission, 2021)). In addition, several guidelines have been developed for the responsible application of AI systems (AI HLEG, 2019; ECP, 2019). An important principle of all these initiatives is that the context in which AI systems are applied largely determines the ethical, legal, and societal impact of these applications and how to deal with this impact responsibly. To further investigate the responsible application of AI systems for first response, we have started a research project to set up a generic framework of ethical aspects of AI systems for first response. Our research is inspired by the Value Sensitive Design (VSD) methodology, which accounts for human values

2https://www.ibm.com/impact/ai-ethics
3https://cyber.harvard.edu/topics/ethics-and-governance-ai

throughout the design process (Friedman & Hendry, 2019). In a previous study (Mioch et al., 2024), first steps were made towards this generic framework by identifying relevant stakeholders and identifying and analysing a first set of human values of these stakeholders regarding AI systems for fire services. These general values have been identified to be important for this domain and should be taken into account when developing AI systems for FR. However, the applicability of the value set depends on the specific AI system and context of use and should be evaluated for each application.

In this research, we further develop and deepen the identified relevant human values for a concrete use case, the development of a specific AI application for the fire services, the AI-based Decision Aid (AIDA). AIDA is a decision-support system that is currently under development by the Dutch Safety Region *Rotterdam-Rijnmond*. The system will structure, analyze, and visualize large amounts of data that are generated (partly in real-time), such as camera pictures of drones or body cams, characteristics of incidents, building properties, historic incident data, etc. This introduction of AI technology offers new possibilities for more efficient and effective decision-making and operations, e.g., prediction of the development of an incident or advice on decisions based on previous incidents; however, the design and development should be done responsibly, taking human values of relevant stakeholders into account.

Research questions in the project concern the identification of expectations of relevant stakeholders, consequences for the organizational structure, how the introduction of AIDA influences work processes and information processing, and which values and value tensions occur when using AIDA in future scenarios. In this research, to identify the impact on human values of relevant stakeholders of the system, we conducted 10 focus group sessions with fire service personnel in which we assess and analyze the stakeholders' values. This article discusses the design and implementation of the study and, as we are still in process of analyzing the sessions in detail, summarizes preliminary insights.

In the following, we first present background on human values for AI development and give an overview of the envisioned AI system AIDA. We then describe the design and implementation of the study and preliminary results, followed by an outlook on next steps and discussion of the results.

BACKGROUND

In this section, we describe the importance of including human values into AI development for FR, give a short overview of previous research on the identification of affected human values, and describe the envisioned decision-support system AIDA, its functionalities and how it will be integrated into the current situation.

Including Human Values into AI Development for FR

In the last years, a lot of attention has gone towards the responsible use and development of AI, amongst others by the EU High-level expert group on AI (AI HLEG, 2019) and IEEE (IEEE, 2021). The AI HLEG identified 4 ethical principles that AI systems should adhere to (i.e., respect for human autonomy, prevention of harm, fairness, and explicability) and 7 key requirements (i.e., human agency and oversight, technical robustness and safety, privacy and data governance, transparency, diversity, non-discrimination and fairness, societal and environmental well-being, and accountability). The AI HLEG stresses that these ethical principles and requirements need to be situated and considered in context and that it should be determined for the specific applications whether these requirements are applicable, possibly supplementing them with additional relevant requirements. This means that for all AI applications, the ethical aspects need to be investigated to determine relevancy and applicability. IEEE also emphasizes the importance of considering ethical values throughout the stages of concept exploration and development.

The importance of including human values into the design and development of (AI) systems is also at the basis of the Value-sensitive design methodology (VSD) (Friedman et al., 2013). VSD is an iterative methodology that integrates three perspectives, namely conceptual, empirical, and technical investigations. These investigations are executed iteratively, though not necessarily in a set order. In this research, we focus on the empirical investigations for identifying impact of AIDA on fire services.

In previous work, ethical issues have been investigated for example for Search and Rescue robotics. Harbers et al. (Harbers et al., 2017) identified and analyzed relevant values affected by rescue robotics; values that were identified were, amongst others, personal safety, safety of others, access to information, well-being, effectiveness, ease of use, authority, health, and contact. Battistuzzi et al. (Battistuzzi et al., 2021) conducted a scoping review on ethical concerns in rescue robotics, identifying seven core ethically relevant themes: fairness and discrimination; false or excessive expectations; labor replacement; privacy; responsibility; safety; trust. In Mioch et al. (2024), as a

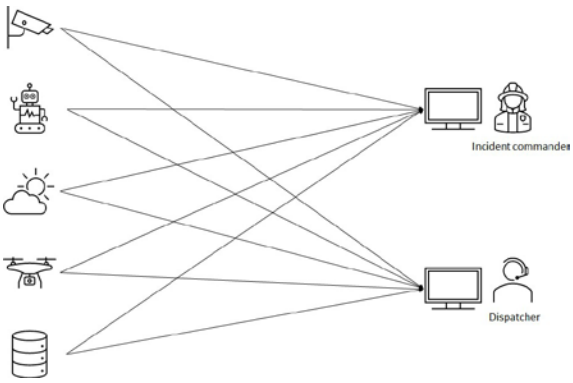

Figure 1. Current system set-up.

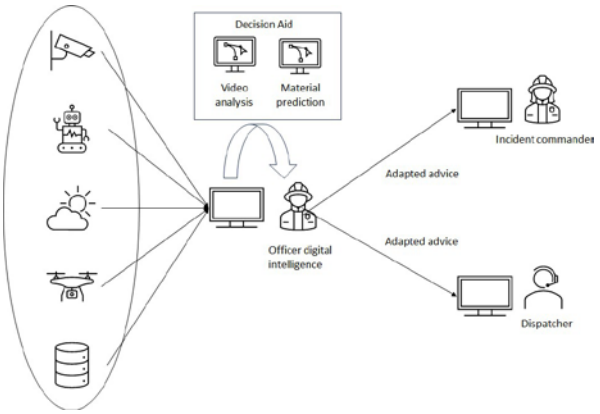

Figure 2. Envisioned set-up with AIDA.

step towards a generic framework of ethical aspects for AI in FR, relevant direct and indirect stakeholders of AI systems for fire services were identified and relevant human values of a prioritized selection of these stakeholders regarding the application of AI systems were investigated. The following stakeholders were identified as most relevant to take into account during the introduction of AI systems: fire fighters, incident commanders, special operations fire fighters (e.g., for hazardous materials and digital exploration), dispatchers, company doctors, incident researchers, citizens, and the surroundings (being an umbrella term for the nearby environment, including objects, people, nature, etc.). Positive as well as negative impact was identified for different human values. Starting point of the identification of values was the account of Friedman et al. (Friedman et al., 2017) as these are considered to be particularly important for technological design. Several values as defined by Friedman et al. were found to be impacted (mostly) positively for the different stakeholders (although there was no value that is only affected positively), i.e., *physical well-being* and *psychological well-being*. Several values were found to be impacted only negatively for the different stakeholders, i.e., *autonomy*, *identity*, *informed consent*, *privacy*, and *trust*. Several other values were identified to be impacted by AI systems, i.e., *accountability*, *transparency*, *reliability*, *security*, and *appropriate training*. AI systems should (explicitly) support the possible positive impact that they could have whereas the negative impact should either be reduced or avoided altogether, e.g., by specifying design requirements that explicitly take these human values into account. In this research, we will further investigate the impact on human values of the (envisioned) AI system AIDA, situating and applying the research by Mioch et al. (2024) for this specific application to further determine relevance of found values.

AIDA

A lot of different data is being generated or accessible by fire services, such as camera images of drones or body cams and building properties; currently, this data is streamed directly to FRs without any analysis or interpretation and displayed on different (sub)screens, see Figure 1. That means that FRs continuously need to monitor large amounts of data to build good situation awareness (SA). This is very time– and work-intensive and can lead to cognitive overload of individual FRs and subsequently to suboptimal decision-making, especially during complex and dynamic incidents and high time pressure. To mitigate these effects, the Dutch Safety Region *Rotterdam-Rijnmond* is developing an AI system, AIDA, to support them in the analysis, interpretation, and visualization of this (real-time) data. This introduction of AI technology offers new possibilities for more efficient and effective decision-making and operations, e.g., prediction of the development of an incident based on data from comparable incidents and information on the current status. In addition, new roles are envisioned to support in the sense-making process and sharing of information.

For AIDA, different modules are being developed. For this research, we will focus on two modules that are designed to help the dispatcher and the incident commander with building up situation awareness and their decision-making, i.e., the *video analysis module* and the *material prediction module*. The main goal of the former is to support shared situation awareness, whereas the latter will provide advice on the material to send to an incident. For both modules, AI systems are envisioned. Shared situation awareness (of for example the incident commander) in the *video analysis module* will be supported by analysing and interpreting different video sources (e.g., drone camera pictures) to identify relevant information, such as locating humans in camera or drone pictures in the incident area faster and with less cognitive effort, aiding with decision-making regarding the deployment of teams and logistical effort (a first prototype description can be found in Heemskerk et al. (2024)). This will be particularly useful in situations in which the situation is very dynamic and complex. Advice in the *material prediction module* will

be given on, amongst others, the expected material that is needed during particular incidents, based on data of previous incidents, real-time characteristics of incidents and other data such as cadastre data. The safety region expects to introduce a new role, the *Officer Digital Intelligence (ODI)*, who monitors and analyses the different data streams and outputs of the different modules and coordinates the information towards the dispatcher and incident commander. Both keep access to all data, but are supported by the ODI, see Figure 2. In the following, the two modules are described in more detail.

Video Analysis

A lot of camera pictures are generated by different cameras during incidents. One source of video data are drones that film the location of an incident from above. The video feeds need to be monitored to recognize relevant information for incident response, such as development of the fire or presence of people. The envisioned AI module will analyze and interpret the video stream and detect humans. It will be able to classify humans into fire fighters, ambulance personnel, and civilians. In addition, a short summary can be made of the video stream based on changes and development of presence of people in the footage.

Material Prediction

A lot of data is available from past incidents, as the development of each incident is logged, e.g., the address of an incident, characteristics of the incident, and material that was requested (type of vehicle, specialization of personnel, etc.). The envisioned AI system will, based on correlations found in the available past data, predict what kind of material is needed for an incident and advise the officer to request the necessary material.

METHOD

To determine the relevant values of different stakeholders for AIDA, we conducted 10 focus group sessions with different stakeholders of the fire services. In total, 40 employees of the fire services participated, of which 1 head incident commander, 16 incident commanders, 19 dispatchers, 3 fire fighters, and 1 emergency coordinator. Many of the participants had several roles in the fire services, e.g., a dispatcher also working as voluntary fire fighter; for this overview, we selected the role that the participants mentioned when signing up. 5 participants were female. For an overview of the participants, see Table 1.

During the focus group sessions, the following steps were followed: first, a short introduction into AI technology was given, its working, possibilities, and limitations, to make sure that participants had a general knowledge of the working of AI systems to be able to identify impact of AI. Most participants had heard of the plans to introduce AIDA, but were not familiar with details. For that reason, the envisioned functionalities of AIDA were introduced as described above, together with the envisioned embedding into the organisation. Two scenarios, one for each module, were used to instantiate the working of AIDA into situation and organizational processes, see Table 2. These scenarios highlighted value tensions. In each session, one of these scenarios was presented as a basis for discussion on the positive and negative impact of the corresponding AIDA module. As a first step for this research, the participants were asked to identify positive and negative impact of AIDA for the roles *Incident commander*, *Dispatcher*, and *Officer Digital Intelligence*. These roles were chosen because (most) participants belonged to at least one of these stakeholder groups, these stakeholder groups will be directly influenced by the results of the

Table 2. Scenario descriptions.

	Scenario 1 - Video analysis module	*Scenario 2 - Material prediction module*
Situation	Large fire in industrial building; The fire brigade explores the situation. A drone team is called and a drone provides a live camera feed of the building and environment. It becomes clear that not all employees are accounted for.	A building in the center of Rotterdam is on fire. The dispatcher receives the 112 call with the location of the fire and notifies the fire brigade with the information; according to procedure, two cars are sent.
Data	Drone camera stream; camera pictures of bodycams.	Historical incident data, characteristics of current incident.
AI technology	The AI system processes the data in real-time and combines the various data sources; it detects humans in the camera pictures and distinguishes between fire fighters, ambulance personnel, and civilians. The system can also give a summary of the video feed.	The AI system predicts, based on historical incident data, what kind of material will be needed. In an adapted version (session 1), the AI system predicts the personnel that should be called up to be deployed (instead of which material should be deployed).
Steps	The ODI requests a summary of the last minutes of video stream, in which newly recognized persons are displayed in the video stream. AIDA identifies people on the video stream and shows a summary of all people found. The system distinguishes between firefighters, ambulance personnel, and civilians. The ODI looks at the summary of the video stream. Several citizens are shown. The ODI provides the relevant information to the dispatcher.	AIDA continuously monitors and assesses the material requirements of incidents, based on various data sources such as land registry data and historical incident data. It predicts that only one car is needed for this incident and passes this on to the ODI. The ODI assesses the advice, agrees with it and passes it on to the operator.

system, and because these stakeholder groups are amongst the stakeholders that were identified in previous research as particularly relevant (Mioch et al., 2024). In the continuation of this research, impact on other stakeholders will also be investigated. The results were shared plenary and discussed. During the discussion, additional impact was added. Also, the participants were asked to discuss how positive impact could be supported and negative impact be reduced. During the focus group sessions, we tried to focus on the impact of the AI modules and not on the impact or the introduction of the new role (the *ODI*).

PRELIMINARY RESULTS

As we are still in the process of analyzing the expert group sessions in detail, in this section, we will describe preliminary results, i.e., a selection of expected impact that was mentioned by the participants. First, we shortly describe impact and requirements of the new role that is suggested to support dispatcher and incident commander with the analysis of the data. After, for each of the two AI modules, we describe a selection of impact participants mentioned and corresponding human values that are implicated, based on the previously identified list of human values that are implicated by AI systems for FR (Mioch et al., 2024). As we are still in the process of analysing the results, these first impressions will later be updated.

New Role *Officer Digital Intelligence* As mentioned above, the introduction of AIDA is accompanied with the introduction of a new role, the *ODI*. Various aspects were mentioned in the sessions that are relevant to the role of ODI, and especially to the collaboration with the incident officer and the dispatcher. First of all, the expertise of the ODI is very important; the ODI needs to have good insight into the tasks and role of both dispatcher and incident commander. Since the dispatcher and officer can be very busy with their own tasks, it is very important that the ODI understands what kind of information the other two need or do not need at any time, so as not to disrupt their process, introduce overload, or miscommunication (by speaking 'two languages'). The ODI should take work off the hands of the dispatcher, but should not make decisions; the ODI should have a support function and work together with the dispatcher and the incident commander.

Video Analysis

The participants discussed the impact of the *Video analysis module* in 5 sessions. In the following, we present a selection of expected impact that was mentioned by the participants, sorted by value or ethical aspect that is affected. Please note that this overview is by no means complete yet and only gives an idea on some of the topics that came up.

Autonomy Autonomy refers to people's ability to decide, plan, and act in ways that they believe will help them to achieve their goals (Friedman et al., 2013). Impact that affects *autonomy* was mentioned for the introduction of both modules. Regarding the module *Video analysis*, participants stated that the systems might lead to less decision-making power because of valuing and interpreting information becomes more difficult, e.g., because of not understanding the information and analysis that the system provides ("But the problem with the system is that it might be better than we are, and that we cannot understand it. [...] It is very difficult to find a good balance: to some extent you want to use it, but otherwise you also want to handle the situation yourself."). Participants mentioned that they are concerned about their dependence on the technology and that if the system fails, their ability to operate might be impaired because they forgot how to handle the situation without the system. Specifically for the application of detecting and summarizing persons in the drone video stream, participants were concerned that it would influence autonomy negatively through disproportional trust in the results of the system ("It's exactly like that video where the monkey walks through the screen where 100 people don't see that monkey, [...], you no longer see the rest of the information, because I become triggered to look at people.")

Identity Identity refers to people's understanding of who they are over time, embracing both continuity and discontinuity over time (Friedman et al., 2013). Impact that related to the value *Identity* was mentioned in several sessions, for example regarding expected changes in tasks for the different stakeholders, e.g., positive impact on the dispatcher ("the dispatcher can focus on his or her main tasks"), but also the expectation that some tasks will no longer be performed by the dispatcher ("The ODI takes quite a bit of work off the dispatcher's hands"). Some participants were afraid that their role will become less relevant and that they will be skipped in the communication between ODI and incident commander. The dispatcher's expertise could be used less which led to feeling threatened in their work ("That can [...] be kind of demotivating for the dispatcher or feel as if they become redundant or irrelevant, or less important").

Psychological well-being Psychological well-being falls under the value *Welfare* as identified by Friedman et al. (2013). Participants mentioned that introducing (summaries) of video streams of incidents for the ODI or the dispatcher will give them more information and overview on what is happening and might improve decision-making. However, it will also introduce pictures of what is happening, which might lead to more PTSD (" you see something that you may not want to see in that role").

Trust in AI Participants mentioned that (appropriate) trust in AI systems is important. Participants said that there is a danger of too much trust, e.g., being influenced in decision-making too much, not evaluating and reflecting enough the situation ("I'm a bit afraid of tunnel vision; that we will focus 100 percent on the system [...] and that common sense will fade into the background"). In addition, it is very important to understand the capabilities and limitations of the system to be able to determine how to include the pictures in the decision-making process ("[...] that you are going to make assumptions, that you do not check whether the pictures from the drones are actually current reality, or that there are aspects that are not filmed.").

Accountability Accountability can be seen in the context of liability (legal responsibility) as well as social responsibility. Participants mentioned that they expect negative impact on accountability, for example when the system provides information that is not followed on by the FRs ("And I think you will soon have another problem, that the information is there, [...] but you have not done anything with it. And then you get public pressure [...] and you will get blamed for it.").

Material Prediction

The participant discussed the impact of the *Material prediction module* in 4 sessions. In the following, we present a selection of expected impact that was mentioned by the participants, sorted by value or ethical aspect that is impacted.

Autonomy Regarding *Autonomy*, participants mentioned that it might be more difficult for dispatchers to make decisions, as it might be difficult to interpret the advice and integrate it in the decision-making process ("We now always say the caller is always right, until proven otherwise. So if the caller says there is a raging fire and the system says that based on that criteria, you have to scale up or down, how do I deal with that?"). In addition, they were concerned about depending too much on the system and about their ability to operate when the system fails ("Are you still sharp at the moment the system does something crazy?").

Trust in AI Participants mentioned that they have difficulty in trusting an AI system that gives advice on aspects that might lead to a less optimal task performance, for example, in the case of sending less material to an incident ("I feel anxious (apprehensive) about scaling down based on technology."). In addition, even if they could understand the advice and rationally, this advice seems sound, then these kind of decisions still also have an emotional aspect that makes it difficult to follow the advice ("You may be able to explain it all rationally, but your feeling... says something different."). Also, they mentioned that there always is a difference between a theoretical reality (e.g., houses that are optimally built regarding fire safety, but where the context such as changes in the building or the inhabitants counteract the optimal circumstances) and practice, which makes systems based on data inherently unreliable.

Accountability Participants are concerned that legal responsibility need to be clearly specified; for example, when following advice of the AI system although it is not correct ("If I scale down and it is nevertheless serious, then it's my fault"). In addition, participants feel a strong social responsibility and see it critically that the *Material prediction* could advise less material to be dispatched ("It goes against your sense of helping").

Privacy Privacy refers to a "claim, an entitlement, or a right of an individual to determine what information about himself or herself can be communicated to others" (Friedman et al., 2013). Impact on the value *privacy* was only mentioned during the first session, in which the scenario (and AI module) was adapted towards planning of which personnel should be called up to be deployed (instead of which material should be deployed). During this session, the topic was discussed fervently, as this directly had links to the monitoring of personnel. Impact on privacy for citizens was not mentioned during the sessions. This might be because the participants were not explicitly asked to identify impact for these stakeholders.

DISCUSSION

Previous research (Mioch et al., 2024) investigated which human values are impacted by AI systems for fire services in general; the investigation was set-up to identify these values broadly and the impact of AI systems was not contextualized. This resulted in an overview of values that might be impacted (positively and negatively), but not in concrete (design) requirements on how to support positive impact and decrease negative impact. With this research, we contextualize this previous research by choosing a concrete AI application and discussing the impact of two example modules on fire services practice. By eliciting expected impact for these concrete AI modules, translating this impact towards affected human values and linking design requirements to these values, we hope to be able to make the step towards defining grounded design requirements for the responsible design and development of these modules.

In this paper, we have made first steps towards identifying relevant human values for two modules of AIDA. To achieve this, we have held 10 focus group sessions, 5 for each module, in which we discussed impact of the modules on tasks and roles of the FRs; we take a socio-technical systems approach, expecting changed task allocations and -responsibility and new human-AI dependencies. We presented first results of these sessions, i.e., statements that can be linked to value considerations, which again can influence design requirements. These design requirements should (explicitly) support the possible positive impact on relevant values whereas negative impact should either be reduced or avoided altogether, e.g., by specifying design requirements that explicitly take these human values into account. There are several things that can be noted on the basis of the preliminary results: first of all, several of the previously identified human values are implicated by the AI modules, e.g., *Autonomy* and *Identity*. In addition, values such as *Trust in AI* and *Accountability* have been mentioned for both modules. During the focus group sessions, the participants discussed the impact of the two AI modules within the context of two concrete scenarios and their fire services practice, including obstacles they see for the introduction of these specific modules and possible implementation choices to enhance positive impact; this discussion will be the basis for the analysis of the design requirements.

During the sessions, it was difficult to keep discussion to the specific scenarios and impact of the selected AI module. Possibly, the scenarios we presented were not specific enough and, in the future, should be made more specific by a simulated collaboration environment (as used in e.g., (Beuker et al., 2021)). Also, possibly because of the very different (technical) expertise and background of the participants, the discussions not always focused on the expected AI-related impact, but also on having access to particular data or other impact of IT-related systems currently in use.

We realize that, as described above, the introduction of AIDA is very complex and that it is not (yet) possible to discuss impact on the tasks, processes, and responsibilities of the different roles, as this also includes organisational changes through the introduction of a new role, the *ODI*. We only superficially touched on this issue when describing preliminary requirements on the expertise of the ODI. In the future, we will also look into these organizational aspects in more detail and analyse, discuss, and advise on the organizational and procedural changes. We also realize that for the participants, it was a challenge to differentiate between the impact of AIDA and the impact of the organizational change. We will take this into account in the analysis of the results.

The focus group sessions have been held right at the beginning of the modelling and development process for AIDA. The functionalities of the system are not yet set. The modelling and development process will profit from our research in several ways: (1) based on positive and negative impact that has been identified, design requirements will be specified that support the positive impact and reduce negative impact, (2) explicitly, values of different stakeholders are taken into account during the design and development process, and (3) the different stakeholders will be regularly involved in the research, which facilitates support and acceptance and improves the quality and suitability of the system. For now, we focused this effort of identifying impact of the two AIDA modules on three stakeholder groups from the fire services (i.e., *dispatcher*, *incident commander*, and *officer digital intelligence*); in the future, we would also like to hold focus group sessions with other FR organizations (e.g., police, ambulance services) and citizens to also take their perspectives into account.

In the future, we will further analyse the results of the expert group sessions and plan to (1) compare value implications between the two modules ('Are different values affected by the two modules?') and (2) compare identified values with the general framework ('Are there additional values affected that have not been identified before, or are some previously identified values not affected by these two modules?'). We will then integrate the results into the ethical framework, together with values found from normative sources, adding results of a scoping literature review on ethical aspects of AI systems applied to first response. The ultimate goal is to develop a framework for responsible development and use of AI in the fire services domain, including requirements and methods (e.g., with regard to identifying values and value tensions), models (e.g., with regard to situated values), design patterns of responsible AI development and deployment, and evaluation methods for responsible AI so that practitioners and AI developers can use the framework as a toolbox towards responsible AI design, development, and deployment.

ACKNOWLEDGMENTS

We would like to thank the first responders of *Gezamenlijke Brandweer Rotterdam*, *Veiligheidsregio Rotterdam-Rijnmond*, and *Veiligheidsregio Zuid-Holland-Zuid* for their participation in this research. This research was supported by the University of Applied Sciences Utrecht (HU) through a '*promotievoucher*'.

ABSTRACT

This work-in-progress paper presents the preliminary results of an exploratory study on the effectiveness of a simulator training for ad hoc collaboration between sea- and airborne professionals in the field of maritime search and rescue. To enable this training, two different types of simulators were coupled. This coupled simulation environment provided the 49 (preliminary) study participants—seafaring and helicopter professionals—with authentic simulator training conditions. Our training was developed and tested using a two-phase approach. In the first phase, we used qualitative methods to identify requirements and design a training using insights from domain experts. In the second phase—the preliminary results of which are presented here—we tested the impact of the training on the acquisition and transfer of competencies as rated by the participants. To uncover contingencies of these training effects, we explore demographic predictors. We show which set of participants perceived that they benefited most from the training.

Keywords

ad hoc teams, learning, maritime search and rescue, simulation, training

INTRODUCTION

In the event of major incidents, such as natural disasters or major accidents, cross-organizational cooperation—involving, e.g., fire departments, police, rescue services or military—is an effective way to mobilize the necessary resources in a short period of time to save human lives (Hällgren, Rouleau, & de Rond, 2018; Steigenberger, 2016). This requires people from different professions and backgrounds (full-employed rescue workers and volunteers) to solve tasks as an ad hoc team—that is, individuals who collaborate to accomplish a task but do not

know each other, and have no prospect of further collaboration (Hollenbeck, Beersma, & Schouten, 2012; Salas, DiazGranados, Klein, Burke, Stagl, Goodwin, & Halpin, 2008)—often under critical conditions (Flin, O'Connor, & Crichton, 2007; Weick & Sutcliffe, 2015; Weick, Sutcliffe, & Obstfeld, 1999; Weick & Roberts, 1993). The organizations that commission these individuals strive for reliability in fulfilling their (sovereign) mission, and thus train these individuals in a standardized manner (International Maritime Organization [IMO], 2014; IMO 2015). Therefore, clearly defined hierarchies, training programs, and internal career paths are characteristic of these organizations. In addition, regular internal training and live exercises ensure that each individual and the organization as a whole are always able to act. In these settings, learning takes place primarily through practical action by systematically reflecting on operations, e.g., in debriefings or by means of after-action reviews (Klein, 2015; Kolb, 2014). These trainings are known to benefit individual's expertise. However, these trainings rarely cover cross-organizational work in ad hoc teams—where different professions from more than one organization are required to collaborate in a critical situation. In consequence, we know little about how rescue workers can be prepared for such incidents. This presents a problem, because large-scale incidents are projected to become more likely as a consequence of climate change (Birkmann, Liwenga, Pandey, Boyd, Djalante, Gemenne, Leal Filho, Pinho, Stringer, & Wrathall, 2022).

This article addresses this relevant shortcoming in previous research. We provide a preview of an ongoing—soon-to-be-completed—study, which analyzes data from a new cross-professional simulator training course (AMARIS[1] training) linking professionals from the shipping industry (shipmasters, nautical officers, and coxswains) and helicopter emergency medical service (HEMS) personnel, i.e. helicopter crews including pilots, medical crew members, and hoist operators. In this study, we seek to explain the AMARIS-induced competence acquisition—i.e., the improvement of professionals' ability to successfully perform cross-organizational work in ad hoc teams—and competence transfer—i.e., the ability to appropriately apply the acquired knowledge in the workplace—of training participants (Blanchard & Thacker, 2023; Shippmann et al. 2000; Thielsch & Hadzihalilovic, 2020). We do this in order to gain an understanding of whether joint simulator training for members of different professions has the potential to prepare them for future ad hoc team collaboration. To maximize practical relevance and impact, we conducted our study in the field of maritime search and rescue (SAR), a setting where cross-professional collaboration is both common in practice but non-existent in training programs. Our study covers three elements: two data collection phases (qualitative and quantitative) and the development of a technical simulator innovation allowing us to train and test inter-professional ad hoc teamwork. Specifically, we coupled[2] the SAR simulator center of the German Maritime Search and Rescue Service (DGzRS) in Bremen with the Air Vehicle Simulator (AVES) of the German Aerospace Center (DLR) in Braunschweig—two fundamentally different types of simulators that serve as a networked training and laboratory environment for the subsequent data collection. AVES consists of three simulators with a Roll-on/Roll-off (RO-RO) cockpit exchange concept and is in operation since 2013. A full motion and two fixed based simulators with large projection systems can carry cockpit modules and interchange them within a few hours. Currently four cockpit infrastructures are available: an Airbus A320, Airbus Helicopter EC135, Advanced Future Cabin (windowless cabin) and Falcon 2000 ISTAR (DLR, 2024). The SAR simulator is based on the networking of five ship handling simulators, two of which can be used multifunctionally: either as a ship, helicopter (tactical) or rescue control center workstations. The system is completed by a Maritime Rescue Coordination Centre (MRCC) cubicle with four workstations including a coastal radio station workstation and two Mobile Operation Stations (MOS), which can be integrated into simulations via Virtual Private Network (VPN) and are also designed to be multifunctional. All simulator cabins are equipped with communication media (e.g., radios, telephone, and e-mail). A central instructor center operates the SAR simulations. While the SAR simulator is used exclusively for training emergency personnel, the AVES is used purely as a research simulator for the development of information and control systems.

There are several previous examples of simulators being networked for research and training purposes. These include the coupling of a ship handling simulator and an engine room simulator at nautical universities or the transnational linking of ship handling simulators in the European Maritime Simulator Network (EMSN) to research safe vessel traffic management (e.g. STM, 2024). Coupling the AVES with the SAR simulator is innovative in its approach, as it is the first to connect simulation environments across organizational boundaries

[1] AMARIS is an acronym for the German project title "Aeronautische und maritime Innovationsumgebung für interorganisationale Simulationen". Information on the project is available from the authors upon request.

[2] AMARIS required a distributed simulation setup across the internet, because the simulators are located in different facilities. While the AVES uses a software environment developed entirely by the DLR, the industrial standard "Distributed Interactive Simulation (DIS)" was used to interconnect both simulators. The SAR simulator works as a host and is capable of reading and writing the DIS-protocol standard. To ensure safety and security during data exchange, a VPN tunnel was used.

and different domains (Figure 1).

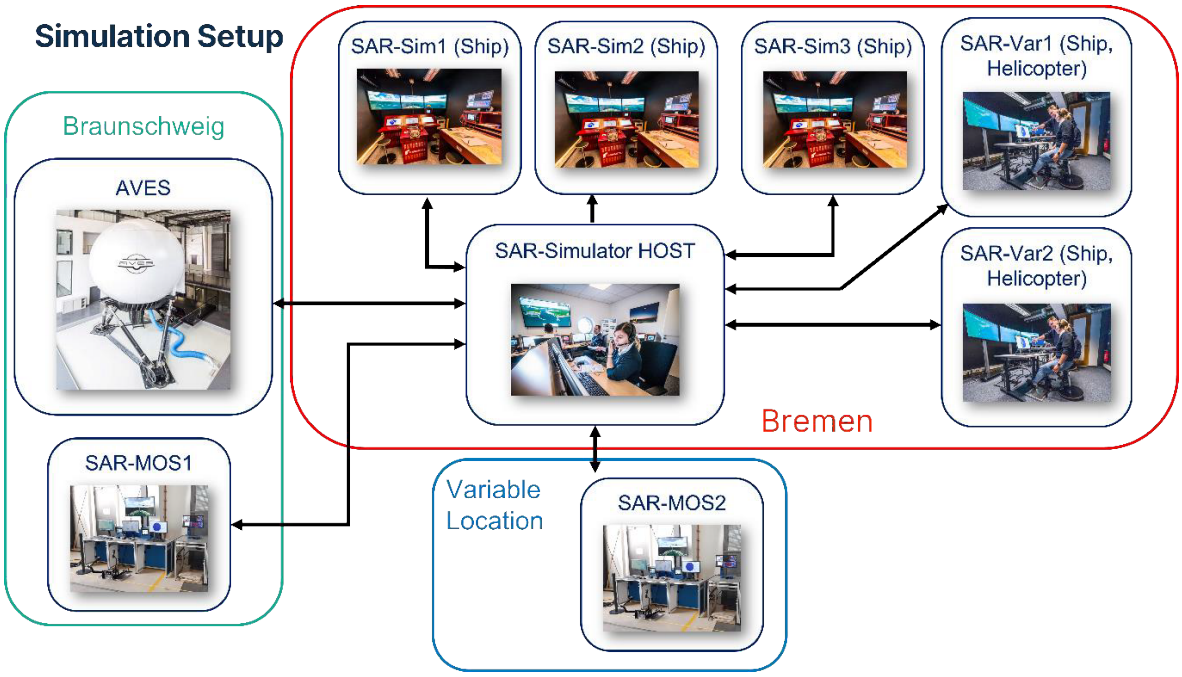

Figure 1. Simulation Setup

With the realization of this innovation, ship crews can train together with helicopter crews in joint scenarios—they can see the other units and have all the means of communication available to them on their real rescue units. In our quantitative study, we evaluate the effectiveness of our training in this innovative simulation environment, by collecting survey data on participants' perceived training success using the Feedback Instrument for Rescue Forces Education (Thielsch & Hadzihalilovic, 2020). This data shows that our training has a positive effect on the acquisition and transfer of competencies as rated by the participants. Additional analysis shows that the extent to which individuals benefit from the training varies based on professional background, age, and tenure. This provides criteria for selecting future training participants to maximize the potential future benefits of the training.

OPERATIONAL BACKGROUND

The close practical relevance of our research has its origins in the operational practice of the maritime search and rescue service in Germany. The authority for this was transferred from the Federal Ministry of Transport to the non-profit organization DGzRS. This organization not only coordinates the rescue operations but also provides the necessary ships (IMO, 2006). In Germany, air support at sea is regulated by a mutual support agreement with the Ministry of Defense, which is responsible for the aeronautical search and rescue service. This means that SAR helicopters from the German Navy are also available on request of the DGzRS for rescuing people in distress at sea. Furthermore—and because international conventions oblige anyone in the vicinity of a maritime emergency to provide assistance—private offshore aviation represent a potential additional resource for DGzRS maritime rescue operations. With the ongoing expansion of offshore wind farms in the German Bight and the western Baltic Sea, these companies are now also present in the German Exclusive Economic Zone. The helicopters of these companies transport people and material to the wind farms or back to shore, and usually have medical personnel on board. The increasing economic use of maritime space for the production of renewable energies therefore generates an increase in the number of ships and helicopters that could assist in rescue operations. Formally, the tactical interaction between these resources in a rescue situation is regulated by an international set of rules. Specifically, International Aeronautical and Maritime Search and Rescue Manual (IAMSAR) published by the International Maritime Organization (IMO) and the International Civil Aviation Organization (ICAO) describes all essential procedures for the search and rescue of human life and is the common action framework for SAR organizations in an international context (IMO & ICAO, 2022). The organizations with a SAR mission—in Germany, the DGzRS and the Naval Air Wing 5—use the IAMSAR Manual as a legally binding tactical interaction framework. In addition, the officers of every merchant ship are required to have a current edition of

the IAMSAR Manual at hand, in case their ship finds itself in distress at sea or has to carry out search and rescue operations on site. The situation is somewhat different in aviation. In civil aviation, the IAMSAR Manual does not have to be carried on board, and it is largely unknown to pilots. In the past, this has been repeatedly observed in the operational integration of offshore helicopters in rescue missions and real live exercises: Although offshore helicopters demonstrate continuously excellent skill at rescuing people in distress from ships or from the water, we found deficits in carrying out search operations because the necessary know-how is not mandatory for helicopter pilots. Taken together, these circumstances provide an excellent setting to advance our understanding of training for inter-professional ad hoc teamwork.

Our training is implemented by the DGzRS simulator training crew. For more than 20 years, the DGzRS simulator crew has been training nautical officers and captains of government vessels, in addition to its own emergency crews, to be able to take on leadership roles during maritime SAR operations (e.g., on-scene coordinators [OSC]). Our study draws on this extensive experience. Specifically, the AMARIS multi-day training course mainly takes place at the DGzRS SAR simulator center with participants from different organizations/authorities, with the HEMS professionals joining the training from the DLR facility in Braunschweig. To operationalize ad hoc teams, we randomly allocate seafaring professionals to trainings teams of three. These participants each occupy a simulator cubicle and apply the course content in scenarios of varying complexity. The HEMS professionals in Braunschweig were not subject to this randomization in team allocation, because there is only one cubicle in Braunschweig.

METHODS

In order to develop and test our training concept for inter-professional (seafarer and HEMS professionals) ad hoc teams, we conducted a two-phase study. First, to identify requirements both for such a training concept and a coupled simulator environment, we conducted an exploratory qualitative data collection using 25 semi-structured, guided interviews. Second, to test the effectiveness of our training concept, we enrolled a preliminary number of 49 unique participants (40 seafaring professionals, 9 HEMS professionals) and subjected them to the training protocol using the linked DGzRS and DLR simulators. In this phase of our data collection, we asked the participants to complete a survey after completing the training. The following paragraphs provide a detailed account of both phases of data collection and analysis.

In study phase one—our interview study—we approached individuals knowledgeable about the phenomenon we intended to study: We interviewed SAR stakeholders, such as helicopter pilots (13) and coxswains of rescue cruisers (8), but also safety officers (2), trainers (1), and training representatives from the participating organizations (1). We decided to use the data collection method of semi-structured interviews, because they offer the advantage of providing comparable responses across cases but can also be adapted to the background and experiences of the interviewees, thus allowing for additional exploration if needed. This is because semi-structured interviews allow for follow-up questions on individual aspects and any ambiguities can be clarified immediately (King, Horrocks, & Brooks, 2019). The interviews were conducted virtually[3] and were recorded and transcribed in accordance with both methodological (Miles, Huberman, & Saldaña, 2020) and data protection guidelines. The interview guideline was developed interdisciplinary, taking into account aeronautical, maritime SAR, and behavioral science perspectives at the same time. It covered items such as description of a recent and demanding incident concerning procedure, key aspects of ship – helicopter teamwork in SAR operations, and assessment of occurring challenges and how they were solved. To provide specific instances where inter-professional ad hoc teamwork is needed, special emphasis was placed on the consideration and description of various hoisting procedures and typical challenges and possible misunderstandings between helicopter pilots and coxswains when carrying out a hoisting maneuver. Another key focus was put on the technical set up of a joint simulation environment. Helicopter pilots as well as coxswains were asked to describe key features which they would like to see in a shared simulation environment. This information was essential to our technical development of a linked simulator environment. Overall, we collected 33 hours of interview data. On average, each interview lasted 78 minutes (min: 48; max: 113). We processed our interview data using content analysis. Our analysis of the qualitative data revealed that although the IAMSAR Manual Vol. III (IMO & ICAO, 2022)—as international SAR standard—regulates the cooperation between seafaring and flying units during missions, relevant regulations were not always sufficiently well known by interviewees, especially among commercial offshore pilots. Flying and seafaring units partly show significant differences in standard operation procedures and in communication routines. We found that this can have a negative impact on the quality of cooperation when carrying out both standard search procedures and hoisting maneuvers. For example, interviewees reported that when conducting

[3] We conducted the interviews virtually due to the COVID pandemic. To ensure interoperability and good data quality, we used the Microsoft Teams platform and its recording capabilities.

hoisting maneuvers, they found it essential that the processes run smoothly and that everyone involved can rely on each other. We also found that although these operations were often practiced under real conditions, the interviews expressed low confidence in their knowledge of the working conditions of the other unit (helicopter or rescue cruiser). Thus, the main result of study phase one was the identification of specific challenges and needs for improvement of joint SAR operations involving helicopters and rescue cruisers. The interview data also provided requirements for realizing a linked simulation environment for aeronautical and maritime SAR training, which informed our technical implementation of the simulator coupling.

We used the findings from study phase one, as well as additional expert workshops, to derive the training concept ("AMARIS Training"). Two workshops involving various SAR experts with either maritime or aeronautical background were conducted to identify and refine both training objectives and corresponding learning objectives. The first expert workshop started with defining the *key objective* of the AMARIS training ("Coordination of multiple [air and sea] units to manage a maritime SAR situation on the basis of IAMSAR III"). On this basis, the learning objectives and the training content to be derived from them were developed gradually and with an increasing level of detail. Using the example of the training objective "Raising awareness of the capabilities and characteristics of seagoing and flying units", the training content includes, for example, "imparting knowledge about the definition of operational limits", "recognizing dangerous situations in practice", and "reacting appropriately to the use of an emergency procedure by the other unit". All learning objectives and training content have to be considered both from an intra-profession and a cross-profession perspective. This means though the AMARIS training aims to improve ship-helicopter interaction, training effects in intra professional cooperation can also be expected.

The second workshop was centered on developing the AMARIS simulator scenarios. These were designed with a focus on the AMARIS learning objectives as well as the knowledge and skills previously identified. We collaborated with groups of aeronautical and maritime SAR experts, with the assistance support of the SAR simulator trainer team, to develop three scenarios. These scenarios varied in task complexity, starting from a less-complex "starter scenario" to a highly-complex major incident. We conducted multiple check-ups to ensure that all previously identified training objectives, knowledge, and skills were incorporated and trained in these scenarios. Once the training scenarios were finalized, we created written training materials. These training materials covered basic and advanced SAR knowledge (e.g., search patterns) as well as information on the special objectives of the AMARIS training.

Finally, an extensive testing and programming work took place in parallel with the content design of the training program to ensure the technical framework conditions (Szczygielski, Gerten, & Wilhelm, 2021).

Procedures and Participants

In study phase two—the testing of the effectiveness of the AMARIS training—we implement the AMARIS training using seafaring and HEMS professionals. We first provide information on the course of the training before describing our study sample. The AMARIS training contains two elements: First, an initial online information session with participants and representatives of the AMARIS project. This session was organized to ensure that both groups of participants (seafaring and HEMS professionals) were well-informed about the theoretical SAR basics, the specific objectives of the AMARIS training, and the research data collection. The session also provided details on data protection and allowed future participants to clarify related questions to ensure informed consent. Second, the AMARIS training in the two linked simulators (DGzRS in Bremen, DLR AVES in Braunschweig). Each training starts with signing the data protection agreement, followed by blocks of theoretical and practical instructions in data collection and simulator handling. Hybrid sections via a virtual communication platform alternate with separate instructions in Bremen and Braunschweig. All scenarios start with a joint virtual briefing and conclude with a virtual debriefing session connecting all teams in Bremen and Braunschweig. In the default mode, each training sessions covers three ship cubicles with teams of three seafaring professionals each in the SAR simulator in Bremen and three HEMS professionals (pilot, co-pilot, hoist operator) in the AVES simulator in Braunschweig, thus matching our theoretical interest inter-professional work. To ensure that (most of) our study participants operated in ad hoc teams, participants in the ship cubicles switched crew compositions for every scenario. As there is only one helicopter crew in the AVES simulator, this crew composition remained constant. Please note however that the inter-professional collaboration between ships—due to their changing crew composition—and the helicopter also operationalizes ad hoc teamwork. The simulator was operated by a team of 3-4 instructors with the support of 1-2 representatives of the Aeronautical Rescue Coordination Centre Glücksburg, Germany (ARCC). These individuals oversaw the training from the instructor room in Bremen, simulating foreign ships, the MRCC, and the ARCC. Data collection, storage, and analysis were performed exclusively by the university research team in accordance with the study's data protection protocol. We pretested the AMARIS training and data collection three times using instructors from sailing and water sports

schools. These pretests resulted in minor modifications of the study protocol.

At the time of writing, 50 participants from various organizations participated in five AMARIS training sessions. Because one participant had to leave the AMARIS training early due to professional commitments, our preliminary sample consists of 49 individuals. Seafaring professionals came from the DGzRS (permanent [17] and volunteer [7] sea rescuers), further participants were also professional seafarers with theoretical and practical expertise in participating in sea rescue operations (16). Helicopter pilots came from the Navy (6), from (commercial) offshore helicopter service companies (2), and from general air rescue service providers (2). The heterogeneity in participants' organizational backgrounds provides an ideal match with our interest to study inter-professional ad hoc teams. On average, participants had worked for their organizations for 9 years (SD = 9.26) and in their jobs for 6 years (SD = 8.07). The mean age was 44 years (SD = 11.22). The gender distribution of 45 (91.84%) males is consistent with the gender distribution in the seafaring profession.[4]

Measures

We collected data on study participants' demographics, professional background, and—after completing the AMARIS training—perceived training effectiveness. These data were collected using a survey. Prior to the data collection, we discussed the survey with representatives of the professional groups involved in the AMARIS study, and we pretested scales with individuals who did not participate in the main study. This pretest consisted of a think aloud protocol to receive structured feedback on the validity and comprehensibility of the scales (Sudman, Bradburn, & Schwarz, 2010).

Outcome. To measure the perceived effectiveness of the AMARIS training, we asked participants to complete the Feedback Instrument for Rescue Forces Education, which we provided as a validated German translation (Thielsch & Hadzihalilovic, 2020). This instrument allows participants to subjectively assess their perceived training success, providing important information on the effectiveness of the AMARIS training. To ensure valid responses, the wording of the items was slightly adapted from the instrument's original firefighting context to our SAR context. Overall, the instrument covers six subscales—Trainer Behavior, Overextension, Structure, Group Behavior, Competence Acquisition, and Transfer—relevant to the AMARIS training evaluation. Answers ranged from 1 ("strongly disagree") to 7 ("strongly agree"). For each subscale, the corresponding items formed a single scale (Trainer Behavior: Cronbach's $\alpha = 0.71$, Overextension: Cronbach's $\alpha = 0.92$, Structure: Cronbach's $\alpha = 0.90$, Group Behavior: Cronbach's $\alpha = 0.83$, Competence Acquisition: Cronbach's $\alpha = 0.96$, Transfer: Cronbach's $\alpha = 0.75$). For this preliminary report, we focus on the two outcome subscales, i.e., self-rated Competence Acquisition and Transfer (Blanchard & Thacker, 2023).

Independent Variables. To identify which individuals perceived to benefit more—and which ones less—from the AMARIS training, we focused on established demographic and job predictors of training outcomes (Nazir, Jungefeldt, & Sharma, 2019; Sellberg, 2017; Colquitt, LePine, & Noe, 2000). Specifically, we tested for differences in the outcome for the following grouping variables: Age, Tenure (Organization), Tenure (Job). To create grouping variables for these variables, we conducted median splits. This procedure resulted in the following independent grouping variables: Age (younger: 25 years – 42 years, older: 43 – 69 years), Tenure Organization (low tenure: 0 – 5 years, high tenure: 6 – 32 years), Tenure Job (low tenure: 0 – 3 years, high tenure: 4 -32 years), and trainees' formal Education (1 = Secondary School, 2 = Intermediate Maturity, 3 = University Entrance Qualification, 4 = Graduate). We do not examine trainee gender due to the limited variance in this demographic in our current sample. However, we tested whether DGzRS Status (0 = non-DGzRS, 1 = DGzRS Volunteer, 2 = DGzRS Employee) explains differences in the outcome variables.

RESULTS

All analyses presented below were performed in Stata 16.1. Table 1 displays descriptive statistics and correlations among our study variables. The directions of the significant correlations are in the expected directions. In addition, as expected, we observe strong correlations between tenure organization and tenure job ($r = 0.72$). Since we do not present a multivariate analysis in this preliminary report, this unsurprising correlation is not a cause for concern.

[4] According to the Baltic and International Maritime Council & the International Chamber of Shipping (2021), women worker represents 1.28% of the global workforce in the shipping industry. The International Transport Workers' Federation (2024) states, the global proportion of female workers in the maritime sector is 2%.

Table 1. Means, Standard Deviations, and Correlations

	Mean	SD	1	2	3	4	5	6
1. Age*	1.47	0.50						
2. Tenure Organization*	1.49	0.51	0.39					
3. Tenure Job*	1.43	0.50	0.34	0.72				
4. Education	3.35	0.80	-0.26	0.03	0.19			
5. DGzRS Status	0.84	0.92	0.35	0.40	0.34	-0.29		
6. Competence Acquisition	4.38	1.58	0.29	-0.31	-0.05	-0.10	0.12	
7. Competence Transfer	4.95	1.32	0.16	0.15	0.41	-0.01	0.28	0.38

n = 49, correlations larger than |0.29| are significant at $p < 0.05$.
* Dummy variables based on median-split (1 = low, 2 = high).

To show the extent to which trainees perceived the AMARIS training to benefit their competence acquisition and transfer, Table 1 provides corresponding descriptive statistics. Table 1 shows an average Competence Acquisition of 4.38 (out of 7). The standard deviation for Competence Acquisition is 1.58, suggesting relevant variance in the participants' perception. The participant's average Competence Transfer (4.95) exceeds average Competence Acquisition, and a slightly smaller standard deviation (1.32), suggesting that the training offers relevant insights for advanced professionals with practical expertise. To better understand which trainees perceive that they benefit more (or less) from the AMARIS training, we performed the non-parametric Wilcoxon rank-sum tests for all binary independent variables. For the two categorical independent variables (Education, DGzRS Status), we conducted Kruskal-Wallis tests.

For Competence Acquisition, we found that trainees with higher Age had a significantly higher level than trainees with lower Age (p = 0.05). Figure 2 provides a strip plot illustrating this result. In contrast, trainees with low Tenure in their Organization had a marginally significant higher level of perceived Competence Acquisition than trainees with high Tenure in their Organization (p = 0.06). Figure 3 provides a strip plot illustrating this result. Surprisingly, we observe that trainee Tenure in the Job does not appear to explain any of the variance in this outcome (p = 0.83). We also do not observe significant differences in perceived Competence Acquisition for different levels of Education (p = 0.81) or DGzRS Status (p = 0.82).

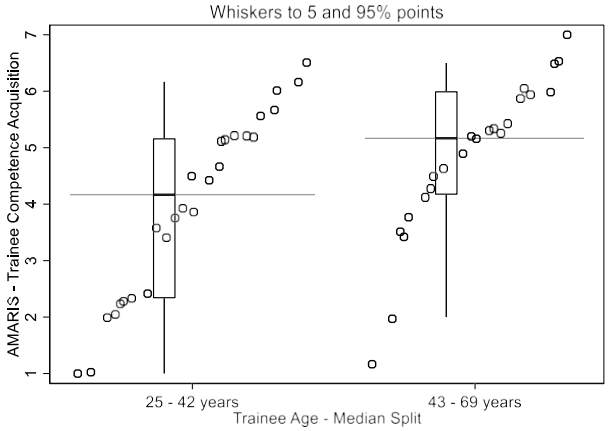

Figure 2. Competence Acquisition and Age

Figure 3. Competence Acquisition and Tenure Organization

For Competence Transfer, we found no significant difference between trainees with higher and lower Age (p = 0.32) and Tenure in their Organization (p = 0.21). However, our results show that trainees with high Job Tenure had significantly higher levels of perceived Competence Transfer than trainees with low Job Tenure (p = 0.01). Figure 4 provides a strip plot illustrating this result. We do not observe significant differences in perceived Competence Transfer for different levels of Education (p = 0.45) or DGzRS Status (p = 0.11).

Figure 4. Competence Transfer and Tenure Job

Taken together, the results for Competence Acquisition are consistent with the notion that older trainees with limited exposure to their current organization perceive themselves as particularly benefiting from the AMARIS training. The results for Competence Transfer are consistent with the argument that trainees with more extensive work experience in the maritime or aviation environment have more extensive mental representations of situations to which they can relate the AMARIS training material and experiences. In addition, as suggested by the non-significant results for both outcomes and Education and DGzRS Status, the AMARIS training does not appear to be exclusive in terms of formal education or professional SAR affiliation, suggesting that the training is inclusive in nature.

DISCUSSION AND CONCLUSION

The data available to us so far shows that the AMARIS training tested in our study is perceived as effective as a cross-professional qualification program. This is a promising initial result, suggesting that the previously identified training needs and critical mission situations cover relevant issues, and that the AMARIS training effectively addresses those issues. We were able to demonstrate that participants perceived that they gained skills

from the simulator training, regardless of their age and professional experience. However, the results need to be scrutinized closely, as we found that older participants, in particular, gained more competencies overall than younger training participants.

This is significant as older professionals are often difficult to reach with simulator training courses (Gully & Chen, 2010) as these professionals often do not consider such courses to be ”real live” or “hands-on“. Two conclusions can be drawn from this, although additional data and analyses are required: First, our simulators may have created a level of immersion that allowed all participants to perceive the situations created in the scenarios as authentic and to engage with them. This would be positive a training-inherent effect, as it could provide effective starting points for inclusive simulator training.

Second, the older participants may have a deeper understanding of the factual necessity of specifically training the topic of cross-professional collaboration (e.g., “effective ship-helicopter interaction”), so that potential concerns or reservations about simulator training may have simply faded. We therefore find a greater awareness of the importance of knowledge among the older study participants, which indicates an increasing level of professionalization over the course of their professional lives.

A surprising result for us was the significant correlation between the length of time spent in the organization—i.e., Tenure: Organization—and Competence Acquisition: participants who have been with their current organization for longer showed a lower level of competence acquisition than people who have only recently started working for their organization. The question of whether this could be due to motivational- or competency-related causes affected by the organizational tenure would have to be investigated using a larger sample, multivariate methods, and potentially additional data sources.

PRACTICAL IMPLICATIONS

The cross-domain networking of two different simulators implemented in the AMARIS project offers the possibility of linking the SAR Simulator Center with other flight simulators. This will allow the implementation of joint training content and new transdisciplinary training formats in the future, but it will also open up new research and development opportunities: The cross-disciplinary simulation of complex rescue missions suggests to be a promising laboratory environment for testing communication paths, operational procedures, and information systems with emergency personnel and obtaining well-founded end-user feedback. the possibility of operating prototypes of newly developed assistance systems during the simulation show great potential for researchers to bring innovation and end users together at an early stage.

LIMITATIONS

Our study does have limitations. Some will be addressed in our full manuscript, while others may inspire future research. First, this preliminary study analyzes a relatively small data set. To provide a robust analysis with our current number of observations, we rely on simple statistical tests. We are aware that we are currently using binary predictors (by means of median splits), and we cannot use control variables to account for potential omitted variable bias. While seafarers were randomly allocated to teams, our study is not an experiment, as it does not have control and experimental conditions. Thus, using multivariate methods once our data set is sufficiently large is our next step to rule out such issues. Second, due to limitations in both the simulator setup and the availability of helicopter pilots, we could not randomize team allocations among helicopter staff within each experiment. Future research should attempt to overcome this shortcoming by operating in settings with sufficiently large populations to ensure full randomization of participants.

ACKNOWLEDGMENTS

The joint research and development project AMARIS is part of the Security Research Program of the German Government and funded by the German Federal Ministry of Education and Research (BMBF), grant no. 13N15500, 13N15501, and 13N15502.

ABSTRACT

The availability of all relevant data in a situation report is key for efficient crisis management. The digital twin concept allows for comprehensive data accumulation, both from real-world sensors as well as augmented by simulations. However, the excessive amount and detail of data can hinder usability and discourage users or impede efficient decision making. To still benefit from such emerging technologies, user-tailored data visualization with appropriate filtering and processing is recommended. This work promotes the use of a standardized data aggregation in order to optimize customized data processing through implementation into existing platforms for crisis management. The concept is showcased for three well-established platforms with data accumulated from a standardized digital twin representation of urban critical infrastructure and emergency units. Each of the examples focuses on different facets of visualization as typically demanded by the respective target user group.

Keywords

Data aggregation, user-tailored data visualization, simulation and sensor data, crisis management

INTRODUCTION

The increasing frequency and intensity of critical situations resulting from both man-made and natural disasters require a heightened focus on security and resilience measures. A major focus of these measures is on critical infrastructure, as the failure or disruption of this infrastructure can have a significant impact, potentially leading to supply shortages and failures, thus reducing the level of public safety. Due to the highly crosslinked nature of the modern world, the shortfall of one single infrastructure provider not only has an impact on the immediate

environment but might also affect other critical sectors. In particular, unanticipated interdependencies and cascading effects between different critical infrastructures may lead to the increased risk of severe disruptions (Rehak et al., 2016; Rehak et al., 2018). Therefore, a deep understanding of interdependencies and cascading effects is required in order to take targeted actions and maintain public safety.

The high level of interconnectedness of critical infrastructure also has an impact on the assessment of a critical situation: Knowledge of a single domain is often not sufficient to respond to the situation, as in many cases several sectors are involved. Nevertheless, it is crucial for decision makers to act quickly and efficiently to prevent worst case scenarios. In such situations, visualization is a key tool to break down the complexity and simplify data access and interpretation. It helps stakeholders to understand, analyse, and respond effectively to complex scenarios, leading to better outcomes and risk mitigation. Furthermore, it enables people from outside the field to gain understanding and interpretation of the situation.

Large sensor networks and shared data bases, especially when augmented by computer-aided modelling and numerical simulations, can provide useful but potentially overwhelming amounts of information about complex situations. For analyses regarding the aforementioned interdependencies and cascading effects, disentanglement and preprocessing of information is needed.

The well-known proverb “A picture is worth a thousand words” underlines the power of a visualization. However, the quality of the visualization is also crucial, as every simplified visualization always runs the risk of leading to misunderstandings and misinterpretations. In order to enhance the correct understanding and assessment of a critical situation, it is necessary to adapt the visualization to the needs of different user groups.

This paper presents the concept of a versatile processing pipeline for large comprehensive amounts of complex, interdependent data using three different visualization tools. All of them are able to highlight relevant aspects of critical situations to their respective user groups. This is made possible by the consistent use of open standards as an intermediary between data producers and consumers. The three compared tools are a representative selection of well-established tools used by different user groups in public safety. However, other visualization software could be used as well.

The chosen tools were all developed at Fraunhofer which provided easy access to necessary implementations by the authors. The *Elektronische Lagedarstellung* (ELD, engl. *Electronic Situation Dashboard*) is used extensively in the context of operations and exercises at local governments in Germany. The *Digitaler Lagetisch* (DigLT, engl. *Digital Map Table*) focuses on shared situation visualization and analysis in civilian and defense applications. The targeted user groups of the operational command software *MobiKat*® range from the command staff to the relief forces of fire and rescue services, as well as disaster managers and the police. All these user groups work on public safety from different viewpoints and have different requirements which led to these different software systems. This paper presents an approach to visualize complex data in these established software systems tailored to each user group.

BACKGROUND

The Fraunhofer Center for the Security of Socio-Technical Systems (SIRIOS) builds a research, testing and training environment based on coupled simulations of complex security scenarios. The developed co-simulation framework is presented in Martini et al. (2024). It is designed to explore and assess the impact on citizens and to be used for training purposes or in real-life situations to evaluate different counter measures to security threats. The framework provides a digital twin representation of relevant critical infrastructure sectors in an urban environment. Special attention is paid to reproducing and disclosing dynamic cascading effects between the respective sectors through a coupled simulation with defined mutual interdependencies. To this end, stand-alone modules for the simulation of several critical infrastructures are included, e.g., power, gas, water, and telecommunication grids as well as the operational dynamics of emergency response units and hazard-dependent vulnerability assessment of building structures. The framework is an ideal information source for the intended processing and visualization pipeline as it offers the ability of incorporating a large variety of heterogeneous simulation modules which are based on, e.g., engineering models rooted in physical principles, on agent- and rule-based modelling or on structural engineering analyses. Especially in conjunction with available real-life sensor data, this approach maximizes the information content deliverable by the digital twin. Thus, it can provide large amounts of interdependent data.

Naturally, each of the incorporated modules produces individual formats of output data. Utilizing well-established concepts from the *IoT* (internet of things) sector together with standardized data models proves to have versatile benefits. The Open Geospatial Consortium (OGC), a neutral and collaborative platform within the geospatial industry fostering innovation and development of open standards (van Rees, 2013), has introduced such a model:

the *OGC SensorThings API* (Liang et al., 2021). It offers a canonical way for embedding arbitrary heterogeneous modules into the framework if their entities and results can be interpreted within the respective *IoT* data model. To reach a level of data harmonization, the presented framework suggests interpreting the key entities of each infrastructure model as *Things*[1] equipped with *Sensors* which provide synthetic *Observations* from the respective simulation results to be stored on a *FROST* server instance (Hertweck et al., 2019; Fraunhofer IOSB FROST, 2023). Additionally, the interdependencies between different infrastructures can be defined on the basis of the thing representation of their respective models. Thereby, it is specified how the inter-modular information transfer required for the coupled simulation can be realized independently of the inner details of the actual simulation modules. Treating simulated and actual sensor data on an equal footing maintains the concept of the digital twin when incorporating simulation results in the accumulated data.

Each of the coupled simulation modules potentially produces an arbitrary amount of data, which might not be completely relevant in all details for the specific user demand of the digital twin framework. Thus, preselection and data aggregation are necessary for optimal, efficient use of the provided data. Assuming applications of the framework in training settings of relief units and task forces, or infrastructure managers or as aid for decision support used by decision makers, authorities, and organizations with security responsibilities, implies human users with diverse professional backgrounds. Besides appropriate preselection and aggregation, suitable and flexible visualization options of the data are therefore mandatory in order to concisely convey relevant information as efficiently as possible.

An increasing number of municipalities, service providers as well as emergency units rely on well-established digital tools like dashboards, geographic information systems (GIS) and even digital twin models to aggregate, display and analyze data. In order to seamlessly integrate the results of the co-simulation framework into such already existing eco systems and to benefit from well-rehearsed workflows for analysis and visualization of the data, providing open standard interfaces is advantageous. This is especially important for retaining an accustomed level of usability together with a low entry threshold after the introduction of new technology into a fast-paced, heterogeneous environment like crisis management. Data representation and storage as well as connecting data entities in the digital twin representation provided by the co-simulation framework relies on the *OGC SensorThings API* standard. Thus, further data processing and analysis followed by suitable visualization can, in principle, be carried out by any tool which is compatible with this *IoT* standard (Russell et al, 2018) (see figure 1). Utilizing the comprehensive digital twin representation as the central information backbone with a standardized interface to various visualization and analysis platforms facilitates additional benefits regarding resource management: Laborious tasks like complex simulation runs as well as data acquisition and aggregation need only to be performed once in a suitable, possibly remote, environment like, e.g., a high-performance computing cluster. Different user groups can subsequently access and update, if possible, specifically funneled data quickly and in parallel over their respective platforms of choice (see figure 1). Furthermore, this pipeline ensures a common and synchronous database through all involved platforms and tools. Note that an update of the common database by one tool might trigger a renewing simulation run with implications for all online tools (as indicated by the reverse arrows in figure 1).

VISUALIZATION TOOLS

In the following, the three representative visualization and processing tools, which are commonly used by the foresaid user groups, are briefly showcased. Their individual properties and features are highlighted together with accordingly customized filtering, summarizing, processing, and visualization options of the data to accomplish efficient data transfer tailored to the respective target user group.

[1] In the *OGC SensorThings API standard*, a *Thing* is an arbitrary *IoT* device or system able to provide streams of sensor data.

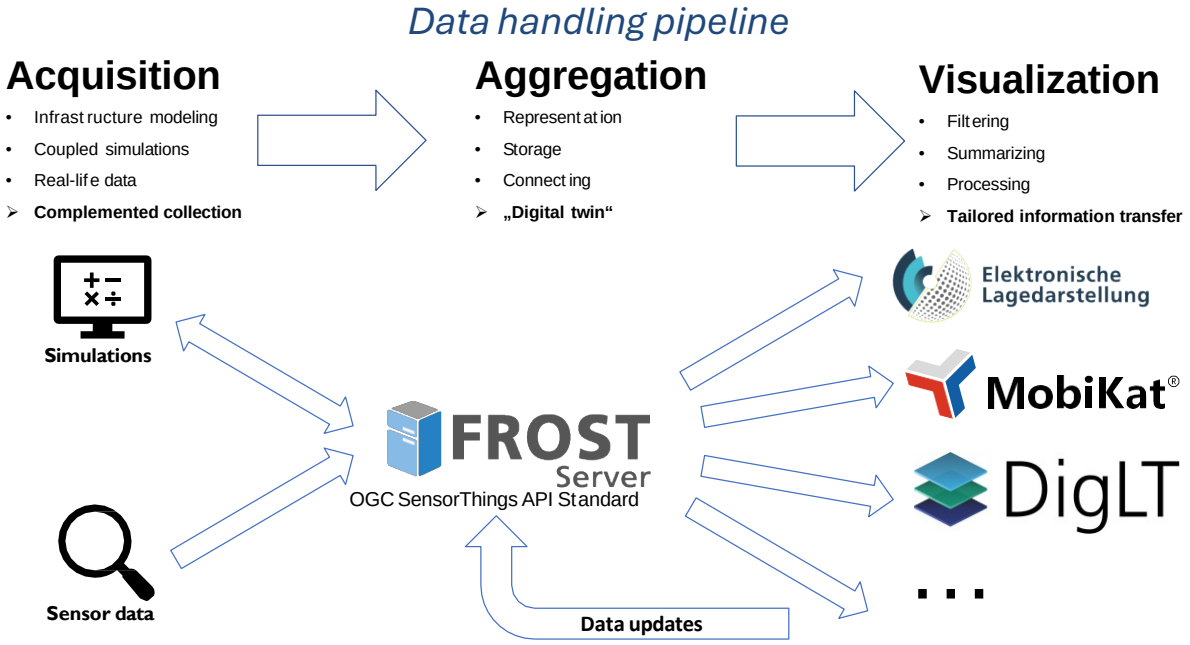

Figure 1. From data acquisition to user-tailored visualization.

ELD

The *Elektronische Lagedarstellung* (ELD, engl. *Electronic Situation Dashboard*) is a web-based information system that links a wide range of data to support decision making. One of its main purposes is to support staff work and crisis management by authorities in critical situations. The software enables the collection, management, and visualization of raw data (e.g., time series from sensors) as well as expert knowledge. The ELD is based on open standards. This allows for easy incorporation of external data sources. It demonstrates its strengths when the given data has a spatial reference as the integration of maps is one key function. Supported formats include Web Map Service (WMS) and *IoT* sensor data such as *OGC SensorThings API* (Fraunhofer IOSB, 2024).

As described in Martini et al. (2024), the proposed co-simulation framework relies on the concept of digital twins – and simulation data can be seen as sensor data. Therefore, the ELD interface to the *OGC SensorThings API* with special support for the open-source product *FROST* allows an integration and visualization of the simulation data. In general, all *Things* on a *FROST* server can be displayed in the ELD, regardless on their level of granularity. Pre-processing of all available data is therefore necessary in order to reduce the amount of data and generate a user-tailored visualization.

The ELD map relies on the concept of individual visual layers. This makes customization of the visible data easy: Layers can be overlaid to aggregate information and hidden to filter information. To this end, the complete result of the co-simulation is broken down to the results of single components. These individual results can in turn be displayed on one or more map layers. Each map layer can then be individualised by defining custom icons, different colours and further settings, e.g., line style. In addition, the use of layer groups makes it possible to preset the visualization for different user groups.

One group could include all data on the public electricity grid for an infrastructure operator, from substations to individual power lines and consumers. Another could contain relevant data about the public networks to provide decision-makers with a holistic view of the situation (see figure 2). This includes knowledge of the supply status per building as well as cumulative statistics per infrastructure. In addition, affected buildings are coloured in order to quickly identify relevant areas.

During the use of the ELD, other software requirements were identified, such as real-time map updates. The implementation of these features is planned for the future. In summary, all results produced in a coupled co-simulation can be integrated into the ELD. However, the data is aggregated and filtered to produce a high-level visualisation and to provide easy access to the data for authorities and decision makers.

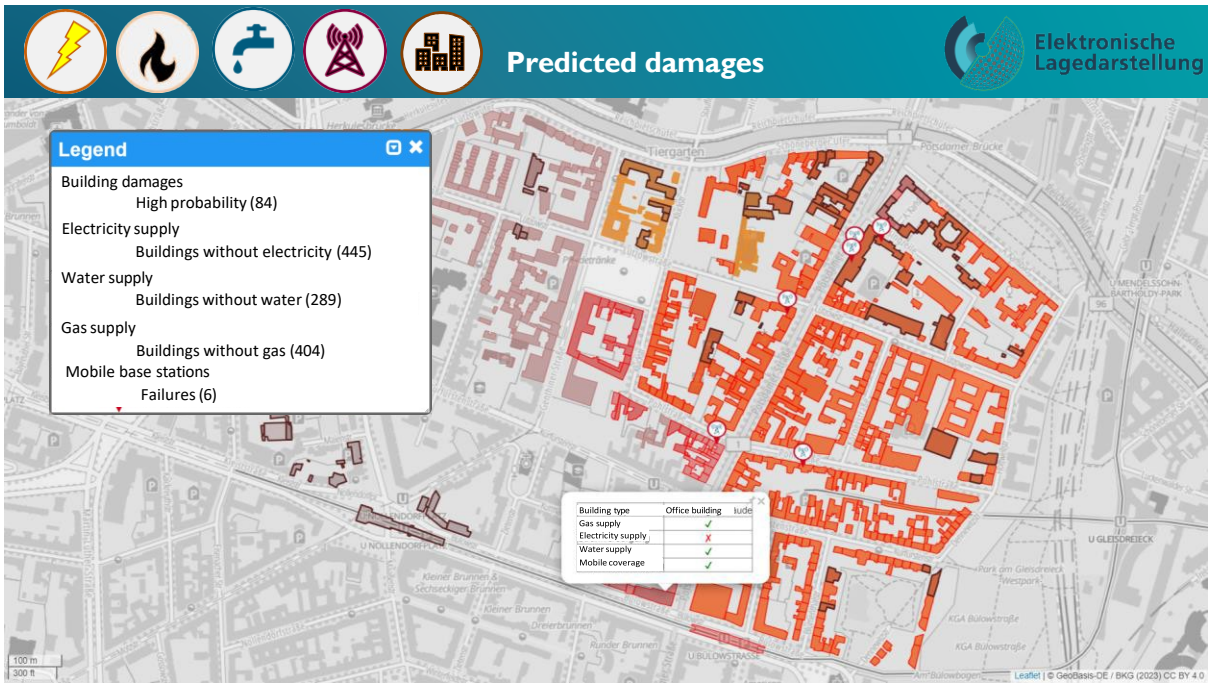

Figure 2. Example visualization in ELD of a predicted multi-layered failure cascade of critical infrastructures (Map data: CC BY 4.0: © GeoBasis-DE / BKG (2023) CC BY 4.0[2])

MobiKat®

Figure 3 shows a simulated crisis scenario in MobiKat® (Fraunhofer IVI MobiKat®, n.d.). It displays the same situation as in figure 2 but focusing on the first responders and respective incidents with subsequent tasks which are partly connected to the infrastructure failures displayed in figure 2. Different types of tactical units from police, fire department and emergency response are assigned to separate missions according to the needs to resolve realistic incidents (see tree view on the left in figure 3). The location and status of each unit is updated dynamically and displayed with its tactical sign on a map in MobiKat® (see map part in figure 3). Additionally, different kinds of statistics characterizing the situation and the availability of resources are being integrated into MobiKat® (see right hand side of figure 3). This provides a good overview of the considered situation and the distribution of resources tailored for users from authorities and organizations responsible for public safety.

MobiKat® is chosen here, because it is a well-established, modular system for the operational command and administration of the corresponding necessary resources. Its user groups are the command staff and relief forces from fire and rescue services, as well as disaster managers and police forces. The system offers various hardware applications for all command levels. The main features are:

- Display of geoinformation about the operation site – e. g., traffic network, aerial images, buildings, land use, information about the terrain
- Visualization of operation-specific information – e. g., flooding zones, tapping points for extinguishing water, critical infrastructures, current water levels, weather, construction sites
- Overview of available staff and resources
- Overview of damages, affected persons and measures
- Documentation of the operation
- Algorithms for the optimization of decision support
- Synchronization of all situational information
- Offline capability and local data storage

In addition to the distributed operational command feature working across levels and organizations with an integrated map, MobiKat® functionalities also include the administration of tasks and appointments, overviews adapted to the current situation as well as analysis and documentation options.

[2] https://creativecommons.org/licenses/by/4.0/

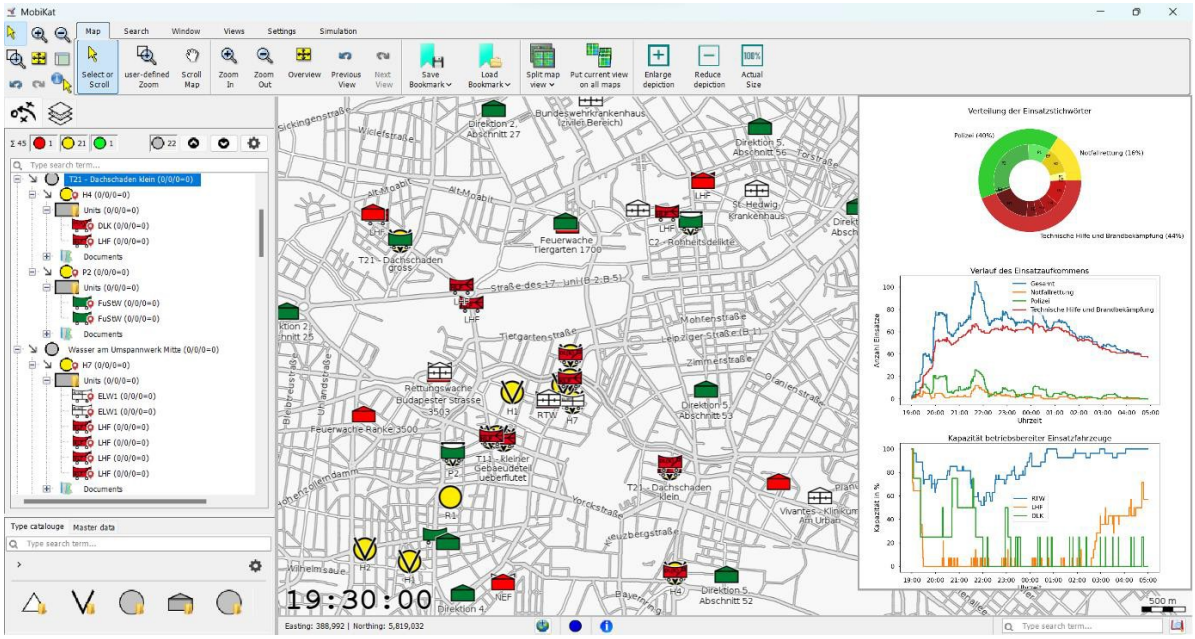

Figure 3. Example visualization of the activity of first responders in MobiKat® (Fraunhofer IVI MobiKat®, n.d.) during a predicted multi-layered failure cascade of critical infrastructures. (Map data: © 2022 OpenStreetMap contributors[3], © GeoBasis-DE / BKG 2019 (data changed))

Summarizing, the visualization and analysis of the aggregated and filtered data of the digital twin in MobiKat® is especially beneficial for users at authorities and organizations responsible for public safety.

DigLT

The *Digitaler Lagetisch* (DigLT, engl. *Digital Map Table*) is a versatile software system designed for collaborative situation visualization and analysis. It allows multiple users to work simultaneously on the same situation using personal computers, digital tables, or other visualization devices (van de Camp et al., 2021; Hoppe et al., 2020). The software is modular and customizable, making it suitable for various applications ranging from education to mission planning, execution, and review. It can integrate diverse data sources and geodata to provide relevant information for each use case, enabling users to make informed decisions.

In addition, the DigLT offers VR capabilities, allowing users to immerse themselves in the situation and experience it in 3D (Strentzsch et al., 2017; Hoppe et al., 2018). Figure 4 shows a screenshot of the VR environment of the DigLT with relief units depicted with tactical symbols. This feature enhances situational awareness and provides a more realistic and immersive visualization of the environment, which is especially useful for training and preparation for future missions. The symbols and icons displayed can be adapted to the needs of the respective user groups (e.g., emergency services, military), which enables a smooth transition from other situation reports.

In DigLT, the concept of individual visual layers allows for easy adjustment and filtering of map information, with the ability to stack and blend the layers for a comprehensive view. The software adheres to open standards, ensuring seamless access to various data sources. For instance, it offers extensive support for OGC and NATO standards, facilitating easy integration of geographical data.

Currently, the digital map table does not have an interface to the *OGC SensorThings API*. However, it is planned to implement this interface in the future. Once implemented, the interface will allow for the integration of the co-simulation results filtered according to the user's needs. For each simulator, this integration will involve creating a new layer on the map that displays all *Things* as corresponding icons or geometries based on the respective

Locations and time stamps. *Datastreams* and *Observations* will be made available as properties associated with each *Thing*. Thus, the DigLT's timeline tool gives the user access to the time-based progress of observed properties, e.g., water pressure or telecommunication network availability at selected sites and the cascading impact any status change has on other infrastructure. As a proof of concept, an interface between the operational

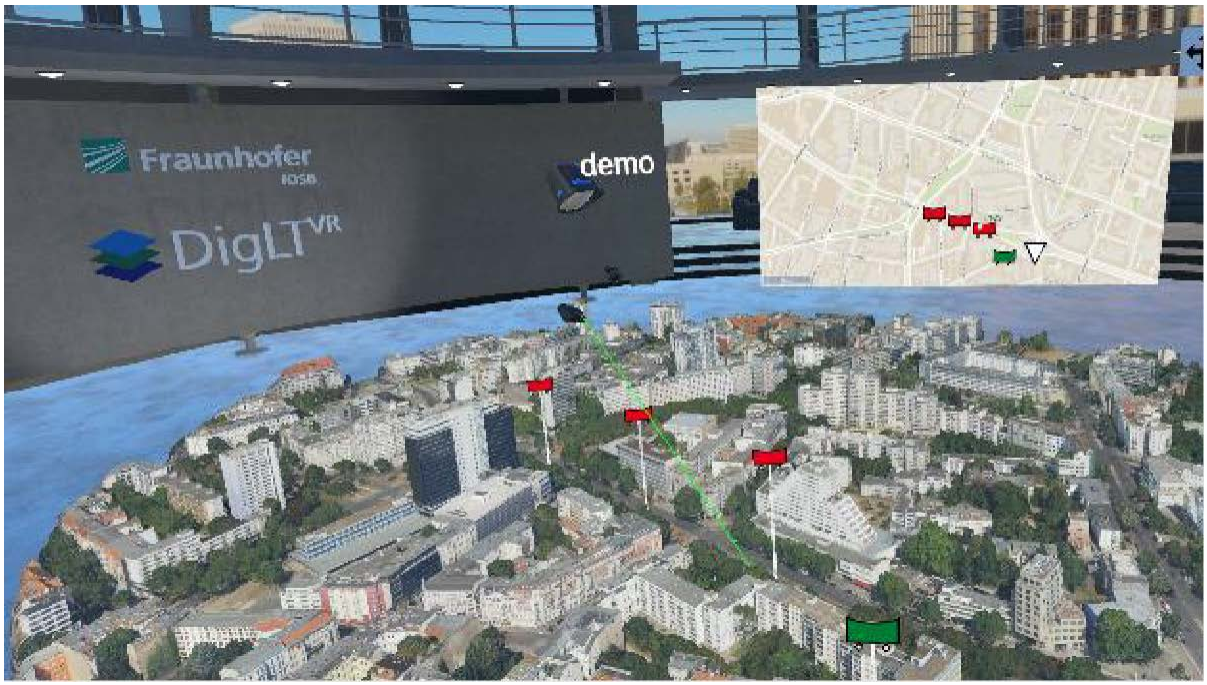

Figure 4. Example visualization of relief units in the virtual reality (VR) view of the digital map table (DigLT). A user is inspecting the current positions of emergency vehicles in the city center of Berlin. (Textures: © 2024 IBCAO, Landsat/Copernicus, Google; Map data: © 2024 GeoBasis-DE / BKG, OpenStreetMap[4])

dynamics simulation module and the DigLT has been established enabling spatial and temporal visualization of incoming emergencies and available relief units both in 2D and VR (see figure 4).

DISCUSSION

A comparison of the three tools for the visualization of simulation and sensor data, ELD, MobiKat®, and DigLT, reveals distinct functionalities that cater to different user groups and operational requirements. Each system offers a range of different functions, aggregates the data in a different way and therefore provides a different form of visualization of a (critical) situation.

On the one hand, the DigLT stands out with its VR capabilities, allowing users to immerse themselves in the situation. The advanced level of this features enables realistic scenarios and enhances situational awareness, both for individuals and in cooperative mode. On the other hand, these VR capabilities require more sophisticated visualization devices and VR equipment. The tool is therefore less suitable for widespread use in critical situations than for mission preparation and training.

The ELD provides decision-makers at all levels of government with a holistic view of the situation. The lack of real-time map updates makes it difficult to visualize dynamic situations and shifts the focus to a more granular view. In addition, the web-based platform offers functions to support staff work and crisis management in terms of communication, information and data exchange.

MobiKat® supports distributed operational use on all command levels and across organizations in desktop, web-based and mobile applications. Compared to ELD and DigLT, it has a more operative and tactical orientated interface aimed at authorities and organization for public safety. At such organizations it is used extensively in daily business as well as crisis situations.

Data integration and usable data sources are robust across all platforms. ELD, MobiKat® and DigLT support open standards, facilitating access to various external data sources. MobiKat®'s modular system allows for a comprehensive overview of public safety-related data. However, the DigLT currently lacks an interface to the OGC SensorThings API, limiting its ability to integrate FROST's sensor data. By addressing this gap in future updates, the DigLT will soon be able to adapt to the presented data processing and visualization pipeline.

In terms of data filtering and preparation for visualization, ELD, MobiKat® and DigLT use a layer-based approach that allows the user to tailor the data displayed. MobiKat® provides an overview of damage, resource and incident-

[4] https://www.openstreetmap.org/copyright

specific data, emphasizing the focus on immediate emergency management.

Recommended user groups for each tool align with these differences. The ELD is well suited for authorities and decision makers at all levels of crisis management who need a comprehensive overview of the situation with spatial data integration. MobiKat® is tailored for executives, emergency responders and disaster managers who need operational command and control and real-time updates. Finally, DigLT is recommended for users who have to deal intensively with the situation, such as emergency services, in order to carry out in-depth analyses and training.
When connected to the digital twin representation through the standardized interface, these tools offer complementary perspectives on the available data gathered in a critical situation and allow for efficient and possibly collaborative work flows in crisis management.

OUTLOOK

Quick action is often required to successfully respond to a critical situation. However, the ever-increasing amount of data available makes it difficult to act quickly in such situations. Data must be aggregated and prepared. A one-size-fits-all approach is not possible as different groups with different needs, such as decision makers, authorities, or infrastructure operators, are involved in the situation. User-tailored aggregation and visualization is therefore crucial for efficient crisis management, and different user groups may require different views of the situation.
The presented visualization approaches access a co-simulation framework (Martini et al., 2024) using the *OGC SensorThings API* standard. This allows for easy integration, also of other data sources, without the need to implement specific interfaces. Other visualization tools addressing further user groups can be easily added.
All presented approaches meet the objective of providing a visualization appropriate to the targeted user group. However, more work is needed to achieve seamless integration of the co-simulation framework and user-tailored visualization. Future work will therefore focus on two main areas: The further development of the tools already in use and the extension of the range of tools.

ACKNOWLEDGMENTS

Part of the authors' research and development, as presented in this paper, is conducted within the Fraunhofer Center for the Security of Socio-Technical Systems (Fraunhofer SIRIOS) funded by the German federal government and the state of Berlin. The authors would like to thank Nils Hückstaedt for his help in creating the visualization within the digital map table and Simon Smaczny for providing background information about the DigLT and proofreading the article.

ABSTRACT

This paper introduces a machine learning tool for service systems, focusing on accurate classification of service requests and swift anomaly detection, particularly crucial during emergencies. Employing a Support Vector Machine model, this tool automatically classifies service calls into predefined categories with high accuracy, while effectively detecting irregular requests that require specific attention from operators. This approach streamlines resource management by reducing the manual categorization workload and enables early detection of emerging service needs. Examining Orange County, Florida 311 System data, with a specific focus on the COVID-19 period, we illustrate the tool's success in automatic request categorization and anomaly detection. Overall, this tool presents an effective automation approach to help with efficient resource management of service systems and proactive assessment of public service needs, promising to revolutionize service request management during crises. Future work will explore additional classification models for enhanced accuracy and integrate automated alerts for proactive disaster management.

Keywords

311 services, classification, anomaly detection, supervised learning, disaster management.

INTRODUCTION

The evolution of information technology-enabled service systems has revolutionized the way governments interact with their constituents. Public service requests offer individuals a direct means to voice their needs and concerns, serving as a vital bridge for citizen-government interactions (Schwester et al., 2009; Wu, 2020). Citizens now have the flexibility to engage with government agencies through various mediums such as online portals, mobile applications, and chat systems. These systems facilitate the seamless collection of requests and enable prompt and effective responses, thereby fostering a more responsive and citizen -centric governance approach. Given the widespread availability and accessibility of public systems, the necessity for streamlined and automated processes becomes imperative to meet the diverse and expanding needs of the population (Hashemi, 2022). Consequently, the automation of handling service requests in public systems emerges as a crucial step toward enhancing efficiency and responsiveness in governance.

Automation in public services refers to the integration of technology and streamlined processes to carry out tasks and functions within government agencies without direct human intervention. This involves the use of software, artificial intelligence, and other technological solutions to handle routine and repetitive tasks, facilitating the analysis of patterns in service requests, anticipation of citizen needs, and optimization of resource allocation

within government agencies (Bianchini et al., 2006; Brogi et al., 2006; Cheng et al., 2022; Pamukcu et al., 2022). The overarching goal is to improve the efficiency of public service delivery and enable agencies to proactively address emerging challenges. The benefits of automation extend to quicker response times, a consistent service approach, and the reduction of human errors, fostering a reliable interaction between citizens and government agencies. Moreover, as automation takes charge of routine tasks, it frees up human agents to concentrate on more complex and critical issues that demand a personalized touch.

The importance of automation becomes even more evident during disasters (Shah et al., 2019). Community members often actively contribute to reporting emerging needs during crises, and automated systems can leverage crowdsourced data to comprehensively identify and categorize new service requirements, providing a more nuanced understanding of the evolving situation (Pamukcu et al., 2021). Accurate categorization of emerging needs and efficient resource utilization becomes imperative to ensure a dynamic and responsive system, even during surges in service requests. This heightened demand for accuracy and efficiency underscores the crucial role that automation can play in effectively managing and responding to the diverse and urgent needs that arise during disaster scenarios.

The recent coronavirus pandemic highlighted critical challenges in current public service request management practices as systems faced a surge in pandemic-related calls, particularly in the early months of the emergency (Filip et al., 2022). The overwhelming volume of calls resulted in an increased demand for system resources, including service operators and personnel hours (Pamukcu et al., 2021). Manual operations, such as assigning each request into its appropriate category, consumed a substantial amount of limited system resources. Additionally, systems began to receive irregular types of requests that did not align with existing categories, posing request categorization challenges, and potentially causing delays in response times as these inquiries required more careful attention.

An illustrative example is seen in the Orange County Florida 311 non-emergency system, where similar requests were inconsistently assigned to different service categories. To address this issue, the system created new categories to address newly emerged service needs under a unified classification. Despite early signs of the pandemic, with the first two cases in Florida reported on March 1 and the declaration of a state of emergency on March 9, a dedicated category for COVID-19 was not established until May 8, indicating a notable delay in adapting to emergent situations (Cutway, 2020). Similarly, the New York City 311 system introduced new categories such as “Social Distancing” and “Mask Covering” to accommodate pandemic -related concerns, highlighting the necessity for a more adaptive categorization process within these systems (Pamukcu et al., 2021). The examples highlight the ongoing need for refined and efficient automation processes, particularly in times of crises.

Automated systems, equipped with adaptive algorithms, effectively tackle challenges arising from the extensive need for human resources in manual operations. This adaptive capability ensures the system remains dynamic and responsive to the evolving nature of service requests. For example, the literature indicates that the incorporation of Natural Language Processing (NLP) in automated systems enhances their ability to comprehend and categorize unstructured data, such as text or voice messages, from affected individuals. Additionally, numerous studies emphasize that the application of machine learning and neural network methods can provide accurate service categorization (Bianchini et al., 2006; Brogi et al., 2006; Hashemi, 2022). This is particularly valuable in identifying newly arising type of service calls that may not be predefined in the system and appear as irregular requests or anomalies. Utilizing such models, systems can become capable of recognizing and categorizing these anomalies based on distinctive patterns and characteristics.

To tackle the challenges associated with categorizing service requests, particularly during crisis periods, our research employs automation techniques to introduce an innovative tool that integrates classification with anomaly detection. This tool automatically categorizes regular requests while promptly identifying anomalies, aiming to improve the adaptability and effectiveness of service management. The goal is to ensure that systems can respond efficiently to unprecedented events, thereby better serving the community in times of crisis.

In this study, we specifically investigate the 311 system of Orange County, Florida, to demonstrate the potential improvements in handling service requests through accurate classification and simultaneous anomaly detection, especially during disaster scenarios. Our analysis is supported by a comprehensive dataset of service requests obtained through collaboration with the Orange County 311 government. This partnership has afforded us access to valuable data, facilitating a thorough evaluation of the system's performance and the potential impacts of our proposed tool.

This study makes a valuable contribution to the efficient management of service systems, especially during crises. First, we introduce a novel and practical method for automatic request classification with high accuracy. We employ Support Vector Machines (SVM), a supervised machine learning technique, to classify service calls. The choice of SVM is motivated by its notable advantages, including rapid processing and robust performance, even with a relatively small dataset. The model is particularly beneficial for text classification tasks, often constrained by the availability of limited labeled samples. Consequently, our approach offers a practical and accurate solution for service providers, empowering them to enhance their operations through automated categorization.

Second, our method innovatively utilizes the decision function of SVM to incorporate anomaly detection capabilities. By adding an "extra category" to the predefined set, defined as "Other," our model dynamically adjusts to unfamiliar types of calls. This adaptability ensures the system remains flexible and responsive to evolving service needs. Moreover, this enhancement significantly reduces the time needed to detect new categories, a crucial step in improving efficient service management, particularly during crises. This feature substantially improves the system's responsiveness and efficiency during crises, ensuring timely and appropriate service delivery.

RELATED WORK

In the literature, there is a notable gap in addressing challenges related to service request management, particularly with a focus on efficient and adaptive service categorization, especially during disasters. This summary encapsulates a few studies utilizing machine learning and artificial intelligence techniques on service data and relevant efforts in classification of crisis-related social media data to help with request management efforts of service systems.

Several studies focus on identifying service request patterns, volumes, and frequencies in different regions. For example, Cheng et al. (2022) employ machine learning techniques to forecast the number of non-emergency service requests in the Miami-Dade County and to identify the neighborhood traits within census tracts that influence call volumes, while Kontokosta et al. (2017) use gradient boosting regression to classify heat and hot water problems in New York City. Wang et al. (2017) explore the use of non-emergency service requests for decision support and socioeconomic trend prediction, employing k-means clustering to categorize census tracts.

Hashemi (2022) addresses automatic detection of service request types using recurrent neural networks, primarily focusing on classifying requests into preexisting categories. While our paper shares similarities with Hashemi (2022), our approach distinguishes itself by incorporating timely detection of anomalies, which demands more careful attention from service providers. Brogi et al. (2006) and Bianchini et al. (2006) discuss the use of semantic descriptions and ontologies in service discovery. Specifically, Brogi et al. (2006) present a matchmaking system for service compositions and Bianchini et al. (2006) propose a semantic-enriched framework for service description and discovery. Unlike previous work, our tool is designed to simultaneously identify outlier service requests, i.e., anomalies, that do not fit within any of the existing service categories while conducting automatic classification of requests.

In addition to efforts for classifying requests to service systems directly, recent studies have also focused on utilizing social media data for service providers' attention. With the increasing use of social media during disasters, relevant information extracted from such platforms has been found helpful for the crisis management efforts of local authorities. Li et al. (2018) utilized SVM among other techniques to classify tweets with high accuracy, but their approach lacks the anomaly detection concept that is helpful for service systems to differentiate the newly arising needs during crises from regular service needs. Similarly, Alam et al. (2019), Li et al. (2021), and Wiegmann et al. (2020) focused on classifying disaster-related content in social media data without the capability of detecting unusual disaster types.

Kersten et al. (2021) propose a machine learning model which improved the detection rate of crisis-related tweets, but this came with a higher false positive rate, leading to more non-crisis tweets being misclassified as crisis-related. Other studies, such as Aipe et al. (2018) and Buntain et al. (2022) were limited to classifying known crises and lacked the detection of unforeseen events. However, our tool extends the SVM model with a distinctive learning approach to identify unforeseen crisis-related requests like those specific to the COVID-19 pandemic, without prior training or information on such specific scenarios. This enables our model to adapt dynamically to emerging crises and enhance its effectiveness in crisis management.

In summary, while previous literature underscores the potential of automated techniques, semantic descriptions,

and ontologies in service requests and relevant social media content, there is limited exploration of machine learning approaches for disaster management efforts in service systems. Our study aims to fill this gap by proposing a dynamic model for accurate service request classification and timely anomaly detection . By doing so, our tool contributes to the advancement of knowledge in this domain, especially in adaptive service management during emergencies. This distinctive approach sets our study apart from existing research, offering valuable insights into automation and efficient decision-making.

PROBLEM CONTEXT: 311 SERVICE SYSTEMS

Cities have increasingly embraced 311 systems for local non-emergency service management, driven by two key factors (Samuel, 2019). First, the implementation of 311 services aims to alleviate the workload on 911 operators by diverting non-emergency inquiries to dedicated 311 call centers. In doing so, calls related to non-emergency issues can be efficiently managed by operators with expertise in directing such concerns to the appropriate municipal departments. Secondly, these services serve as a convenient channel for residents to request serv ice and access information on a diverse range of municipal topics, spanning from garbage collection and snow removal to tax regulations and new local laws. This enhances citizen engagement and provides a centralized resource for obtaining relevant information. Consequently, 311 services often encompass a variety of predetermined categories for which residents might seek assistance. This structured approach ensures that residents receive prompt and specialized attention for their specific concerns, contributing to more effective municipal service delivery (O'Brien, 2016).

Over 300 cities and counties in North America have integrated 311 as a fundamental resource for municipal information and services (Winbourne, 2022). These systems function independently from each other, leading to a lack of uniformity in their operational frameworks. Different cities adopt various strategies in their service management based on their local needs, preferences, and agreements with business partners. For instance, while Chicago 311 fully incorporates automation technologies to streamline and categorize service requests(City of Chicago, 2018). Orange County Florida 311 favors manual categorization of requests and relies on human operators for the management of calls, showcasing the diverse approaches cities take in utilizing 311 services (Pamukcu et al., 2021). The significance of these systems in helping with local disaster management efforts was particularly highlighted during the COVID-19 pandemic when 311 served as a vital conduit for disseminating information critical to safeguarding the health and well-being of residents and their families (Pamukcu et al., 2021).

DATA AND METHODOLOGY

Data Description

For our study, we examine the Orange County, Florida 311 system to demonstrate accurate classification and prompt anomaly detection. Our analysis is supported by comprehensive service requests data from OCFL311, obtained through collaboration with the Orange County 311 managers. The dataset comprises 1,055,678 records spanning 2016 to 2021 with 14 predefined main categories of service calls. A record in the context of this study refers to an inquiry, which is created upon the receival of the service request. Each record is uniquely stored in the database, and it undergoes updates as necessary, such as follow-ups or closure upon resolution or forwarding to a specific municipal depa rtment. The deliberate choice of the Orange County 311 system was driven by its commitment to meticulous manual processing of service requests, with a primary focus on achieving the highest level of accuracy in request categorization.

Upon receiving service requests through various channels such as phone calls, chat, or mobile apps, each entry undergoes a comprehensive triage and processing phase facilitated by trained 311 operators. This careful handling is designed to guarantee the precise assignment of requests to their respective and appropriate categories. It's important to note that the manual triage of requests places a substantial demand on system resources, and the efficiency of this process directly impacts the overall performa nce of the system, as highlighted by Pamukcu et al. (2022). This underscores the significance of optimizing the request categorization process to enhance system efficiency and effectiveness.

The Orange County Florida 311 dataset offers comprehensive information about each request, including the exact location of the incident, detailed issue descriptions, along with the issue creation and completion dates, and resolution information. To enhance manageability and focus on essential aspects relevant to our study, we only retained critical information pertinent to our study, such as the main categories and detailed subcategories of the requests, along with descriptions and creation dates of the reported issues. These retained columns are instrumental for training our model, providing valuable insights into the nature and classification of service

requests. The subsequent section will delve into the specifics of our data preprocessing methodology, providing a clear understanding of the steps taken to refine and prepare the dataset for our analytical processes.

Data Preprocessing

In this stage, we meticulously conducted data preprocessing as an integral part of our approach to text classification. Recognizing the importance of clean and well-structured data for the success of machine learning models, we employed a series of preprocessing steps. This included the removal of punctuation, conversion to lowercase, and elimination of stop words to refine the textual information and enhance its focus. We also addressed missing data to ensure the dataset's reliability and consistency. Tokenization and vectorization were applied to transform the text into a format suitable for our chosen machine learning model.

In order to transform text into a format suitable for our chosen machine learning model, we opted for the widely used Term Frequency-Inverse Document Frequency (TF-IDF) vectorization method. TF-IDF proved to be a robust choice, capturing the importance of terms in the context of the entire dataset, and providing a numerical representation that retained the significance of words while mitigating the impact of common term s (Shah et al., 2019). Furthermore, we labeled and encoded categorical labels, facilitating numerical representation. Our commitment to thorough data preprocessing played a crucial role in preventing overfitting and promoting efficient model training. The resulting clean and well-structured data contributed to the interpretability of our model results and facilitated the identification and resolution of potential issues.

Automatic Classification of Issue Descriptions with SVM

SVM is a supervised machine learning model that utilizes algorithms for classification problems (Cortes & Vapnik, 1995). The SVM model is trained on a set of labeled training data for each category, enabling it to categorize new text. In our investigation, we leveraged the SVM algorithm for the intricate task of multi-class classification in the context of issue description categorization. Originally designed for binary classification, SVM is extended to handle multiple classes through a one-versus-the-rest (OvR) approach (Cortes & Vapnik, 1995; Hsu & Lin, 2002). The OvR involves training a binary classifier for each class against the rest, and the class with the highest confidence score is assigned during prediction (Galar et al., 2011).

Specifically, the classification task was approached using the Linear Support Vector Classification (LinearSVC) algorithm, a variant of SVM tailored for high-dimensional datasets (Gualtieri & Cromp, 1999). The core hyperparameter governing the model's behavior is the regularization parameter. This parameter, set by default to 1.0, serves as the inverse of the regularization strength. Higher values of this parameter lead to reduced regularization, allowing the model to fit the training data more closely. Striking the right balance for this parameter is crucial as it determines how much emphasis the model places on fitting the training data versus preventing overfitting (Hastie et al., 2009).

The optimization process to prevent overfitting in LinearSVC involves minimizing a cost function that combines a hinge loss term for classification accuracy with a regularization term (Hastie et al., 2009). The Pegasos algorithm, a variant of stochastic gradient descent, is used to iteratively update the model parameters based on a subset of training examples, allowing the model to adapt to the complexities of the data (Shalev-Shwartz et al., 2007) The convergence of the training process was guided by adjusting the tolerance parameter. As the algorithm iterated over the dataset, the training process would stop when the change in the cost function (a combination of hinge loss and regularization) dropped below the specified tolerance. This ensured that the model achieved a satisfactory level of convergence, balancing accuracy on the training data with generalization to new, unseen examples (Apidopoulos et al., 2022).

Anomaly Detection for New Categories

In addition to our primary classification objective, our study emphasizes the early detection of new patterns through the integration of anomaly detection. This facet adds a crucial layer to our automatic classification system, enabling the timely identification of instances that deviated from established categories. The importance of early detection lies in the system's ability to proactively recognize emerging trends, ensuring a responsive approach to evolving data dynamics.

Anomaly detection, as a pivotal component, operated by identifying outliers within the dataset —instances that exhibited novel or unexpected patterns. These outliers, which are a new type of call, were promptly categorized as “Other” in a dynamic and iterative manner, marking a departure from traditional classification frameworks. The iterative nature of this process allowed our model to continuously refine the “Other” category as the dataset evolved, making it a proactive mechanism for adapting to shifts in patterns and trends.

In the technical intricacies of our automatic classification system, the decision function scores play a crucial role, offering a nuanced and data-driven approach to categorizing instances beyond predefined labels. The decision function scores, obtained through the LinearSVC algorithm, provide a measure of the distance of each instance from the decision boundary. These scores represent the model's confidence in its classification decision, with lower scores indicating proximity to the boundary.

The importance of finding the optimal decision score threshold cannot be overstated. This threshold delineates the boundary between instances classified within established categories and those categorized as "Other". The process of determining the threshold involved careful calibration to strike the right balance between sensitivity and specificity in anomaly detection. Sensitivity ensured the accurate identification of true anomalies, while specificity prevented the misclassification of instances merely representing variations within known categories.

In the quest for the best decision score threshold, we engaged in a systematic exploration, considering various values to assess their impact on the model's performance. This involved a trade-off analysis, as adjusting the threshold influenced the number of instances classified as "Other" and the potential impact on overall model accuracy.

The technical complexity of this process lies in its adaptability to changing data dynamics. As the dataset evolved, the decision score threshold underwent recalibration to accommodate new patterns and maintain the efficiency of anomaly detection. This dynamic adjustment allowed our automatic classification system to stay attuned to the subtle shifts in data patterns over time.

ANALYSIS AND RESULTS

As previously mentioned, we demonstrate the effectiveness of our approach in automatic request categorization and anomaly detection using the Orange County, Florida 311 System data. The system classifies requests into 14 main categories, as illustrated in Figure 1. The graph indicates the number of service requests and the proportional distribution of main service categories for the period between 2016 and 2021 after preprocessing the data . Notably, the Animals category experiences the highest call volumes, followed by Public Safety, and then Neighborhoods & Housing. This visualization provides insights into the relative frequency of service requests across different main categories during the specified time frame. Figure 1 also shows the imbalance across the 14 main categories, a challenging problem in the realm of text classification. Following data cleaning and preprocessing, which involved the removal of missing and incorrectly labeled data, the number of observations decreased from 1,055,678 to 600,362. This is a crucial step in the text classification before training the machine learning model.

Pandemic-related Requests Categorization in Early Phase

Our analysis is rooted from early signals indicating challenges in categorizing emerging service needs during the initial phases of the COVID-19 pandemic. Following the declaration of a state of emergency on March 9, the Orange County, Florida 311 system started to receive many pandemic-related calls. However, a dedicated category for COVID-19 was not established until May 8, 2020. Following this, the system introduced 23 new subcategories to consolidate pandemic-related inquiries under dedicated classifica tions.

In our preliminary analysis, we observe that similar requests were inconsistently assigned to different service categories. The absence of a specific category for this emergency led to the classification of pandemic -related inquiries into various existing categories, each managed by different departments. To identify the categories to which these inquiries were assigned, we filtered 311 requests based on the issue description attribute using keywords such as "covid," "corona," "pandemic," and "epidemic" directly related to the COVID-19 crisis. Our analysis of this subset revealed that the system had already received 3440 unique pandemic -related service requests, constituting 9.5% of the total requests, from the beginning of the pandemic until the creation of a new category to accommodate calls that did not fit well under any existing category. Similar types of requests were addressed under different main categories, specifically *Public Safety*, *Neighborhoods & Housing*, *Families*, *Health & Social Services*, and *General*.

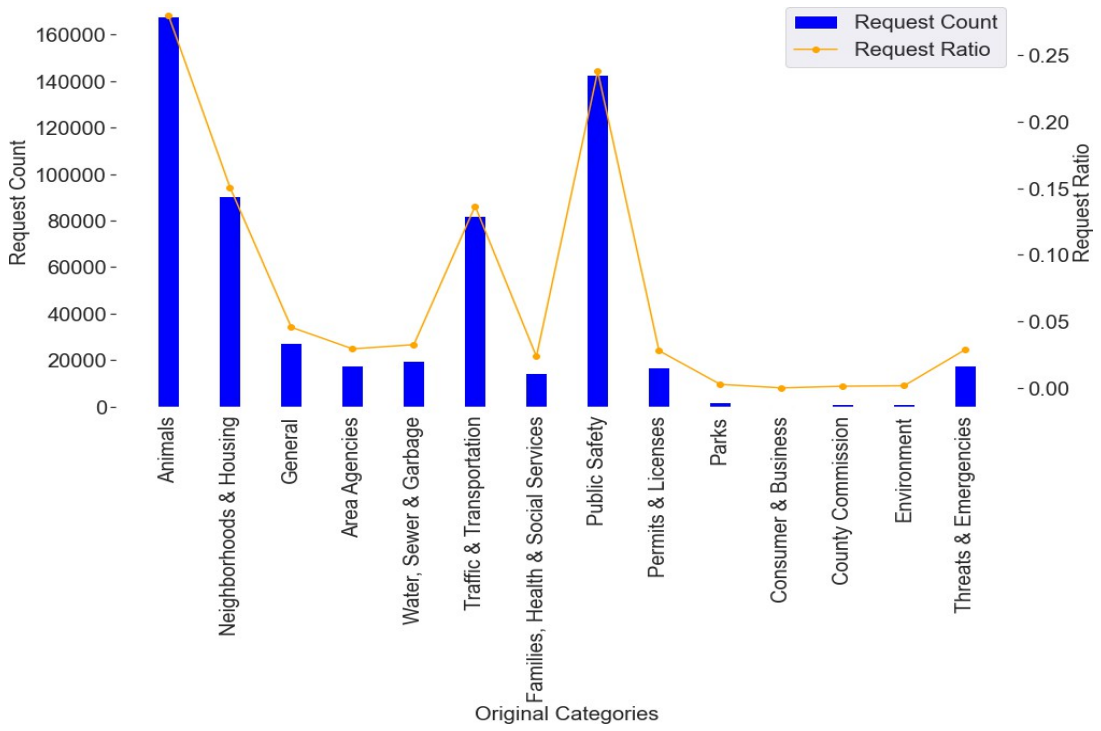

Figure 1. The proportional distribution of main service requests from 2016 until 2021

Support Vector Machine Model Results

The full preprocessed dataset was used in this stage to train and test the data with the LinearSVC algorithm. The dataset first has been divided into training and testing sets where 80% formed the training set and the remaining 20% formed the testing set. The TF-IDF vectorizer is then used to extract features from the data and finally the transformed features are used to fit our model. The testing set is then used for prediction and evaluation of the performance of our classifier model.

Table 1. SVM Model Results

Performance Metric	Result
Accuracy	92.19%
Precision	91.95%
Recall	92.19%
F1 Score	91.96%

Table 1 summarizes the results on the testing set, showcasing the proficiency of the SVM model in classifying service calls. With an accuracy of 92.19%, the model demonstrates remarkable reliability, correctly categorizing service calls with a high degree of certainty. Precision and recall, standing at 91.95% and 92.19% respectively, further underscore the model's precision in minimizing false positives and its comprehensive ability to capture relevant instances. The harmonized balance between precision and recall is encapsulated in an F1 score of 91.96%, highlighting the model's adeptness in maintaining equilibrium between exactness and completeness. Such robust performance metrics not only affirm the model's effectiveness in navigating classification challenges but also bolster its potential as a pivotal tool in the context of service request classification.

In order to thoroughly evaluate the performance of the proposed classification algorithm, we delved into a granular analysis of the model's predictions and the corresponding actual outcomes using the confusion matrix. Figure 2 provides a comprehensive breakdown, offering insights into the algorithm's performance across different true categories and their respective predictions. Within the confusion matrix, the diagonal elements stand as representations of instances correctly classified for each class. The varying shades along the diagonal convey the degree of success in true classification, with darker blue denoting higher accuracy. The figure showcases the

model's robust performance across the majority of categories, except for *General* and *Water, Sewer & Garbage*. In these specific areas, the model's performance appears to exhibit some challenges, suggesting opportunities for further investigation and potential refinement to optimize classification accuracy.

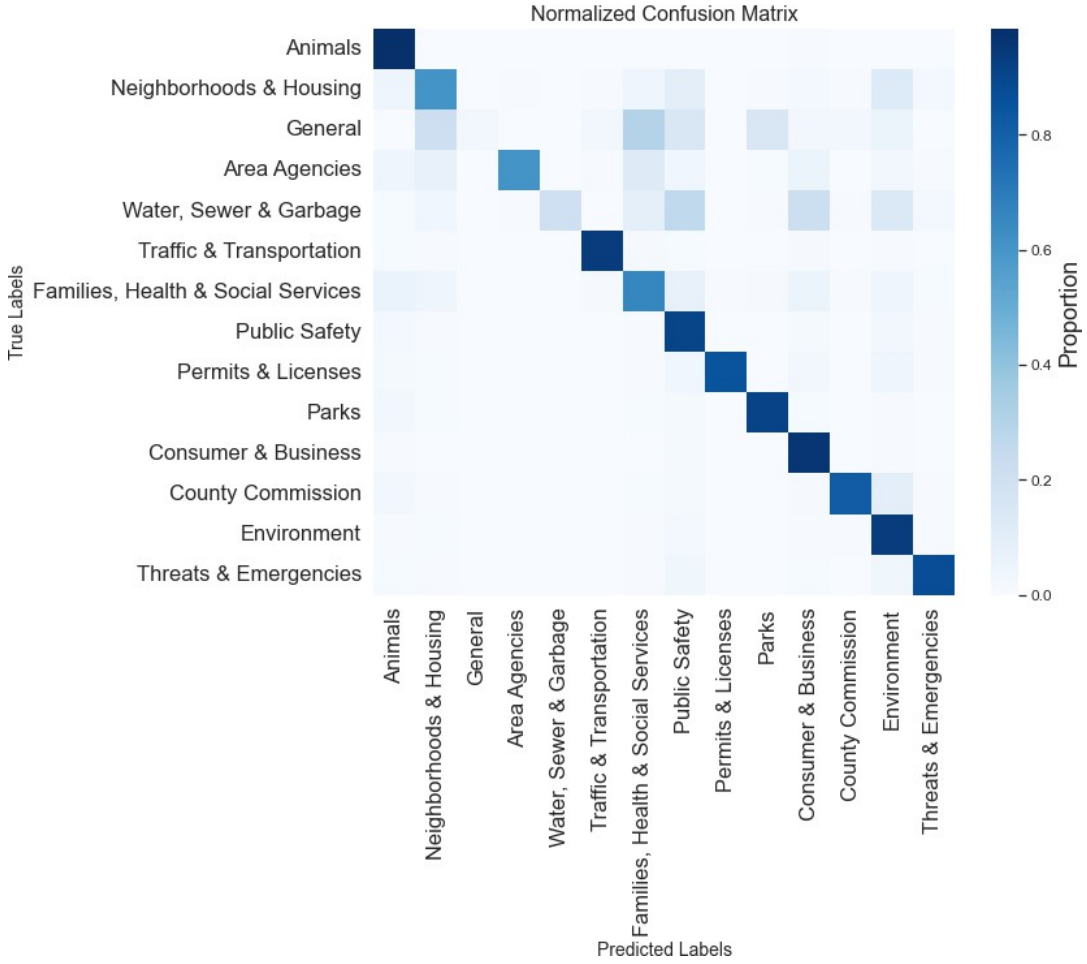

Figure 2. Confusion matrix for multiclass classification of Orange County, Florida 311 service categories

The complexity in classifying requests in the *General* category aligns with its nature, encompassing diverse requests related to information systems, incomplete calls, disconnected calls, undeliverable requests, or general inquiries not directly tied to any other category. Conversely, an examination of request s directed to the *Water, Sewer & Garbage* category reveals shared issues with several other categories, including concerns about water quality, hazardous waste, and standing water. This shared nature poses challenges for the model in accurately classifying these types of service requests. These insights contribute to a comprehensive understanding of the algorithm's strengths and areas for improvement, guiding future efforts to refine and optimize its perf ormance across diverse service request categories.

Anomaly Detection for Unveiling Emerging Categories

In this part of our study, we employed the previously outlined anomaly detection methodology to identify irregularities within the service request patterns. This approach helps recognize unusual request types, signaling for new public needs and a possible emergence for additional request categories. To detect anomalies in service requests, the SVM model was trained on data spanning from January 1, 2016, until December 31, 2019. This timeframe was deliberately selected to encapsulate the anomalies that surfaced during the first year of the pandemic crisis, which broke out in Orange County, Florida on March 9, 2020.

Figures 3, 4, and 5 highlight these irregularities, starting from January 1, 2020 , classified under “Other” category. The analysis reveals a notable number of anomalies in the service calls within the specified time frame. The surge in request volumes in this category immediately following the pandemic outbreak is indicative of atypical request patterns during the crisis. It serves as a clear signal for service operators to consider establishing new service

categories to unify service requests related to the ongoing crisis. Illustrated by the COVID-19 crisis, the presented tool proves valuable in identifying an increase in anomalies within service requests, regardless of the specific emergency scenario.

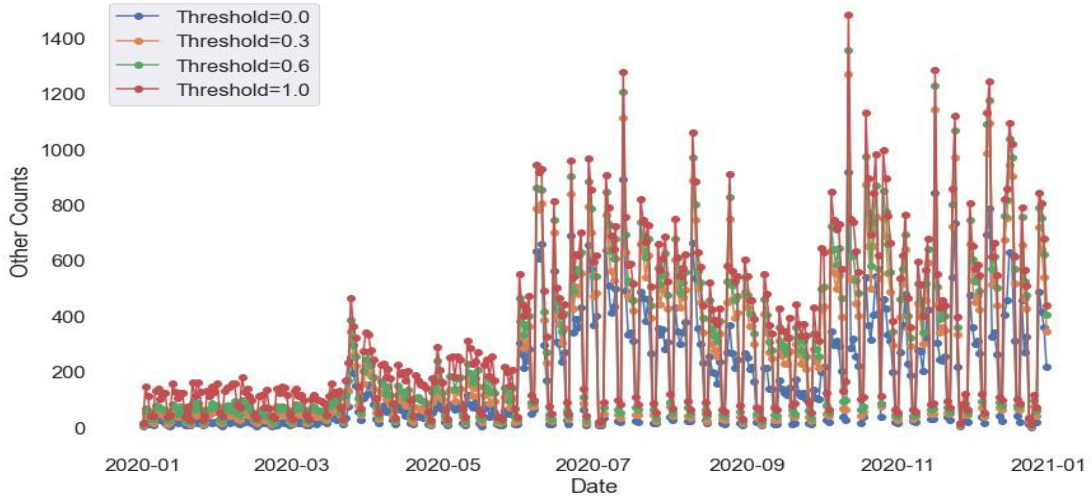

Figure 3. Number of requests classified in "Other" category with different selection thresholds.

To establish the optimal confidence threshold for classification for the "Other" category, we have examined four different thresholds ranging from 0.0 to 1.0, illustrated in Figure 3. In our anomaly detection model, the proximity of a request to each category is expressed by a confidence value, and a threshold is defined to assign requests to "Other" category if the confidence falls below the minimum threshold. This is crucial for capturing an anomaly when a request does not fit well into any of the existing categories, especially when the ratio of "Other" calls to the total number of calls is minimal.

Through a sensitivity analysis on various threshold values, we concluded that a confidence threshold of 0.0 establishes the optimal boundary. While the anomaly pattern remained consistent across different thresholds, our observations indicated that choosing higher thresholds resulted in the model incorrectly classifying requests under the "Other" category since the model became less sensitive. The selected threshold of 0.0 enhanced the accuracy of our model and effectively distinguished between well-known categories and anomalies, ensuring appropriate classification under the "Other" category.

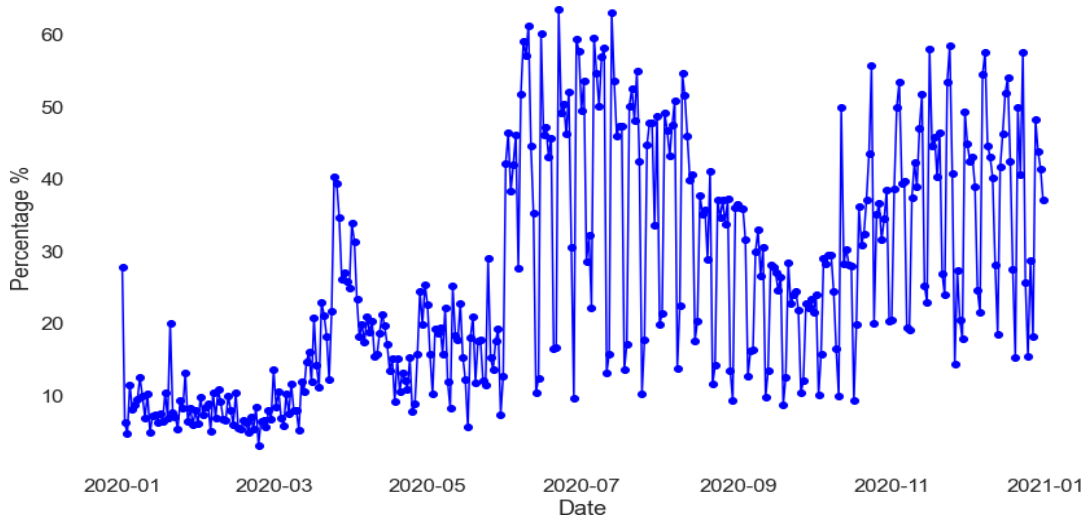

Figure 4. The percentage of requests in the "Other" category among the total number of service requests

Figure 4 illustrates the proportion of "Other" category requests in relation to the overall service inquiries. The data, trained up until January 1, 2020, shows a consistent pattern up to March 2020. Post-March 2020, however, there is a noticeable increase in variability, indicating a rise in service requests falling under the "Other" category.

This period coincides with the intense phase of the COVID-19 pandemic, leading to a surge in unique inquiries in the system. Consequently, the model began to assign these COVID-19 related inquiries to the "Other" category. This finding highlights the utility of our tool in identifying significant increase in unique calls, underscoring a potential need for introducing new categories within the service request system.

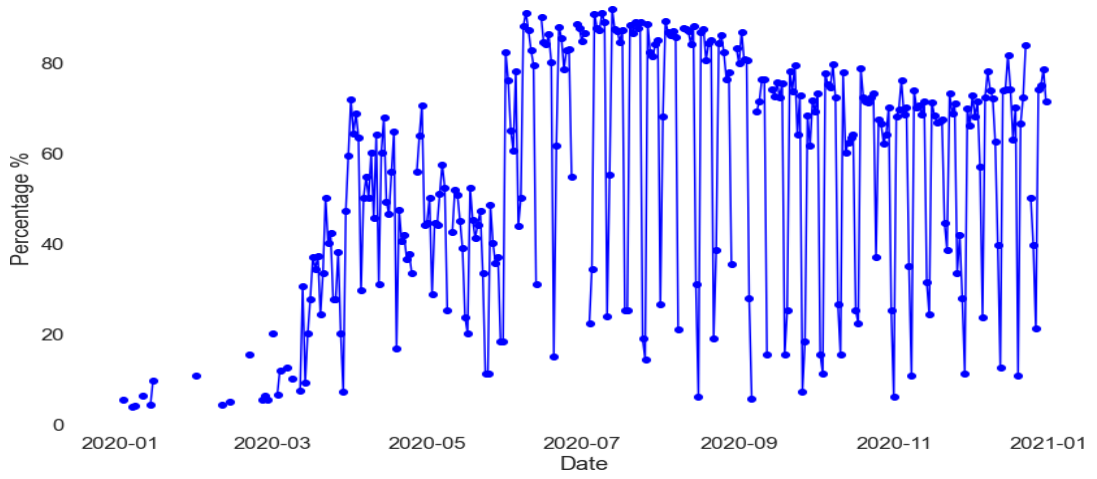

Figure 5. The percentage of pandemic-related anomalies within the total number of requests in the "Other" category

Moreover, to illustrate the proportion of pandemic-specific inquiries within the detected anomalies, we present the percentage of pandemic-related anomalies relative to the total number of requests in the "Other" category. Figure 5 indicates an increase in this percentage after March 2020, aligning with the emergence of new types of calls in response to the state of emergency declared in Orange County, Florida , on March 9, due to the COVID-19 outbreak. Another significant rise is observed in June, coinciding with the announcement of the Coronavirus Aid, Relief, and Economic Security (CARES) Act by the Orange County Government to provide financial support to residents, business owners, nonprofits, municipal and community partners in response to the pandemic (*Orange County Government, Florida*, n.d.)

Consequently, these calls were classified under "Other," contributing to the overall rise in the number of "Other" service requests. These results affirm the effectiveness of our model in identifying such anomalies, which were later addressed by adding new service categories specific to these needs. Specifically, during the COVID-19 crisis, the Orange County Florida 311 system established 23 new subcategories, such as Orange CARES, Vaccine Outreach, and Testing, to group these pandemic-related requests under distinct subcategories within the *Public Safety* main category. Our analysis indicates the success of the presented model in promptly detecting emerging needs which can notify service providers about the emergence of new categories before the number of anomalies increases extensively.

Moreover, through periodic retraining of the model, the tool gains the ability to recognize whether the system has introduced new categories. This ensures that incoming calls are appropriately classified into recently established categories, rather than defaulting on the generic label of "Other." This adaptability is crucial for staying responsive to evolving circumstances and augmenting the system's precision in categorizing service requests.

To highlight the advantages of periodically retraining the model, Figure 6 illustrates the variation in the number of service calls classified under the category "Other", comparing the data trained before and after the onset of COVID-19, depicted in red and blue lines, respectively. Initially, the dataset was trained on records up to March 1, 2020, marked in red, which did not include specific categories for pandemic-related issues. Subsequently, the model was retrained with data up to April 1, 2021, during which time, new categories to capture COVID-19 related inquiries were established.

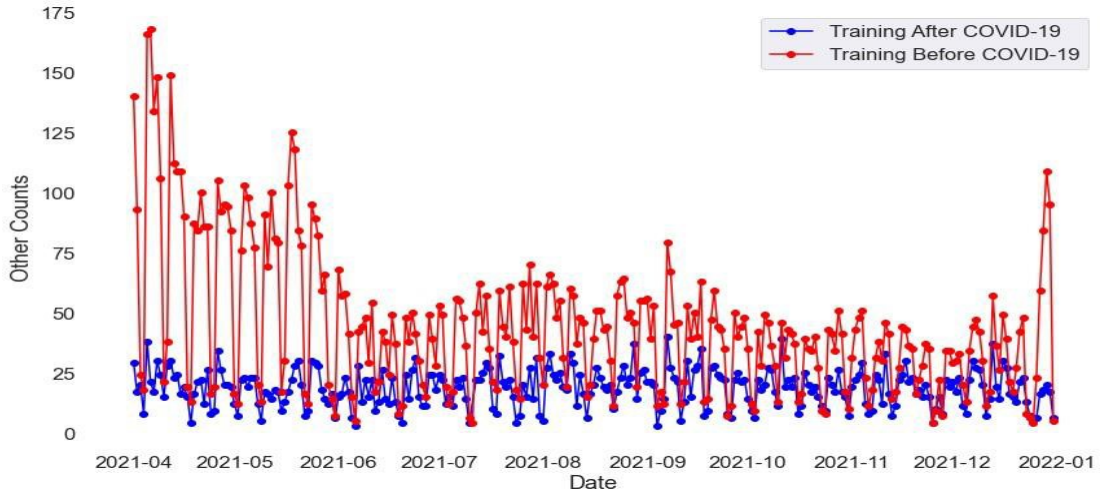

Figure 6. Number of requests classified under "Other" category with training before and after COVID-19

The visualization illustrates a high number of calls classified as "Other" with training before COVID-19, as indicated by the red line, due to the model interpreting all pandemic-related inquiries as anomalies. In contrast, the blue line shows much smaller calls in "Other" category and a consistent pattern after the model is retrained with data up to April 2021, encompassing the first year of the pandemic. The blue line exhibits a small and stable call volume, since COVID-related inquiries are now accurately classified into *Public Safety* main category. Notably, the remaining calls in the "Other" category suggest anomalies stemming from other factors that the model struggles to categorize.

This analysis demonstrates that periodic retraining enables the model to reassign requests previously labeled as "Other" to newly established categories if these inquiries become regular. Hence, the categorization of requests as "Other" is continually refined with each retraining cycle, ensuring it only reflects current anomalies. Thus, the model acts as a valuable tool for service operators, signaling the need to periodically review anomalies and consider creating new categories to effectively classify the evolving types of service calls.

DISCUSSION AND CONCLUSIONS

This work-in-progress paper emphasizes the significant potential of automatic classification of service requests and prompt detection of anomalies to identify emerging needs, especially during disasters. This capability is instrumental in supporting crisis management efforts by enabling public service providers to take timely actions during emergencies. The study's scientific contribution lies in bridging the gap identified in existing literature regarding machine learning approaches for disaster management efforts in service systems. Specifically, while previous studies have primarily focused on classifying service requests into preexisting categories, our proposed model addresses this limitation by incorporating timely anomaly detection.

Our preliminary investigations highlighted a critical issue—the delay in opening new categories for emergent types of service calls. This challenge was especially notable during the COVID-19 period, where it took an extended two months to introduce a category dedicated to COVID-19. Our tool markedly enhances this process, facilitating swift and precise categorization of requests and the identification of irregular requests. Notably, the application of the SVM model demonstrated a 92.19% accuracy rate in classifying service categories. The utility of the approach extends beyond reducing manual classification time for operators; it expedites the recognition and proper categorization of new types of categories. This streamlined approach enhances the overall process by not only automating classification of regular requests but also freeing up human agents to concentrate on detected irregular requests that necessitates a manual evaluation.

The contribution of the study extends beyond merely detecting anomalies related to specific crises; it offers a flexible and adaptable approach applicable to any service system facing disruptions due to evolving service needs during emergencies. Consequently, the presented tool is adaptable and responsive, capable of recognizing and managing newly emerged types of service requests. This underscores the model's extensive applicability in service request management, showcasing its potential to enhance the adaptability and responsiveness of public service systems, particularly in addressing evolving societal needs. This flexibility emphasizes the practicality of the tool in service call systems.

Although the current model excels in classifying main categories, this study faces limitations in classifying requests into subcategories due to the limited number of observations for numerous subcategories. Future research should prioritize improving the model's ability to classify subcategories, which has significant potential in achieving a more nuanced and precise service call categorization and identification of anomalies.

Further improvements could include exploring additional classification models to benchmark against our current method, determining if enhancements are necessary. Moreover, integrating automated alert systems could dynamically notify relevant authorities or response teams upon detection of new types of service needs. Such proactive approaches would ensure swift and targeted responses to emerging challenges, significantly contributing to a more effective overall disaster management strategy.

In conclusion, this study offers a substantial foundation for improving service call categorization systems, with potential widespread implications for emergency response and disaster management. Nonetheless, c ontinuous advancements are essential to fully realize the tool's capabilities and to address the ever-evolving landscape of societal needs. As part of our future work, we plan to incorporate additional classification algorithms, explore different sets of hyperparameters, and implement cross-validation techniques. These efforts will ensure the robustness and generalizability of our findings, enabling a more comprehensive comparison of different modeling approaches and their impact on the classification task.

ACKNOWLEDGMENTS

This research was supported by the University of Vermont's Sustainable Development Policy, Economics, and Governance (SDPEG) interdisciplinary Ph.D. program, and by a grant from the National Science Foundation (NSF-SCC #1952792). The authors would like to thank Orange County, Florida 311 for their collaboration and for sharing their datasets. We also acknowledge the primary and equal contribution of the first and second authors, Hakan Unveren and Ayesh Abu Lehyeh, to this work.

ABSTRACT

In today's interconnected society, we are witnessing crises traversing into new domains and effortlessly cross boundaries. Therefore, it is crucial to develop adequate foresight in order to chart a course of action. In this paper, we propose *scenario planning* as a key technique. Based on an explorative study of 30 interviews with representatives from all Dutch safety regions, we answer the question: *in what ways can scenario planning facilitate foresight in crisis information management?* Our results indicate that all regions in the Netherlands are investing in training and capacity building for scenario planning, but there is no consensus on the chosen methods and institutionalization. Qualitative approaches to scenario planning are dominant, while opportunities arise for quantitative approaches. We propose *real-time* and *strategic foresight* as a promising research agenda, and suggest ways for information systems research to develop data-driven tools that may help chart the impact of future contingencies.

Keywords

Scenario planning, foresight, polycrisis, sensemaking, information systems.

INTRODUCTION

When a crisis emerges, agencies are confronted with an acute threat that requires immediate action. Time pressure, incomplete information, and the demand for prompt decision-making add to the sense of urgency crisis managers experience (Rosenthal & Kouzmin, 1997). This urgency pulls crisis managers into the 'here and now', which often results in a reactive modus operandi with a limited time horizon (Jaques, 2010). Consequently, persons managing a crisis often find it difficult to look ahead and incorporate future contingencies in their decision-making. This short-term focus is also reflected in the academic debate, which tends to focus on the response phase. Crisis research is packed with single case studies that offer in-depth analyses of the response to a specific crisis (Wolbers et al., 2021). Yet, the dominant focus on single case studies limits our view on multiple dimensions or spill-over effects of crises, which could be problematic. Like the saying has it 'trouble always comes in threes'.

In late 2022, the Financial Times columnist and historian Adam Tooze coined the concept of a 'polycrisis'. Tooze argued that the world is enmeshed in a variety of crises that are entangled and strengthen each other. He described the interplay between the COVID-19 pandemic, the war in Ukraine and the energy, cost-of-living and climate crises (Tooze, 2022). In a polycrisis, different crises interact so that the whole is even more overwhelming than the sum of its parts (c.f. Jervis, 1998). While the term polycrisis resonates predominantly in the public realm, in the academic debate we are familiar with typologies that describe how crises become too complex to manage when crossing geographical or functional boundaries. We speak of a transboundary crisis *"when the functioning of multiple, life-sustaining systems is acutely threatened"* (Boin & Rhinard, 2008, p. 3).

The manifestation of a transboundary crisis tends to morph as its impact prolongs. When a transboundary crisis impacts multiple domains, the nature of the crisis itself may also change. For example, the alleged Russian 'Not-Petya' cyber-attack during the Russia-Ukrainian war showed how the crisis almost instantly traversed domains around the world. Within minutes the bug rendered both the FedEx distribution system and Maersk worldwide

container shipping network unusable (Greenberg, 2018). Such escalation pathways point us to the necessity for crisis managers to look ahead for ways to address a crisis traversing into new systems and domains. They require crisis managers to develop *strategic foresight*, the capacity of decision-makers to chart the organization's future course of action (Vecchiato, 2012). Developing strategic foresight entails identifying factors that are likely to induce future changes, while also dealing with those changes by deciding on currently appropriate organizational responses (Iden et al., 2017).

Developing strategic foresight during a crisis is not easy. In an extreme situation, limited awareness of possible escalation pathways may result in the 'collapse of the future', when the long-term perspective disappears from crisis managers' time horizon (Pot et al., 2022). Short-term decisions can have consequences that stretch far beyond the critical period. If crisis managers do not take the long-term into account, they will miss cues that point to opportunities for de-escalation, or miss cues that point to the escalation of the crisis into other domains. Therefore, crisis managers need to create moments of reflection and look for decision-support tools that can help them refocus on the long-term in order to foster strategic foresight. Foresight support systems may play a crucial role here as they feature a combination of information system and decision-support tools (Von der Gracht et al., 2015).

In this paper, we highlight the role that scenarios can play to embrace uncertainty and focus on the long-term (Wilkinson & Kupers, 2013; Wright, 2005). Scenarios are a tool to help decision-makers chart possible future developments by *"making the unexpected expectable by developing a set of narratives that incorporate uncertainty"* (Wright, 2005, p. 95). In developing alternative futures, crisis managers can challenge dominant frames in the current crisis. As such, scenarios form prospective sensemaking devices that can facilitate structuring the future in order to identify opportunities for action (MacKay, 2009; Burt & van der Heijden, 2003).

Given that scenario planning is a trend in crisis management, it is helpful to explore and chart the ways in which scenarios are used. We relate the relevant literature on scenario planning and use that to map the current state-of-the-art developments in scenario planning in the Netherlands. We pose the question: *in what ways can scenario planning facilitate foresight in crisis information management?* We base our analysis on an explorative study consisting of 30 interviews with regional crisis agencies in the Netherlands. Based on this analysis, we explore the goals, different scenario methods and design choices that characterize scenario planning in said agencies. This enables us to reflect on state-of-the-art developments and identify an agenda for future research that may inspire crisis scholars investigate ways in which to support scenario planning and the development of foresight. For information systems scholars, we identify opportunities to complement qualitative scenario processes by integrating quantitative methods to support real-time and strategic foresight.

DEVELOPING SCENARIOS TO ENABLE FORESIGHT

From the very first impact of the crisis onwards, it can be helpful for crisis managers to develop strategic foresight to foresee and plan for possible escalation pathways and chart a future course of action (Vecchiato, 2012). In order to rethink plausible developments and generate options for action, many crisis teams are currently investing in scenario methods (Ramírez & Wilkinson, 2014). Scenarios are a helpful tool for ordering one's perceptions about alternative futures to inform decision-making (Schwartz, 1996). They can function as a tool to enable prospective sensemaking (Wright, 2005), which is referred to as the process in which actors anticipate future developments and construct expectations about the future (Sandberg & Tsoukas, 2015). This is similar when crisis managers engage in the process of scenario development, where they engage in continuous inquiry and re-evaluation of interpretations that helps them to make sense of a rapidly changing context (Ansell & Boin, 2019).

Different concepts are used to describe the process of generating scenarios, such as scenario planning, scenario thinking and scenario development. In this paper we use the definition provided by Bishop et al. (2007) who suggest that scenario planning is part of a foresight study, where scenarios help to *"create actual stories about the future. Scenario planning is a far more comprehensive activity, of which scenario development is one aspect"* (Bishop et al., 2007, p. 6). As scenario planning is booming in business continuity and crisis management, a multitude of methods are being developed, contributing to a wide array of concepts and approaches (Martelli, 2001). Surprisingly, in the crisis management literature there is scarce attention for scenario planning and foresight.

Scenario methods can be categorized into different schools representing either *plausibility* or *probability* based approaches (Bradfield et al., 2005). *Plausibility-based approaches* are qualitative approaches that aim to explore possible futures and focus on facilitating prospective sensemaking. In this approach, scenarios are used as prospective sensemaking devices that help to transition from a retrospective to a future-oriented focus by patterning cues and plots into frames to imagine alternative futures (Wright, 2005; Ramírez et al., 2013; Wolbers & Boersma, 2013).

A well-known approach is the 'intuitive logics' approach, first developed by Shell in the 60s to envision trends in the energy sector beyond the year 2000. In contrast, *probability-based approaches* are quantitative approaches that aim to predict the future by modelling historical data to extrapolate trends and determine what consequences the probability of unprecedented events has on these trends (Bradfield et al., 2005). Approaches like 'Trend-Impact Analysis' and 'Cross-Impact Analysis' are used to determine conditional or proportional probabilities to calculate impact and generate a range of alternative futures. During Covid-19 we have seen the extensive use of quantitative methods and modelling, primarily regarding infection rates, covid related deaths and ICU-capacity, to support strategic policy decisions (i.e. Shinde et al., 2020). Such data can help foster grounds for decision making, yet evaluations stressed the importance of the validity of data and the need to keep assessing whether assumptions are still valid as the crisis progresses (Dutch Safety Board, 2023).

What becomes clear from these different approaches of scenario planning is that they serve different goals and outcomes (Burt & Van der Heijden, 2003). For the use of scenarios in crisis management, it matters whether scenarios are used in the acute phase of a crisis to enhance option awareness about escalation pathways (Liu et al., 2011; Pfaff et al., 2023), or if scenarios are used to devise alternative futures in a slower paced or creeping crisis (Sætren et al., 2023, Mascio et al., 2020). In the acute phase, when there is little time, intuition will play a key role in scenario developers' ability to recognize and analyse cues and patterns (Barlett et al., 2013). In a slower or creeping crisis, a more structured form of sensemaking can be based on the extrapolation of risk calculations from databases. Information systems support can be helpful to create these databases. Glenn (2015), for example, argues the use of collective information systems as a way of using and supporting foresight methods, and Keller et al. (2015) propose a foresight database to serve as a 'knowledge pool' for foresight support systems. Needless to say, the quality of such risk calculations will depend on the availability of relevant (historical) data.

METHODS

In order to map the current developments in scenario planning amongst crisis actors in the Netherlands, the primary author conducted an explorative study into the use of scenario planning in all 25 safety regions in the Netherlands (Luesink & Boin, 2023). A safety region is a regional crisis management organization facilitating interdisciplinary cooperation of emergency services during a (major) incident or crisis. For the study, 30 respondents were interviewed, who were selected based on their involvement with scenario planning in education, training and practicing within the safety regions. This resulted in 24 interviews with representatives from the 25 safety regions (two regions share their staff). The study is thus representative of crisis management at the regional level in the Netherlands. In addition, six interviews were held with relevant crisis management partners who also teach scenario planning to crisis managers: the Police Academy, National Academy for Crisis Management, the Public Health Academy, Intelligence & Security Academy of the Ministry of Defense, a consultancy firm, and the Netherlands Institute for Public Safety. In semi-structured, open interviews, respondents were asked to reflect on the process of implementing scenario planning trainings between 2016 and 2022. They reflected on the choices made in this process and shared their experiences with scenario planning in crisis situations. The interviews lasted around 60 minutes. All interviews were recorded and transcribed. The transcripts were coded in the manner of grounded theory (Charmaz, 2014). During the coding process, the authors discussed the interpretation of the data and possible categories with each other on a weekly basis in the course of a month. The categories were identified that included the characteristics of the scenario processes, the goals that were set for scenario planning, the design and methods used, and the intended audience for the scenarios (Luesink & Boin, 2023). Together this created a solid overview of the state-of-the-art developments in scenario planning in the Netherlands.

FINDINGS

Goal & Purpose

Scenario planning gained traction in the Netherlands in the wake of the Covid-19 pandemic, as crisis teams began to chart possible futures to gain a sense of control over the prolonged crisis. Respondents point to a desire to 'get out in front of the crisis' in order to organize a proactive, rather than a reactive, response (Luesink & Boin, 2023). While a multitude of regions had already invested in teams that structurally monitored safety related developments in the 'cold' phase, the pandemic gave the quest for foresight a final push. Across all safety regions, agencies rapidly allocated human resources, hired trainers and established teams to carry out scenario planning in order to advise decision-makers. As of now, most regions and national crisis centers in the Netherlands use some form of scenario planning in crisis management. This rapid scaling up has given rise to a great diversity of applied scenario methodologies.

Overall, respondents noted two main purposes of scenario development. A primary goal is to create awareness about possible future developments. Scenario teams aimed to create a shared idea of possible futures so they could provide crisis managers with plausible grounds on which to devise a future course of action in an uncertain context. Some respondents focused on getting a grip on an uncertain situation by stating that *"the aim is to keep some level of control over the situation and to recognize how a crisis is developing."* Others emphasized the need *"to walk through a possible scenario together to make sure we are all on the same page"* (Luesink & Boin, 2023, translation ours).

A secondary, complementary goal that respondents identified is anticipating possible future developments and (proactively) taking measures accordingly. This goal corresponds with the need to formulate appropriate organizational responses (Iden et al., 2017). Even though the situation might be highly uncertain, and little verified information is available, decisions and measures can be taken in consideration of plausible escalation pathways of the situation at hand. A respondent stated that the purpose of scenario planning is *"to recognize the scenario we are in and to identify preventive and reactive measures"* (Luesink & Boin, 2023). The first goal can be described with the 'what if' question. The second goal entails the subsequent 'then what' question.

These two main purposes of scenario development, as identified by respondents, correspond with the dual tasks related to fostering strategic foresight (Iden et al., 2017): anticipation and taking (preventive) measures. The first step is exploring the situation at hand and identifying factors that could influence future developments. The second step is imagining and, possibly, preparing intervention measures to facilitate desirable and prevent undesirable developments.

Design & Methodology of Scenario Development

In the literature on scenario planning, several authors including Martelli (2001) decry the 'methodological chaos' in the field that stems from a plethora of scenario methods. Luesink & Boin (2023) find a similar diversity of scenario methods in the Netherlands. This is not necessarily a problem. After all, there seems to be no 'one size fits all' scenario method, since the selection of the most appropriate method should be guided by goal and organizational context of the scenario developers (Burt & Van der Heijden, 2003).

We provide an overview of the different scenario methods used in the crisis management landscape in the Netherlands in Table 1. These are four main methods taught in safety regions during scenario development training: 'Forward Thinking', 'IRS model', 'Imagination', and the 'Shell method' (i.e. intuitive logics) (see Table 1 for an explanation of each). These four scenario methods are all qualitative methods yet differ from one another in several ways. An important difference is that the 'Forward Thinking', 'IRS model' and 'Imagination' methods were designed or adapted to cater to the needs of crisis managers, whereas the 'Shell method' was designed to facilitate long term strategic thinking in a competitive business environment. The scenario formulation process of the first three methods also takes up less time than the 'Shell method', thereby offering a good fit for more high-paced crisis situations.

The 'Forward Thinking' and the 'Shell method' are both focused on strategic crisis processes. By engaging in these methods of scenario planning, crisis managers can get a better handle on the inherent uncertainty of a crisis situation and open their minds to multiple possible futures. The 'IRS model' and 'Imagination method', on the other hand, are characterized by an action-oriented purpose whereby the scenarios are intended to facilitate the identification of options for intervention and possible measures. Particularly in the 'IRS model', the scenarios are not the main outcome. Rather, scenarios aid in imagining a possible future state in order to formulate possible measures for intervention during the crisis.

These scenario methods portray a different operationalization of the dual tasks of strategic foresight. Whereas all methods engage with the situation at hand to explore possible futures, and subsequently identify options for response, the way scenarios help to identify these options differs. The 'Forward thinking', 'IRS model' and 'Imagination' methods demarcate the future through a best-case and worst-case scenario: developments that fall "between" these two scenarios are deemed most likely and should be considered when making decisions. In the 'Shell method', scenarios are created by ranking factors on uncertainty and their impact. Consequently, the scenarios are created based on the perceived uncertainties of the situation at hand.

Table 1. Overview of four common scenario methods as used by safety regions (between 2016 and 2022) to train crisis managers in scenario development.

Method	Source/based on	Crisis management level	Purpose	Approach	Process	Outcome
Forward thinking	Crisis management training consultancy	Strategic level	Coping with uncertainty	Strategic analysis	1. Analyze the current situation 2. Develop a favorable and unfavorable scenario 3. Identify strategic dilemmas for each scenario 4. Prioritize strategic decisions	Two scenarios and prioritized strategic decisions
IRS model	National Police	Operational and tactical level	Identifying and prioritizing measures	Risk analysis	1. Identify risks 2. Rank risks based on probability and impact 3. Develop a best, realistic and worst-case scenario for the high priority risks 4. Propose measures (preventive and reactive) for one or more scenarios	Risk matrix
Imagination	National Academy of Crisis Management	Operational, tactical, and strategic level	Identifying opportunities for intervention	Exploration of different future pathways	1. Analyze the current situation 2. Develop best, realistic and worst-case scenarios 3. Identify scenario drivers 4. Describe opportunities for intervention	Three scenarios, scenario drivers and opportunities for intervention
Shell method	Schwartz (1996)	Strategic level	Challenging mindset of decision makers	Exploration of possible alternative futures	1. Identify the focal issue or decision 2. Identify key forces in the micro-environment 3. Identify driving forces in the macro-environment 4. Rank the key and driving forces based on uncertainty and importance 5. Place the two key uncertainties on the axes of the 2 x 2 matrix 6. Write the four scenarios 7. Explore the implications of each scenario 8. Select indicators and triggers for monitoring	Four scenarios and robust response options

Data retrieved from interviews with respondents from the scenario methods; 1. Nijhof Teamadvies (consultancy), 2. National Police, 3. National Academy of Crisis Management, and 4. the Shell method as described by Schwartz (1996).

Organization and Institutionalization

A key difference noted in the safety regions in the Netherlands concerned the organizational level at which scenario development should take place and, thus, which crisis managers should be trained. In safety regions, crisis management is organized at three levels: the operational level (focused at the crisis response on the incident ground), the tactical level (focused at supporting the operational level and/or advising the strategic level) and the strategic level (focused at longer-term decisions by public local/regional authorities). Twenty-two respondents regarded the tactical level, and particularly the leader of that team, as the most suitable context for the development of scenarios. In the words of one respondent: *"the crisis team at the tactical level is most suited for scenario planning because they have more time to develop scenarios than the operational level and because the team takes both the operational and strategic level into account"* (Luesink & Boin, 2023). The crisis managers at the tactical level are expected to consider information from the operational level and translate it to long term effects and strategic dilemmas. The subsequent scenarios can be focused on either the operations or the strategy of the crisis response.

Many respondents pointed out challenges for scenario planning at the operational and strategic levels. Respondents argued that the operational level already has a great deal of tasks to complete in very little time, making scenario planning too much to ask even if it could be to their own advantage. A concern regarding the strategic level that several respondents shared is that the strategic crisis team would focus too much on the operational level instead of sticking to strategic dilemmas and decisions. Indeed, previous studies have often established that strategic teams which engage with operational units frequently fall prey to 'operational fixation' (Boin et al., 2017; Wolbers, 2022). Moreover, the majority view among respondents is that tactical crisis managers can strengthen their advice to strategic decision makers through the use of scenarios. *"The strategic level has advisors at the tactical level which support them in their decision making through scenario planning"*, in the words of one respondent (Luesink & Boin, 2023).

The discussion of who should engage in scenario planning concerns not only the level at which it should be done. We also noted different approaches to where in the organization to embed scenario planning: integrated in the work of every crisis manager of the responsibility of a designated scenario team? A quarter of the respondents argue in favor of keeping scenario development closely related to other crisis management processes such as sensemaking and decision-making, and thus integrated within the crisis team. Sixteen respondents, see advantages to having a separate scenario team. *"A separate scenario team would have more time to develop scenarios during a crisis and could consist of crisis managers who have more affinity with foresight"*, as one respondent stated (Luesink & Boin, 2023). Eight of the sixteen respondents, however, argue that a scenario team would only work during complex and/or protracted crises. The utility of a scenario team during shorter, less complex crises is drawn into question by these respondents, who note that by the time scenarios are developed and relayed, acute decisions will have already been taken and the crisis might already be under control. Setting up rapid scenario teams could also make the number of actors involved in the crisis response disproportionately high, resulting in higher coordination costs (Luesink & Boin, 2023).

CONCLUSION AND THE ROAD AHEAD: DEVELOPING REAL-TIME AND STRATEGIC FORESIGHT

After the COVID-19 pandemic, scenario planning and foresight have received much attention. Actors across safety regions and national crisis agencies in the Netherlands have invested in training and capacity building. Organizations are fully engaged with anchoring scenario methods in crisis response processes and structures through scenario teams. Currently, however, the variation in opinions and approaches between the regions and organizations is telling. No consensus between the crisis organizations exists on the questions of when, how or by whom scenario planning should be done. Flexibility and adaptability are key in crisis management, so scenario practices do not have to be pinned down completely – still, respondents attest to missing common ground. Within, but especially between, the 25 safety regions, sharing a common understanding of the goal of scenario planning and methods is deemed most applicable for different types of scenario development.

Looking towards the future ourselves, we note two pathways of interest that will help in advancing scenario planning: *real-time foresight* and *strategic foresight*.

Real-Time Foresight

Scenario planning is often related to broader processes of risk analysis and monitoring. Real-time foresight concerns the process by which crisis organizations *"concurrently prepare for and respond to a crisis"* (Wells et al., 2021, p. 35). It entails foreseeing future developments that can be acted upon by crisis managers. In that sense, real-time foresight links to the third level of situational awareness, which entails the anticipation of future developments, based on a detailed understanding of the situation at hand (Endsley, 1995).

To facilitate the process of real-time foresight, we can look to foresight support systems, such as dashboards, collective intelligence systems, data-mining, and web 2.0 approaches (Von der Gracht et al., 2015). When organizations are able to access or construct databases that help to identify trends and prognoses, it could deliver indicators that can be monitored. We have already seen examples in the Netherlands of dashboards monitoring the influx of Ukrainian refugees and virtual assistants in crisis teams to provide actionable advice.

The difficulty in monitoring is knowing what to look for. No crisis unfolds exactly like its predecessors. The explorative study of scenario planning demonstrates the current focus on qualitative, intuitive logics scenario planning in crisis management (Luesink & Boin, 2023). This type of scenario planning can be useful for analyzing the current situation, exploring possible future developments and identifying indicators which can be monitored. Once relevant indicators have been established, quality and availability of data become the next obstacles. Very few databases will likely be available to conduct trend analysis at the start of a crisis. However, a prolonged crisis, like climate change or migration, can give the necessary time to construct relevant databases.

Strategic Foresight

Developing strategic foresight is the major challenge of the era of the polycrisis. While most scenario teams are still focused on a singular crisis, recent developments require that attention to the possibility that crises may entangle and strengthen each other. The polycrisis points to the importance of foreseeing escalation pathways and imagining the relationship between different domains. For example, the World Economic Forum Global Risk Perception Survey (2023) has identified a range of escalation pathways between crises. Looking ahead for ways to address a crisis that might traverse into new systems and domains can be facilitated by using specific scenario methods that help to foster strategic foresight (Vecchiato, 2012). To find the right approach, researchers and practitioners need to explore a variety of scenario tools that may help 'zoom out' from the acute threats of a single crisis and let crisis managers consider the interrelated nature of our worldwide networks and infrastructures. As systems become ever more connected, and the destructive potential and cascading effects of crises increase accordingly, scenario planning may play a crucial role in supporting the anticipation and mitigation of future crises.

The Road Ahead: Developing Information Systems for Scenario Planning

Scholars widely recognize the unique capabilities of technology to enhance foresight (Marinković et al., 2022). Information systems research provides promising avenues into data-driven and quantitative tools that help to assess the relevance and possible impact of future contingencies (Von der Gracht et al., 2015). As we witness the increasing availability of new data sources, such as social media, web 2.0 and open data, in combination with machine learning algorithms and computing capacity, a rich set of possibilities is opening up to advance the capacity for foresight (Geurts et al., 2021). It is time to take the next steps to develop systems that provide collective intelligence capabilities in order to increase the analytical leverage for crisis managers struggling to engage in foresight processes and scenario planning. Especially the integration of qualitative and quantitative methods can strengthen foresight processes. Examples of such steps in different contexts can be seen in, for instance, the Regional Innovation System (Keller et al., 2015) and the Risk Assessment and Horizon Scanning project (Durst et al., 2015). Through such information systems foresight processes are enhanced, by offering consistency checks, collaboration of geographically dispersed experts, and database construction.

Still, we are not there yet. First, academic research on foresight seems to be primarily focused on business strategy, business continuity and innovation, whereas research on foresight in crisis management is scarce. Second, a persistent challenge is to explicate the required capabilities of participants in foresight processes (Durst et al., 2015). Without a clearer idea on what foresight processes entail in crisis management, what kind of information is required, and what kind of assessments help to foresee escalation pathways, it remains hard to offer a fitting technological infrastructure. Our research indicates that training in scenario planning is currently primarily focused on qualitative methods, while adequate risk assessment and monitoring require the integration of quantitative tools and databases. Such integration may help to validate and test the intuitive future contingencies that crisis managers foresee. Furthermore, it remains a key challenge to assemble the right information in the middle of a crisis. It would be interesting to explore whether other countries face similar challenges or have already found solutions. A lot of potential is offered by unlocking new data sources, such as artificial intelligence, web 2.0 and open data, in order to provide a richer and more responsive data environment to the crisis manager. To enable both real-time and strategic foresight in the midst of a crisis, we need to combine best of both worlds to design a fitting technological infrastructure. We hope the ISCRAM community can play a leading role in fostering such innovative capacity for crisis managers struggling to set a future course of action in the rugged and unpredictable landscape of the polycrisis.

ABSTRACT

Command and Control (C2) for emergency and crisis response is a n important field that poses several research challenges. This paper suggests that Command and Control should be viewed from a holistic point of view, that is the C2 activity system, and that technical C2 support systems must be understood in the broader context of the whole C2 activity system. Studying individual components of C2, such as decision-making, is important, but studying individual components mask out the complexity of C2 as a socio -technical activity. The paper presents an approach to studying C2 based on a generic C2 model combined with a technical core system for connecting different sub-technologies and services – which creates a re-configura ble environment for research efforts in the field of C2 that can span different activity system parts and focus areas.

Keywords

Command and Control, Core system, Command and Control Research, Socio -technical systems

INTRODUCTION

Command and Control (C2) systems are socio-technical systems created with the intent of coordinating resources to manage an unfolding situation. While C2 systems can be fully prepared before a crisis, as seen in military organizations, the degree of preparedness varies in civilian contexts (Trnka & Johansson, 2009). Crisis response without some form of C2 has a small chance of success. C2 systems provide "a foundation for resilience and the management of emergencies and crises" (Landsberg, Schmidt, & Mudimu, 2022, p. 392).

This paper addresses the important issue of enabling holistic evaluations of C2 technologies. While studies of individual C2 support systems, such as decision support or situation awareness technologies, are common, few studies take an overall grasp of the issues of C2, especially when considering novel or prototype technologies that have not yet been integrated into existing C2 support system configurations. While many such evaluations are done with the best of intentions, they are of limited value due to the inherent limitations of the approach. These limitations can include evaluations of individual C2 support systems providing information only about the impact of a particular application and its effect on an individual decision-maker or team, or the study only considering a specific part of C2, such as planning. There are many explanations for this. First, most research or development projects have a limited scope and can only cover a specific part of a C2 system. Second, C2 systems are inherently difficult to evaluate as they often comprise a large number of technologies and individuals who are involved (Landsberg, Gleibs & Mudimu, 2023). Third, the process itself is indirect (this will be discussed further below), and it is hard to differentiate between effectiveness and efficiency (Baroutsi, 2018). However, a very practical issue also haunts C2 research, particularly research involving prototype systems (as is often the case in research):

in many cases, it is hard, if not impossible, to connect all technical systems used in the C2 system. In this work-in-progress paper, we present an effort to create a core system that makes it possible to connect a variety of C2 support systems to enable a holistic approach to C2 in crisis or emergency response, henceforth called the *Core system*. A scenario has been developed within the *WASP Research Arena for Public Safety*[1] (WARA PS) project (Andersson et al., 2021) to capture the challenges of emergency response. This scenario has been used in combination with the Core system to demonstrate the potential of emerging technologies, such as semi-autonomous drones for sea rescue. This case is presented in the paper to show how a core system that connects multiple prototype technologies can be used to study the impact of such technologies on C2. Further, the future development of the Core system is presented with an example of large-scale drone operations. These examples are both part of an overarching project arrangement called Virtual Demo (VD) which focus a number of demonstrator projects around a search and rescue scenario. To establish a firm connect with existing theories on C2, the generic model of C2 developed by Landsberg, Schmidt and Mudimu (2022) is used to show the importance of capturing the diverse aspects of C2.

COMMAND AND CONTROL – WHAT IS IT?

C2 is often considered as a core capability of crisis response (Olsén et al., 2023; Landsberg, Schmidt & Mudimu, 2022; Landsberg, Gleibs & Mudimu, 2023)., 2022), although it is often used interchangeably with "Crisis management" and similar terms. How C2 in crisis management is organized and conducted differs between different nations and even within nations (Sahin, Kapucu & Unlu, 2008). C2 as a research field is inter-disciplinary and has been approached from several scientific fields and theoretical strands (Wikberg, Granåsen & Johansson, 2021; Grant, 2018). Depending on the scientific point of departure, C2 research tend to focus on spe cific aspects of C2, such as decision-making (Brehmer, 2006; Bryant et al., 2004), leadership (Taylor & Rosenbach, 2005; Bullis, 2003; McCann & Pigeau, 1999), situational understanding (Boyd, 1987; Endsley, 1995), systems thinking (Lawson, 1981), adaptive capacity (Alberts & Hayes, 2003), management (Taylor, 1947), organization (Mintzberg, 1979), to mention a few.

Approaches to C2 (NATO, 2010; 2014) range from loosely organized, collaborative, and lacking centralized authority, to strict hierarchical organization with centralized mandate. Independent of how the C2 system is manifested, the purpose of C2 remains the same, to arrange activities and capabilities in time and space to create certain effects in the pursuit of specified goals (Johansson, Herkevall & Lantz, 2023). This implies that C2 comprise the activities of defining goals and coordinating resources to pursue these goals. In practice, this demands several processes to be successful, such as the ability to assess what is happening, dividing tasks and responsibilities, monitor progress, and communicating with executing parts of the concerned organizations. C2 thus consist of a number of activities which form a purposeful system – failure to do so will inevitably result in poor situational understanding, inefficient utilization of available resources, uncoordinated efforts, and possibly increased risk for responding units.

MODELS OF COMMAND AND CONTROL

A *C2 system* is comprised of the involved personnel, the equipment they use, the processes that take place, and the rules or laws that govern work. A C2 system can thus in many respects be seen as equivalent to the definition of a Socio-Technical System (Baxter & Sommerville, 2011 Emery & Trist, 1960). The important point, derived from the use of the word "system", is the holistic perspective of C2 as system created to produce not only orders, but also a system that continuously set goals, assess the situation at hand, create plans, and evaluates the effect of actions. Several attempts to create models of C2 have been made. As in the case of theoretical perspectives on C2, the models differ depending on which discipline they originate from and the purpose of the model. Roughly, a distinction can be made between structural models, that relate different components within the C2 -system, decision models which describe the perception-decision-action cycle, such as Boyd's OODA-loop (Boyd, 1987), and procedural models that describe the various steps of a command cycle in terms of the C2-functions involved and their relation in time, such as Brehmer's Dynamic OODA-loop (Brehmer, 2006; 2009). There are also conceptual models that relate specific dimensions of C2 to each other, most notably the NATO SAS-050 C2 approach space (NATO, 2006). While most of these models were designed in the context of military operations, many of them have been used in the context of crisis management and response due to the lack of established model within the field of crisis management and response. Fortunately, a major research effort has been conducted by Landsberg, Schmidt and Mudimu (2022) in creating a generic model of C2 that can be used in crisis management and response research.

[1] See http://portal.waraps.org/

A Generic Model of Command and Control

Landsberg and his colleagues endeavoured to create a generic C2 model for crisis management with the purpose of supporting research on C2 in terms of evaluation and design (Landsberg, Schmidt & Mudimu, 202 2). The model is based on seven different documents from five different countries describing C2 processes for emergency response and crisis management (ibid). They also used the NATO Code for Best practice for C2 Assessment (NATO, 2002) when designing the generic C2 model to assure that it can be used for evaluation of different aspects of C2. The generic C2 model offers a variety of approaches for research, such as supporting the identification of appropriate key performance indexes (KPIs), identifying important milestones in the C2-process, and identifying relevant components to includes in the analysis (Landsberg, Schmidt & Mudimu, 2022). The model, in its simplified form, includes seven main process steps (denoted A-G, see Figure 1). Landsberg and colleagues aimed to make the model scalable in the sense that it should be applicable to a range of situations from on-site emergency response to large-scale crisis management.

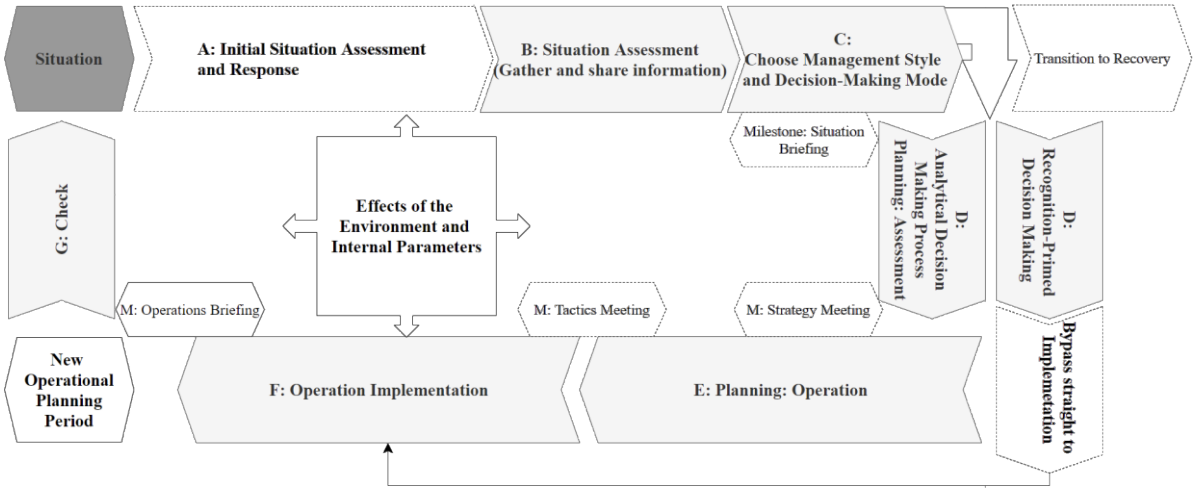

Figure 1. A simplified generic model of C2 (used with permission from the original author, Landsberg, Schmidt & Mudimu, 2022)

In the context of this paper, the model is appealing as it provides a holistic C2 model firmly based on real-world examples and best practice that can be used as a point of departure for identifying and understanding the need for connecting various C2-components and evaluate them as one system rather than isolated parts. The fact that the model is firmly based on a number of real-world C2-systems provides ecological, as well as face, validity. The fact that the model it is relatively scalable in terms of command levels also makes it relevant for many different scenarios, ranging from emergency response to crisis management. However, to make holistic evaluations or research on C2, all or most parts of the model must be in play. This demands at least one of the following things: a full-scale exercise involving all C2 functions that would be in play in a real-world case; a dedicated simulation environment that provides all C2 functions, or, a system capable of connecting a number of individual C2 functions that jointly form a complete C2 system. We argue that the latter approach is the most viable one as this creates a flexible solution that also enables joint research efforts where different research groups can provide solutions that can be developed at different paces and be brought together for more holistic evaluation. Also, such a system should be modular in the sense that it should be possible to exchange individual systems without interfering with the operation of other systems, apart from the fact that certain data generated by that function will not be generated unless it is replaced with another system. Below follows a presentation of such a Core system in the WARA PS system.

ONE SYSTEM TO CONNECT THEM ALL

Similar to the generic C2 model, the Core system of the WARA PS project constitutes a holistic approach, well suited for high level research in C2. As mentioned previously, WARA PS is a Swedish national effort to create a research arena for artificial intelligence (AI), autonomous systems, and future software systems with the aim of shortening knowledge transfer between academia and industry. This collaborative environment comprises test beds that allow for research and development of unmanned surface vehicles, drones, and underwater vehicles (Andersson, et al., 2021). The implementations in the WARA PS Core system maps well to the seven main process steps in the generic model (**Table 1**). The Core system is composed by three interacting layers: the Service layer,

the Tools layer, and the Agents layer (see **Figure 2**) whom all are supported by the Core. The Core part of the system serves as a broker for messaging, packeting, rights, APIs etc. The Tools layer serves as the interface to human users and is essentially where the C2 functions can be realized, and its effects be studied. The Services layer provides necessary services to all the tools, agents and users, as well as other services available. The Agents layer connect both real-world and virtual vehicle, sensors or agents with the other layers and services. Depending on the scenario at hand, different agents, services and human-machine interfaces can be combined. The Core system is therefore flexible enough to support C2 on different levels, ranging from individuals operating equipment to more overarching orchestration of activities on tactical and strategic levels. It is domain agnostic and could be used to connect activities in different domains, such as cyberspace and the physical world. Several activities consisting of individual C2 loops working towards different goals could be set up in a collaborative environment which is transparent and accessible from a research point of view.

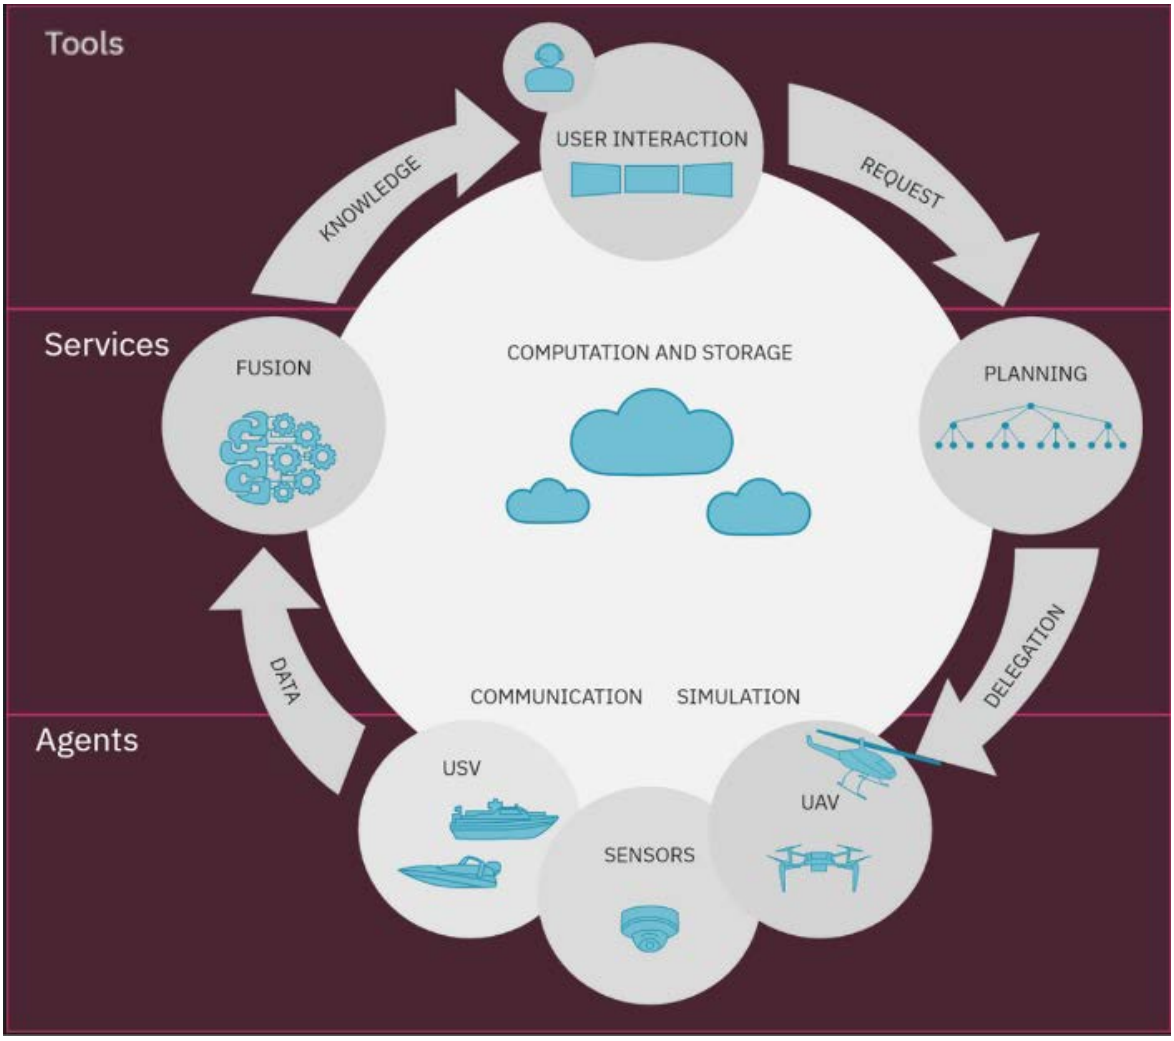

Figure 2. The Core system.

While the Landsberg generic model describes how individual C2 functions are connected through process, the Core system offers a multitude of possible configurations. The Core system can be configured to plan and organize certain aspects of C2, such as planning and analysis of sensor data , both in the form of services provided through the service layer, see **Table 1**. It can also be configured to provide situational pictures to human users, and to study their interaction and behaviour.

Below follows a description of the current status of the WARA PS Core system based on a demonstration of the system made in 2023 the *WARA PS Search and Rescue demonstrations*. This is followed by a description of a system that will be connected to the WARA PS Core system in the future, the *UTM City Drone simulation*, which will add a strategic level of operations to the overarching C2 system once incorporated with the Core system.

Table 1. Mapping the generic model to the Core system of the WARA PS case.

Generic C2 model	Core system – Examples
A. Initial Assessment and Response	Agent layer – Agents interacting with the environment or simulated environment to collect and analyze data Service layer – anomaly and object detection on fused data to assess situation Tools layer – Brief initial Situational Picture Looped until initial situation assessed
B. Situation Assessment	Agent layer – sensor data from Agents Service layer – sensor fusion and (re)planning Tools layer – Situational Picture(s) Looped until situation assessed
C. Chose Management Style	Human Activity – Commanders must decide if they are to manage the situation based on trust and dissemination of decision rights to sub-ordinate units, or if the situation demands a more centralized, directive command style. Combinations of the approaches may occur depending on level of command and domain. Agent layer – what kind of C2 management does the agents demand? Can they be configured to act upon different styles. Service layers – what kind of structural configurations of the C2 system is possible. The Core system offers a high degree of flexibility. Tools layer – what management styles are supported by the HMI components? For example: must orders be produced in the form of directives, or does the system offer some flexibility in the formulation of orders?
D. Decision-Making	Tools layer – Decision support. Decide complexity of operation and needed amount of planning
E. Planning Operations	Tool layer – HMI for human interaction Service layer – planning of operations based on available resources and operational needs Agent layer – provide information of available agents, capabilities and services.
F. Operation Implementation	Tool layer – C2 command systems Service layer – Fusion services for analysis like object detection, anomaly detection and data fusion. Also (re)planning Agent layer – execution of orders, simulation, search, move, pickup and drop objects. Provide data for analysis.
G. Check	Tools layer: Decide if new strategy needed or operational objectives fulfilled. Services layer: Support for analysis and evaluation of operation progress.

Current Status - The WARA PS Search and Rescue Demonstrations 2023

The WARA-PS Core system has been used during demonstrations of search and rescue missions, using real and simulated unmanned arial vehicles (UAVs), unmanned ground vehicles (UGVs) and unmanned surface vechicles (USVs) together with human agents and humans in C2 . The unmanned vehicles had varying degrees of autonomous capabilities and act as agents integrated in the system. They communicate using high level commands such as Search Area, Move To, Pick up and Drop. Each vehicle acts independently and interprets the commands/tasks in its context and executes based on its capabilities (see **Figure *3***). The system offers a way to communicate and share tasks and data in the same mission.

A scenario has been used in the demonstrations. In the scenario, victims of a fictive boat accident were spread out in water and on land. Victims in water were represented by floating tennis balls to challenge detection algorithms and create a fast and interesting demonstration illustrating activities and decisions. On land the victims were played by humans acting in the role as injured.

A simplified activity model of the operation conducted in the scenario was used, where the autonomous agents conducted the following activities simultaneously to search and rescue victims in the scenario. The involved agents changed activity depending on the type of task in collaboration with human decisions.

- **Prepare** for a probable upcoming situation, by placing drones and aid on right place
- **Surveillance** to detect anomalies, as an ongoing activity to identify changes or assess situation
- **Search** to detect interesting objects as an activity to assess (initial) situation
- **Inspect** detected objects to identify them as victims as candidates to rescue
- **Rescue** by delivering useful aid to identified and prioritized victims
- **Evaluate** to learn, improve and be ready for a new planning period or a new operation

In an operation all those activities are ongoing as parallel activities and agents shifts activity based on needs to perform an efficient operation.

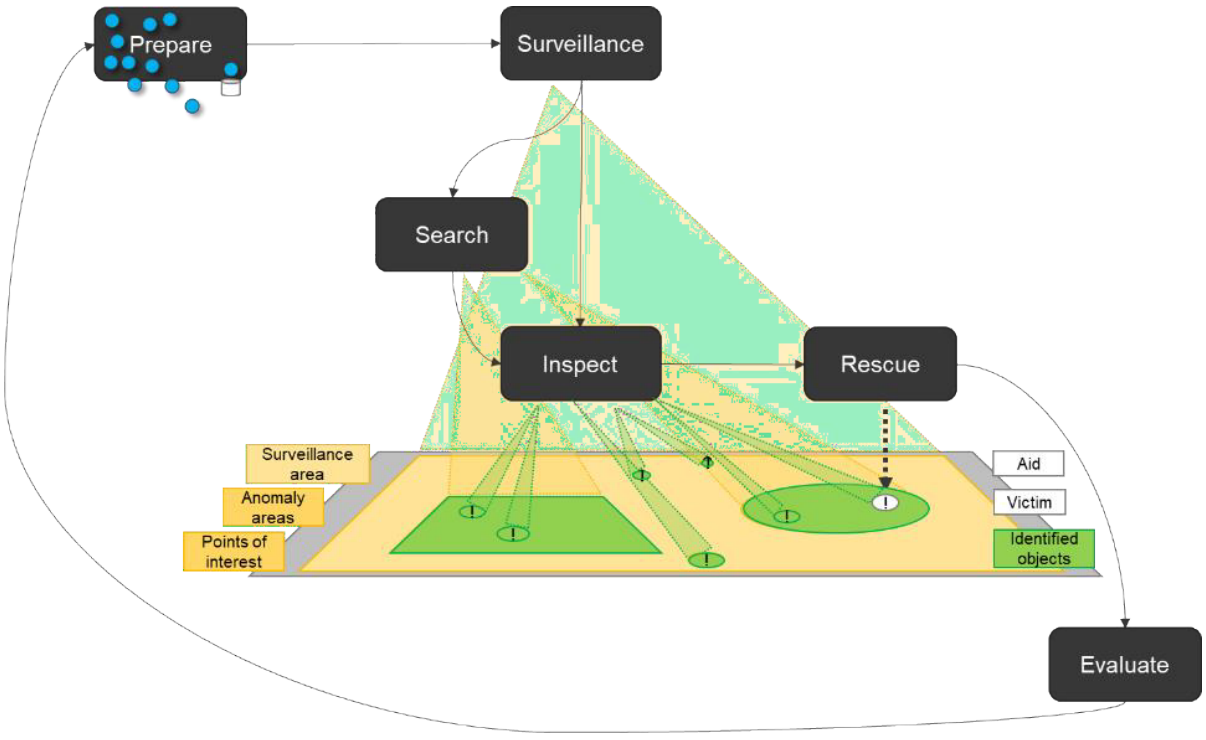

Figure 3. Activities in a search and rescue operation performed by using the WARA-PS core system with autonomous agents.

The demonstrations were performed in September 2023 in Sweden at the Gränsö drone testing range during the WARA-PS demonstration week. With an audience of over 200 persons the scenario was played multiple times on two days where the activities constantly changed due to weather and different introduced disturbances.

During the demonstrations the physical agents was represented by:

- Two UAVs flying over the scene with cameras assessing the situation performing surveillance and search for victims. To rescue they have a device to drop medical kits at safe distance from victims. The UAVs was prepared to support both activities over land and water based on upcoming needs by changes in the situation.
- One Boston Dynamics Spot robot for close inspection of detected objects. The Spot robot can also pick up the dropped medical kits and move close to victims for rescue.
- One Saab Piraya USV boat to search the sea using camera and lidar. This larger USV was meanwhile performing autonomous navigation with collision avoidance testing.
- Four small mini-USVs working together to inspect detected objects in water by moving closer to the objects detected by the Piraya USV and UAVs. Using cameras, the mini-USV supported the humans in C2 to identify and prioritize the objects as victims to be rescued.
- A human on stand-up paddle board equipped with a mobile phone application to serve with capability of moving close to victims and pick them up on the board for transport to shore.

The core system offered exchange of data and tasks to provide all agents and humans in C2 with shared situational picture including objects, victims and changes. The C2 tools used was the WARA PS *Arena Map* where two human operators supervised the operation and supported with decisions by commanding the agents. Additional instances of the C2 were active to give the audience a situational picture containing live video feeds, map and 3D overview. The USVs had their own USV C2 to supervise and make decisions on lower level to support the larger USVs (Piraya).

Communication in the system was a mix between 4G/5G, wifi and dedicated radio links. Human operators in C2, field agent on paddle board, safety pilots for the vehicles and demonstration leader used separate voice communication. Services developed from different organizations was executed in cloud and on agents to support object detection, anomaly detection and task delegation/distribution. Besides the physical agents the system introduced multiple simulated agents to investigate how the system and operation can be scaled.

There was also a couple of other separate demonstrations ongoing simultaneously using air space and facilities that was coordinated to give audience an insight of how the core system and resources can be used and what has been done during past year. Collected data as positions, decisions and video was recorded for analysis and evaluation. Besides the sha red recording many of the involved systems has their own storage of information to be extracted and used for research purposes and to improve she systems.

Ongoing Development – Integrating the UTM City Drone Simulation at the Strategic C2 Level

An example of adding new integrated functionality, to combine lower levels of C2 with higher levels, in the WARA PS systems is the *Unmanned traffic management, for air traffic in cities* (UTM City) platform (Westberg, Palmerius & Lundberg, 2022; Lundberg, Arvola & Palmerius, 2021). The Core system contains a mission-management component, the *Arena Map*, where resource usage can be planned, as well as specific routes to use for drones in the air, at sea, on land. UTM City adds capabilities for coord inating the use of physical air space between co-located missions. The UTM CITY platform is a collection of software for drone traffic simulation and control. It is the result of eight years of research on drone traffic planning and management, visualization, and human-automation interfaces. The platform consists of two main parts: a drone traffic infrastructure simulator that we call *dronesim*, and a user interface for this simulator.

The *dronesim* module handles the simulation of all activities involved in drone traffic, and has been designed to test separation of concerns and communication between the actors by isolating the simulation of 1) drone operators, setting up drone activities, sending plans for authorization and controlling the drone flight, 2) airspace authority, holding the airspace design, responding to queries about traffic situation, and validating, modifying and authorizing flight plans, and 3) activities performed by a unmanned tra ffic control officer (UTCO).

The *user interface* module connected to this simulation module provides a 3D map over the designated area and simple means to activate various data and layers, and two different menus for scenario control and air traffic management, respectively. The menu for scenario control provides means to draw activities for dron e operators on the map, for automatically generating potentially hundreds of drones quickly and with little effort. The menu for air traffic management lets the user control airspace parameters, such as minimum allowed distances, as well as create, activate/deactivate and adjust no-fly-zones.

The dronesim module automatically reacts to airspace changes, sending signals to the affected operators that their plans need to be renegotiated. They will subsequently calculate new plans based on the remainder of their ongoing activities and submit these for authorization. The airspace authority uses the airspace configuration to adjust these

plans if necessary and responds with the updated plans. The UTM CITY platform also has a streaming log module, to capture what goes on in the system, for real-time analysis or after-action review.

By the integration of this functionality in the WARA PS case, yet another concrete implementation related to the generic model is available for the study of C2, especially concerning drone traffic planning and management. Not only are such studies supported by the implemented functionality, but also by the C2 contextual framework of the Core system of the WARA PS case, see **Figure *2***, and **Table *1***.

In a simulation, UTM CITY operators can work on a more strategic level than when using the Mission Management module in the Core System. In UTM CITY, common airspace structures are established, such as flight common-use routes or airspace areas for shared operational spaces, as well as flight levels, geofences and geocages for isolation of operation. In the Mission Management component, the Arena Map of the Core System, different agents can request routes or destinations or geofences, that are then coordinated in UTM CITY. UTM CITY can also perform basic simulations of prototype services such as mass-deliveries and surveillance, point-to-point deliveries – to be able to identify and foresee problems in the airspace by stressing and simulating situations rapidly (but not on a detailed level). By connecting the sub-systems in the Core System, mission management can be studied at the same time as airspa ce management, in an integrated Virtual Demonstration; or a Physical-virtual Demonstration, or a purely physical demonstration.

Thus, in a setting such as a search-and-rescue mission, different teams need to collaborate and act together. The use of airspace for their missions can then be coordinated in the UTM CITY platform. In future versions of UTM CITY, surface mission areas or sub-surface mission areas could also be managed in similar ways.

DISCUSSION – CREATING A HOLISTIC C2 RESEARCH ENVIRONMENT

Creating conditions for holistic research on socio-technical C2 activity systems is possible. Far too often, aspects of C2 are studied, such as individual ICT components supporting situational pictures, communications, social media analysis etc. While these efforts are both necessary and admirable, they are also problematic from a systems point of view. When studying "bits and pieces", we mask out some of the actual complexity of a C2 system , both in terms of the complexity of interconnected technical systems and in terms of inter-personal aspects of C2. It should also be noted that creating a system like the Core system is not done to impose control over several interconnected systems – it is done to be able to study how C2 manifests and evolves in different scenarios under different configurations of C2 capabilities. The focus is thus on interconnectedness rather than control, on the ability to farm data from a multitude of systems, and on the possibility to study C2 as a whole rather than individual components.

We have exemplified how the integration of a new component in the Core System can enable a new kind of integrated study of C2. Rather than starting from scratch to study collaborative mission-management and operational space management, the Core System integrates two separate m odules (Mission Management and Operational Space Management). By doing so, it is also integrated into the larger whole of the Core System, to make use of other components, and enabling other kinds of studies. For instance, to include studies of autonomous systems operation across mission management and operational space management. While this example focuses on drone operations in emergency response, this must not be the case. The Core system has general capabilities to connect other kinds of systems. As can be seen in **Table *1***, the word "agent" must not be equivalent to a drone, and services and tools must not be specific to drone operations. In this sense, using the generic model has expanded the focus of the Core system by looking beyond demonstrations of emergency response with drones to a more holistic view of experimentation and research on C2 systems. For example, the mission management system, which can be used on the operative level for A. Initial Assessment and Response, B. Situational Assessment, and F. Operational Implementation, can be combined with the UTM City system to include D. Decision Making and E. Planning Operations on the strategic level. Further, these systems were developed independent of each other, now coming together under the Core system umbrella .

Bringing Research Into the Picture

The WARA PS Core system example demonstrates how a usable research tool for C2 can represent a concrete representation of relevance to the generic C2 model, and at the same time allow for variations in implementation of relevance for applied C2 research. Therefore, the Core system is also well suited for studies of the ma in processes, their interdependence, and their internal characteristics. Indeed, the Core system has been described as "a system architecture for industrial and academic collaboration" (Andersson et al., 2021). On the one hand, adding of components can enable operational capabilities, to carry out exercises. On the other hand, can also add research capabilities such as logging and recording of exercises. When integrating components, it is important to

integrate both kinds of capabilities, to enable studies that go across different C2 activities. As pointed out by Landsberg, Gleibs and Mudimu (2023) in their systemic approach to C2 assessment, C2 can, and possibly must, be evaluated on several levels. They suggest that C2 systems can be evaluated in terms of *physical characteristics*, *structures and processes*, and *C2 system effectiveness*. The Core system focus mainly on creating conditions for evaluating C2 system effectiveness but can naturally be used to examine the other levels as well. The modularity of the system may create some challenges in this regard as a joint analysis of a multitude of supporting systems and services on all core system levels (Tools, Services, Agents) must be conducted to understand the physical level, which the systemic approach of Landsberg and colleagues describe in terms of bandwidth, connectivity, and computer capacity. However, structure and process, described in terms of for example time to complete tasks, time to transfer information, number of personnel involved in different activities etc (Landsberg, Gleibs & Mudimu, 2023) could easily be captures by comparing different parts of an implemented scenario with different inputs to, and interactions with, Core system components. The third level, C2 system effectiveness is in the Landsberg and colleagues framework proposed to evaluate situational awareness, workload, sensemaking, synchronization of effort, communication, and leadership (ibid.). These aspects of C2 are also possible to evaluate in the context of the Core system, but we suggest that focusing on scenario-based measures of success could be an addition. Measuring human factors aspects of C2 such as situational awareness and workload is interesting if we want to understand how different C2 components impact humans in the system, but we also need to keep focus on the overarching performance of the C2 system and evaluate the effects on human operators in the light of this.

The WARA PS core system is dynamically adjustable for applied studies of C2. This means that a wide range of research questions can be, and has been studied, of which some examples has been provided above. The way the WARA PS scenario and the implementation in the core system has been designed, makes it not only suitable for system research, but also for research on methods and approaches. Since also future capabilities, not yet realised in today's practise is represented, it is well suited for applied research of future challenges and possibilities in C2. The main goal for the future development of the Core system is therefore to create possibilities for connecting further, and future, systems to the environment.

CONCLUSIONS

To create possibilities for holistic evaluations of socio-technical C2 activity systems, it is important to not only be able to connect different C2 solutions, but also that capabilities for studying C2 are in place. The Core system is based on modularity and interconnectedness rather than a tailor-made approach for studying a specific problem. Instead, it can be configured to enable applied research on a number of issues related to C2 in emergency and crisis response. A case describing such research, as well as suggestions for future development has been described above in terms of the WARA PS Gränsö demonstrations and the UTM City simulator. The generic C2 model by Landsberg, Schmidt and Mudimu (2022) has been used to show how the layers of the Core system can be connected to a model of C2 to assure that all relevant aspects of C2 are captured. Using such a model of C2 is necessary to assure that no aspects of C2 are neglected. Further, the generic model can be used to understand what parts of C2 a newly developed technology can support, and how it is related to other C2 systems, i.e. what types of connectivity it must have to be part of the whole. The generic C2 model also provide key performance indicators that are useful for evaluating the impact of different kinds of C2 support systems or agents, for example in the form of drones or new autonomous capabilities.

ABSTRACT

Effective disaster recovery depends on highly-skilled practitioners. Like any sector, however, the education and training systems that build these skills can experience crises that disrupt their ability to function effectively. These can be one-off events (e.g. a major flood) or extend over long periods (e.g. a pandemic or a vocational crisis). Based on the observation that there is a shortage of trainers and teachers in the education sector, as shown by indicator D7 (OECD, 2023), in this article we study the ongoing ability of a French vocational training organization to transmit skills that are useful to society in the event of a natural disaster, and in particular those that will shorten the recovery time of buildings and infrastructures. We propose a model that simulates the flow of people through the educational system and the institution's ability to generate enough trainers to maintain a chain of know-how transmission. In the simulation of this work in progress, we have parameterized the actual success rates, which we vary in order to define a minimum success rate limit to ensure the renewal of human capital. Based on the proposed model, further testing and analysis will be used to characterize a range of resilient flow behaviors and to provide recommendations for maintaining the condition of the human know-how transmission chain.

Resilience, Education System, Evaluation, Key Performance Indicator, Decision Support, Steering

INTRODUCTION

The impacts of climate change on modern societies are still in their early stages. An acceleration in the frequency and magnitude of natural disasters will increasingly lead to damage to people and property (Intergovernmental Panel On Climate Change, 2023). Beyond the public policies implemented to address these crises, it is crucial to recognize the need for skilled workers to help restore, as quickly as possible, the infrastructure, buildings, and industrial facilities essential for the proper functioning of human societies (Bruneau & Reinhorn, 2006). The capabilities required of these workers, in terms of know-how, emotional intelligence, and an understanding of the most effective actions available, take many years to develop and require significant ongoing investment in order to avoid obsolescence (Sandborn & Prabhakar, 2015).

Many of the decision-making skills needed by such expert tradespeople are also needed for effective decision making in other crisis management contexts. For example, it is important to have the capacity to understand complex

situations, to withstand stress and pressure, and to make quick decisions, as well as to coordinate and communicate, to demonstrate adaptability, ethics, and responsibility, and to synthesize feedback. These skills therefore represent a critical resource that needs to be developed and maintained in order to avoid a shortage of expertise that could have devastating repercussions in a crisis.

In France, the *Association Ouvrie`re des Compagnons du Devoir et du Tour de France* (AOCDTF) has been helping to train high-level experts in over thirty trades, mainly in construction and industrial technology, for several centuries. This type of manual know-how enables emergency repairs to be carried out and essential infrastructure to be maintained, such as public buildings, power plants and housing. In so doing, it contributes to the resilience of society.

Here we consider resilience as *"the ability to prepare and plan for, absorb, recover from or adapt more successfully to actual or potential adverse events"* (National Research Council, 2012). The expertise provided by crisis response and recovery organizations is critical for helping society to be resilient, but these organizations may also face disruptions to their own ability to properly train new workers. To play their part in community resilience (Valinejad et al., 2022), therefore, organizations like the AOCDTF (or the *"Compagnons"*) must also have resilient education and training systems, in order to ensure that each organization maintains its own human chain of know-how. This resilience means taking into account the flow of people through the system, and in particular ensuring that the system generates sufficient numbers of graduates and has the capacity to continue doing so. In the case of the *"Compagnons"*organization, this means ensuring that enough young professionals become trainers, so as to maintain the training capacity for the incoming apprentices. When this isn't the case, it creates problems for the organization's economic model, which is then forced to call on former members of the system or external professionals whose remuneration is higher. Furthermore, the pedagogical model of the *"Compagnons"* is based on community life and on there being only a small age gap between learner and supervisor. A disruption in the training system thus also puts pressure on young people who have not yet completed their apprenticeship to take on the job prematurely to fill the gap, which is an undesirable outcome.

With this in mind, this article seeks to contribute to improving the resilience of human capital in training organizations, focusing particularly on the issue of the shortage of trainers for the highly skilled workers needed for disaster recovery efforts. We propose to model the flow of learners and its consequences on the flow of teachers or trainers, in order to better understand the resilience of these educational organizations to internal disruptions, and thus to support decision-makers in their efforts to respond to and recover from such disruptions more effectively. We first introduce a generalized model and provide its mathematical formulation. We then discuss the specific context of the *"Compagnons"* organization in more detail, and apply the model in that specific context, to illustrate its use.

BACKGROUND

Educational systems are intricate organizations, challenging to comprehend to the extent that advanced tools are necessary for modeling them to anticipate their behaviors (Jacobson et al., 2019). Furthermore, such systems are challenging to transform (Burner, 2018), and they often operate in a volatile, uncertain, complex, and ambiguous (VUCA) environment (Waller et al., 2019). This environment exposes such systems to various risks that they must be capable of assessing in order to devise strategies to ensure their proper functioning (Dehdashti et al., 2020). In the face of such complexity, asking questions about resilience such as Meerow et al. (2016)'s five W's (Who? What? When? Where? Why?) is important for allowing educational systems and organizations to gain a broader understanding of the specific context within which they seek to achieve such resilience.

With this in mind, Table 1 enumerates the risks impacting educational systems, classifying them according to the transdisciplinary perspective required for the integration of sustainability and resilience into risk (Nielsen & Faber, 2021). It is self-evident that these risks are not exhaustive, and each educational organization must undertake a comprehensive survey tailored to its environment.

Our focus here is on the trend towards a shortage of teachers within such systems, which is a challenging phenomenon because it unfolds over an extended period of time. It offers an example of a so-called "slow-motion disaster" (or "slow-onset disaster") where the impacts (in this case, a corresponding shortage of highly skilled workers) are not immediately felt. Pierrehumbert (2006), in discussing climate change and carbon dioxide emissions, defines slow-motion disasters as events where the consequences manifest over a century or more. Draus (2009), in the study of Detroit's population and drawing on numerous other works, refers to slow-motion disasters by focusing on the consequences of multiple vulnerabilities that can accumulate and whose effects become visible over the long term. He introduces a sociological component, represented by a cascade of cause-and-effect relationships. Additionally, he identifies slow-motion disasters at the structural, process, or situational state levels.

Table 1. Risks in Educational Organizations

Risk Family	Risk	Capacity from / to
Human Assets	Lack of trainers	Managing human resources
	Excessive attrition rate	Supporting learners
	Demographics	Adapting the organization
Production	Teaching obsolescence	Update skills
	Reputation	communicate
	Cheating	Fostering integrity
	Operational under-performance	Leading and empowering staff
Health	Psycho-social	Taking care of people
	Contagiousness	Organizing health constraints
Earth system, Environment, Food, Water, Natural resources	Ethics	Training stakeholders
	Environmental	Minimizing the organization's footprint
	Shortages	Securing supply
Economy	Budget limits	Manage fluctuations
	Corruption	Control integrity
Systems engineering, Infrastructures, Free market systems, Governance	Universal access uncertainty	Plan
	Organizational under-performance	Continuous improvement
	Technological disruption	Adapt strategy
	Administration	Organize and plan for the future
	Competition and globalization	Satisfy stakeholders
	Legal	Track activities
	Regulatory	Ensure compliance
	Crisis management	Prepare for action

The evaluation of educational systems is most often used for assessment rather than for guidance (Michel, 2000), and there can be challenges with accepting evaluation by those involved in vocational education (Jorro, 2007). Our ambition is to provide indicators that can contribute to both measuring and improving the resilience of human trainer resources in this context. We thus need to know inputs, outputs, objectives, and instructions, as well as human, technical, and financial resources, in order to appropriately characterize how such an organization functions. To evaluate the behavior of these processes, we then also need to have key performance indicators (KPIs) at our disposal that will enable us to measure effectiveness (which is the relationship between objectives and result), efficiency (which is the relationship between means and results), and relevance (which is the relationship between means and objectives) (Nadoveza Jelic et al., 2018; Saikia & Bezborah, 2014).

MODEL

To support evaluating the resilience of educational systems in the context of slow-motion disasters, we propose a discrete, generalizable mathematical model that represents the flow of individuals—learners, graduates, and trainers—through time.

By creating this model, we aim to reach two goals: to have a better overall understanding of the dynamics of the system and to be able to answer questions such as the following, in order to guide resilience-focused decision making:

- What is the sustainable growth level of the system?
- What happens if the rate at which learners become trainers varies upward or downward?
- What occurs if the inflow rate slows down (due to demographic changes, different choices of orientation by entrants, etc.)?
- What happens in the event of a crisis (i.e., a sudden decrease in learners or trainers)?

Because of the length restrictions of a work-in-progress paper such as this, our discussion below focuses on only one such question, illustrating the potential of the new mathematical model by analyzing the effect of changes in the student attrition rate.

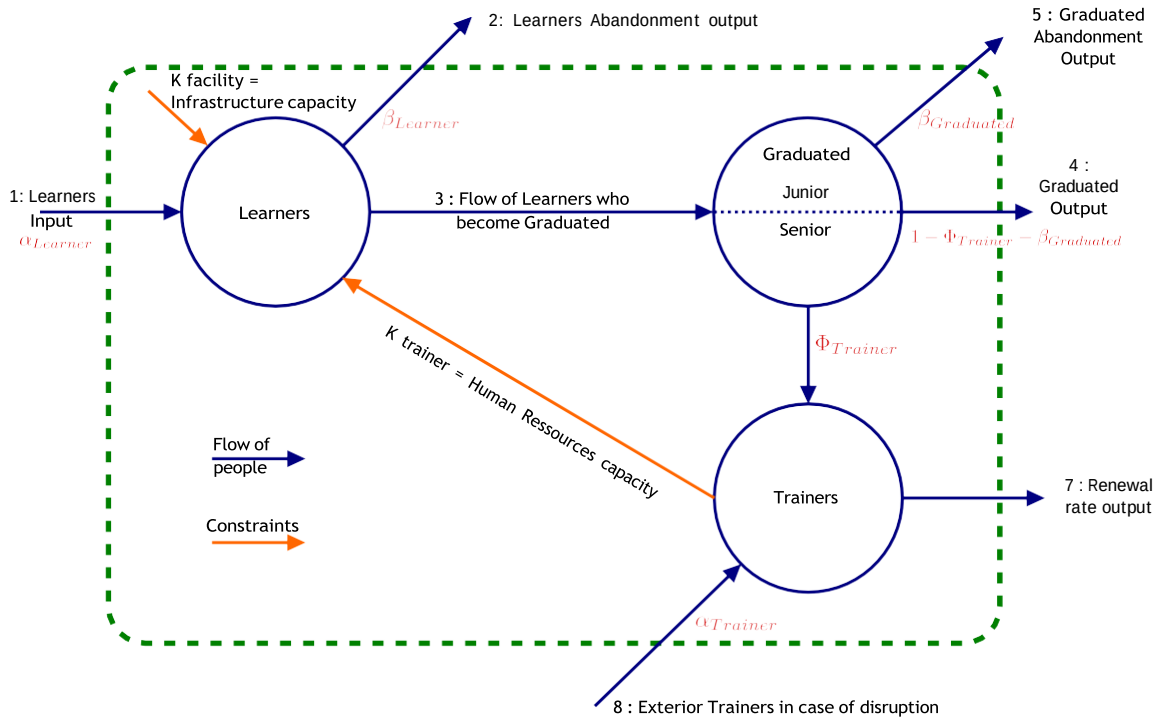

Figure 1. Trainer flow model

In order to enable an education system's managers to project their available human resources (i.e., the personnel who serve as trainers), we propose the model shown in Figure 1. In this model there are 3 pools of resources :

- The Learners : The behavior of the Learners in the system is defined by equation (1). The training will last a duration of $\tau_{Learner}$ years. Each year the pool of learners will suffer losses $\beta^t_{Lear\ ner}$ due to drop-out, reorientation, or breach of contract between the learner and the host company (flow 2). Those who will succeed through all the training will be the input of the Graduated pool.
- The Graduated : The behavior of the Graduated in the system is defined by equation (2) and equation (3). A Graduated is first a Junior for one year before becoming a Senior. These graduates may subsequently use their expertise to support the training efforts for an additional period of time, with this group also suffering $\beta_{Graduated}$ losses due to abandonment and other reasons (flow 5). After a certain time, τ_{Senior} , a compliant flow out of the system takes place, for reasons of career development, updating of knowledge, or other reasons (flow 4). A proportion $\Phi^t_{Tr\ ainer}$ of Senior graduates will then change state to become the input flow of the Trainers pool.
- The Trainers : The behavior of the Trainers in the system is defined by equation (4). Trainers will stay for time $\tau_{Trainer}$ before leaving the system (flow 7). In the event of a shortage of trainers, it is possible to call on external sources of trainers: $\alpha^t_{Tr\ ainer}$ (flow 8).

We also have added several infrastructure constraints: $K_{Facilit\ y}$ is the capacity of the training centers, representing the upper limit of learner intake, and $K_{Trainers}$ is the ideal number of trainers needed for the system to perform as expected. Based on this description of the training system, we introduce the associated mathematical flow model. The relevant parameters on which the flow model is based are as follows :

- τ_{Learner} : the duration of the training.
- τ_{Senior} : the minimum time before leaving the system as a Graduate.
- $\tau_{Graduated}$: the minimum time before becoming a Trainer.
- $\tau_{Trainer}$: the minimum time before leaving the training system.
- $\Phi^t_{Tr\ ainer}$: the Trainer transformation rate: the portion of the Graduated that will become Trainers
- $\beta^t_{Lear\ ner}$: the Learner abandonment rate
- $\beta_{Graduated}$: the Graduated abandonment rate, before becoming either a Senior or a Trainer

- $\alpha_{Learners}$: the input of Learners each year.
- $\alpha^t_{Trainer}$: the input of external Trainers each year.

$$Learner^t = \alpha^t_{Learner}$$
$$Learner^t_i = Learner^t_{i-1}\left(1 - \beta^t_{Learner}\right) \quad \forall i \in [2, \tau_{Learner}] \tag{1}$$

$$Graduated^t = Learner^t_1 \left(1 - \beta^t_{Learner}\right)^{\tau_{Learner}}$$
$$Graduated^t_i = Graduated^t_{i-1}\left(1 - \beta_{Graduated}\right) \quad \forall i \in [2, \tau_{Graduated}] \tag{2}$$

$$Senior^t = Graduated_{\tau_{Graduated}}\left(1 - \beta_{Graduated} - \Phi^t_{Trainer}\right)$$
$$Senior^t_i = Senior^t_{i-1}\left(1 - \beta_{Graduated}\right) \quad \forall i \in [2, \tau_{Senior}] \tag{3}$$

$$Trainer^t = Graduated_{\tau_{Graduated}}\Phi^t_{Trainer} + \alpha_{Trainer}$$
$$Trainer^t_i = Trainer^t_{i-1} \quad \forall i \in [2, \tau_{Trainer}] \tag{4}$$

The parameters $\Phi^t_{Trainer}$, $\beta^t_{Learner}$ and $\alpha^t_{Trainer}$ are time dependent and will vary depending on the system regime. Three types of regime are defined in equation (5) and differentiated by the learner supervision rate as follows:

- Regime 1, which incorporates over-capacity utilization of the organization (one trainer for more than X2 learners). This situation will lead to a deterioration in service in terms of quality of welcome, supervision, and ultimately success.
- Regime 0, which represents operations as designed, with one trainer responsible for training X1 to X2 learners.
- Regime -1, which represents under-utilization of capacity, with fewer than X1 learners for one trainer.

Regimes 1 and -1 are undesirable, as the former degrades service quality while the latter is not financially sustainable.

$$Regime = \begin{cases} 1 & \text{if } Learners \geqslant K_{Trainers} \text{ or } Learners \geqslant K_{Facility} \\ -1 & \text{if } Learners \leqslant X1 \\ 0 & \text{if } X1 \leqslant Learners \leqslant X2 \end{cases} \tag{5}$$

USE CASE

We now provide a specific example of applying the model above. The chosen example concerns the influence of the educational system's efficiency on maximizing the flow of learners to complete a full course in a French vocational training establishment, and its consequences for trainers' critical resources.

The *"Compagnons du Devoir"* vocational training system is based on the principle of traveling to learn a trade by gaining experience in different companies. After initial training, young company employees and work-study students travel from one training center to another, in France and abroad, to acquire the knowledge and skills specific to the trade they are learning. The training, accommodation, and catering facilities have been managed by associations of former beneficiaries of the scheme since the Middle Ages, forming a collaborative network for multiple trades where knowledge, know-how and interpersonal skills are exchanged.

As a highly skilled workforce, spread across the network of companies for which they work, the people trained by the *"compagnonnage"* system contribute to the restoration of infrastructures damaged by natural disasters. This takes the form of underpinning and reinforcement work, waterproofing when roofs are damaged, or repair work on industrial sites, depending on the type of damage. Each of these capabilities, taken together, will enable a building, an infrastructure component, or a piece of equipment to return to a functional state, thus ensuring the resilience of society as a whole.

"Compagnonnage" needs to design and ensure its resilience through the transmission of specific skills that can only be learned through experience. Over the last ten years, the number of apprentices joining the AOCDTF has doubled from 1,500 to 3,000. The training cycle lasts between 5 and 7 years, and the vast majority of trainers come from the end of the training course. Once they have become *"Compagnons"*, and have benefited from free,

Table 2. Assumptions on simulation initialization parameters

Parameters types	Definition	Values
$\tau_{Learners}$	the duration of the training	6 years
τ_{Senior}	the minimum time before leaving the system as a Graduate	3 years
$\tau_{Graduated}$	the minimum time before becoming a Trainer	1 year
$\tau_{Trainer}$	the minimum time before leaving the teaching system	2 years
$\Phi^t_{Trainer}$	the trainer transformation rate: graduated that will become trainer	50%
$\beta^t_{Learner}$	the learner abandonment rate (attrition rate)	35%
$\beta_{Graduated}$	the graduated abandonment rate, before becoming Senior or Trainer	10%
$\alpha^t_{Learner}$	the input of learners each year	417 per year
$\alpha^t_{Trainer}$	the input of external trainer each year	result of balance

high-level training, highly-skilled young workers commit to staying with the organization for 3 years, passing on the knowledge they have acquired to younger workers. This is the "Duty" that the *"Compagnons"* will carry out by becoming a trainer, or by continuing to travel and supervise the system of evening classes enabling workers to be promoted. 90% of young journeymen respect this commitment. They are the critical resource for the smooth running of the system. This 3-year transition time between graduation and leaving the system is taken into account and could be compared in the academic world to the situation of a doctoral student who for 3 years after obtaining a degree will continue to progress in his or her field of expertise until leaving the training process.

By simulating the training process for the *"Compagnons"* organization via the mathematical model derived above, we aim to answer the question: *"What happens when the attrition rate changes"* or *"What is the impact of improving the success rate?"* Studying the behavior of these variations will enable us to estimate the limits and regime changes facing the organization. We are basing our model on real data from *"Compagnons"* carpenters, in order to verify its conformity with reality.

We therefore experiment with the mathematical model, as implemented in Python, varying the attrition rate ($\beta^t_{Learner}$) to characterize the associated changes in system behavior. The initial conditions are given in Table 2.

RESULTS AND DISCUSSION

As shown in Table 3, we can see the variation in the annual attrition rate (AR), which accumulated over 6 years gives us the success rate (SR). We can see from the simulation results that, with an annual attrition rate of 35% of the workforce, if we start with 417 learners, after 6 years we still have 31 carpenters who have become *"Compagnons"*. Considering that 50% have the capacity to be trainers, this means a potential number of between 15 and 16, which is not enough to cover the annual requirement of 17 carpenter trainers. When we increase the attrition rate to 36%, we find that the number of *"Compagnons"* carpenters falls by a further 3 units, worsening the trainer deficit to -3 positions and -4.5 positions for 37% attrition. Similarly, by varying the attrition rate downwards, the simulation results show that the trainer balance becomes positive again at 33%, even releasing a potential of 2 additional trainers for each percentage point gained.

As listed in Table 1, in our future work we will be testing a range of risk factors specific to maintaining human capital, i.e. the lack of trainers, the attrition rate, and demographics, by testing extreme scenarios. By simulating the flow of people, we can also test the economic impact on the organization, as well as the budgetary limits of these fluctuations. As far as systems engineering is concerned, this flow simulation system contributes to planning, continuous improvement, updating strategy, and projecting the organization's administration into the future. All of these risk factors, which represent a range of real-world issues, give us confidence that organizations addressing these risks will become more resilient.

By testing these risk factors, we will accumulate information that will enable us to better understand the behavior of knowledge and know-how transmission systems. This will help us to more fully answer a variety of research questions, such as those posed at the beginning of the Model section, and thus help us to more effectively characterize the sustainability, limits, speeds and crisis sensitivity of human skill and knowledge chains.

Table 3. Carpenters simulation results

AR: Attrition Rate; SR: Success Rate; TR: Trainer Requirements; TB: Trainers Balance

AR/year(%)	SR after 6 years(%)	*Compagnons*	Variation	Annual TR	TB
37	6.0	25	−6	17	−4.5
36	6.7	28	−3	17	−3.0
35	7.4	31	0	17	−1.5
34	7.9	33	2	17	−0.5
33	8.6	36	5	17	1.0
32	9.6	40	9	17	3.0
31	10.6	44	13	17	5.0
30	11.5	48	17	17	7.0
29	12.5	52	21	17	9.0

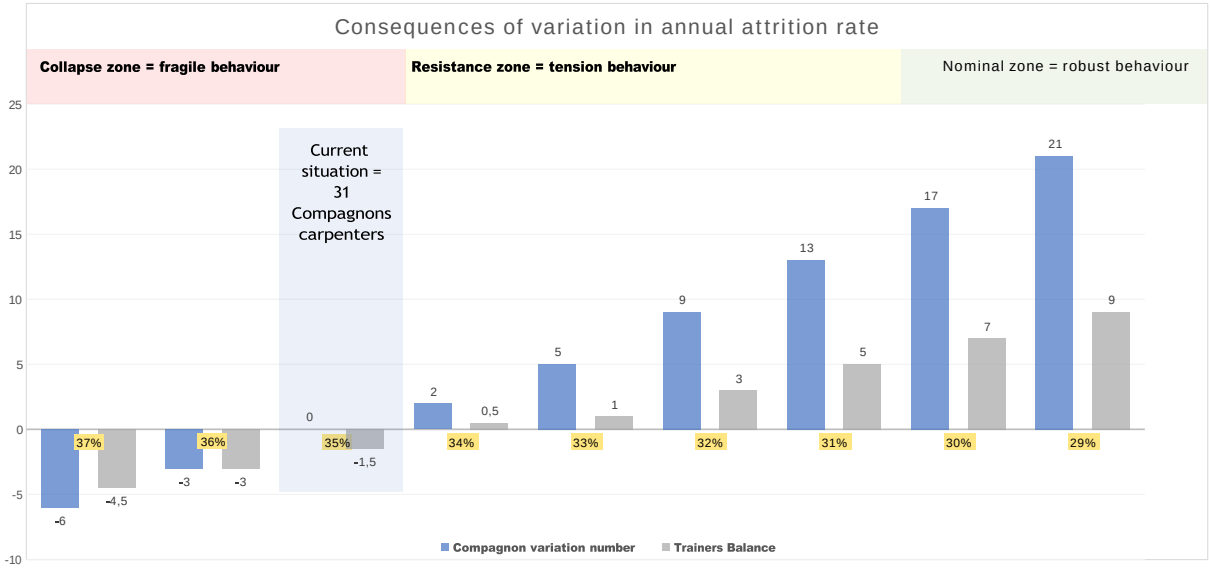

Figure 2. Attrition rate variation

ANALYSIS

Figure 2, which shows the variation in the percentage of attrition, enables us to analyze the preliminary results. The x-axis shows the variation in the attrition rate between 37% and 29% of the workforce, while the y-axis shows the workforce balance. The current benchmark of 35% is unsustainable, as it generates a chronic shortage of trainers. We have decided to position the simulations showing a trainer deficit in the collapse zone, which reveals the system's fragile behavior. We have arbitrarily chosen to place the scenarios between 34% and 31% in the resistance zone, which reveals that the system is under stress. We consider that in the case of *"Compagnons"*, from 30% attrition per year, the system remains in the nominal zone, suggesting robustness with constant behavior.

MODEL LIMITATIONS

This is a first version of our vision of the behavior of a learner flow in a know-how chain perspective, and like any model under construction, it does not claim to predict an indisputable result in an exact and precise manner. However, it is already useful for understanding the principles of circulation of flows of people transmitting knowledge, and can be used to estimate whether the system is in tension or not.

Attrition rates are parameterized linearly, whereas they tend to follow an irregular slope, with a sudden loss at the end of the 2nd year approaching 75%. This will be taken into account in the next iteration of model improvement, but in our case has no impact on the final number of trainers. This will help us to assessing the potential stock of learners, which is of interest for estimating the sizing of future infrastructures and the demand for trainers.

At this stage, we have not yet modelled regime changes. The various experiments we are going to simulate should enable us to define a high and low threshold for assessing the resilience of the transmission chain as practiced by the

"Compagnons". Empirically, it is generally accepted that an apprentice section is viable from 12 learners upwards, and that it becomes difficult to supervise more than 20 learners without degrading the quality of supervision, notably for safety reasons. We will integrate the consequences of these regime variations by giving ourselves the possibility of increasing the attrition rate as soon as the regime moves into overcapacity, and to parameterize a section collapse rule in the case of understaffing, starting from limits to be defined during our future simulations.

The model was initially implemented in Python, and a range of different outcomes were generated deterministically by varying the attrition rate and the number of incoming learners. Future extensions include further incorporating stochastic behavior in order to better characterize the range of possible outcomes.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

As mentioned above, the *"Compagnons organization"* is currently experiencing a growth crisis of varying severity, depending on the trade. For Carpenters, the average annual need for trainers is 17. If we consider that one out of every two *"Compagnons"* has the capacity to become a trainer, we can immediately see a chronic deficit of 1.5 trainer positions, which accumulates over the 2-year cycle and is confirmed by the interviews conducted with *"Compagnons"*. By varying the loss rate downwards in 1% steps, we can see the effects of making the balance positive from 33% loss, by releasing a sufficient number of journeymen with the capacity to be trainers, and thus covering the need.

These results show how the organization is behaving, and make it more straightforward for managers to become aware of the situation by providing them with the tools they need. Simulating learner flow makes it easier to understand the issues involved in maintaining the ability to transmit know-how or knowledge. This insight highlights the importance of questioning the *"Compagnons"* training system, so that it pays greater attention to the success rate of learners, which is one of the keys to renewing this human chain of know-how. It also indicates that this type of model could be helpful in other long-term training contexts where shortages are already identified, such as in healthcare services or civil security.

With regard to the model, we will continue our efforts to improve it, taking into account the fact that the attrition rate is not linear, so as to be able to forecast the number of learners, grads, and trainers per year with greater reliability. We will also implement the possibility of simulating a regime change to vary success rates by an additional factor. This will bring us closer to real-life behavior, where we can observe a deterioration in success rates when staffing levels are insufficient, or when a training course eventually disappears due to low enrollment. Ultimately, many factors need to be identified and combined in order to fully answer our research questions.

It is, of course, also important to recognize that many different types of crises can disrupt education systems over extended periods of time, such as armed conflicts resulting in conscription of young people (collapse of incoming numbers), demographic crises (fewer births and consequent drop in incoming numbers), financial crises (drying up of apprenticeship funding), vocational crises (poor image of manual trades), reputational crises (trades perceived as degrading for society following a news item resulting in a bad reputation), or public health crises (confinement preventing professional practice). Furthermore, although we have focused here on such slow-motion disasters, sudden-onset disasters such as floods, wildfires, major storms, or terrorist attacks can also impact the proper functioning of an education system in a number of different ways. The impacts of such events could also be incorporated into the simulation model through their effects on training times and abandonment rates; however, to fully explore this more traditional disaster management context it will help to develop a more detailed flow model that incorporates more of the logistics of the training process.

The differentiation of the organization's behavior into three types - fragile, resistant or robust - still needs to be qualified and tested in our next iterations of the model. Once we have gathered the available data to align as closely as possible with reality, we will be able to test the behavior of different scenarios. We will implement an experimental design by varying key parameters, thereby gaining the ability to make recommendations.

In order to evaluate the resilience of the knowledge chain, we will test our model to define its resistance thresholds. A design of experiment will therefore be conducted to observe the system's absorption capacity according to scenarios of input flow and attrition rate variability. We will also observe its recovery time under different hypotheses. Finally, we will assess the potential for adaptation in order to prescribe recommendations for improving the overall resilience of the chain and avoiding disruptions that have consequences in terms of loss of know-how and societal capacity to cope with natural disasters.

There are 36 *"Compagnons"* trades, each with a different learner flow behavior and resilience level. Once the model has been tested, we'll be able to diagnose this behavior, make appropriate recommendations, and assist decision-makers by simulating the potential impact of their wishes. Once all 36 scenarios have been aggregated, we

will also be able to identify a trend in the resilience behavior of the *"Compagnons"* organization as a whole, first of all to trainer shortages, but ultimately to a wide variety of different types of disruption. This, in turn, will support the organization's ongoing efforts to continue training new members and it will allow them to continue providing the necessary expertise to make our critical infrastructures more resilient.

ACKNOWLEDGEMENTS

Thanks to Virginia Tech, Maggie Webb, Dr Marie Paretti, and Dr Mathieu Besanc¸on for support and advice, and to the *"Compagnons"* from the AOCDTF for funding this research work.

ABSTRACT

Data sharing is a major driver to disaster Risk Reduction (DRR), which is essential to cross-border regions' resilience. However, sharing data for DRR at borders remains challenging and a limited spectrum of regions have been significantly progressing on this path. While the literature recommends that cross-border regions and organizations settle data ecosystems, studies also evidence that ecosystems face difficulties in developing sustainable rules for data sharing. A better understanding of the impediments of data sharing in cross-border DRR ecosystems is therefore necessary and remains missing in the literature. This research, based on a qualitative and collaborative design, is a work in progress focusing on the Italian-French border. Based on 24 qualitative interviews and archive analysis, we have identified four major challenges that organizations need to overcome to support data sharing for DRR at borders. First, cross-border DRR actors struggle harmonizing their perspectives over their common environment, whether it is environmental or da ta-related. Second, they face persistent elements of fragmentation, particularly reinforced at frontiers. Third, these organizations meet the challenge of building a sustainable bond of trust between one another about data. Fourth, they lack data maturity, thus impeding good use of data within the ecosystem. Our findings contribute to a more situated understanding of data sharing at borders and ca ll for more consideration of the border settings from practitioners that participate in data sharing.

Keywords

Disaster Risk Reduction (DRR), cross-border, data sharing, natural risk, ecosystems.

INTRODUCTION

On the 13th of August 2023, heavy rains in the Savoy region in France generated flash muds in Bardonecchia, in Italy. Also, the rise of temperatures generated major landslides in the Alps, for instance on the 27th of August at La Praz, next to Modane, in the Maurienne valley. These events disrupted railways and highways that support transportation, workers mobility and economic exchanges between Italy and France. The main direct railway between France and Italy for now is and will remain close until the end of 2024. These examples illustrate how vulnerable to disasters cross-border regions can be.

Cross-border regions comprise natural separations such as rivers and mountains. They tend to get marginalized from the center of countries both economically and politically (Şlusarciuc, 2015). However, they frequently host critical infrastructures such as highways, dams, industrial and energy plants. They can even attract exploratory investment, such as in the case of the economic corridor that has been developing between Pakistan and China (Lim, 2019). For these reasons, the capacity of organizations at borders to prevent and address disasters has become a major concern for local and national authorities but also international organizations (Abad et al., 2018). Therefore, all these actors have been working at supporting cross-border DRR, which consists of identifying and

preventing risks that can generate disasters (Palliyaguru et al., 2014). DRR also encompasses collective response to these disasters.

Data can drive DRR cooperation across borders (Kanbara & Shaw, 2021). First, as a digital resource, it is easy to replicate and share. Second, it calls for collaboration because understanding and preventing disasters cannot rely on a single source of data (Petrenj et al., 2013), as illustrated in the case of Bardonecchia . Indeed, the heavy ra ins that struck the Italian village had started on the other side of the border, in France.

What is data sharing? Data sharingdoes not boil down to sporadic sending or reception of data sets. As explained by Jussen et al. (2023), data sharing refers to the collective organizing of data access within a specific ecosystem. To that extent data sharing is sociotechnical and does not restrict to technological interoperability (Liverani et al., 2018). Many barriers can prevent data sharing within ecosystems (Gelhaar et al., 2021), going from the lack of understanding of the value of data to fears regarding data security. In the context of cross-border DRR, data sharing has been already documented but studies on the topic from a technical stance lack (e.g. Toro et al., 2019), leaving the topic of data sharing barriers insufficiently explored (Petrenj et al., 2013).

Given the foregoing, this work addresses the following question: " *What is the nature of barriers against cross-border data sharing for DRR?"*

This work aims at addressing this question by relying on a qualitative research design. We have considered the case of the Italian-French border, which has been struggling with the increasing frequency of disasters triggered by landsides and floods in the Alps. While Italy and France have been separately working on elaborating data bases on natural risks and vulnerabilities, there is no official data sharing system between the two countries. This research is still in progress and requires further enrichment. So far, data has been collecting through 24 interviews, archives and meetings with experts and practitioners. We have been following grounded theory principles (Glaser & Strauss, 1967; Suddaby, 2006). Some preliminary findings have been emerging and outline four major barriers against data sharing at borders: lack of a shared vision of DRR and data, fragmentation, lack of trust and lack of data maturity. We detail each barrier as well as the interdependencies between the barriers. We then discuss the novelty of these findings, the future avenues to improve the research as well as their practical implications.

THEORETICAL BACKGROUND

Disasters and DRR at borders

Borders are particularly exposed to disasters and critical situations. Most borders are shaped by topological elements prone to disruptive events. For instance, water zones – like the Rhin between Germany and France – or the Tanganyika Lake between Democratic Republic of Congo and Tanzania- are subject to floods. As another example, mountains – like the Alps between Austria and Italy or the Himalayas between China and India- are subject to landslides and earthquakes. Cross-border regions have been increasingly vital for economic integration, in all the continents (Brunet-Jailly, 2022). Paradoxically they also become more vulnerable because they host critical infrastructures, such as nuclear plants, energy infrastructures, dam s and transportation channels.

For this reason, cross-border regions – defined here as territories at the jointure between distinct countries separated by a topological or administrative border – need to become resilient. DRR can drive the strengthening of this resilience while achieving sustainable development by preventing new and reducing existing and new disaster risks (Palliyaguru et al., 2014).

There has been discussion of the key concepts of DRR (Palliyaguru et al., 2014). Disaster risk corresponds to the possibility of harmful consequences resulting from the interactions between hazards and vulnerable conditions (UN-ISDR, 2009). In this context, vulnerability covers both exposure to hazards and capacity to address them. In other terms, vulnerability is the combination of, on the one hand, the degree of exposure of a system (societal, productive, etc.) and on the other hand its capacity to prepare for and respond to the hazard (UN-ISDR, 2009). It is important to note that hazards are not purely natural. Indeed, floods, fires and landslides can be favored – if not triggered - by urbanistic design and human intervention.

Based on the review provided by Palliyaguru et al., DRR can be approached as a set of four interdependent strategies, namely i) eliminating (avoiding the risk), ii) mitigating (which means reducing the impact of hazards, as well as their frequency, intensity and scale), iii) preparing (developing resilience and response capacities and plans) and iv) advocacy (favoring good practices through influence). Mitigating disaster related risks thus depends on decades-long projects that involve international and national planning (McConnell & Drennan, 2006). Also, advocacy is a long-term stake of DRR because it consists of lobbying institutions, organizations and communities.

Furthermore, the management of crises and disasters at borders requires collaboration between a large spectrum of organizations: companies, administration, agencies, communities and authorities, from multiple countries and

sectors (Ansell et al., 2010; Ansell & Boin, 2009). In line with this view, DRR at borders involves a large spectrum of stakeholders, from local to national and international actors. At a local level, municipalities endorse the responsibility of citizens but also of access to commodities including water, transportation, etc. Communities are involved to promote well-being and sustainability of economies, which also depend on infrastructures. At a national level, states are responsible for the protection of their population and the mobilization of their emergency actors. At an international level, transborder organizations can encourage - legally or not - the use of good practices. Increasingly, DRR actors have been aiming at integrating the diversity of processes and approaches to disaster risks, but without significant success (Abad et al., 2018).

Data Sharing for DRR at Borders

A critical resource to manage disasters is reliable data (UNDRR, 2015). Organizations involved in disaster response hardly dispose of the data that can address all their informational needs (van den Homberg et al., 2018). For this reason, organizations need to work on data preparedness (van den Homberg et al., 2018) by sharing data before a disaster strikes (Sarker et al., 2020). Data used for DRR can be very diverse, ranging from natural and industrial risks to demographic data. However, challenges remain regarding timeliness, completeness and precision of data.

Growing use of data for DRR illustrates the search for digital maturity worldwide, supported by the United Nations (for more detail check the UNDRR report 2022). While some countries in the world have been working on centralized disaster data systems, other countries have been promoting collaboration to share data. These countries have put efforts in developing data ecosystems (van Esch, 2021) and open data (Kanbara & Shaw, 2021).

In the scholar sphere, data sharing has been investigated as a socio-technical phenomenon observable in a large spectrum of sectors (see for instance Hazell et al., 2023 and Ure et al., 2009). This means that data sharing does not restrict to the settling of infrastructures and programs that can make data sets interoperable. Rather, data sharing is also a human practice that involves multiple organizations (especially for DRR) and requires willingness and efforts to harmonize data and make it accessible to others (Migliorini et al., 2019). However, there has been a persistent knowledge gap regarding the use of multiple data sets (for instance provided, consumed and exchanged in a data ecosystem) in the programming of resilience (Migliorini et al., 2019).

Therefore, data sharing represents a major component of resilience. At European borders, projects such as ESPRESSO or GIOCONDA (Toro et al., 2019) have outlined the benefit from data sharing across the border. Also, the European commission has been supporting the rise of data ecosystems by producing data frameworks to help organizations address the diversity of rules and standards about data (European Commission. Joint Research Centre., 2021). Beyond Europe, the World Economic Forum (WEF) has supported the sharing of data between Turkÿe and Greece to produce an early warning system about fires. In Asia, such at the border shaped by the Mekong river, cross-boundary organizations were created to promote data sharing between countries (Thu & Wehn, 2016).

The mutualization of data can better help grasp the nature and the amplitude of a risk. Once the crisis strikes, data sharing can help coordinate actions (Liverani et al., 2018). Even when tensions arise between countries, organizations still persevere to collect and share data (Thu & Wehn, 2016), which also reveals the importance of data sharing. However, sharing data for DRR at borders remains easier said than done. The literature has reported many difficulties. First, data sharing, as a socio-technical phenomenon, is complex (Liverani et al., 2018). It relies on a set of technologies whose interoperability needs to be designed (Jussen et al., 2023; Toro et al., 2019). Going further, the literature has documented the diversity of issues inherent to data sharing in ecosystems (Jussen et al., 2023)

Despite growing interest in data sharing in the context of cross-border DRR, there is a lack of comprehensive understanding of the challenges inherent to data sharing at borders. This calls for more investigation of the nature of phenomena that can prevent data sharing. In the following section we detail the methodology that we have been following to address the research question.

METHODOLOGY

Research Design

As a reminder, this work addresses the question of the nature of the barriers against data sharing for DRR across borders. To do so, we have been conducting a qualitative research design, which focuses on the case of the Italian-French cross-border regions. We detail in this section our choices and the challenges that we met to collect data. We also present our analysis practices and tools. In a nutshell, this study embeds into a wider collaboration with

a Non Governmental Organization (NGO) to conduct an action research project. This study is also inclusive and has been involving master students.

Case Study: the Italian-French Cross-Border Region

To address the research question, we have been conducting a case study focusing on the Italian -French border region, which comprises multiple valleys (such as the Suza, Vésubie and Roya).

The Italian- French cross-border regions have been impacted by natural hazards several times. The two countries are separated by the Alps and share a common Mediterranean coast. The latest disasters were the most impactful. For instance, in October 2020, Alex storm impacted the cross-border territory between Liguria (Italy) and Alpes-Maritime (France). Alex destroyed many infrastructures (including cemeteries and roads) as well as houses. The damages from Alex are still being addressed. In August 2023, a major railway connection between Lyon and Torino was damaged by a landslide. As a result, transportation of goods had to be deviated towards Vintimiglia in the South of Liguria. Last summer, massive waves of mud damaged roads, cars and buildings in Bardonechia. These waves resulted from particularly heavy raining on the French side.

To understand barriers against data sharing in this case study, we first identified the actors involved in DRR in the region. Data collection from both a literature review and some interviews (see below) led us to list over 70 entities, of which 31 are Italian, 37 are French, 5 are international actors and 5 are European . Interestingly, the diversity of the DRR ecosystem implies the possibility for organizations from various sectors to share data (hea lth, transports and energies, security of people and goods, etc.). The ecosystem also comprises organizations with complementary interests in data (from consuming to producing and communicating). However, few interactions between organizations at the border about DRR involve data sharing. Organizations might tend to cooperate when they are linked hierarchically or functioning. But sharing a same territory does not incent organizations to share data.

Data Collection

We have been collecting data from both experts and individuals from organizations that participate into DRR at the Italian-French border. During our interviews, we have been relying on a dictionary theme and an interviewer guide that have been iteratively refined. In the interviews, we first ask the interviewee to present one's work and contribution to DRR and resilience. Some interviewees were specialized in territory cohesion, some others in natural risks and others in responding to disasters. We have been collecting data on the various steps of DRR. In parallel, we also relied on various archives (such as articles and reports on the use of data for DRR at borders). Even though cross-border data sharing for DRR is not extensively documented in the literature yet, many organizations (such as the European Commission in Europe) as well as communities have been organizing events to promote collaborative usage of data for DRR at borders. Table 1 presents the interviews that we have already conducted, it highlights the diversity of interviewees, in terms of occupation and profiles. Roughly, we did our best to interview experts who have knowledge and expertise of cross-border cooperation, natural risks and DRR, as well as subjects who had some practical experience of cooperation for DRR and data sharing. Finally, we interviewed people from various nationalities, including Italian, French, but also German and Canadian.

Approaching the topics of data and data sharing has been a challenge in our study. While experts can have a precise idea of the data needed for DRR (in particular at borders), they do not always have an exhaustive view on the data practically used by organizations. Similarly, some operationals could not tell us which data they use and whether these data have been shared. Our difficulty collecting precise and exhaustive data about data remains unsurprising. As documented, data is not a trivial asset for orga nizations. Most of the time, its access remains confidential. To address the difficulty of interviewees expressing themselves about data, we multiplied interviews. We also made a parallel search in 2023 to find data sets that were accessible on the web (through portals and open data sources). We then identified the organizations that provided the data and contacted them. We also relied on snowball sampling to identify organizations that shared data with the interviewees. By doing so, we have progressively improved the richness and relevance of the interviews and we almost reached semantic saturation. Our next step is to refine our coding through cross-coding and conduct the interviews necessary to reach semantic and theoretical saturation.

Despite our focus on the Italian-French frontier, we have been expanding data collection on multiple borders in Europe and beyond. For instance, we have been considering the cases of the Greece-Turkÿe, as well as the frontier formed by Mekong River between Thailand, Lao, Cambodia and Vietnam. This has helped us identify whether the barriers identified in our data related to the Italian-French border specifically or manifested in other cross-border regions as well. This practice has helped us refine our findings and supports the reliability of it.

Data Analysis

So far, we have been relying on qualitative coding of the interviews on MaxQDA to identify themes and let them emerge in an inductive modeling. We are still processing the analysis of the collected data and it seems that, as said, we have almost reached semantic saturation.

Our data analysis has been following the principles of grounded theory. First, based on literature reviewing and focus groups, we identified a main concern, which corresponds to the practical issue that the subjects of the study intend to address (Glaser and Strauss 1967). Second, we systematically compared data across interviews. By doing so, our findings emerged from data. We also based our reasoning on abduction by putting into perspective the various sources of data. For instance, based on literature reviewing and focus groups, we elaborated a theme dictionary that we iteratively refined when completing interviews.

We found several ways to support the reliability of our coding. First, we relied on dialogical reasoning to challenge each other's views to refine our findings. Second, in April 2024, we will present these findings during a workshop

gathering both some experts and some operational actors. This will be an opportunity to discuss and refine our findings.

FINDINGS

The findings of this research remain preliminary and require refinement. Though, we present in this section four interrelated barriers against data sharing for DRR across borders. We have been inferring them from our data analysis. First, multiple legal, institutional and political legacies co-exist at a border. In addition, countries work on different standards and methods that do not necessarily meet. We label this phenomenon fragmentation. Fragmentation results in poor knowledge and awareness of other organizations' needs and data usage at the border. It thus contributes to the lack of mutual trust especially related to data use. Also, organizations are not equally acculturated to data in relation to DRR. This implies the lack of mutual understanding of data usage between organizations and thus the lack of trust regarding data. The lack of data maturity among organizations also undermines the building of a shared vision of data for DRR. Finally, both lack of mutual trust and shared vision of DRR and data prevents organization from addressing fragmentation.

These four challenges are depicted in Figure 1. Each barrier is symbolized by a box. The arrows represent how one barrier fuels another. In the findings section we detail each barrier but also their interdependencies.

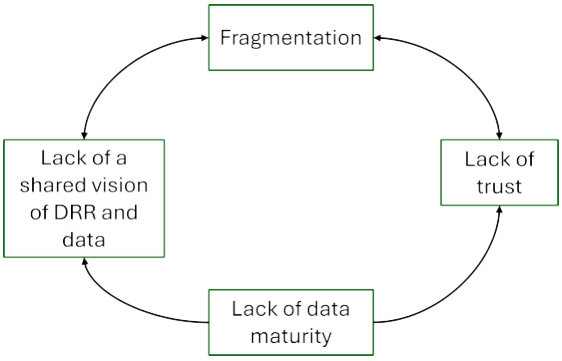

Figure 1. Interdependent barriers against data sharing at the Italian-French border

Fragmentation at Borders

In this work, fragmentation refers to the divides, differences and inconsistencies of views and practices between multiple stakeholders. Fragmentation manifests in the lack of cooperation but also technical inconsistencies (organizations using different standards), organizational and cultural divides. Fragmentation can also stem from different languages. Borders are naturally fragmented territories because they comprise natural or artificial separations. Even on the same side of a border, divides and rivalries exist between organizations.

In a fragmented ecosystem, organizations might be interested in the same topic but never interact with each other. An expert explains how fragmentation, by preventing communication between DRR actors, impedes the development of a shared knowledge on the risks and the methods to address them :

"France is specific in that responsibilities are spread between various organizations. In France, these organizations do not communicate with each other. This means that organizations do not share their knowledge on risks inherent to a specific territory. This also means that no organization has a complete understanding of the risks. This electricity provider, for instance, focuses on the risks that are the most important to its functioning and relies on its own methodologies. It is the same for train transportation companies. The State manages national roads, and the issue is the same. Highways? The same. And so on. No exchange". [26_01_Op_07].

This quotation highlights that each organization deals with the risks it could be affected by, whereas their concern should also extend to the risks that can affect other organizations and the other side of the border. Fragmentation represents a vicious circle. The less organizations are aware of the multiplicity of risks (and methods), the more they focus on their own risks and methods. And the less they become aware of the systemicity of risks on a cross-border territory. Because organizations hardly communicate on risks, they hardly develop an overview of risks at the border. This means that in the long run, fragmentation undermines the emergence of a shared vision related to DRR. Fragmentation is also a problem in terms of data sharing because it prevents the emergence of a common representation of data, both from a technical perspective (formats, metadata that is necessary, means to store the data) and from an organizational/social perspective (how to use data, methods to transmit the data).

Lack of a Shared Vision of DRR and Resilience at Borders

Cross-border territories are often characterized by the presence of topological obstacles, whether these obstacles are embodied by a river, a mountain or a desert for instance. Organizations from the diverse sides of the border might not identify the same risks and/or not prioritize risks in the same order. This is the case at the Italian-French border, where Italy has developed stronger vigilance towards volcanoes' activity and earthquakes than France.

Simultaneously, Italian and French plans might struggle to coexist in a unique framework. To nuance our view, though, a shared vision of cross-border DRR is emerging. The two countries have recently experienced cross-border disasters (such as Alex storm and 2023 landslides). They both agree on the need to tackle these risks. However, this vision of cross-border DRR turns out fragile. Primarily, DRR is still perceived as a local issue and cross-border territories remain traditionally approached as two separated territories rather than one single liminal space. An expert of the Italian-French border explained that the Alps remain a line and a separation between two territories rather than a single shared territory. In addition, DRR actors suffer from a lack of clear overview on how the Italian-French cross-border area will practically tackle disaster risks in the future. The building of a shared vision implies the need to redefine the cross-border territory.

This prevents DRR actors from making choices about the future avenues to support data sharing. Frequently, frontiers are primarily represented as lines of separation. This is how they appear on maps and official documents for instance. Historically approached as a separation, the Italian French border was not an object that required attention. Therefore, collaboration for cross-border DRR requires the renewal of the vision of the border.

Also, beyond these topological matters, the lack of vision concerns what data could be helpful for and what usage should be settled in priority. Even though DRR actors share common concerns across the border (for instance, how to reduce vulnerabilities, how to evacuate people and how to allocate resources), a shared vision of what data could help achieve remains missing and prevents the development of a shared data culture.

In other terms, the absence of a shared vision impedes data sharing. Indeed, most interviewees outlined that the rise of a cross-border strategy for DRR should be inclusive and involve proactive collaboration. In particular, DRR can be co-constructed by actors that share diverse types of expertise. As explained by an expert frequently involved in resilience projects, co-constructing solutions to address disaster related risks appears very beneficial. Co-construction of solutions implies repeated interactions that provide the opportunity for DRR actors to understand each other's roles and values well:

"[Organizations] rely on us because we have some expertise and some data to bring. We bring technical expertise to them. When we deliver this expertise, it is clear that we increasingly co-construct the final product or service [with these organizations]. This is the way it is. Co-constructing things is a way for us to be sure that we will address the demands [from organizations]. It is a way to well understand what [organizations] need and to be sure that we well address needs and to understand how our services can be used for what action afterwards". [26_01_Op_07]

Co-construction offers DRR actors not only an avenue to know each other, but also an opportunity to understand how each actor contributes to a collective effort and develops an inclusive strategy for DRR. The absence of shared visions, by impeding such co-construction, restrains the development of trust that is necessary for data sharing. Because of siloed visions, actors tend to interact only with their closest counterparts, which can also aggravate fragmentation.

Lack of Trust

Our empirical findings suggest that cross-border cooperation requires dynamic and continuous engagement from every side of the border. Developing resilience is impossible without full participation of citizens and communities. Cooperation at borders requires trust and working on mutual trust, as suggested by both these two interviewees:

"If they need us, they have to trust us and if we want to work to help some other partners (...), we need to believe in it (...). And if we think that there is no trust, I think we should rather put the matter on the table and tackle it or clarify our intervention". [26_01_Op_07]

"Fundamentally, this is what we look for, trust, as it is essential to cooperation, which itself is essential in order to solve these problems". [18_01_Exp_11]

Interviewees suggest that trust is not accumulative but rather dynamic. This means that organizations need to keep testing their ties, for instance through collaboration on data . From this perspective data can represent a relevant resource and driving force to cooperation on DRR. However, settling and maintaining cooperative projects over time across a border is demanding for organizations, particularly because of politics and the potential legacy of conflicts at frontiers. Conflicts can also question organizations' participation into data sharing projects without

notice.

To illustrate this point, our archive analysis reveals that Greece and Turkey face common natural hazards such as earthquakes, extreme droughts, volcanic eruptions, mudslides, flash floods, forest fires and potential tsunamis in the Mediterranean Sea. Despite the need for bilateral cooperation to mitigate these risks, the relationship between the two countries is characterized by a strong historical antagonism that hinders risk and disaster reduction. Past cooperation agreements on DRR were endangered by the continuing political tensions. In the future, additional communication breakdown between Greece and Turkey would likely compromise DRR cooperation and data sharing.

Moreover, the interviewees highlight the fact that data has a contradictory effect on trust. On the one hand, data represents a valuable resource to collaborate on risks because, as mentioned earlier, one single organization (or country) cannot produce on its own all the data necessary to predict disasters. On the other hand, data can be a lso used to produce manipulative narratives. As explained by an interviewee:

"So data is not data. Data is information about something that happened or might happen and it's controlling narratives. So what I have seen and what the literature also says is that people is more afraid about the narrative than sharing the data. So is the data saying that I'm good at it? It's going to say that I'm under control, it's going to say that I'm not under control in the case, it's saying that I'm capable to do something. So it's about the narrative, the data more than the technicality of how to share data. The other part that is more technical, but it's not just technicalities is about data for itself. Although it's a narrative, it doesn't talk for itself and that's what a lot of actors are really afraid of sharing data because if you don't know the context in which the data was collected, for which purposes, you can quite easily misuse it or misunderstand it and it's almost super difficult to explain all the context. (…) [Data's] power is narrative (…) it doesn't tell the whole story". [28_02_Exp_04]

In sum, data sharing calls for trust and is essentially collaborative. However, trust about data remains fragile at frontiers. In addition to persistent sources of defiance related to politics and conflict's' legacy, data can be perceived as a major threat. Therefore, DRR actors need to overcome this fragility, which complicates cooperation and data sharing. From this perspective lack of trust represents a major barrier against data sharing.

Data Maturity Within the Ecosystem

Data maturity is of utmost importance to promote data sharing in cross-border regions. At the Italian-French border, the relationship between organizations and the concept of data is imperfect and uneven. DRR actors and organizations are not always properly trained in data tools and processes. Therefore, these organizations lack adequate tools to experiment and collaborate about data. As a result, some participants might collect data, but without any perspective on its future use and sharing. Unawareness of the importance of data sharingmight lead to situations where data has been collected yet not shared before a disaster. As explained by an expert of border resilience:

"*I think it's a question of knowledge and information, of being well-aware which type of data, how many different data, what means strategic data or operational data… I think, at the end of the day, what we have is a lack of knowledge, of how to handle data*". [14_02_Exp16]

Eventually, data collected without any perspective on its usage eventually becomes obsolete and irrelevant. Organizations need to update data on a regular basis to keep it relevant. At the cross-border scale, this means that interoperability between data sources and meta data should be constantly ensured. Even when updated, data needs to be kept in the data collector's "language".

Interdependencies Between the Barriers

Our empirical data suggests that the four barriers outlined here interact and self-feed themselves. These interactions are more detailed in the following lines.

First, the fragmentation and the absence of a shared vision of DRR and data are mutually dependent. Fragmentation renders organizations ignorant about one another. Overcoming divides and rivalries - possibly inherited from past conflicts at the border - requires doubling efforts to identify synergies between data sources. In parallel, as outlined by the interviewees, the absence of a shared vision implies that organizations get closer to their closest partners. This attitude, in its turn, fuels fragmentation and the setting up of "bubbles" of actors rather than a diversified and transversal ecosystem.

Second, fragmentation prevents organizations from building trust which, in turn, aggravates fragmentation Cross-borders areas are characterized by their plurality of equipment and processes. Making it interoperable might not

be doable, at least in the brief term, thus preventing actors from understanding each other's methods and mistrusting it. As a result, each actor tends to rely on his own practices, fueling the existence of silo es and fragmentation.

Third, data immaturity impacts both the existence of shared visions and of trust. Of course, not understanding what data is and how it can be used makes it impossible for a common vision of the potential use of data to emerge. At the same time, as they perceive data as a "niche" matter far from them, actors under-experiment with it, yet it is precisely experimentation that makes it possible to build trust. Two other interactions implying data immaturity can be imagined, but still need some more evidence. First, we might think that the lack of shared visions deters organizations from acculturating to data: as they don't have a common goal they wish to reach, they are not encouraged to support the costs of training. Second, lack of trust in other participants' might persuade organizations to keep distant from their data and more generally from data "literacy".In short, solutions to one barrier shouldn't be considered independently from those to the other ones. Even when a shared vision is reached, it must be accompanied by a behavioral adaptation (tools, language, etc.) that will lighten fragmentation. What's more, these technical/practical issues are not sufficient: the relational dimension of trust seems to be fundamental. Eventually, these "ease" in relationships between actors should reflect in an ease in the relation ship with data, made possible by a process of data acculturation.

DISCUSSION

Data sharing has been identified by institutions and scholars as a major driving force to DRR. Data sharing at borders does not seem effective yet at multiple borders. The nature of the barriers against data sharing for DRR at borders remains partially known. For this reason, this research addresses the following research question: " *What are the barriers against data sharing for DRR at borders?"*

Our empirical findings outline four major barriers, namely i) visions of data and territories that do not meet, ii) elements of fragmentation particularly heightened at border, iii) the paradoxical building of trust about data at borders and iv) insufficient development of data acculturation. In this section, we first detail the expected contribution of the research. Then we infer some theoretical insights from our findings. Finally , we briefly present some practical contributions from the first findings.

Expected Contribution From the Research and Avenues for Future Development

The research is still in progress. In the future months, we intend to pursue the analysis of the collected data to propose a comprehensive model of the barriers against data sharing for DRR at borders. Ideally, the comprehensive model will help induce recommendations for organizations at the Italian-French border to strengthen data sharing and cooperation for DRR. As mentioned herein, this research is part of a wider project that aims at the development of a sustainable data ecosystem at the Italian -French border. The results from the research will be used as a scientific basis to design a governance plan for the ecosystem.

Theoretical Insights: DRR Ecosystems and Data Sharing

Our findings outline the importance of fragmentation between the Italian-French border. This finding echoes previous research on borders (Kratke, 1999). However, this work goes a little further by exploring the implications of cross-border inconsistencies on data sharing. So far, the literature has outlined that data sharing at borders confronts a lack of interoperability, divergent vocabularies, norms and equipment (Liverani et al., 2018). Those are the elements we referred to as "fragmentation" in this pa per. However, the literature has more rarely explored some deeper root causes of operational issues, such as the absence of common perspectives on territories and data. This research aims at providing a comprehensive view on these root causes. By doing so, we hope to better help organizations address invisible yet powerful barriers against data sharing at borders.

Also, the literature has explained how organizations can gather in ecosystems to organize and govern data sharing for DRR (van Esch, 2021). By doing so, they can develop many to many – rather than one to many - connections. Not only they enlarge the spectrum of usable data. Also, they can mutualize resources to host data and invest into infrastructures. Our empirical findings outline fragmentation, lack of trust and lack of data maturity as serious obstacles to data sharing, which could even block any initiative to govern data sharing. Developing ecosystems at borders require the tackling of issues that are not inherent to the ecosystems itself, but rather related to the cross-border settings they have been developing in.

Practical Implications

Our research also outlines the importance of shared efforts to build trust between actors: they cannot be designed in a top-down fashion. More precisely, our preliminary results suggest the need for a bottom -up, inclusive and practical leadership on data sharing. As empirical findings suggest, DRR actors across the border need to dismantle issues that can undermine cooperation on a very regular basis.

Also, our research suggests the need for cross-border DRR actors to overcome fragmentation and the lack of trust through the design of rules to share data. Future development of this research will focus on how to integrate fragmentation and lack of trust into a governance plan. Practically, this means the need to identify which rules can aggravate fragmentation of views on data and which rules can, on the contrary, contribute to a unified vision of data sharing. Similarly, there is the need to identify which rules can undermine or foster DRR actors' trust towards each other about data.

CONCLUSION

This research aims at better understanding the nature of the barriers against data sharing for DRR at borders. Based on a qualitative research design, it has been exploring the case of Italian and French data sharing for DRR at the border. This research is still in progress but outlines four persistent barriers that need to be tackled: i) the lack of shared visions of yet common environments, ii) the persistence of elements of fragmentation, iii) the fragility of trust in relation to data and iv) lack of familiarity with data. While still preliminary, these findings suggest the need for DRR actors to increase their knowledge of data usage but also its barriers at borders. Also, it suggests the need to incorporate such knowledge in the design and maintenance of data governance between two or more countries.

While the literature advocates the creation of ecosystems to ease data sharing (European Commission. Joint Research Centre., 2021), we alert on the limitations of "by-the-book" solutions to do so. Adoption of frameworks and tools without considering the features of the cross-border region that hosts the ecosystem can be misleading. On the contrary, at borders, DRR actors need to collaboratively construct a specific vision of DRR and data. This implies the need to overcome siloed visions, fragmentation, lack of trust and underdeveloped capabilities in relation to data. In its future development, this research aims at providing a more comprehensive understanding of the barriers against data sharing for DRR at borders.

ACKNOWLEDGMENTS

This research has been financially supported by the European Commission (EC) and is part of the ECHO Red Roses project (101101221). ABSTRACT

First responder organisations (FROs) participating in European research projects often seem dissatisfied with their participation. This is because they are unable to implement the project results. This article looks at this phenomenon through the lens of ambidextrous organisations. It examines the different factors contributing to failure to innovate for FROs in EU projects by using interviews. The main results show that the structure of European projects is a major contributor to failure to innovate of the project results in FROs. Nonetheless, the structure of the FROs themselves can also provide hinderances.

Keywords

End-users, first responder organisation, failure to innovate, ambidexterity, project management.

INTRODUCTION

For the period of 2021-2027 the European Commission has invested over 1,8 trillion in European research projects (European commission, Directorate-General for budget, 2021a). Examples include the Seventh Framework, HORIZON 2020, HORIZON EUROPE, ISF, EUCPM, ESA and many other initiatives. One of the underlying principles of these frameworks is to not only invest in fundamental research, but also foster innovation and accelerate the adoption of new academic insights into practical applications. As the European Commission outlines: *"bringing about tangible results and positive change in the lives of citizens and other beneficiaries is, and will remain, a key priority for the Commission in all the interventions supported by the EU bud get."* (European commission, Directorate-General for budget, 2021a , P4.)

This extends to specific programs aimed at increasing the resilience of the European Union in the field of emergency response and crisis management, among others in the Disaster Resilient Society program (DRS). Especially in these programs the connection between research and valorisation of the results to support first responders' organisation is strongly advocated. This is, among others, embodied by the program's requirement to include first responder organisation in the consortia that are submitting their project proposals under the call.

The question about the impact of these programs has been asked before (European Commission, Directorate-General for Research and innovation 2018). This paper examines specifically if the impact is applicable to the daily practise of first responder organisations, and if participating in EU projects is of added value for first responder organisations (FROs). This way, it examines if there is a disconnect between the intended outcomes of the projects and the actual impact they have in FROs.

Problem Description

There may be multiple reasons why such a discrepancy occurs. First, the EU projects and programs may have (too) strong a focus on innovation and research with a lower direct applicability to the objectives and operations of first responder organisations. However, this is not only addressed in the call for proposals, but even a strong requirement. For example, a certain technology readiness level (TRL) in Innovative Actions is expected to ensure a higher and quicker adoption rate (Rösner, 2023). Second, innovation and research programs may have insufficient connection to 'practice'. This is however also addressed in the programs by ensuring participation of First Responder Organisations in the consortiums as well as specific dissemination plans addressing primary end users (i.e. FRO's) throughout the project. Furthermore, participating FROs may lack resources to fully engage in these projects and/or adopt their results (Meijers et al., 2006). Again, measures such as increased funding rates are aimed at addressing these potential shortcomings. Most importantly: it is also not a shortcoming due to a lack of need, motivations or drive to participate in these projects. The need to innovate, adapt and gain new knowledge is well understood by FROs. It is evidenced by the following quote from one of the respondents in this research:

"[innovation] is essential. The world in which we work evolves quickly. As an organisation we need to stay relevant in this world we work in (…) it is not the question if we should, it is evident we should."

As the quote above from one of the respondents demonstrates, implementation of research and innovation (RI) is necessary for first responder organisations working in our fast-paced society. This article examines implementation of such project outcomes in FROs. Specifically, by focusing on the organisational capabilities and capacities to successfully leverage the potential of innovation projects in general, and EU-funded research programs aimed at first responder organisations in particular.

Research Questions

As mentioned in the introduction, there seems to be a failure to innovate European results at FROs. Thus, one objective of this article is finding out why that is the case. Therefore, the first research question (RQ) asks:

1. Why is there seemingly a failure to innovate of European Project results at first responder organisations?

The conceptual model in figure 2 shows two main relations that are of interest. The one between EU projects and project results, and the one between project results and implementation in FROs. If there is failure to innovate, there must be a breakdown in one of these relationships which interrupts the innovation stages. Therefore, the analytical interviews are used to examine where this breakdown occurs, why it occurs and what factors cause it to occur. The second research question goes one step further and asks what can be done about that breakdown.

2. Which action can first responder organisations take before, during and after European projects to prevent failure to innovate?

To answer RQ2, a handbook was developed for FROs to use before, during and after European projects which includes worksheets that can be used. Thus, the handbook should help FROs feel better prepared to work on EU project, but it should also make them aware of the pitfalls that may be common to FROs.

THEORETICAL BACKGROUND

Ambidexterity and First Responder Organisations

When considering the role first responder organisations play in society, a strange dichotomy presents itself. On the one hand, FROs need to react quickly to a crisis, while maintaining coverage of their district to respond to other incidents. On the other hand, FROs need to be prepared for the future, and the crises that come with that. In other words, FROs need to be ambidextrous. Preparing for the future also means being able to implement new RI in the organisation. Ambidexterity originated in the literature as a concept meant for companies. It is the ability to both maximise current profits and sales but are also being flexible and adaptable enough to respond to the future by implementing RI (O Reilly & Tushman, 2004; Birkinshaw & Gibson, 2005). Nowadays scholars also apply it to public organisations and non-for-profit organisations. For example, Narayanan and Altay (2021) use ambidexterity to describe humanitarian organisations like food banks and the salvation army. Others use it to describe to the functioning of the army during war time versus during peace time (Soeters 2008). Thus, applying it to FROs has precedent.

Another aspect of FROs is that they are often public in nature. Thus, the theoretical background takes into account literature around RI implementation for ambidextrous organisations, but also for public organisations. This information is fused with the results of the exploratory interviews, creating a conceptual model considering the unique characterises of a FROs as both a public organisation and an ambidextrous organisation.

FROs in European Projects

In this article "European projects" is used for all projects that are completely or partially funded by Europe (European commission, Directorate-General for budget, 2021a, 2021b). This article distinguishes 3 phases for European projects, based on the exploratory interviews and the literature. Firstly, the proposal phase, secondly the execution phase and thirdly the result phase.

- Proposal phase: during this phase the proposal is being written, and the consortium is created. Important steps in this phase are: 1) finding relevant partners, 2) dividing the budget, 3) dividing the tasks, 4) describing the expected impact. The proposal is then evaluated (European commission, 2018, 2021c, 2021d, 2022a, 2022b; Cunningham, O'Reilly, Hooper, Nepelski & Van Roy, 2020).
- Execution phase: during this phase the Grant Agreement needs to be executed. End -users (the role of participating FROs) often enact the following tasks:
    - Defining gaps in the work field
    - Formulating end user requirements
    - Scenario building
    - Validation of results
    - Dissemination of results (European commission, 2022c; 2022d)

  One of the respondents mentioned the following*: "FROs work on the practical side. We organise field trials, we test with the work field if something works or not. We start after the research has been done."*
- Result phase: in this phase the official project period has ended, and so had the financing. During this phase, the results should be implemented in either the participating organisations or the member states (European Commission, European Innovation Council and SMEs Executive Agency, Scherer, Weber & Alveen, 2022a).

According to Serwiak (2022), not all end users seem satisfied with the project results of EU projects. The following difficulties are often encountered:

1. Not enough resources to participate
2. EU projects are not part of the core tasks
3. Too little experience with EU projects
4. It takes too long for results to be usable
5. Shifting priorities of end users during a project
6. Bad experiences in previous projects (Serwiak, 2022)

Reasons to participate in European projects are similar for FROs as the reasons to participate in RI implementation. They want to improve the efficiency or effectiveness, involve citizens or corporations, increase safety and equality, or increase their own legitimacy (De Vries, Bekkers & Tummers 2014; Rip, 2016).

Factors Influencing Implementation

The process of innovation has multiple stages. In this article, 4 stages are identified. These are the initial stage, the development stage, the adoption stage and finally the implementation stage (Somech & Drach -Zahavy, 2013; De Vries, Bekkers and Tummers, 2014; Allen et al., 2017; Singh, Akbani & Dhir 2020). These stages overlap with the phases of European projects as seen in figure 1.

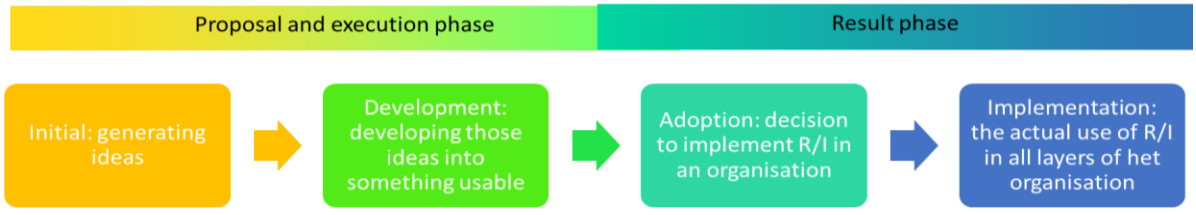

Figure 1. Overlap between innovation stages and EU project phases

The factors that influence research and innovation implementation in FROs can be divided into four categories. These are the characteristics of the project results, individual factors, organisational factors and environmental factors. The table below show the factors that can influence implementation (simplified). A "+" refers to a positive relation with implementation, while a "–" refers to a negative relation. The factors in bold have been emphasized because of their importance for RI implementation. There are a few factors that have a +/- sign, in this case there is either debate on the positive or negative relation, or it could work both positively or negatively depending on the other factors. This table does not show possible interactions between the factors.

Table 1. Factors influencing implementation

	Implementation (literature)	**Implementation (exploratory interviews) for European projects**
Characteristics RI (Meijers et al, 2006; De Vries, Bekkers, Tummers, 2014; Alexander, 2015; Owen, 2018; Brooks, Grugulis & Cook, 2021; MED1stMR, 2023 respondents)	- Abstraction + Complexity + Concrete solutions + Congruency with current way of working + Ease of use **++ Added value** - Costs + Testability + Access	+ Adaptability +/- Low TRL level

Environment (Young, Charn & Shortell, 2001; Strejcek & Theil, 2003; Mulgan & Albury, 2003; De Vries, Bekkers, & Tummers, 2014; Mosadeghrad, 2015; European Commission, Directorate-General for Research and innovation, 2018; Clausen, Demircioglu & Alsos, 2020; Brooks, Grugulis & Cook, 2021, respondents)	+participation in isomorphic networks +/- Economic pressure +/- Political pressure - changes in pressure	- European environment +/- societal relevance

Conceptual Framework

Based on the above literature and the exploratory interviews, a conceptual model can be created where the presence of factors is integrated with figure 1. This can be seen in figure 2. The figure shows that the EU project has influence on the project results that are achieved. The factors present in FROs influence that relationship via their participation in the project. Those project results then need to be implemented during the result phase. In this phase, the factors present in FROs influence that as well.

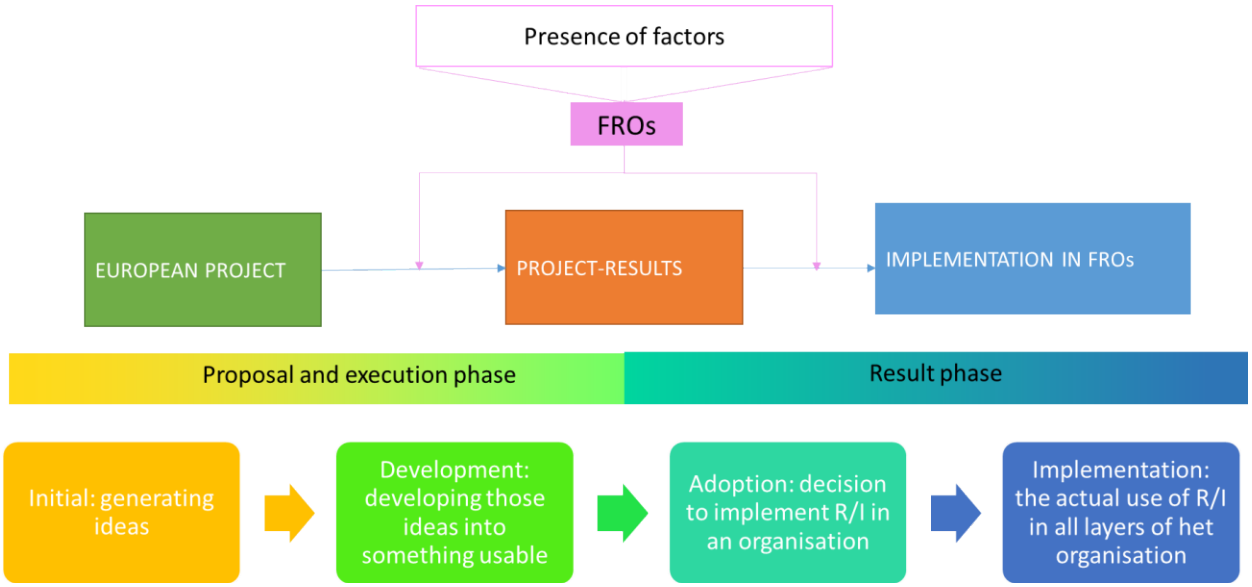

Figure 2. Conceptual model of FRO implementation of EU project results (own design)

RESEARCH APPROACH

Figure 3 shows the methodological approach in this article. Firstly, literature was found about implementation in public organisations and in ambidextrous organisations. On top of that, a round of five exploratory interviews was conducted to complete the theoretical framework. That framework exists out of a conceptual model and the first version of a handbook for FROs[1]. This model and the handbook were then evaluated in a second round of six analytical interviews. Based on those interviews, the conceptual model and the handbook were adjusted to their current version.

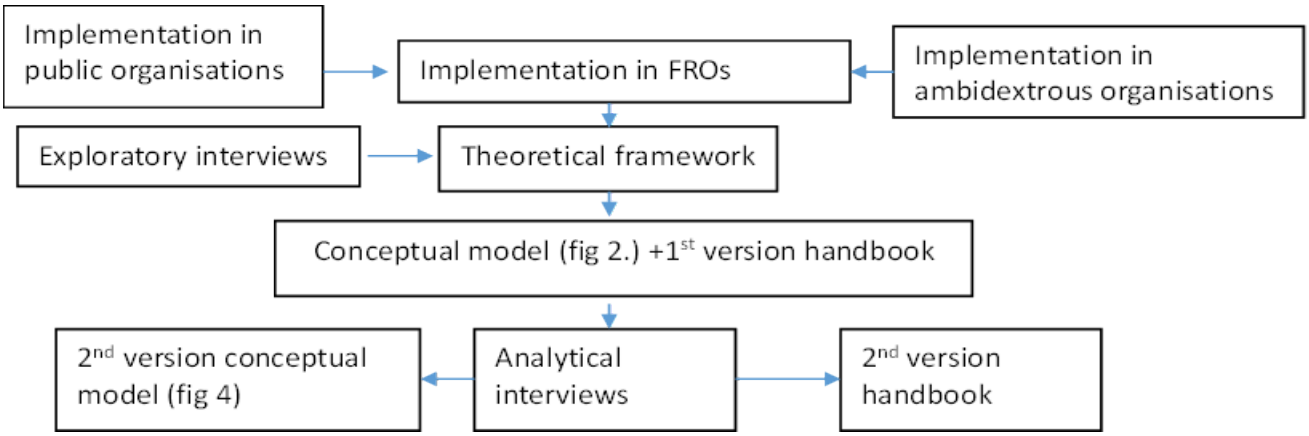

Figure 3. Methodological approach (Own design)

Data Collection

To choose what literature to use in this paper, we set up an excel table that tracked a ll found literature. It was then checked for inclusion of: RI implementation elements, if the end user was a FRO and if the paper addressed European projects. The articles in this paper include at least 2/3 elements. On top of that, priority was given to meta-analysis to get an overview of the different factors that influence implementation.

There were two rounds of interviews done for this research. The first round was the exploratory interviews. The

[1]Since this was only a concept version, it is not included in this article.

goal of these interviews was to gain a better understanding of the relationships in the conceptual model. For both interviews, we used the snowball method. On top of that, we tried to create a good spread of respondents, including both managerial roles as well as operational roles. The exploratory interviews were open conversations, belonging to the category of non-structured interviews. The shortest exploratory interview was 36 minutes and the longest was 1 hour and 12 minutes. The interviews were conducted in Dutch. 4 of 5 respondents were from the Flemish part in Belgium, and one was from the Netherlands. Of those exploratory interviews, 1 worked for the fire services and was a trainer in a training centre, 1 worked for the police department of a training centre, 1 worked for the national police, 1 for the medical services as well as being a trainer in a training centre and 1 as an advisor EU projects for a training centre. The exploratory interviews were transcribed via Amberscript. They were coded via the inductive method. Text fragments of interest were chosen and pasted into excel. Every new concept was then assigned a code that best represented the text fragment. This was done to all text fragments of the exploratory interviews. Because many codes were identified, some were linked to each other in themes. these themes were derived from the literature review done before.

For the second round of interviews, the analytical interviews, 6 respondents were interviewed. All 6 respondents were from the Flemish part of Belgium. the shortest interview was 1 hour and 2 minutes, while the longest was 2 hours and 16 minutes. Of these respondents 1 was from the fire services, 1 an advisor EU projects for a training centre and from the fire services, 2 worked for the police, 1 worked for a training centre, and 1 worked for a national crisis centre. All the respondents had experience with European projects, mostly with ISF (internal security fund) and HORIZON 2020 projects. In contrast to the exploratory interviews, the coding of the analytical interviews was done deductively. The codes and themes were based on those developed during the coding of the exploratory interviews. Nonetheless, new codes could still be added if necessary. This allowed for a structured but flexible framework through which to interpret the interviews. A semi-structured interview method was chosen for the analyticalinterviews because there were specific points that needed to be addressed. By using an interview protocol, we could make sure to discuss all those points. During the interviews there was room for new insights that could challenge the conceptual model made from the theoretical framework. Following an interview protocol but allowing for deviations made the semi-structure interview the best choice for this research.

Relevance and Validity

This research is exploratory in nature, more research is needed to explore the subject fully. The research is based on a total of eleven interviews, 5 exploratory and 6 analytical. The respondents of this research were found via the snowball method. The small number of respondents and the methods of finding respondents could lead to undesirable bias. It could be the case that the respondents are not representative for FROs working on EU projects, which could influence the validity of this research. On top of that, two authors work for a FROs that participate(d) in EU projects. This too could lead to unconscious bias, for example with confirmation bias.

RESULTS

For the analytical interviews, a total of 735 text fragments were encoded. Table 2 shows the top 10 codes[2] most associated with either the EU project structure or the FRO structure and table 3 shows the codes most used per project phase, mostly used for RQ2. Table 4 shows the top 3 codes associated with the themes. Interpretation of these results is found in the discussion.

Table 2. top 10 codes associated with project structure and FRO structure

EU projects structure codes top 10	**Amount**	**FRO structure codes top 10**	**Amount**

DISCUSSION/CONCLUSION

The Role of Characteristics

During the analytical interviews, it became clear that the characteristics play a crucial role in the implementation of results. The results needed to have added value and offer concrete solutions to relevant problems, but they often did not. Many respondents felt that the structure of EU projects was to blame for this. The following quote illustrates that: "*It often feels that end users in research project are an afterthought. We make a nice academic project, but we also need to involve first responders because of the commission. To tick all the boxes. So, we look for a few FROs that are not allowed to think in the front end about what we are investigating. We are going to research something that is academically relevant, the practical relevance does not matter.*"

Another respondent mentioned that you need to involve FROs to get the right characteristics. "*If you ask organisations to implement results that have been thought out only in the ivory tower, the results will be much worse than if they would have had actual good contact with our colleagues. Then you know, this has been developed by people like us. The moment it becomes abstract, it does not go well.*"

This section shows that if the results do not offer concrete solutions, added value or relevance, the implementation process stops after the EU project (RQ1). Thus, it is the creation of these characteristics during the project that is of importance. Furthermore, there are also hints that once a result is complete, the characteristics moderate the relationship between all the other factors (individual, organisational, environmental), and the implementation. De Vries, Bekers and Tummers (2014) mentioned that there is less interest in the influence of characteristics in the RI field for public organisations. This article shows that characteristics do play a major rule. Thus, characteristics especially should be considered a target for future RI research, and especially its possible moderating role.

Factors That Influence Characteristics in EU Projects

The next question that needs to be asked is which factors specifically are important for the creation of the characteristics. According to the respondents this is mostly the composition of the consortium, and the coordination of the project. Respondents mention (and are supported Cunningham, et al. (2020)), that often coordinators have a scientific or industry background, and that this influences their priorities. One of the respondents only participates in EU projects when they coordinate, while others mention that they do not have the means or experience to coordinate a project.

The composition of the consortium is another factor that influences the result. According to respondents it should be *"as big as needed and as small as possible"*. There is one respondent who prefers to work in consortia only with FROs, while the others believe that diverse consortia with different kinds of organisations are still the best to work with.

Respondents also mentioned that the European environment should do more to stimulate implementation of project results. For example, by representing the interest of end-users. Requiring their presence in a consortium is not enough. On top of that, it would be necessary to bridge the gap between the end of a project, when a result is (often) not ready to be implemented, and the actual time a result is implementable. Currently, the respondents feel that this is not being done sufficiently which harms the implementation. Furthermore, respondents feel that the administration that is needed to participate in EU projects is too time-consuming. One of them said: "*Of course you need to be accountable in EU projects. It is public money. But if you look at the archaic software in which everything needs to be reported and how you need to report the same thing three or four time, it takes many hours and many people working to do those things that have no use at all.*"

Apart from the interim evaluation of the different European project programs, there was little research on the specific factors that influence characteristics in EU projects. Thus, this can be a possible gap in the literature that should be studied more in depth.

Other Important Factors for FROs Participating in EU Projects

Other impact factors to consider for FROs that participate in EU projects are:

- Individual
  - Ego: the respondents mentioned that many FROs were proud of the job they do, and wanting to implement change could be read as criticising the current way of working.
  - Own initiative: this can be illustrated by the following quote: "*Research and innovation [in FROs] is completely non-committal and depends on individual interest and initiative"*.
  - Open attitude: the respondents remark that some first responders have a conservative attitude, while others have an "early adapter" mentality. Unlearning could be a way to convince FRs with a more conservative attitude, as discussed by Brooks, Grugulis & Cook (2021).
- Organisational
  - Time, resources, and a shortage of personnel are all hindrances to RI implementation in FROs. The importance of these practical factors is also underlined in the literature. The absence of these can completely block implementation (Mulgan & Albury, 2003; Edmond, et al., 2006; Meijers et al., 2006; Moussa, McMurray & Muenjohn, 2018; Smara, & Bogatyreva, 2023).
  - According to respondents, there is a lack of vision and objectives for RI in their organisations, which hinders implementation. One said: *There is no structured innovation in our organisation. (…) there are innovation procedures, but it is very incremental and slow. It is not based on a thought-out structured flow within the organisation, that is simply not present."* This confirms that vision plays an important role, which is concurrent with the literature (Young, Charns &

Shortell, 2001; De Vries, Bekkers, Tummers, 2014; Singh, Akbani & Dhir, 2020; Stelzl, Röglinger & Wyrtki, 2020)

- Environmental
  - Formal mandate: respondents mention that there is often not a formal mandate from the government to work on RI, or it is very limited. This means that all RI activities are done on top of the normal workload. Additionally, there are many different FROs who all have different mandates, and different speeds of implementation. This means that there is a lack of a harmonised approach. Even with a top down approach, this fragmentation could lead to a difficult implementation, as suggested by Boersma, Wagenaar and Wolbers (2012).

This article thus confirms the literature on the organisational level. However, on the individual and environmental levels, more research is needed, especially on the effect of ego and own initiative, as well as on the role of a formal mandate for RI. Literature highlights that in ambidextrous organisation, RI is part of the job description of individuals (Meijers et al., 2006; Owen, 2018; Brooks, Grugulis & Cook,2021; Koskinen, 2021). It however does not mention a formal mandate for FRO to work on RI.

Conceptual Model

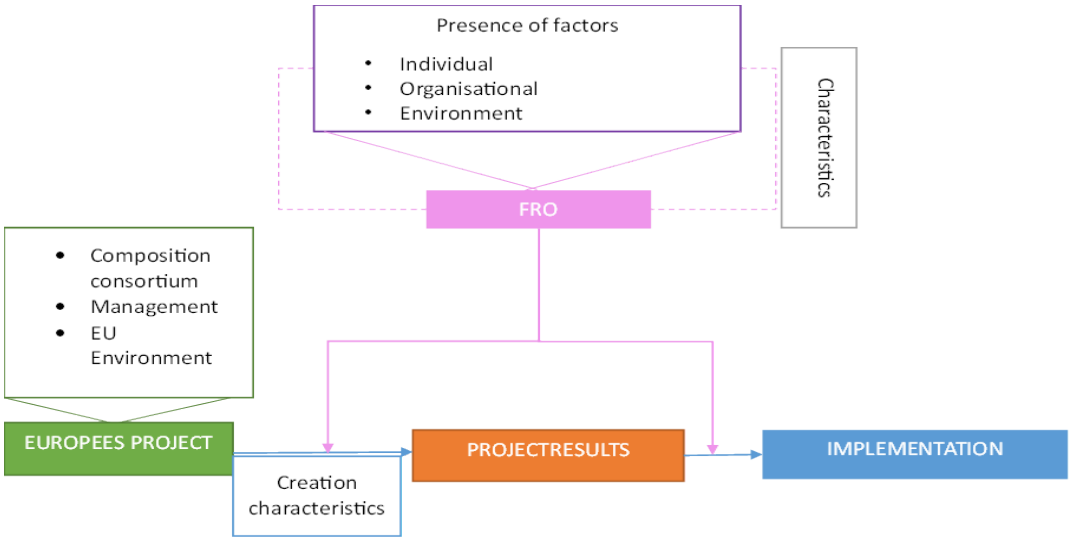

Figure 4. the renewed conceptual model

The above section has shown the role of the characteristics of EU project results, of the composition of the consortium the management, and the EU environment. This is visible in the new conceptual model in figure 4.

RQ1 asked: Why is there seemingly a failure to innovate of European Project results in FROs? It is clear from the respondents' answers that there can be a failure to implement project results. They often do not have desirable characteristics and thus, there is no enthusiasm to use them within FROs. The next step is determining why this is so. Is it the case because of the structure of EU projects? Or because of the structure of FROs? Or both? The respondents highlighted that the structure of the EU project can often be the problem . When the creation of characteristics goes wrong it leads to un-implementable project results. This happens during the EU project. It is however, also undeniable that there are factors in FROs that make implementation difficult to begin with. For example, a lack of vision and working without a structured flow of RI implementation.

Handbook

To give FROs a toolkit to prevent failure to innovate, and to answer RQ2, a handbook was created. This handbook was examined by all respondents and exists out of the following chapters (translated handbook: https://zenodo.org/records/10964582).

- Chapter 1 and 2: what are EU projects?
  - An explanation about the creation of the handbook, and of the most used jargon in EU projects.
- Chapter 3: requirements
  - The requirements that are needed for FROs to participate in EU projects. Of these requirements, a mix of people with project management experience and operational experience were

emphasized by the respondents. One respondent said: *"It is about bringing an operational background, the terrain knowledge to a more scientific or strategic project. You cannot get that knowledge from people who only know the procedures."*

- Chapter 4: selecting calls
  - Information on how to select calls. Respondents emphasised the importance of choosing project calls based on the concrete vision and objectives of the FRO. This chapter also gives an explanation on how to read project calls, based on Rösner (2023).
- Chapter 5: the proposal phase
  - During this phase, respondents mentioned that FROs should be aware of the composition of the consortium and of the coordinator. *"You need to look at: what is this project about, and how are we going to realise that with this group of people? That it is not all the same type of people when the call asks for someone else"*. Additionally, respondents mention that practical considerations need to be kept in mind.
- Chapter 6: the execution phase
  - Many respondents mention that during the execution phase, it is important to keep in mind your own vision and objectives and to be able to communicate those to the project partners.
- Chapter 7: the result phase
  - According to the respondents, this phase is crucial, but also the most overlooked. This is the time period that determines if results get implemented or not.
- Attachment: work pages
  - These can be filled in by FROs before, during and after the project, allowing them to track the project from beginning to end.

Recommendations

Based on the findings of this article, a few tentative recommendations can be made. Firstly, the current structure of EU projects includes hindrances that can lead to failure to innovate for FROs. These hindrances should be reduced. As such, the administrative burden of EU projects should be lowered if possible. On top of that, the current requirements demanded by the EC (high TRL for IA, required participation of end user organisation and specific dissemination plans) appear insufficient to ensure implementation in FROs. The utility of these requirements should be further evaluated. Secondly, FROs should be better prepared to participate in EU projects. They should develop a vision with concrete objectives about research and innovation implementation in their organisation. This should also explicitly address the project they are participating in. Thirdly, the gap between academics and FROs should be further closed by "translating" academic literature into concrete solutions, so that the project results are less abstract.

An overarching organisation that specializes in EU projects that employs active first responders and disseminates project results in different FROs could be a solution that addresses most of the recommendations. There would be expertise on the EU environment in this organisation, they would be prepared to participate, and they could support academics in the "translation" process.

Limits and Further Research

This was exploratory research only. More research is needed to further examine the findings of this article. A study with more FRO respondents in multiple European countries could be a good starting point. Additionally, how to encourage implementation of results in FROs should be further researched. For example, by exploring which additional requirements for EU projects could lead to more implementation.

There are several limitations to this research. Firstly, there is the possibility for a negativity bias, the tendency of respondents to focus more on the negative aspects then on positive aspects during an evaluation (Ito, Larsen, Smith & Cacioppo, 1998). Secondly, this article is focussed only on the FROs participating in European projects, it thus excludes the point of view of researchers, commercial parties, and the European Commission. Thirdly, the article had a small sample size, used the snowball method and was geographically in Belgium and the Netherlands. This sample therefore might not be wholly representative of all FROs participating in EU projects.

ABSTRACT

The availability and quality of the information system supporting crisis management depends on the existence of up-to-date, comprehensive and reliable knowledge bases, despite the multidisciplinary nature of the information to be exchanged, the actions, and the decisions to be taken. This article proposes a method to benefit from pre-trained language models to automatically update these knowledge bases at both design time and run time. We offer a model-based extraction process and a dedicated automated validation process. These two contributions are illustrated and discussed around a case study: an emergency decision support system used to prepare for and respond to an unexpected mass gathering at an abandoned French aerial base.

Keywords

Decision Support System, Knowledge Base, Generative AI, Crisis Management, Information Management

INTRODUCTION

Disaster management is usually structured around four phases: prevention, preparedness, response, and recovery (Alexander, 2002; Altay & Green, 2006). During a crisis response, situational awareness is the key to efficient and effective management of the situation (Coche et al., 2021; Endsley, 2001). Decision-making processes rely on a good understanding of the situation. In the context of the ever-growing amount of available data coming from the crisis sites, crisis responders can rely on decision-support systems that are able to process it through previously acquired knowledge. These systems are very useful in offering visualization and analysis tools to increase the understanding of the situation, but to function, they rely on a knowledge base. This knowledge base needs to be filled before the crisis and updated every time the situation evolves. This is crucial to ensure that the model of the situation given to the crisis responders is always relevant and represents what is currently going on. If extracting information about crises during the preparation phase has become rather easy, the question is how can they (i) fit into the structure of the knowledge base and (ii) be integrated with pre-existing knowledge to feed the situation model and eventually result in relevant and efficient decisions. How can the knowledge base of decision-support systems be filled with information and knowledge, both before and during the crisis? There are several ways to fill a knowledge base with information before the crisis, but the urgency and unexpectedness of crises make it impossible to have fully and sufficiently complete knowledge bases. This means that a way to update and complete the knowledge base during the crisis, to keep up with the ever-changing situation, has to be found.

The task of knowledge base population then consists of finding, for the situation under configuration, all instances of metamodels concepts as well as the relations that link them. As the crisis evolves, both instances and relations can be modified or updated. Some new instances may appear (a new risk is arising), and existing instances may see their relations with other instances appear or evolve (a resource is no longer available in a given area, the arisen risk impacts one or several actors). This constantly evolving nature of crisis associated with the high amount of information to be integrated to render a relevant model of the situation justifies the need to automate the updating of previously evoked concepts. This leads to the problematic addressed in this paper: How can we keep knowledgebases up to date without overwhelming managers in nominal mode, before the crisis, and in emergency mode, during the crisis?

Section 2 presents the context of the study and feedback on the use of conversational AI to update an existing knowledge base at design time and run time. Section 3 presents a literature review of the existing solutions to automatically fill knowledge bases. Section 4 presents our proposal to keep our knowledge base up to date without overloading emergency managers. Finally, Section 5 concludes with the impact and benefits of our feedback and proposal.

CONTEXT: THE DECISION-SUPPORT SYSTEM R-IOSUITE

This section presents our feedback on the use of pre-trained language models to facilitate the instantiation of the knowledge base of a decision support system: R-IOSUITE. R-IOSUITE is an open-source software dedicated to emergency management Salatge´ and Rebie`re-Pouyade, 2023.

R-IOSUITE Before Conversational-AI

The decision-support system (DSS) R-IOSuite presented in Fertier et al., 2020b aims to help decision-makers and crisis responders solve the crisis most efficiently. It has four main functionalities to achieve that goal: (i) manually

populate a knowledge base and model a crisis situation (ii) automatically interpret data flows, real or simulated, to update their model according to the current situation (Interpretation functionality); (iii) deduce, orchestrate and supervise a process combining human or automatic tasks to react to the current situation (Deduction functionality); (iv) adaptation to adverse events (Adaptation functionality). All these functionalities depend on a knowledge base, where R-IOSuite stores and infers information. The information concerns both general, core, knowledge common to several crisis instances, as specific, application, knowledge describing one particular site (location, sensitive building or infrastructure nearby, geographical information...) and its available stakeholders (firefighters, policemen, trucks or ambulances...). It is structured by a meta-model dedicated to represent collaborative situations (Benaben et al., 2020): the objectives, actors, resources, or risks, and their undergoing relations.

There are several ways to fill the R-IOSUITE knowledge base: manually with experts in design time (approximately 80% of the knowledge), during the preparation phase, manually in run time by the emergency managers during the response phase (1%), automatically in run time during the response phase (Coche et al., 2021; Fertier et al., 2020a) via machine learning (text from tweets, images form tweets) or complex event processing (sensor data and open data) (19%).

To illustrate the manual and automatic update of a knowledge base in R-IOSUITE, we propose a case study on an unauthorized mass gathering in a decommissioned airbase, developed in the context of the PICADORS research project. This project is funded by the European Union through the Re´gion Haut-de-France. The unauthorized aspect of this use case enhances the unexpected side of crises and the need to find ways to fill the knowledge base during the crisis, as the situation changes. Several actors are involved in the resolution of this crisis: the firefighters, the police, the French Red Cross, and the Prefecture of Cambrais where the aerial base is located. These actors have skills and competencies that must also be stored in the knowledge base so that the DSS can use that information to attribute the process' tasks.

R-IOSUITE Using Conversational AI to Fill Its Knowledge Base

Another possibility to fill the knowledge base would be to directly use conversational AI. This possibility can be used before the crisis, in the preparation phase when the knowledge base is filled with the available resources and concepts, but also during the crisis if the situation evolves and must be updated quickly. This second option is particularly interesting because it allows to enrich the knowledge base quickly, without having to look for information in operation plans or documents which can sometimes be hard to find. In the following subsection, we describe these two possible uses.

Filling the knowledge base before the crisis

Many of the actors involved in crisis management are the same from one crisis to another. This means that it is possible to anticipate the crisis by filling the knowledge base with information that is relevant in any kind of situation: for instance, a firefighter can extinguish a fire, and that is always true. To fill the knowledge base with this kind of information, it can be done manually, by automatic information extraction such as presented in the previous section, or with conversational AI.

In R-IOSuite, the knowledge base is filled with concepts such as roles that have functions: the role "firefighter" has functions such as "extinguish a fire" or "rescue people". It is possible to define these roles and functions either manually, or by requesting a conversational AI such as Chat GPT or Google Bard. In this case, the AI responds with several propositions that must be validated by the users of the DSS.

In the PICADORS use case, we asked the AI to help us find the functions of the actors from the Red Cross. It resulted in a list of possible functions such as treating injuries or sorting casualties. Among this list of functions, we were able to choose the ones that we thought were relevant to the use case and store them in the knowledge base.

Filling the knowledge base during the crisis

One of the characteristics of a crisis is its unexpected aspect. It is impossible to foresee every possible evolution of the situation and to be prepared for every possibility. Thus, it is necessary to be able to quickly modify or complete the knowledge base to keep it up-to-date. There again, it can be done manually, or with information extractions, but in some cases, it might be useful to use conversational AI.

In the PICADORS use case, we can imagine that the evolution of the situation requires at some point that some new actors get involved. If this evolution is unforeseen, the functions and skills of these new actors are probably missing from the knowledge base, which means that the DSS is unable to involve them in its response process proposal. Thus, we need to complete the knowledge base before asking R-IOSuite to deduce a new response process relevant to the new situation. Thanks to conversational AI, it is possible to quickly find the functions corresponding to the new actors and integrate them into the knowledge base if they are judged relevant by the decision-makers.

Benefits and Limits of Conversational AI to Fill an Existing Knowledge Base

The use of conversational AI-enabled us to reduce the time needed to implement the use case in R-IOSUITE. It also enables us to complete a knowledge base to cope with unexpected events, requiring specific knowledge that we wouldn't have thought of at the design stage. However, superfluous knowledge is added (noise) in the same way as missing knowledge, and AI cannot ensure the authenticity of the knowledge generated.

LITERATURE REVIEW ON DIFFERENT METHODS TO FILL THE KNOWLEDGE BASE

The aim of this section is to determine the extent to which a pre-trained linguistic model or machine learning models can be used to automate the updating of an information system's knowledge base, at both design and runtime.

Knowledge is available across an extensive collection of sources, ranging from structured data (databases, graphs, spreadsheets, etc.) to semi-structured (markup and JSON documents) and unstructured data (texts, such as PDF files, website pages, social media posts and comments, etc.).

Understanding, tagging, and structuring this large amount of data available from the web space into knowledge bases cannot be entirely achieved by hand, especially in the time-sensitive context of crisis management. Moreover, it is necessary to align the collected data with the existing knowledge structure on which the decision support systems rely (namely ontologies in the broad sense – as Gruber, 1993 originally defined it –, from OWL ontologies to knowledge graphs). The knowledge base population steps must then be automated to lessen the human effort and speed up the process of non-added-value tasks.

The literature review is based on the Scopus database, from 1980 to 2024, on the title, the abstract, and the author keywords fields. Table 1 presents the four parts of the query linked with the AND operator. It searches for publications about automated techniques of knowledge extraction, acquisition, population, feeding or collection of structured knowledge.

The first part of the query [1] looks for tools for structuring data in the broad sense (hence the use of keywords such as ontology, structure, base, etc.). The second part [2] seeks ways to get this knowledge automatically. The third part [3] focuses on the crisis management application domain. The fourth and last part of the Scopus query filters results by excluding domain areas that are not relevant to the research question (e.g., "VETE" for veterinary and "DENT" for dentistry).

The 56 papers returned by the query are filtered regarding their relevance with crisis domain and knowledge extraction concern. The 10 remaining related works are presented in Table 2 and evaluated through three criteria which are (1) the automated nature of the proposed extraction method, (2) the ability to refer to existing knowledge structure, (3) the complexity of extracted relations and (4) the type of processed data. The first column indicates the article reference. Columns 2 to 4 present our three criteria. Column 5 indicates which kind of data was used to perform knowledge extraction.

Table 1. The Scopus query

Operator	Number	Part of the query
	[1]	(base* OR database* OR structure* OR repositor* OR model* OR ontolog*) W/1 (knowledg* OR data OR fact* OR relation* OR entit* OR ontolog*)
AND	[2]	automat* W/1 (extract* OR acqui* OR populat* OR feed* OR collect*)
AND	[3]	cris* OR disast* OR "adverse event*" OR "unexpect* event*"
AND	[4]	EXCLUDE (SUBJAREA , "DENT") OR EXCLUDE (SUBJAREA , "VETE") OR EXCLUDE (SUBJAREA , "NURS") OR EXCLUDE (SUBJAREA , "CENG") OR EXCLUDE (SUBJAREA , "IMMU") OR EXCLUDE (SUBJAREA , "PHAR") OR EXCLUDE (SUBJAREA , "CHEM") OR EXCLUDE (SUBJAREA , "MATE") OR EXCLUDE (SUBJAREA , "ARTS") OR EXCLUDE (SUBJAREA , "PHYS") OR EXCLUDE (SUBJAREA , "EART") OR EXCLUDE (SUBJAREA , "BIOC") OR EXCLUDE (SUBJAREA , "MEDI")

Table 2. The results of the literature review organised according to our four criteria. ***Abbreviations : N.R Not Relevant; N/A Not available***

Reference	Automated method	Compliance	Complexity	Data
Angeles and Kijewski-Correa, 2022	No	Yes	Model specific	images, texts
Bayramog˘lu and Uzar, 2023	No	Yes	Taxonomic	images
Chasseray et al., 2021	Yes	Yes	Taxonomic	texts
Chaulagain et al., 2019	Yes	No	Taxonomic	texts
D'Amico et al., 2011	No	Specific	Non taxonomic	discussions
Guo et al., 2023	No	No	*N.R.*	images
Nguyen et al., 2011, 2012, 2013	Semi	Yes	Non taxonomic	tweets (semi-structured)
Venkatachalam et al., 2020	*N/A*	Yes	*N/A*	texts
Wang et al., 2020	Yes	Specific	Non taxonomic	texts
Zong et al., 2022	Semi	BDD	Non taxonomic	tweets (semi-structured)

A few related works extract territorial information that are relevant in case of a crisis based on aerial data. Bayramoğlu and Uzar, 2023 focus on the inventory of roads from unmanned aerial vehicle images. Similarly, Guo et al., 2023 identify cropping zones that have been affected by bad weather conditions and are susceptible to crop lodging. They use satellite image and image processing techniques to identify the concerned zones. In the same area of research, Park et al., 2015 build topographic landscape representation, and notably tree height for the management of disasters such as forest fires. As techniques presented in these articles are relevant in term of information extraction, they do not involve the population of an existing knowledge structure or are not related to a decision support system. Bayramoğlu and Uzar, 2023 is the only one proposing an ontology built on 4 classes to reference extracted elements such as Bicycle (road), Sidewalk, Road and Marking. However, these classes are not pre-existing the extraction method and are designed on purpose based on the extraction task results.

Angeles and Kijewski-Correa, 2022 couple image sourced information extraction with semi-structured textual data such as tax assessor data or building permits. Their framework results in a model characterizing the sensibility of buildings. This model can be reused in case of a crisis or disaster inducing high winds. However, as no pre-existing knowledge structure is used, the created models can't be easily integrated in a more global crisis management system.

More generally, Babic˘ et al., 2022 list a wide group of ontology learning tools that can be used in the case of crisis management for the building of a knowledge structure. These tools are nevertheless not relevant when dealing with an existing knowledge structure such as a metamodel or an ontology which has to be populated and not rebuilt from scratch.

Nguyen et al., 2011, 2012, 2013 propose the definition of earthquake semantics networks, that can be populated from tweet analysis and further integrated in a crisis management system. As such a knowledge management system ensures interoperability with crisis management systems, the population of the expected knowledge graph from tweets requires prior training steps and associated training datasets which makes the approach not fully automated.

Some automated extraction methods for crisis have been proposed in the literature. Chaulagain et al., 2019 use named entity recognition and the definition of specific patterns for the extraction of crisis-related components

(number of deaths, injuries, date and locations). Similarly, Chasseray et al., 2021 apply their domain-independent ontology population patterns to a crisis metamodel, for the extraction. As the proposed methods in these works are both automated, they focus only on taxonomic relations (extraction of concept-instance relations) and do not tackle the domain-specific relations that may occur between two instances of a knowledge base. **Is there a possibility to benefit from pre-trained linguistic models, while limiting the generation of noise and optimizing the authenticity of the generated knowledge?**

PROPOSAL

As natural language processing can be used to populate a knowledge base, their performances are highly dependent on the domain and considered case study. This section discusses the possibility of designing extraction systems encompassing a larger amount of information. As enlarging the volume of extracted information also supposes a rise in irrelevant information, a proposition is made to pair the extraction systems with a conversational AI that could be used as an automated validation tool in order to filter the generated noise.

Natural Language Processing for Relation Extraction

Considering the fact that exploited data is of a textual nature, the field of Natural Language Processing provides a large pallet of tools that can be mobilized to extract knowledge based on unstructured data. Among all tasks of natural language processing, two are relevant for knowledge base population which are instance extraction and relation extraction.

Instance extraction identifies in textual data, pieces of text that can semantically be linked to an existing concept as an instanced version of this concept. This is especially used in ontology and knowledge graph population, as it allows, from a set of defined concepts, to extend some of them with real-world instances.

Relation extraction is a process that aims at extracting semantic meaning linking to parts of a given text. Commonly, the parts to be linked through a relation correspond to instances of previously defined concepts (author-artwork, country-capital city, athlete-discipline).

Our illustrative case study focuses on the extraction of relations between role instances (Firefighter, Caregiver, Policeman, Military person, RedCross, Institution, Officials, Security agent) and function instances (Establish a perimeter on site, Extinguish a fire, Launch an alert, Heal a victim, Drive an engine). We state that instead of extracting instances and relations in separate processes, it is either possible to use the former to extract the latter or to extract both in the same process.

In our specific case, a scenario can be imagined where the objective is to know which Role is involved in the crisis and which Function this role has (what is a policeman able to do in case of a fire ?). This need exists both during the preparation phase and response phase, as associations between a Role and a Function may also appear during a crisis, due to its evolution, if a Role sees itself granted with new functions for example.

Knowing that RedCross is a role, and Protect people is a Function, the goal of the first approach is to identify all occurrences of the RedCross instance and Protect instance in a given text and see if they can be related in the text. This approach is relatively direct, but supposes that instances are already known.

When, none of these instances is identified however, another approach could be to drive the extraction with information contained by the semantic meaning of the relation linking the two concepts. Knowing the type of relation that we want to extract is a great advantage regarding the diversity of textual data. The proposed rule-based approach, presented in Figure 1, hence relies on the richness of verbal relation in textual data and the information they provide to identify instances. For each relation identified in the metamodel, the extraction process can be decomposed into three main steps:

1. Identifying all active verbal forms that may traduce the relation identified between the two concepts of interest. In the case of Role-Function relations, this list can contain verbal forms such as *Is able to*, *Can*, *has to*, *acts to*, *Is tasked with*, *Is capable of*, for example all traducing the ability of a Role to operate a task (Function).
2. Based on the identified forms, build all possible triples involving one of the verbal forms identified in the text and extract the pieces of text that the verbal form links using a predefined extraction pattern structure.
3. Validate the triples and register them in the knowledge base linking each piece of text to its attributed concept (attributed concepts are known as they are linked to the relation in the metamodel).

This approach is relevant as it does not need any pre-training on data specifically related to the crisis domain, as would a language model dedicated to crisis management area for example.

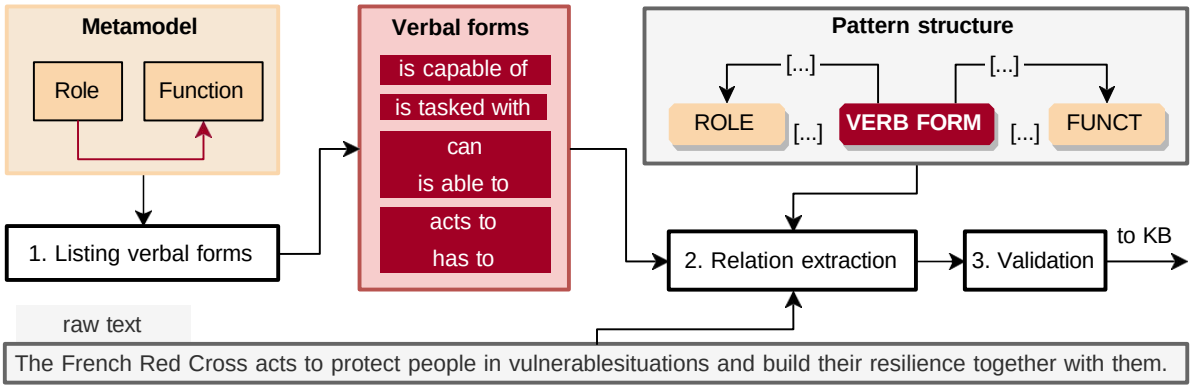

Figure 1. Proposed pattern-based extraction process of Role-Function relations

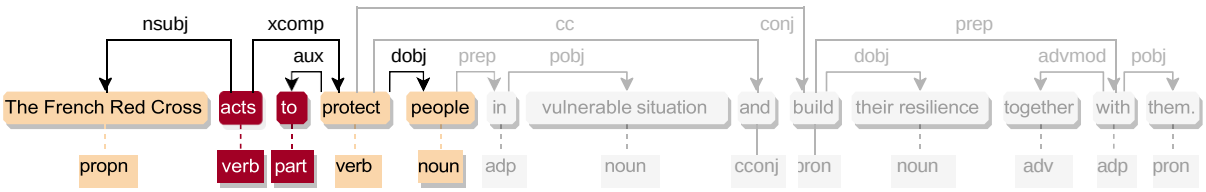

Figure 2. Application of a restrictive Role-Function extraction pattern

Defining Covering and Generic Extraction Pattern

Step 2 of the proposed approach can be performed through the application of extraction patterns. A main limitation of extraction patterns however is that even though they are very precise when specifically defined, they can miss a lot of information. If this information is expressed through a slightly different expression, a pattern that previously worked and extracted the wanted information is no longer effective. Loosen the pattern, at the opposite, tends to greatly extend the range of covered possibilities, but in counterpart, may lead to the extraction of a lot of irrelevant or false information.

Figure 2 and Figure 3 show two examples of extraction patterns being respectively restricted to direct expression of a function (figure 2) and extended to encompass more possibly valid relations 3. In the represented sentence : *The French Red Cross acts to protect people in vulnerable situations and build their resilience together with them.* Two Role-Function relations can be identified and should be extracted which are the relation between the Role *Red Cross* and the Function *Protect people* and between the Role *Red Cross* and the Function *build their resilience*.

To extract these relations, a possibility is the definition of extraction patterns, adapting the definition of patterns proposed by Chasseray et al., 2023, which allows the generic extraction of concept-instance relations so that they can extract relations based on previously defined verbal forms.

First pattern (2) looks for the restricted extraction of the following sequence of tokens:

$$\text{PROPN} \overset{\text{nsubj}}{\dashrightarrow} [\text{VERBAL FORM}] \overset{\text{xcomp}}{\dashrightarrow} \text{VERB} \overset{\text{dobj/pobj}}{\dashrightarrow} \text{NOUN}$$

Where :

1. the NOUN may later be defined as a Role,
2. the RELATION VERBAL FORM matches with one of the verbal form defined in step 1,
3. the VERB $\overset{\text{dobj/pobj}}{\dashrightarrow}$ NOUN sequence is used to identify a potential Function.

Using such a pattern on the example results in the extraction of one correct function in that context (*protect people*). This pattern can nevertheless be criticised as it misses the second function expressed in the sentence (*build their resilience*) as it is restricted to a limited group of expressed relations.

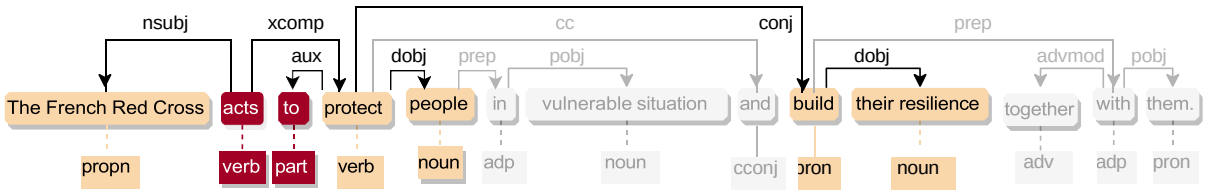

Figure 3. Application of a loose Role-Function extraction pattern

A larger extraction pattern looking for a more generic sequence of tokens:

$$\text{NOUN} \overset{\text{any}}{\dashrightarrow} \ldots \overset{\text{any}}{\dashrightarrow} [\text{VERBAL FORM}] \overset{\text{any}}{\dashrightarrow} \ldots \overset{\text{any}}{\dashrightarrow} \text{VERB} \overset{\text{dobj/pobj}}{\dashrightarrow} \text{NOUN}$$

allows the extraction of every candidate on each side of the matched VERBAL FORM, without paying attention either to the nature of syntactic dependencies linking the different elements to extract or the length of the dependency path linking them. In the provided example (see Figure 3), this pattern performs well as it is able to extract both targeted relations.

Contrarily to specific dependency patterns described in Chasseray et al., 2023, this extraction pattern is agnostic regarding the nature of the dependency links, which ensures a wider coverage and a larger amount of extracted information.

However, as relaxation of the extraction pattern can be seen as a solution to cover all needed information, the risk is flooding the relevant information in too much noise. When applied to larger textual content, a larger pattern might then include numerous relationships, some of which may not be semantically correct, leading to an accumulation of incorrect triples, that will surely extend the validation task. In that case, manual validation of extracted triples is not reasonable, especially during the response phase, where deduced scenarios and taken actions should be proposed as fast as possible to decision-makers.

Assisting Validation Filtering with Conversational AIs

In the methodology proposed, the third step is crucial to ensure that the knowledge base is provided with information that is correct, and sufficient for scenario deduction. This inherent nature of pattern extraction is in conflict with the objective of a complete model of the situation, by stating that too precise patterns will not extract all the available information, resulting in an incomplete model.

Despite the fact that conversational AI outputs are raising questions concerning their relevance or the lack of sources from which they suffer, they can be used as a tool to validate already extracted (and sourced) knowledge.

Directly asking a large language model and its associated conversational AI to populate a knowledge base remains questionable depending on scenarios and use cases for two main reasons which are (i) the impossibility of tracking the origin of the extracted information and (ii) the risk to face inferred knowledge and add apparently realistic information, that does not exist in real life, or not in the current situation.

However, using such conversational AI as a post-extraction validator does not affect the whole knowledge base population system as it is provided with traceable information, and only states its validity. We propose a first algorithm flowchart diagram in 4 to automate validation using conversational AIs. The proposed methodology lies on predetermined verbal forms and extracted relations to generate different prompts for validation. Generated prompts are submitted to a conversational AI and validation outputs (True/False statement + confidence) are aggregated to establish a general True/False statement on the relation. Extracted relations that are stated as False by the conversational AI are ignored. Validated relations are however added to the knowledge base. Human validation is however still required to confirm the extracted relation as true and available for further use by a decision support system. This is mandatory, as conversational AIs and Large Language Models can falsely qualify an extracted relation as True. Implementation of such a knowledge extraction framework can be parameterised with a threshold stating when a relation should be considered True or False. This threshold could be set on the average rate of decision, but can also use the confidence indicator.

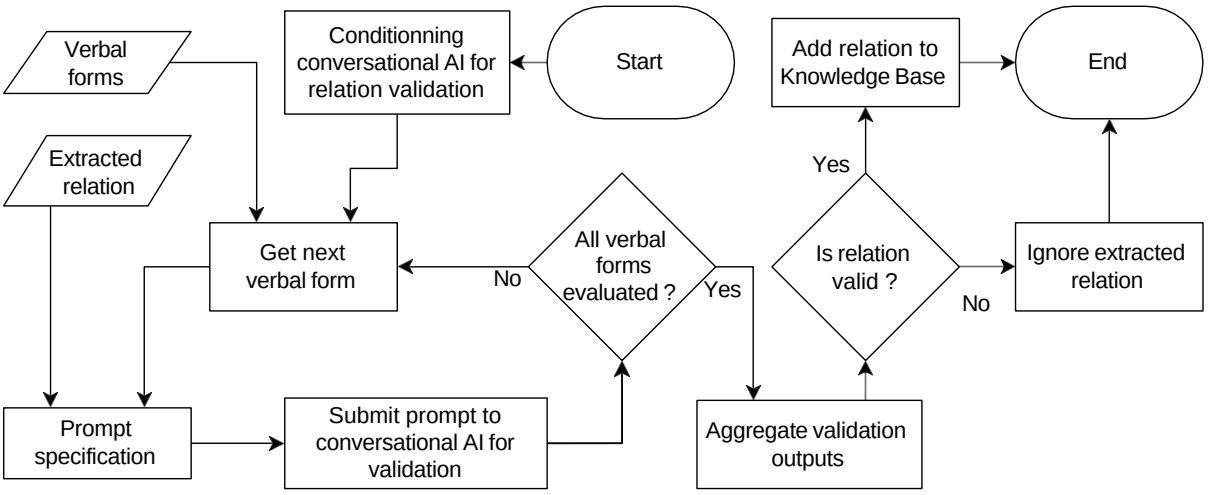

Figure 4. Flowchart diagram for the automated validation process of extracted relations

DISCUSSION ON IMPACT AND BENEFITS

The use of the methodology proposed could improve the ways to fill the R-IOSUITE knowledge base: automate part of the manual updates with experts in design time (at least 80% of the 80%), during the preparation phase; automate part of the unexpected manual updates during the response phase (at least 50% of the 1%); and improve the interpretation of texts or images from tweets, during the response phase; while limiting noise and optimizing the authenticity of the knowledge generated.

For the French fire department in the Pas-de-Calais department, our method of preparing and assisting a response to an unexpected mass gathering has enormous potential. This innovative approach could revolutionize crisis management by enabling pre-filling and automatic, controlled updating of the knowledge base of the emergency decision support system. What's more, in the event of a crisis, this system could prove invaluable in enabling the reconfiguration of prepared emergency plans. This would guarantee a more informed and effective response.

CONCLUSION

This paper presents four contributions: a feedback on the use of conversational AI to instantiate a knowledge base at design time and run-time; a literature review on existing systems able to automatically instantiate a knowledge base in the crisis management field; a method to extract instances and relations (patterns); and a method to automatically validate the extracted patterns.

The example provided in this article is detailed for illustration purposes. Future work on this subject could consist of systematic implementation of the proposed AI-assisted knowledge base population methods to apply it to several crisis cases and assess its adaptability to different use cases.

ABSTRACT

This paper addresses the evolving relationship between Artificial Intelligence (AI) and crisis management, spanning over a decade. Initially sparked by social sciences' interest and facilitated by abundant data, particularly from social media, the collaboration between these fields has streamlined decision-making processes. However, the distinctive, uncertain nature of crises presents challenges in adapting AI to varying contexts. In exploring existing frameworks like Common Operational Picture (COP), Situational Awareness (SA), and Sensemaking, the paper finds a potential misalignment between recent AI architectures, predominantly symbolic or neural, and these established frameworks. To bridge this gap, the paper proposes a bio-inspired neuro-symbolic AI architecture, emphasizing its application at the Sensemaking level during crisis data exploitation. Leveraging insights from neurosciences advancements, the paper aims to enhance the adaptability and effectiveness of AI systems in crisis situations.

Keywords

Situation Awareness, Sensemaking, neuro-symbolic AI, neurosciences

INTRODUCTION

For more than a decade, the crisis management community has been interested in using Artificial Intelligence (AI) to support decision-makers and their information needs (Palen et al., 2020). This enthusiasm first came from the social sciences, whose studies were historically prevalent in the study of past crisis management, and naturally joined the field of AI thanks to easier access to voluminous streams of data - notably social media - that can be exploited computationally(Palen & Anderson, 2016). The literature shows that the two fields have been able to work together quickly and effectively, and the richness of the inter-disciplinary collaborations set in motion on this occasion no longer needs to be demonstrated, particularly within the ISCRAM community (Reuter et al., 2018).

With this in mind, the last few years have seen a strong interest in the application of AI to quite specific and not always generalizable tasks. While the basic issue remains that of saving crisis managers time and resources in accessing and exploiting rich, heterogeneous data flows, the challenges are not limited to this. The context of a crisis is unique in that it is by definition uncertain, sometimes unknown, and each time different in the course of events.

Slam et al. (2015) summarizes three challenges for designing a decision-support system for crisis management: represent knowledge, reason about knowledge in real-time, and adapt knowledge to unknown situations. Knowledge

representation capability refers directly to the decision support system's ability to process data flows in real time in order to establish an up-to-date map of the crisis context and its events. The systems affected by crises are generally complex, and the decision-making process, in its first stage of understanding the situation, is just as complex, involving a wide range of expertise and points of view. AI, with its ability to deal with large data flows and apply logical rules, is a strong ally to promptly address this first information need problem in decision support systems. In the literature, this ability of a decision support system to process data (human or machine) in order to understand a crisis situation is generally grouped under three terms, each with specific levels of processing and complexity: *Common Operational Picture (COP)*, *Situational Awareness (SA)* and *Sensemaking*. Although the definitions were clearly formulated a few years ago, the work proposed in AI, influenced since then by a remarkable progress in technology, has sometimes been developed independently.

While most AI architectures developed for crisis management are based almost exclusively on symbolic or neural architecture, neuro-symbolic architectures seem more likely to solve certain challenges, especially at the Sensemaking level. Yet, neuro-symbolic AI architectures, beside several attempt, still do not meet the level of expectation of a Sensemaking-level AI support. In parallel, neurosciences have undergo a strong progress in the last years and human brain cognition processes are now better known, providing promising inspiration for future AIs.

In this context, this paper serves two purposes. The second Section of this paper questions the current alignment between state-of-the-art AI architecture and the information needs of crisis responders formulated in COP, SA, and Sensemaking literatures. Hence, it focuses on a litterature review of the three formulations of informational needs and discusses the underlying processes for information extraction by individual or (inter-)organizational crisis responders. The third Section proposes a bio-inspired neuro-symbolic AI architecture to address the Sensemaking-level challenges in the exploitaiton of data to extract crisis comprehensive situation models. Finally, the conclusion will provide an opportunity to take a closer look at the current limits of the approach and future work.

LITERATURE REVIEW

Informational Needs and Human Processing

Common Operational Picture

The aim of a COP, which is generally the heart of Command and Control Systems, is to provide decision-makers with a *single* perceived and shared situational picture (Kuusisto et al., 2005). In essence, the SA-based decision-making paradigm involves the actor utilizing their knowledge to make decisions based on their perception, understanding, and projection of the dynamic environment they are operating in. On the other hand, COP serves as an information-sharing tool, allowing for the unambiguous modeling of a situation and therefore facilitating a fluid communication between actors.

Situational Awareness

SA is generally associated with Endsley (1995)'s famous framework, which involves perceiving, understanding, and projecting a situation as a reliable basis for decision-making. First, Endsley unambiguously positions SA as a state of knowledge, and refers to the process of accessing this state as *situation assessment*, enabling to "achieve, acquire and maintain SA". Second, in SA, Endlsey includes knowledge of the state of a dynamic environment and explicitly excludes any static knowledge or expertise. While the boundaries of this dynamic state of knowledge of a system in motion are clear, they gain in complexity in "real life", where decisions reflect coordination and even collaboration between several actors, just as in crisis management. Here again, Endsley's framework proposes a definition of *team SA*, i.e. a complete SA of each individual concerning his or her responsibilities, with areas of overlap between actors being acquired individually or through information sharing.

According to this definition of a state of knowledge necessary for decision-making, the acquisition process itself underpins cognitive mechanisms specific to human reasoning. This definition aligns with the broader understanding of reasoning by Leighton and Sternberg (2004) : "reasoning is broadly defined as the process of drawing conclusions. [...] these conclusions inform problem-solving and decision-making endeavors", thus also unifying goal-oriented paradigms, which in turn require the implementation of an attention mechanism on the part of the actor. Although Flach (2015)'s argument is probably beyond the scope of this paper, he stresses the importance of thinking about SA within a contextualized framework in which "meaning is defined in terms of functional significance or utility", and questions the status or rather the influence of sociotechnical systems ("thinking machines") in this framework.

SA can be realized through the individual access to *actionable information*. Actionable information is defined by Zade et al. (2018) as " the right information [that] reach the right person at the right time". Coche et al. (2021) operationalize the actionable information under four criteria: relevant, timely, precise and reliable. Therefore, the automation of actionable information mining comes as a crucial challenge to support SA with intelligent systems.

Sensemaking

Finally, the process of Sensemaking, although variously defined in the literature (Klein et al., 2007; Pirolli & Card, 2005), refers to processes "by which people seek plausibly to understand ambiguous, equivocal or confusing issues or events" (Brown et al., 2015). The term "Sensemaking" originates from Organizational Studies, but there is no consensus in the literature regarding its mechanism (Brown et al., 2015; Muhren & Van de Walle, 2010; Weick et al., 2005). The notion of the collective is called into question, as Sensemaking may be understood as an individual and/or collective process. In the context of crisis management, Weick's work in favor of a collective Sensemaking process is best summed up in the 7 properties summed up in the following citation: "Taken together these properties suggest that increased skill at Sensemaking should occur when people are *socialized* to make do, be resilient, treat constraints as *self-imposed*, strive for *plausibility*, *keep showing up*, use *retrospect* to get a sense of direction, and *articulate descriptions* that energize. These are micro-level actions. They are *small actions*. But they are small actions with large consequences." (Weick et al., 2005).

On COP, SA and Sensemaking Integration

As a conclusion of this section, we demonstrate that comprehending a situation, a crucial step towards decision-making in a dynamic environment, must be considered at three interconnected levels: (i) the cognitive processes that underpin human reasoning; (ii) the social context that influences individual evolutions as much as individuals influence social behavior; and (iii) the importance of a common language with a moderate level of interpretation, so as to favor non-ambiguous shared modeling.

Moreover, an AI to support Sensemaking, in its collective process definition, should address a two-dimensional challenge:

- *horizontal dimension* - the expertise and type of data to be processed fluctuate according to the type of crisis and the specific context;
- *vertical dimension* - the granularity of the information extracted from the data varies directly with the level of crisis (e.g. regional or national) and the decision-making level of the decision-maker who has the AI tools in hand (Benaben et al., 2016).

Artificial Intelligence to Meet Informational Needs

The field of crisis management, like many other fields in recent years, is showing strong growth in the use of AI, as can be seen from Figure 1, representing the number of publications on Scopus in response to the search "('crisis management' or 'emergency management') AND 'artificial intelligence'".

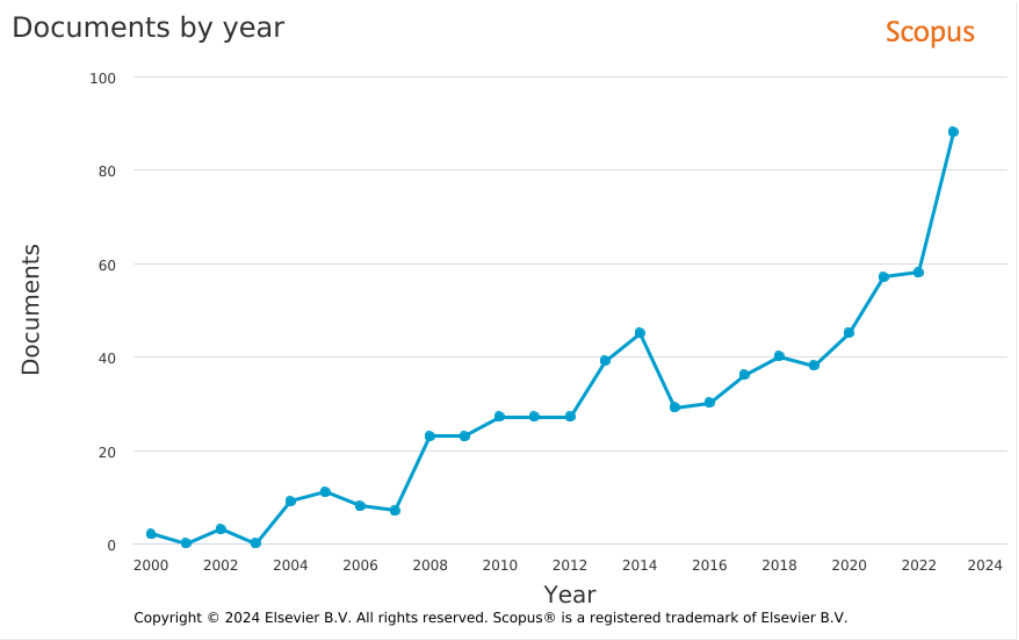

Figure 1. Evolution of the number of published paper on the Scopus scientific database, search string *TITLE-ABS-KEY ("artificial intelligence" AND ("crisis management" OR "emergency management"))*.

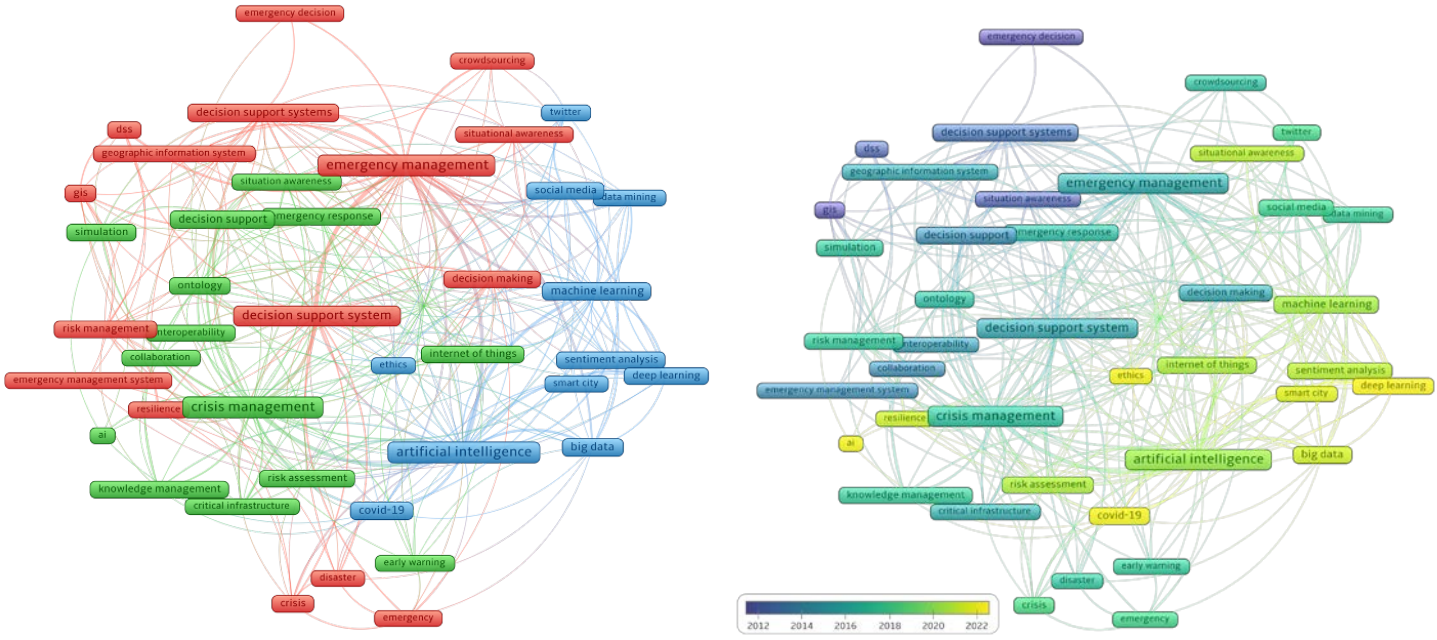

Figure 2. Usage of the authors keywords by clusters - on the right - of interest and year - on the left , search string on Scopus database *TITLE-ABS-KEY (("artificial intelligence" OR "AI") AND (emergency OR crisis) AND management AND survey)*. Generated with VOSviewer visualization software.

A keyword study (see Figure 2) highlights the use of AI for:

- **Achievements and purposes - red cluster** : Includes operational research and decision support systems to optimize decisions.
- **Knowledge-based systems - green cluster** : Includes systems for situational awareness or early warning systems based on expertise modeling.
- **Machine learning-based systems - blue cluster** : Includes big data (and especially social media data) processing with machine and deep learning methods.

The first cluster is excluded from this study, as it focuses on optimized decision-making rather than information processing itself.

In the following two sections, we provide an overview of the current state of the art in: (i) knowledge-based systems that enable static modeling of expertise on the basis of pre-defined concepts; (ii) systems based on learning approaches to solve specific problems in data processing; and (iii) systems that attempt to approach a multi-dimensional interpretation of data.

In order to target article searches in the Scopus database, the search strings were refined using keywords from the green (i) and blue (ii) clusters.

Knowledge-Based and Expert Systems : Symbolic Approaches

Knowledge-based and expert systems are based on a triptych consisting of a schema or structure for representing knowledge, a knowledge base subject to the representation schema, which embeds and computerizes the knowledge accumulated by domain experts, and a set of inference rules providing the system with logical reasoning for discovering or updating knowledge.

Numerous studies have focused on the implementation of such systems to support the information processing efforts of crisis decision-makers. Regarding knowledge representation, the terms meta-model (derived from model-driven engineering - MDE) and ontology are used as references: whatever the formalism used, it is a question of one way or another for experts to conceptualize the semantics of a domain, most often by qualifying the classes of interest

and the relationships that link them. Works such as (Alheadary, 2023; Christensen & Madsen, 2020; Correia et al., 2018; Kontopoulos et al., 2018) offer structured and possibly populated knowledge bases relating to the crisis management domain.

A reasoning layer, based on inference, can then be added on top of the knowledge base to take advantage of it, through the use of expert rules. Benaben et al. (2020), Rezaei and Vahidnia (2023), and Slam et al. (2015) propose this type of inference mechanism in their work, enabling them to offer users of the software developed an explicable framework of recommendations.

In order to make knowledge-based systems more reactive and autonomous, they have also been augmented by paradigms such as Complex Event Processing (CEP), enabling data to be received (from sensors, for example) and processed by rules in real time in order to relate it to knowledge already stored in the system, possibly triggering inferences. Systems of this kind, as proposed by Barthe-Delanoe¨ et al. (2014), Fertier et al. (2020), and Mijovic´ et al. (2019), have been widely used in the development of early warning systems.

In view of the uses to which they have been put, knowledge-based systems have undeniable advantages. In particular, they enable:

- Establish and unambiguously represent a semantic framework, thus ensuring unified interoperability;
- To a certain extent, to reason (by logical rules possibly integrating the notion of uncertainty) about knowledge with speed and explicability in order to draw conclusions.

Nevertheless, their lack of genericity and adaptability, due to a semantics fixed in a predefined semantic framework, makes it difficult for these systems to take advantage of heterogeneous data flows.

All these features qualify knowledge-based systems as ideal candidates for the realization of a COP.

Single-Task Performance Systems : Machine and Deep Learning Approaches

The use of AI learning techniques has been growing steadily over the past fifteen years. This growth can be relatively easily explained by the era of Big Data, with its increasing capacity to collect data (from connected and distributed sensors, imaging systems and social media, in particular) and store it at low cost, to drive machine learning and deep learning algorithms.

While the Scopus search "('crisis management' OR 'emergency management') AND ('machine learning' OR 'deep learning' OR 'big data' OR 'data mining')" has returned 792 papers from conferences and scientific journals since 2015 (as of February 13, 2024), adding the criteria "('social media' OR 'social network*' OR 'twitter' OR 'tweet*')" brings up 234 papers. In 2015, Imran et al. (2015) publish a survey on the use of AI methods to process social media messages for mass emergencies. Imran et al. explore three main challenges: data pre-processing, event detection and characterization, and aggregation into actionable information for end-users. Whatever the challenge addressed, the AI methods listed in this article remain classic, i.e. trained to perform the specific, often supervised tasks of topic modeling, message classification, named entity recognition and text summarization.

The observation can also be generalized to AI applications in crisis management for processing all other types of data (satellite and aerial imagery, sensors, remote sensing robotics, for instance), as shown by the very comprehensive systematic literature recently proposed by Sun et al. (2020) with the development of AIs highly specific to the tasks they perform. Kyrkou et al. (2023) raises the challenges that the state of the art is currently tackling:

- a broadening of the data types processed, using multi-modal models to solve problems of heterogeneity (joint processing of text and images, in particular)
- the ability to generalize and adapt AIs to new situations by generating learning data (through generative AI or the use of digital twins, lowering in the same way the cost and time of training datasets devlopment to supervise AIs)
- the enhancement of user confidence through explicability
- algorithm security

Today's learning-based AI methods are reviving the literature on automated data processing in crisis management with definite avatars:

- far greater generalization capacity than knowledge-based systems, making them highly adaptable
- deeper and deeper learning thanks to the use and fine-tuning of accessible foundation models, enabling excellent performance.

Nevertheless, work on the use of machine or deep learning algorithms in crisis management is focused on very specific tasks, the relevance of which is not always assessed in real time during the occurrence of a crisis whose stakes are always very specific (for example, different floods in different contexts for different responders require the analysis of aerial imagery in different ways). Furthermore, while the multimodal capability of algorithms now makes it possible to broaden the spectrum of types of data processed, the ability to select relevant data for processing and to produce different points of view and level of composing on the same system is not possible under the governance of these AIs.

All these features qualify ML and DL-based systems as ideal candidates for the realization of a SA.

Neuro-Symbolic Approaches

The SA paradigm suits fast individual decision-making, while the Sensemaking paradigm is for groups facing ambiguity, needing collective knowledge, inferences, and diverse perspectives to reach a shared understanding. The translation of this problem to AI is not obvious.

Although not new, neuro-symbolic AI approaches are currently undergoing a revival in tandem with advances in connectionist AI. The temptation is great to hybridize these two approaches in order to benefit from the advantages of each paradigm. Hitzler et al. (2022) notes a second reason for this flourishing, coming directly from the cognitive sciences: "we can understand artificial neural networks as an abstraction of the physical workings of the brain, while we can understand formal logic as an abstraction of what we perceive, through introspection". Wang et al. (2022) exposes the ability of human cognition to juggle 4 dimensions of symbolism and connectionism: Symbols vs Neurons, Deduction vs Induction, Compositionality vs Continuity and System 1 vs System 2. The first two dimensions are fairly common. It is nevertheless important to focus on the other two. *Compositionality vs Continuity Continuity* refers to the sequential activation of neurons in a continuous but variable signal (notably in the "weight" of information circulating) transmitted from neuron to neuron. *Compositionality* refers to the encoding of information in more or less large structures, enabling the generation of composite knowledge representations at variable levels of abstraction. *System 1 vs System 2* Kahneman (2011) proposes that human brain is composed of two conceptual systems. *System 1* is fast and intuitive but can be sometimes imprecise and *System 2* is logical, delibirative and conscious but slower and requires concentration.

In light of this, the literature shows that neuro-symbolic systems are particularly promising for implementing a form of dynamic between the perception of a situation and its understanding according to several levels of composition and expertise in dynamic environment under uncertainties, as required by the Sensemaking's *horizontal* and *vertical* processing of data. Recent articles such as (Booch et al., 2021; Dong et al., 2019) show efforts have been made in this direction. That said, Wang et al. (2022) notes that no hybridization paradigm currently allows us to effectively address the 4 dimensions between symbolism and connectionism sought in the Sensemaking process.

Limits of Current AIs to Meet Information Needs

In conclusion, several observations can be made concerning the state of the art. With regard to the information needs of decision-makers and the improvement of decision-support systems (particularly at this stage of understanding the situation), this is a complex and multifaceted cognitive and human process that is difficult to generalize. It involves coordinating different interpretations at different levels, depending on the scale of the crisis, the expertise involved and the often heterogeneous vocabularies, in a highly dynamic context that is unexpected at each subsequent event.

AI, with its advanced capabilities for processing massive data flows, has become a valuable ally in the development of modules for understanding crisis situations in real time in decision support systems. Symbolic AIs enable logical inferences to be defined and proposed on the basis of a vocabulary established by users, according to their needs. This includes early warning systems: for example, Fertier et al. (2020) offers an expert system based on listening to water level sensors combined with business rules collected from experts in the field (belonging to various institutions such as the Centre for studies and expertise on risks, the environment, mobility and development, Regional Department for the Environment, Planning and Housing, Regional Road Information and Coordination Centre, Interministerial zone headquarters). This type of system proves very effective to infer and confront information when the context of the crisis has already been anticipated and studied (even if it has not yet been encountered in the past), and is based on a strict vocabulary established in advance of the crisis. The dynamic context of the crisis is taken into account as

long as the business rules effectively respond to the conditions encountered in real time. Setting up such systems is laborious, not only in algorithmic terms but also time-consuming for the experts, given the complexity of the systems studied. This severely limits the adaptability and realism of such AIs, and shows the need to mix them with more flexible approaches.

ML and DL, by their mechanism of training by past experience, show remarkable capabities for adaptation and generalization, while drastically reducing the demands made on experts. Such systems are extremely useful for reducing the time taken by humans to monitor data, allowing them to devote their attention to tasks linked to the decision-making itself. For example, Suwaileh et al. (2022) offers such an AI dedicated to inferring geolocation of social media posts during a disaster for humanitarian purposes, based on very few data. Unlike an expert system, the AI allows extremely rapid inference, without having to draw up exhaustive lists of potential locations and their grammatical uses (an otherwise unrealistic task). However, these AIs respond to very specific tasks that need to be defined in advance of a crisis and cannot be created on the fly during a crisis, should new types of information prove interesting to extract.

While symbolic AIs make it possible to mimic expert control of the situation understanding process, ML and DL are AIs that are themselves controlled by humans, capable of carrying out tasks flexibly. So, with the aim of establishing AIs close to the needs of the Sensemaking process, neuro-symbolic approaches make it possible to imagine autonomous, flexible and realistic situation understanding modules in future decision support systems.

PROPOSAL

The finding shared by Kautz (2022) and Wang et al. (2022) lies in the promising potential of a neural architecture embedding symbolic reasoning engines, deemed closest to Systems 1 and 2 of Kahneman (2011), to support the Sensemaking process. Whether AI should follow the path of a biological or a non-biological architecture remains a large question. There are however strong beliefs that considering the notable progress of neurosciences, bio-inspired architecture are promising (Hole & Ahmad, 2021).

Neurosciences enable us to better understand these two systems, and most importantly now highlight a so-called inhibition System 3, which plays an executive role in regulating the use of the other two Systems (Houde′ & Borst, 2014). This key role makes System 3 the seat of human reasoning, in its ability to question preconceived perceptions and models, and to consider situations both holistically and with subtlety, especially thanks to the ability of meta-cognition given by System 3. However, while we have shown that the AI literature is interested in using the System 1 and System 2 paradigms to propose a hybridization architecture, no proposals have been made for System 3.

This section therefore aims to propose a new high-level integration architecture of a hybrid neuro-symbolic AI inspired by the System 3 allowing both *Compositionality* of the reasoning and *Continuity* of the information flow through neural networks.

We present this proposal in two parts. The first subsection focuses on the observations and theories currently proposed by the neurosciences around three biological subsystems - neurons, cortical columns and distributed inhibition processes - and the roles played by each in levels of human cognition. We use these 3 key biological subsystems to justify our proposal for a neuro-symbolic architecture, set out in the second subsection.

Three Key Biological Sub-Systems for the Human Cognition

In his book *A thousand brains: A new theory of intelligence*, Hawkins breaks down human cognitive capacity into three sub-parts that are found in the human neocortex possessing both *hierarchical - i.e. vertical, in columns -* and *distributed - i.e. horizontal, interaction and voting -* roles.

Neurons

Neurons are the basic building blocks of the human neocortex, transmitting information through impulses. When stimulated, a neuron generates an action potential that travels down its axon, leading to the release of neurotransmitters at the synapse, facilitating communication with other neurons. The structure of neural networks is dynamically influenced by experiences through a phenomenon known as neuroplasticity. When engaging in new situations, the connections between neurons, can be strengthened or weakened. Over time, the observations show that repeated experiences can lead to long-lasting changes in neural pathways, contributing to the continuous evolution of the brain's structure and functionality.

Thanks to their ability to transmit the information in a distributed and loose way, neurons ensure the *Continuity* of the cognitive system. Moreover, the neural map at time t represents the knowledge stored by the individual at this exact instant.

Cortical Columns : One Model Generation

The cortical columns of the neocortex are highlighted by Mountcastle's work in 1957 (Mountcastle, 1957). Cortical columns are sensory-motor systems of the neocortex made up of vertically aligned neurons, all with the same laminar structure and consisting of "functional units of information processing". They perceive data from outside, process it through a back and forth circulation of data and provide specific models of sub-systems of the environment. According to Hawkins et al. (2017), cortical columns "learn complete predictive models of observed objects". Thanks to neural sparse connections between columns, one cortical column can infer models of objects based on the partial knowledge of the adjacent columns, hence ensuring low-level information complementarity in the construction of a model.

The ability of the columns to create atomic models of objects in the environment from individual points of view contributes to the cognitive capacity of *Compositionality*. Models can be closely related to symbolic representations of the environement. Moreover, the ability to inhibit the flow of information from neuron to neuron within the columns at the neuronal level, also associates it with capacities close to those of Kahneman's two systems.

Inhibition and Voting Process : Several Models to One Perception

Mountcastle (1997) observes that columns can also be linked to each other by long-range connections. Hawkins (2021) defends the existence of a voting process by which the thousands of models produced by cortical columns offering different points of view of the same environment can be reconciled into a single, also stable, perception of the environment. These long-range connections enable precisely this process of voting between columns.

Houde´ and Borst (2014) describe a comparable inhibition process that associates Kahneman's two systems with a higher-level executive system (meta-cognitive) that is nonetheless clearly distributed within the neocortex. Inhibition System 3 enables us to implement a conscious deductive approach in response to unknown or complex situations.

The regulatory capacity provided by these two complementary theories enables a high-level compromise between *Compositionality Continuity* by reconciling the model of an object underpinning several points of view and levels of submodels, and thereby ensuring cognitive consistency over time. Such higher-level inhibitory system (at a meta-cognition level) is typically not proposed by Hole and Ahmad (2021).

Perspectives for a Bio-Inspired Neuro-Symbolic AI Architecture for Sensemaking Support

Inter-Disciplinary Framework

Figure 3 presents a framework that summarizes and justifies how neurosciences can, through the three levels of neurons, cortical columns and inhibition and voting processes, inspire the creation of AI responding to the very specific informational needs questions demanded by the three paradigms of COP, SA and Sensemaking.

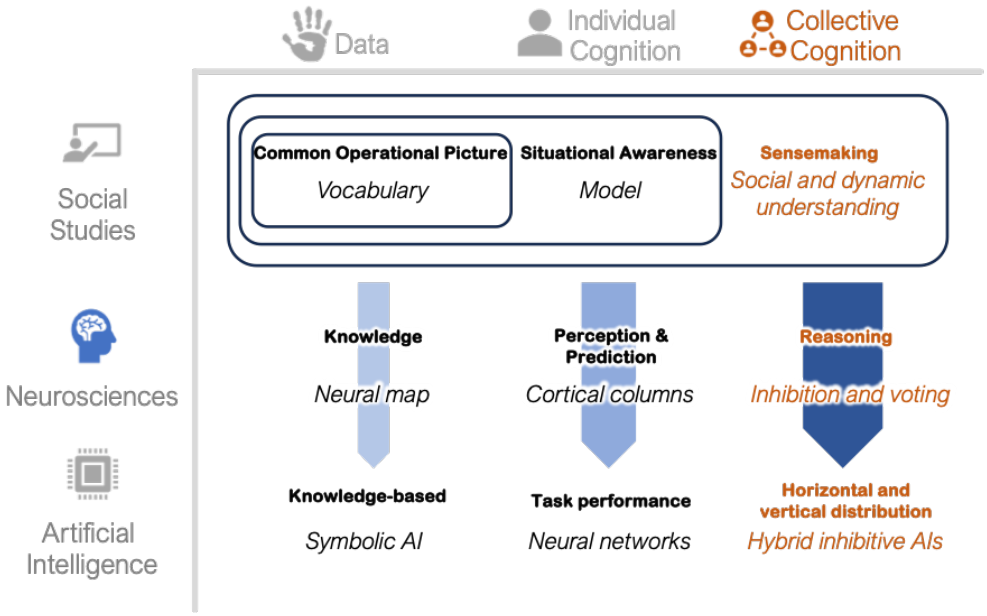

Figure 3. Neuro-sciences as a promising pivot to create new AI aligned with the crisis managers' informational needs.

Bio-Inspired Neuro-Symbolic AI Architecture

Based on neuroscientific observations of human reasoning, we can extract a number of specifications for the construction of a bio-inspired neuro-symbolic AI, capable of embodying the notions of *Compositionality*, *Continuity* and those contained in Kahneman, Houde´ and Borst's *Three Systems* and support Sensemaking.

- **Sequencing neural networks within columns**: sequencing neural networks ensures *Continuity* in the flow of information. On the one hand, deeper neural networks enable a complex level of abstraction, by producing more higher-level of aggregation of the input data. In terms of sense Sequencing neural networks thus addresses the *verticality* problem of Sensemaking.
- **Parallelization of columns**: in the same way that cortical columns are used in human cognition as individual computational units enabling atomic models (a point of view, a subsystem - *Compositionality*) of an environment to be established in a parallelized processing process with different data, we propose to parallelize neural networks. The more neural networks there are in parallel, the wider the scope of possible perception by integrating more data sources. In order to share partial models, like adjacent cortical columns, neural connections can be set up between columns. Parallelization of neural networks thus makes it possible to address the *horizontality* problem outlined of Sensemaking.
- **Executive system distributed on two levels**: an executive inhibition system regulates the use of columns on two levels. At a meta-level, a voting process is used to unify the models produced by the columns into a situation model delivered to the crisis manager, thus meeting contextualized information needs. To make this possible, a second process, this time inhibitive, is implemented to regulate the use of columns according to their relevance (i.e. signals perceived from the outside) and the connections between columns. The interest of such an executive system is to ensure coherence between (i) the informational models generated and (ii) the cognitive reasoning implemented within and between the columns. Thus, this executive system is at the heart of the concerns in the development of such an AI architecture: it no longer addresses vertical and horizontal problems independently, but proposes an architecture that is adaptive to needs on both dimensions.

CONTRIBUTIONS, LIMITS AND PERSPECTIVES

This paper makes two contributions: (i) while no AI in the literature is currently capable of supporting the collective cognitive effort made during Sensemaking, current knowledge of the cognitive mechanisms of the human brain observed in neurosciences allows us to propose a pivot between informational needs and the implementation of adapted AIs ; (ii) the proposal of a new AI architecture based on voting and inhibition mechanisms distributed between cortical columns enables us to envisage meta-cognitive capacities capable of supporting Sensemaking in its *horizontal* and *vertical* dimensions (see contributions on Figure 3).

That being said, the proposal remains at its early stage and especially needs further investigations that are the current perspectives of this proposal:

- **Methodologies to better understand mechanisms involved in human cognitive executive system** : current medical imaging techniques do not allow to observe inhibition behaviours at the neuronal level. Hence, very specific experimental methodologies must be implemented to allow a proper control of all parameters and to enable in-depth conclusions to be drawn.
- **Transferring human tests to AI tests**: tests usually carried out by humans to observe their cognitive mechanisms are not directly transferable to AI (for example, the Strooper test - Color-Word Interference Task - requires inhibition on the part of the human, but remains a very simple test for computers).
- **Evaluation of the AI performances** : new measures need to be created to (i) evaluate the predictions generated by this type of AI, given that they would not be dedicated to a single task (ii) and evaluate the added value of this AI according the two-dimensions (horizontal and *vertical*) of Sensemaking.

ACKNOWLEDGEMENT

We acknowledge the use of an AI for translation purposes.

ABSTRACT

Artificial Intelligence (AI) in Emergency Management integration has become crucial to improving crisis response efficiency and effectiveness. AI presents new paradigms for responding to emergencies but poses technical and operational challenges, ethical considerations, and the need for robust regulatory frameworks. The study examines various AI applications in emergency scenarios and employs a systematic literature review methodology to identify solutions and future directions for ethical and effective AI integration. The findings highlight the critical balance between leveraging AI capabilities and ensuring safety, privacy, and ethical compliance. Understanding AI's full scope and potential in this critical field is essential as we navigate technological advancements. The article contributes to understanding AI's potential to transform emergency management practices and emphasizes the importance of ethical considerations and regulatory frameworks.

Keywords

Artificial Intelligence, Emergency Management, Ethical Considerations, Technologies.

INTRODUCTION

Integrating Information and Communication Technologies (ICT) and Artificial Intelligence (AI) in emergency management is a transformative development representing a significant shift in how societies respond to crises. The deployment of AI applications in emergency scenarios has the potential for profound positive impacts but also carries inherent risks, thus necessitating a rigorous ethical framework. The central focus of this discourse is the application of AI to enhance the efficacy of emergency responses while navigating the complex ethical landscapes these technologies inhabit.

AI-powered tools in emergency management have the potential to revolutionize the traditional approaches to crisis response. They leverage advanced signal processing and systems analysis techniques commonly used in fields such as aeronautical engineering and medical diagnostics. When applied to emergency management, these methodologies

provide unprecedented capabilities in real-time evaluation of complex and dynamic situations, offering actionable intelligence to support informed decision-making.

The widespread use of sensors has resulted in the generation of rich data streams, which provide a unique opportunity to enhance emergency response situational awareness and responsiveness. Additionally, advancements in AI methodologies, such as Machine Learning (ML) and cognitive computing, offer potential solutions for addressing the complex challenges of large-scale emergencies (Freeman, 2020; Yadav, 2024). Emergency management can significantly improve efficiency and effectiveness by utilizing AI for predictive analysis, incident detection, resource allocation, and deployment. These developments offer the possibility of reducing human and financial losses and promoting more sustainable environmental practices, which can mitigate the pressing global challenges through innovative AI applications.

The main aim of this section is to carry out a targeted literature review to highlight the recent developments and emerging trends in integrating AI into emergency management. The study is centred around three key areas: firstly, exploring how AI tools can improve the efficiency and effectiveness of emergency management while identifying any associated technical and operational challenges and secondly, examining the necessary regulatory frameworks for the safe use of AI in emergency management. Lastly, the study delves into the ethical implications of employing AI in emergency management.

The structure of this paper is outlined as follows: Section II discusses the background, highlighting the role of AI in emergency management, including technological challenges and ethical considerations. Section III describes the methodology used for the systematic literature review. Section IV analyzes and presents findings from the literature review. Finally, the paper concludes with a discussion and conclusions, emphasizing the potential for future research, the strengths and weaknesses identified in the study, and the overall conclusion.

BACKGROUND

AI is undergoing rapid change, particularly in its application to emergency management. However, this integration of AI poses both technological challenges and ethical considerations throughout all phases of the emergency management cycle, from preparation to response and post-disaster recovery. Ethical considerations must be prioritized when deploying AI technologies in emergency situations, ensuring adherence to ethical standards and promoting equitable outcomes. Furthermore, AI's role in promoting sustainable development and enhancing resilience is crucial, highlighting the broader implications of AI applications beyond immediate emergency response scenarios (Freeman, 2020).

AI will play a critical role in emergency management by enhancing the abilities of first responders to handle various crises, including natural disasters and industrial incidents. This is achieved by developing advanced Situation Awareness (SA) models that incorporate real-time sensor data, enabling dynamic decision-making. The European ASSISTANCE project is a prime example of this, as it has created an actionable SA (aSA) module that integrates AI technology with sensor data to predict and display gas distributions in emergency scenarios. This module aids first responders in their decision-making processes. (Mioch et al., 2021)

A study conducted in Xuwen County, China, examined the impact of AI applications on public perception and trust related to emergency management services. The study found a significant positive correlation between public expectations of emergency management services and their satisfaction with these services. The introduction of AI governance, characterized by scientific prediction, prevention, and management, plays a vital role in mitigating the damage caused by natural disasters and strengthens public trust in government services. This shift towards AI-driven governance can revolutionize traditional emergency management models, fostering a more harmonious relationship between the government and the public (Chen et al., 2023).

The findings suggest that in the future, emergency management will heavily depend on AI technologies for efficient response and to satisfy the public. By integrating AI in emergency response, decision-making processes can be streamlined, and a trust-based relationship can be established between emergency management authorities and the public. This advancement implies a more responsive, efficient, and publicly endorsed emergency management framework that harnesses AI's capabilities to meet the complex demands of modern crises.

RESEARCH METHOD

A systematic review uses a detailed, reliable, iterative, and thorough methodology, which includes planning, conducting, and reporting the review, as outlined by the Kitchenham and Charters, 2007 methodology.

Planning the Review

This systematic review aims to gather and analyze the tendencies, challenges, and solutions to provide a nuanced theoretical understanding and practical strategies for the ethical integration of AI technologies into emergency management systems. This work will support a discourse on ensuring that AI implementation aligns with ethical standards and supports the resilience and efficacy of emergency responses.

Three pivotal research questions guide this study, each reflecting the urgent need to explore the expansive role of AI within the domain of emergency management:

RQ1. How can AI tools enhance emergency management, and what are the inherent technical and operational challenges?

RQ2. What regulatory framework is required to support AI's safe and ethical adoption in emergency management while fostering innovation?

RQ3. What are the ethical implications of employing AI in emergency management, and how can we ensure transparency and accountability in its applications?

Data Source Identification and Search Strategy

To collect primary studies, we referred to the digital libraries of prominent organizations, such as Scopus, WoS, and the Iscram Library. Our search focused on the past five years, from 2019 to January 2024, to capture the latest trends in AI.

Our study covered conference proceedings and journal articles, thoroughly examining paper titles and abstracts. Considering their unique syntax, it's important to mention that the search string notation was tailored for each digital library. The search query employed was:

- Scopus and WoS : ("Artificial Intelligence" OR "AI") AND ("emergency management" OR "crisis management" OR "disaster response") AND ("regulations" OR "ethical considerations" OR "legislation" OR "law*") AND ("tools" OR "technologies" OR "applications")
- Iscram Library: ("Artificial Intelligence" OR "AI")

Criteria for Selecting Primary Studies

The criteria for selecting primary studies involve an automated search through digital libraries using a predefined search string. However, it's possible for retrieved articles to not directly align with the study's focus, even if they contain the search string terms in their titles and abstracts. Hence, to ensure a consistent approach in including or excluding articles, we refer to the criteria outlined in Table 1. Articles meeting these criteria will be accepted or rejected based on their alignment with the study's focus.

Quality Assessment

In assessing studies selected for our investigation on the integration of AI in emergency management, we applied predefined inclusion, exclusion, and quality assessment criteria. Initially, we identified studies that specifically addressed the application of AI in emergency management scenarios, including those that discussed technical and operational challenges, regulatory frameworks, and ethical implications and provide case studies or practical applications. Studies not focused on AI in emergency management, lacking in academic rigour, or not within the scope of our research questions were excluded. For the quality assessment, each study underwent a thorough evaluation by five reviewers, focusing on criteria such as the clarity of AI application, the depth of analysis regarding challenges, discussions on regulatory and ethical considerations, methodological rigour, relevance and currency of the research, and its contribution to the field. Scores were assigned as Low, Medium, or High based on a consensus between the reviewers for each criterion. This rigorous process ensured that only studies of high relevance and quality were considered for our analysis, facilitating a robust synthesis of current knowledge and practices in using AI for emergency management.

Table 1. Inclusion and Exclusion Criteria for AI in Emergency Management Research

Criteria Type	Inclusion Description	Exclusion Description
Thematic Scope	Focuses on AI applications in emergency management, including technical and operational challenges.	Irrelevant to AI or emergency management, covering areas not focused on these topics.
Regulatory and Ethical Framework	Examines regulatory and ethical frameworks for safe and ethical AI adoption in emergency management.	Works that do not address regulatory or ethical aspects of employing AI in emergency scenarios.
Publication Type	Peer-reviewed journal articles and conference reports providing innovative insights.	Non-peer-reviewed publications, blogs, news articles, and non-academic content.
Publication Period	Published within the last five years for relevance.	Publications older than five years, considered technologically obsolete.
Language	English publications for international accessibility.	Non-English documents without available translation.
Research Methodology	Empirical, qualitative, quantitative, or mixed methods studies.	Opinions, editorials, and articles without a solid empirical or theoretical foundation.
Case Studies and Practical Applications	Includes real-world applications or case studies of AI in emergencies.	Theoretical studies without practical applications or real-world case studies.

Data Extraction Strategy

We categorized the research inquiries into various criteria to extract data from the chosen primary studies. Table 3 provides an overview of the data extraction criteria (EC) for classifying the gathered solutions and applications. The data extraction criteria and their options are described as follows:

EC1 *Innovations and Technologies*: What innovations and technologies are being utilized or explored in this context?

EC2 *Domain Described*: What is the primary domain or area of study where these AI applications are being utilized?

EC3 *Technical and Operational Challenges*: What technical and operational challenges are faced when implementing these AI applications?

EC4 *Impact on Efficiency and Effectiveness*: How do these AI applications impact the efficiency and effectiveness of the operations?

EC5 *Case Studies or Practical Application Examples*: Are there any case studies or practical examples where AI has been applied successfully in this field?

EC6 *Existing Regulatory Frameworks*: What regulatory frameworks currently govern the use of AI in this domain?

EC7 *Ethical Considerations*: What ethical considerations must be considered with the use of AI in this area?

EC8 *Model Used*: What AI models or methodologies are being employed in these applications?

The criteria corresponding to EC1, EC2, EC3, EC4, and EC5 correspond to RQ1, EC6 to RQ2, and EC7 and EC8 to RQ3.

Conducting the Review

The process of identifying primary studies in digital libraries took place in January 2024, resulting in the acquisition of thirty-five papers. There were instances of duplication among these papers due to their presence in multiple digital libraries. Table 2 shows the distribution of papers across different digital libraries, along with the screening process at each stage, culminating in the total number of studies incorporated into the review.

The selection of papers followed specific inclusion and exclusion criteria. Notably, many papers sourced from digital libraries were initially considered potential candidates based on the presence of the search string in their titles and abstracts. However, upon closer examination, including full paper scans, it became evident that the topics diverged from the scope of our investigation. Consequently, eighteen papers were ultimately selected for our study. The selected studies by the database are shown in Figure 1.

Table 2. Results of conducting stage

Source	*Potential Studies*	*Removing duplicates*	*Scanning title and abstract*	*Selected Studies*
Scopus	16	16	12	6
WoS	6	2	1	0
Iscram Library	13	13	12	12
Total	35	31	25	**18**

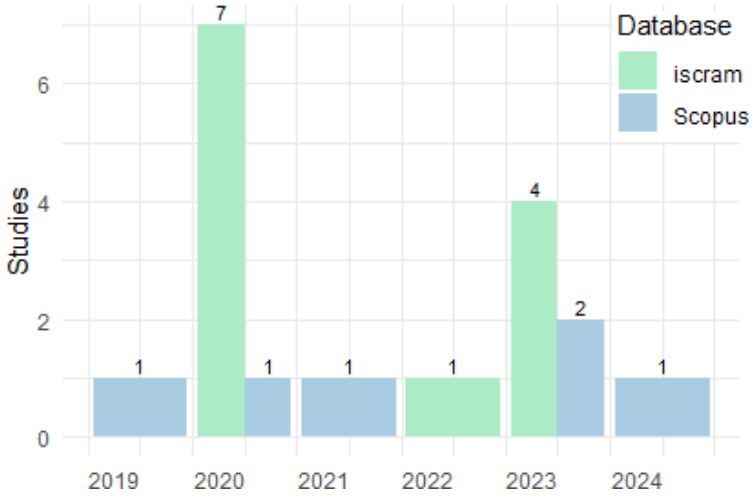

Figure 1. Annual Distribution of Selected Studies by Database

ANALYSIS AND FINDINGS FROM THE LITERATURE REVIEW

The systematic review found eighteen selected studies. Table 3 summarises the extracted information quantitatively (for a detailed synthesis of the selected studies, please refer to Appendix A).

Each data extraction criterion and the obtained results are discussed.

EC1. Innovations and Technologies

In the domain of emergency management, recent literature has illuminated the significant role of AI and ML in pioneering Innovations and Emerging Technologies. Machine Learning is the most prominent area, accounting for 27.78% of the studies (Farasin et al., 2020; Imran et al., 2020; Ortiz et al., 2020; Palomba et al., 2020; Ramsey et al., 2023). This is followed by Generative AI (Freeman, 2020; Karinshak, 2024; Tsai et al., 2023) and Neural Networks (Jiang et al., 2021; Moumtzidou et al., 2020; Wu & Shan, 2021), each comprising 16.67% of the research. Decision Support Systems, although significant, represent a smaller portion at 11.11% (Nussbaumer et al., 2023; Suciu et al., 2021). These results demonstrate a diverse range of interests within the field of AI, highlighting Machine Learning as the most extensively explored area.

Systems like Sahana EDEN exemplify the integration of AI into disaster management, enhancing emergency response capabilities (Nussbaumer et al., 2023). The serious game format has been utilized to elucidate AI applications in crisis contexts (Adam & Lauradoux, 2022), while the synergy of crowdsensing with AI signifies a novel approach to emergency solutions (El Barachi et al., 2020). The emergence of commercial gaming technologies such as Oculus Rift and Photon Cloud marks a notable advancement in creating immersive environments for training emergency responders (Sharma et al., 2019). The CitizenHelper system (Pandey et al., 2020) and the adoption of platforms like Google Dialogflow for chatbots (Tsai et al., 2023) demonstrate the innovative use of real-time, AI-infused analytics and conversational interfaces in emergency management training. Further, computational creativity has been applied to scenario modelling, and pyramid ConvLSTMs have been introduced to enhance high-dimensional data analysis for emergency scenarios (De Nicola et al., 2019; Jiang et al., 2021). Integrating VR for immersive training and AI for data analysis reflects a commitment to developing sophisticated training solutions (Xia et al., 2022). Progress in flood detection has been achieved through semantic segmentation and

ML, while AI's predictive analytics are increasingly utilized for emergency preparedness and response (Ortiz et al., 2020; Suciu et al., 2021). Combining AI with crowdsourced human feedback for image categorization (Imran et al., 2020). Applying Random Forest and U-Net models to satellite imagery is a testament to the evolving intersection of human intelligence and AI (Palomba et al., 2020). The innovative application of deep learning to satellite data, especially using Sentinel-2's capabilities, transforms crisis management (Farasin et al., 2020). Moreover, developing interactive visualizations for explaining complex ML models enhances the interpretability of AI (Ramsey et al., 2023). AI-based predictive dispatch for emergency vehicle routing underscores the efficiency gains possible in emergency fleet management (Landsberg et al., 2020). Collectively, these studies showcase a trend towards technologically sophisticated, efficient, and adaptive emergency management systems.

EC2. Domain Described

In the context of emergency management and crisis management, studies have explored a diverse range of areas. This theme represents the primary focus, accounting for 83.33% of 15 studies. The research encompasses natural disaster scenarios (Karinshak, 2024; Moumtzidou et al., 2020; Nussbaumer et al., 2023; Pandey et al., 2020; Tsai et al., 2023; Xia et al., 2022), education and society (Adam & Lauradoux, 2022), and the use of crowdsensing and social media (El Barachi et al., 2020). Integrating satellite-based flood mapping in crisis management is another significant area, as shown in Moumtzidou et al., 2020.

Public health, another important domain, contributes 16.67% with three studies (Adam & Lauradoux, 2022; Ramsey et al., 2023; Wu & Shan, 2021). Training, essential for AI application, comprises 11.11% (Pandey et al., 2020; Xia et al., 2022). Among these, studies Wu and Shan, 2021 and Sharma et al., 2019 delve into social governance and public health emergencies, underscoring AI's crucial role in complex scenarios. The deployment of technologies in smart cities for pandemic management and earthquake risk is detailed in (Pandey et al., 2020) and (Tsai et al., 2023).

EC3. Technical and Operational Challenges

Technical and Operational Challenges constituted 94.44% of the research with 17 studies. This is followed by Emergency Management Challenges, which involve seven studies and account for 38.89% of the total research. Public Health Challenges and Disaster Response Challenges, each covered by 1 study (5.56%), represent a smaller portion of the research. Research addressing emergency management's technical and operational challenges highlights this field's diverse and complex hurdles. The unpredictable and variable nature of disasters poses significant challenges, demanding the development of robust and resilient response mechanisms (Nussbaumer et al., 2023). In serious gaming for disaster education, the primary challenge is creating engaging and informative experiences with operational relevance (Adam & Lauradoux, 2022). Integrating crowdsourced data into AI algorithms for emergency response faces the critical need for accuracy and timeliness in data analysis (El Barachi et al., 2020).

The paper Sharma et al., 2019 examines the operational challenges in emergency management, including the complex orchestration of multiple systems and stakeholders. The convergence of Virtual Reality (VR) and Artificial Intelligence (AI) in creating immersive training environments, along with the intricacies of data collection and processing, is emphasized in Xia et al., 2022.

Managing and effectively auguring vast datasets to enhance disaster response is a core focus, as delineated in (Moumtzidou et al., 2020; Wu & Shan, 2021), while Ortiz et al., 2020 concentrates on integrating varied data sources for dependable emergency management. Data preprocessing and model training, particularly challenging with limited data during emergencies, are significant operational hurdles, as discussed in Palomba et al., 2020. Additionally, Suciu et al., 2021 explores the complexities of merging different data sources and ensuring interoperability amidst a pandemic. The delicate balance required between AI precision and human judgment in damage assessment tasks is critically explored in Imran et al., 2020.

EC4. Impact on Efficiency and Effectiveness

Research emphasizes enhancing emergency response capabilities through AI-driven real-time data analysis and improving efficiency in predictive tasks (Adam & Lauradoux, 2022; El Barachi et al., 2020; Farasin et al., 2020; Landsberg et al., 2020; Suciu et al., 2021; Wu & Shan, 2021). Sharma et al., 2019 showcases the effective deployment of AI agents in collaborative virtual environments designed for emergency response training. Ramsey et al., 2023 examines the role of visualizations in enhancing the interpretation of model decisions to boost operational efficiency. Moreover, Landsberg et al., 2020 explores the potential of AI to refine dispatch strategies, which could lead to faster response times and improved patient outcomes.

Studies investigating the operational impacts highlight resource allocation challenges and the vulnerabilities arising from increased dependence on technology (Jiang et al., 2021; Nussbaumer et al., 2023; Pandey et al., 2020; Tsai

Table 3. Summary of the Result (N=18)

Extraction Criteria (EC)	Criteria	# Studies	%
EC1	Specific AI Applications	18	100%
	Decision support systems	2	11.11%
	Serious game	1	5.56%
	Crowdsensing	1	5.56%
	AI Simulation	2	11.11%
	Machine Learning	5	27.78%
	Generative AI	3	16.67%
	Virtual Reality	1	5.56%
	Neural Networks	3	16.67%
EC2	Emergency/Crisis Management	15	83.33%
	Public Health	3	16.67%
	Training	2	11.11%
EC3	Technical and Operational Challenges	17	94.44%
	Emergency Management Challenges	7	38.89%
	Public Health Challenges	1	5.56%
	Disaster Response Challenges	1	5.56%
EC4	Impact on Efficiency and Effectiveness	18	100%
	Real-time data analysis	6	33.33%
	Decision-making during response	5	27.78%
	Technological Reliance	4	22.22%
EC5	General mentions of case studies or practical application	15	83.33%
	Without specific details provided	3	16.67%
EC6	Adherence to Data Protection Laws	3	16.67%
	Alignment with Privacy Regulations	7	38.89%
	Focus on technical aspects	6	33.33%
	Not specified	2	11.11%
EC7	Ethical Considerations	18	100%
	Privacity	12	66.67%
	Bias	3	16.67%
	Data	9	50%
EC8	Model Used	14	77.78%
	Not specified	4	22.22%

et al., 2023). Selected studies also illuminate AI's advanced understanding and decision-making capabilities during crises (Adam & Lauradoux, 2022; Jiang et al., 2021). Additionally, various studies collectively identify significant improvements in training methods, flood detection, and the overall efficiency of emergency response (Moumtzidou et al., 2020; Ortiz et al., 2020; Xia et al., 2022)

EC5. Case Studies or Practical Application Examples

The results strongly focus on practical applications and case studies in AI and emergency management, with 83.33% This indicates that most of the research is geared towards applying theoretical AI concepts in real-world situations or analyzing existing case studies. In this context, Sahana EDEN is highlighted as a key solution in coordinating responses (Nussbaumer et al., 2023). A simulation game reflecting municipal council decisions during disasters offers insights into the complexity of disaster response (Adam & Lauradoux, 2022). Using drones for real-time accident monitoring is emphasized (El Barachi et al., 2020). AI's role in public health emergencies for efficient resource allocation (Wu & Shan, 2021). Also, VR is shown to be effective in Mass Casualty Incident (MCI) triage training Xia et al., 2022, while Sentinel-2 satellite imagery proves vital for environmental monitoring in natural disasters (Moumtzidou et al., 2020). The response to Hurricane Florence showcases practical technology applications (Ortiz et al., 2020). The STAMINA project illustrates AI's use in disaster management (Suciu et al.,

2021). The rapid damage assessment during Hurricane Dorian demonstrates the importance of swift evaluations post-disaster (Imran et al., 2020).

Additionally, AI's application for crisis management reflects its adaptability (Palomba et al., 2020). While lacking in detail, another study indicates AI's broad potential in disaster management (Karinshak, 2024). AI's practicality in real-world scenarios is also exemplified (Farasin et al., 2020), including its use in monitoring bridge health during natural disasters (Ramsey et al., 2023). Finally, AI's role in predicting disease spread is presented, underlining its importance in disaster planning and response (Landsberg et al., 2020). However, 16.67% of the references lack specific details, suggesting these discussions are more general or conceptual (Pandey et al., 2020; Sharma et al., 2019; Tsai et al., 2023).

EC6. Existing Regulatory Frameworks

The outcomes of our research reveal various dimensions in the study of using AI in emergency contexts within existing regulatory frameworks. Studies such as El Barachi et al., 2020, Wu and Shan, 2021, and De Nicola et al., 2019 emphasize adherence to data protection laws and the broader regulatory landscape encompassing AI in emergencies, accounting for three studies or 16.67% of the sample. The importance of aligning AI applications with regulations like the General Data Protection Regulation (GDPR) and German privacy laws is underscored in Farasin et al., 2020, Ramsey et al., 2023, and Landsberg et al., 2020, representing seven studies or 38.89%. In contrast, a focus on technical aspects, accounting for six studies or 33.33%, is seen in works that overlook in-depth regulatory discussions (Moumtzidou et al., 2020; Ortiz et al., 2020; Pandey et al., 2020; Sharma et al., 2019; Tsai et al., 2023; Xia et al., 2022). Nussbaumer et al., 2023 suggests that ethical imperatives should guide software development principles rather than directly addressing regulatory frameworks. Similarly, Adam and Lauradoux, 2022 focuses on the ethical and societal implications, prioritizing these over formal regulations. Jiang et al., 2021 addresses data privacy and user consent linked to regulatory compliance, while Karinshak, 2024 emphasizes ethical guidelines and advocates for a normative regulatory approach. Studies not specified in these categories account for two or 11.11% of the sample.

EC7. Ethical Considerations

A detailed analysis of ethical considerations in AI research is extensively covered by 18 studies, representing the entirety (100%) of this segment, including references This comprehensive coverage underscores the importance placed on ethical issues in AI research.

Privacy emerges as a crucial area of concern. A significant number of studies (12, accounting for 66.67%) delve into privacy issues, emphasizing the pervasive nature of privacy considerations in AI research highlight bias in data and algorithms, reflecting a critical awareness of potentially skewed interpretations and the need for unbiased computational methods (Adam & Lauradoux, 2022; Pandey et al., 2020; Wu & Shan, 2021).

Data handling and protection are also key areas of focus. Nine studies (50%) shed light on the importance of secure and ethical data management practices (De Nicola et al., 2019; Farasin et al., 2020; Jiang et al., 2021; Landsberg et al., 2020; Moumtzidou et al., 2020; Pandey et al., 2020; Suciu et al., 2021; Wu & Shan, 2021; Xia et al., 2022).

EC8. Model Used

A significant majority of the studies (14 out of 18, or 77.78%) specify the models they employ, including . These studies demonstrate a broad application of diverse computational techniques and models across different domains. In this sense, ML models and techniques are notably utilized, as indicated by studies (Ortiz et al., 2020; Pandey et al., 2020; Wu & Shan, 2021). Particularly, Wu and Shan, 2021 stands out for its implementation of neural network models and expert systems, highlighting the versatility of neural-based approaches and the reliance on structured knowledge.

Deep learning techniques, known for their depth and complexity, are employed in studies like (El Barachi et al., 2020; Jiang et al., 2021), reflecting their growing importance in extracting intricate patterns and insights from data. Karinshak, 2024 explores generative AI models for simulations and the broader application of generative AI, showcasing innovative uses of AI in creating dynamic and predictive environments. The role of AI in image processing is emphasized in Imran et al., 2020, enhancing the analysis and interpretation of visual data. Moreover, Palomba et al., 2020 presents the application of Random Forest models, exemplifying the use of ensemble learning methods for robust decision-making processes. On the other hand, a smaller proportion of studies (4 or 22.22%) do not specify the models used El Barachi et al., 2020; Nussbaumer et al., 2023; Tsai et al., 2023; Xia et al., 2022.

This diverse application of technologies, from ML to generative AI models, demonstrates the expansive reach and potential of AI and computational methods in advancing both research and practical applications.

Discussion

Strengths and Challenges

Integrating AI and ML in emergency management has highlighted several key strengths. A prominent one is the varied *AI Applications* in different contexts such as crisis scenario games and crowd sensing. Systems like Sahana EDEN are notable examples, significantly enhancing emergency response capabilities. In the realm of *Training*, technologies like Oculus Rift have revolutionized immersive training environments, while platforms like Google Dialogflow showcase the innovative use of AI in real-time analytics. *Data Analysis* has also seen advancements with tools like pyramid ConvLSTMs, demonstrating a commitment to developing sophisticated AI solutions. The *synergy between AI and Human Intelligence* is increasingly evident, with AI being combined with crowdsourced feedback for tasks such as image categorization. This synergy is further exemplified by applying models like Random Forest to satellite imagery. Lastly, a major strength lies in the *Transformation in Crisis Management*, where the use of deep learning on satellite data and the development of interactive visualizations for complex ML models enhance the interpretability of AI and lead to greater efficiency in emergency management.

However, the field also has notable challenges, representing key areas for future research and innovation. The unpredictability and variability of disasters present significant hurdles in developing robust and resilient AI-based response mechanisms. The user-friendliness and accessibility of serious gaming experiences, particularly for people with disabilities, is crucial for effective disaster education and remains an area needing improvement. Another challenge is ensuring the accuracy and timeliness of data for emergency responses, where AI support is essential yet still evolving. Careful attention to data collection and processing is necessary in virtual reality training integrated with AI. Another vital aspect is managing large datasets and ensuring their interoperability to improve disaster responses. Balancing AI precision with human judgment, especially in critical tasks like damage assessment, remains a crucial concern. Legal and data processing challenges, particularly in complex regulatory environments like Germany, also underline the need for harmonious legal frameworks and efficient data processing protocols. These challenges highlight the multifaceted nature of AI applications in emergency management and underscore the importance of ongoing research and development in addressing these issues effectively.

Highlighting the Potential for Future Research

Recent research in AI for emergency management underscores the importance of integrating ethics, enhancing communication, and ensuring interoperability. There is a growing need for further research into privacy-preserving AI techniques to bolster data analysis and establish secure data collection and sharing protocols with a strong emphasis on privacy. Advanced platforms in virtual environments are recommended to improve emergency response training and increase user engagement. The importance of integrating diverse data sources for better pattern recognition and chatbot refinement in disaster management is underscored, particularly in Indigenous communities, highlighting the need for cultural sensitivity in AI applications.

Continued research in AI ethics and regulation is crucial, focusing on enhancing model accuracy and efficiency. The expansion of VR and AI technologies for training and the development of broader AI tools for emergency management is advocated. Collaboration between humans and AI is vital, particularly in refining algorithms for various risk scenarios. The expansion of datasets and improvement of models are also essential, with an emphasis on ethical AI usage. Proposals for technological advancements include adopting cutting-edge data-cleaning technologies and improving visualization techniques to enhance data presentation. A major area of focus is increasing predictive accuracy in incident management and emergency vehicle routing, exploring AI's potential in areas such as predictive firefighting.

These recommendations collectively shed light on the future directions for integrating AI into emergency management, pointing towards a path of ethical and effective AI use in this critical field.

CONCLUSION

The integration of AI in the field of emergency management presents both groundbreaking opportunities and significant challenges. Various studies highlight the importance of incorporating ethics into information systems, improving communication and interoperability, and safeguarding privacy. It is recommended that serious games be used as educational tools for AI and its ethical implications and that further research into privacy-preserving AI techniques be conducted.

The findings suggest expanding AI applications in diverse cultural contexts and developing culturally sensitive AI solutions for disaster management. Expanding the use of VR and AI in training and developing AI tools for a wide range of emergency management applications is critical to enhancing the accuracy and efficiency of AI models.

For our future work, we plan to take a comprehensive approach to exploring the cultural, psychological, and logistical challenges of implementing AI in emergency settings. This will help us better understand how AI can effectively integrate into emergency management. In addition, our focus will be on identifying and investigating potential areas for further research and development. By doing so, we aim to extend the scope of our current study and improve its relevance and impact on AI applications in emergencies.

ABSTRACT

This study reports findings from a survey administered in 2023 to investigate New Orleans households' social support networks: family and friends who can provide them with accommodations and other assistance during evacuations caused by hurricanes and other hazards. Findings describe the demographics and evacuation destination and accommodation intentions of households with and without social support, as well as the factors these households consider when choosing an evacuation destination. Preliminary findings show that 86% of respondents report at least one relative or friend with whom they can stay during an evacuation. However, the range and size of respondents' social support networks vary and influences where they will go and stay during an evacuation. In contrast, 14% of respondents lack social support and these respondents are most likely to stay at a hotel or public shelter during an evacuation. Implications for the design of evacuation management systems are discussed, including systems that support the discovery of vulnerable households and coordination with community organizations that provide transportation and temporary housing during evacuations.

Keywords

Disaster management, evacuation, social capital, survey, vulnerability.

INTRODUCTION

This work-in-progress study examines the social support networks of Greater New Orleans households: family and friends who can provide them with accommodations and other assistance during an evacuation. While prior survey research examines where households travel during an evacuation, and whether they stay at the homes of family and friends, hotels, or public shelters (Lindell et al., 2019), these studies do not examine the extent to which households can obtain accommodations with friends and relatives, and the demographic characteristics and evacuation intentions of households with and without social support. Lacking insight into households' social support networks presents two problems for research attempting to understand large-scale evacuation behavior and design information systems that can support household and community evacuation planning.

First, survey studies show that evacuees overwhelmingly rely on family and friends for temporary accommodations, but seldom examine households' social support networks to identify vulnerable groups who, lacking assistance from family and friends, may require assistance from community organizations during an evacuation. Surveys of intended and actual accommodations show that the majority of evacuees stay at the homes of family and friends, fewer stay in hotels, and far fewer stay in public shelters (Lindell et al., 2011; Mesa-Arango et al., 2013; Mitchell et al., 2017; Wong et al., 2018; Wu et al., 2012; Zeigler et al., 1981). Although emerging studies highlight unequal access to social support among households (Grace & Na, 2024; Na & Grace, 2022), empirical studies of households' social support networks are needed to characterize vulnerable groups that likely require transportation and accommodation assistance from public authorities and community groups during an evacuation.

Second, survey studies show that evacuees travel to diverse in-county, in-state, and out-of-state destinations (Morrow & Gladwin, 2005; Smith & McCarty, 2009; Wong et al., 2018; Wu et al., 2012), but do not adequately

explain why households travel to one destination over another. Beyond hazard proximity and related risk perceptions, such as residence in coastal counties threatened by hurricanes (Huang et al., 2016), studies observe weak or inconsistent correlations between evacuation destination and demographic variables such as age, disability, home ownership, income, race, and social vulnerability (Adeola & Picou, 2017; Asfaw et al., 2019; Baker, 1991; Bolin & Kurtz, 2018; Wu et al., 2012; Yabe & Ukkusuri, 2020). Understanding where households can travel to stay with family and friends can provide insight into households' likely evacuation destinations and, in turn, predict demand for accommodations such as hotels and public shelters.

These gaps in our knowledge of households' social support networks limit, in turn, our ability to design decision-support, simulation, and geographic information systems that can help emergency managers plan community evacuations by, for example, predicting the time of departure, routes of travel, destinations, and types of accommodations evacuees will require after leaving an evacuation zone (Lindell & Prater, 2007a; Yang et al., 2019). Simulating evacuation behavior requires empirically validated models of household evacuation destination and accommodation decision-making (Lindell et al., 2019; Murray-Tuite & Wolshon, 2013). These models and simulations support emergency management planning that involves coordinating public transportation and locating public shelters. Furthermore, knowledge of social support network availability and accessibility can inform the design of systems that can help identify and connect vulnerable households with transportation services and temporary accommodations.

To address these gaps in the literature, we report findings from an intended response survey administered to households in the Greater New Orleans area (n=305). Survey respondents were asked where they could go to stay with family or friends during an evacuation, where they would go and stay in the event of a future evacuation, and what factors they consider when choosing an evacuation destination and accommodations. We answer three research questions in this work-in-progress paper:

1. *To what extent can households stay at the homes of family or friends during an evacuation?* We identify households with and without social support networks, i.e., family and friends who can provide them with temporary accommodations during an evacuation.
2. *What are households' intended evacuation destinations and accommodations?* We compare where households with and without social support intend to travel and stay during an evacuation.
3. *What factors do households consider when choosing an evacuation destination?* We compare the relative importance of decision-making factors such as cost, transportation, and destination familiarity to households with and without social support.

The following sections describe, first, prior research on the relationship between social support and evacuation intentions and behaviors. Second, we describe the methods of survey design and data analysis. Lastly, we report our results in answer to the three research questions above and discuss implications for technologies that can support evacuation planning.

BACKGROUND

Prior research informs our knowledge of the availability of social support and the relationship between social support and evacuation intentions and behaviors. This research includes studies that examine households' (i) social support and related concepts like social capital, (ii) accommodations, and (iii) destinations observed during actual and planned evacuations from areas threatened by hurricanes, wildfires, nuclear accidents, and other disasters.

Definition of Social Support

Social support refers to informational, material (e.g., accommodations), and emotional assistance that households receive or expect to receive from their friends and relatives, i.e., social support network, during an evacuation (Asfaw et al., 2019). Studies of evacuation have long realized the importance of social support networks during evacuations. Quarantelli (1985), for instance, discusses "social support systems" as the family and friends who provide evacuees with temporary shelter (short-term accommodations) and housing (long-term accommodations), observing that the characteristics of households' social support systems (what we refer to as social support networks) make them more or less resilient when forced to remain away from home for varying lengths of time.

The concepts of social support and social support networks respectively distinguish the type and source of assistance that households receive or expect during an evacuation. By doing so, they unpack individual-level measures of social capital (Meyer, 2018), which can describe evacuees' "access to and use of resources embedded in social networks" (Lin, 2001, p. 5). In this study, we refer to social support networks and social support rather than social capital to understand the geographic distribution of households' family and friends and the types of

resources these social network ties can locally provide to households, respectively. While households can receive information and some material assistance (e.g., money) from remote family and friends, in this study we focus on the provision of local assistance, namely accommodations.

Social Support and Evacuation Accommodations

Accommodations are arguably the most important and common type of material assistance that evacuees receive from their social support networks. Prior survey studies examine where respondents traveled during a past evacuation (i.e., actual response) or where they intend to travel for a future evacuation (i.e., intended response). Actual response surveys typically find 50-90% of evacuees staying with family and friends, fewer staying in hotels or motels, and the fewest staying at public shelters (Table 1). These studies also show that evacuees tend to stay with relatives versus friends (Siebeneck & Cova, 2012; Wong et al., 2018). Wong et al. (2018), for instance, surveyed 368 evacuees from Hurricane Irma to find that 44% of respondents stayed with relatives while only 16% stayed with friends. Additionally, these studies note that some respondents stayed at "other" locations such as peer-to-peer rentals (e.g., Airbnb, etc.), churches, and workplaces (Mesa-Arango et al., 2013; Wong et al., 2018).

Table 1. Actual and intended (in gray) evacuation accommodations of U.S. survey respondents.

Disasters	Family/Friends	Hotel	Shelter	Other	Unknown
Three Mile Island nuclear accident in PA (Brunn et al., 1979)[1]	81%	17%	0%	4%	
Hypothetical nuclear accident in PA (Brunn et al., 1979)[1]	70%	15%	9%	5%	
Hurricane Bonnie in NC (Whitehead et al., 2000)	70%	16%	5%	9%	
Future hurricane in NC (Whitehead et al., 2000)	60%	24%	12%	4%	
Hurricane Katrina in LA (Wu et al., 2012)	54%	31%	3%	13%	
Hurricane Katrina in LA (Mitchell et al., 2017)[1]	54%	30%	6%	9%	
Future hurricane in LA (Mitchell et al., 2017)	51%	33%	5%	8%	3%
Future hurricane in LA (Morrow & Gladwin, 2006)	57%	27%	5%	3%	8%
Hurricane Harvey in TX (Bierling et al., 2020)	58%	33%	1%	8%	

[1]*Values reported in the original study do not equal 100%.*

Intended response surveys ask respondents about their planned evacuation accommodations and destinations for future evacuation scenarios, such as a "major hurricane like Katrina" (Morrow & Gladwin, 2006). Table 1 also describes the findings of intended response surveys administered to U.S. households threatened by hurricanes and, in the case of Three Mile Island, the partial meltdown of a nuclear reactor. These and other studies suggest that respondents' accommodation intentions correspond with actual accommodation decisions observed during prior or future evacuations (Kang et al., 2007). For instance, in a survey of Southeastern Louisiana residents, Mitchell et al. (2017) observe that respondents' accommodation intentions for a future hurricane generally match the actual accommodations they obtained during Hurricanes Katrina and Gustav.

Studies also investigate the relationship between evacuees' actual and intended accommodations and demographic and evacuation factors. Some studies observe that low-income households with young children, elderly persons, or persons with disabilities/special needs are more likely to evacuate to homes of family or friends or stay at a public shelter than stay at a hotel (Whitehead et al., 2000; Wong et al., 2018). Studies also observe that whites, large families, and high-income households are more likely to stay in hotels and less likely to stay in shelters (Lindell et al., 2011; Wu et al., 2012). Lastly, other studies observe a relationship between households' home city/state and choice of accommodations. For example, Wu et al. (2012) find that Louisiana households were more likely to stay in hotels than Texas households during Hurricane Katrina.

Evacuation Destinations

Studies show that most U.S. residents of the Gulf and Atlantic Coasts evacuate to in-state and out-of-state

destinations in response to hurricanes, but some evacuate to destinations within their home county or parish (Lindell & Prater, 2007b). Table 2 reports the actual destinations of surveyed evacuees, showing that respondents reported a wide range of in-county (1-49%), in-state (30-81%), and out-of-state (0-56%) destinations. These measures vary significantly depending on the geographic area surveyed. Dash and Morrow (2000), for example, surveyed residents of the Florida Keys and observed that none evacuated the 400+ miles required to leave the state of Florida. In contrast, many New Orleans residents surveyed by Mitchell et al. (2017) and Wu et al. (2012) traveled to relatively close out-of-state destinations in Texas and Mississippi.

Table 2. Actual and intended (in grey) evacuation destinations of U.S. survey respondents.

Evacuation	Evacuation destinations		
	In county	**In state**	**Out of state**
Hurricane Georges in FL (Dash & Morrow, 2000)	19%	81%	0%
Hurricane Floyd in SC (Dow & Cutter, 2002)	9%	32%	56%
Hurricane Ivan (Morrow & Gladwin, 2005)	32%	37%	31%
Multiple hurricanes in FL (Smith & McCarty, 2009)	49%	30%	21%
Hurricane Katrina (Wu et al., 2012)	1%	80%	19%
Hurricane Rita (Wu et al., 2012)	1%	47%	52%
Hurricane Katrina/Gustav/Isaac (Mitchell et al., 2017)	14%	34%	52%
Hurricane Irma (Wong et al., 2018)	17%	34%	49%
Future hurricane in LA (Mitchell et al., 2018)[1]	-	27%	73%

[1]*Did not report in-county evacuation destinations.*

Lastly, research explores relationships between households' evacuation destinations and demographic and non-demographic factors such as social support. In general, demographic factors such as age, disability, home ownership, income, race, and social vulnerability fail to predict evacuation destinations and distances (Adeola and Picou, 2017; Asfaw et al., 2019; Bolin and Kurtz, 2018; Howard et al., 2017; Yabe and Ukkusuri, 2020; Wu et al., 2012). However, emerging studies that examine social support from family and friends observe that evacuees plan to travel shorter distances when evacuating to destinations where they can receive assistance from family and friends but travel farther when planning to evacuate to destinations lacking social support (Na & Grace, 2022).

METHODS

Although prior evacuation research examines the accommodations and destinations of households fleeing natural hazards like hurricanes, a gap exists in our understanding of social support available to households and how the availability of social support influences where households choose to go and stay during an evacuation. To address this gap, we surveyed Greater New Orleans households about their social support networks and evacuation intentions. We describe the design of the survey and methods of data analysis below. This survey research was approved by a university institutional review board (IRB2023-735).

The survey was administered to an online panel (n=305) composed of Southeast Louisianna residents mostly located in New Orleans Parish, but including respondents from surrounding areas, including St. Charles, Jefferson, and St. Tammany Parishes. Respondents completed a 34-question survey that included demographic, evacuation, and social support-related questions. These questions were based on prior survey research on evacuation behavior (Bierling et al., 2020; Mitchell et al., 2017) and FEMA's National Household Survey (2023).

Our analysis of the survey data addresses the following research questions: (RQ1) To what extent can households stay at the homes of family or friends during an evacuation? (RQ2) What are households' intended evacuation accommodations and destinations? (RQ3) What factors do households consider when choosing an evacuation destination? We cross-tabulated the survey data to understand the number and demographics (RQ1), accommodation and destination intentions (RQ2), and destination decision-making factors (RQ3) of respondents with and without social support.

RESULTS

In this section, we report survey findings to compare the demographics, evacuation intentions, and destination decision-making factors of respondents with and without social support networks that vary in range and size.

Availability of Social Support

Of 305 survey respondents, 263 (86%) identified at least one relative or friend who could provide them with accommodations during an evacuation, while 42 (14%) did not identify a source of social support (Table 1). These two groups represent households for whom social support is available and unavailable.

The demographics of respondents with and without social support are roughly similar (Table 4). Respondents with social support are more likely to be female, married, and in early and middle adulthood (25-65), whereas respondents without social support are more likely to be male, unmarried, and elderly (65+). Additionally, there are more respondents with social support who earn less than $55k or more than $100k annually than respondents without social support who are more likely to be middle-income earners. Respondents with social support tend to have more evacuation experience than respondents without social support. Importantly, however, the two groups are roughly similar in terms of race, educational attainment, employment status, and household size.

Table 4. Demographics of respondents with and without social support.

Characteristic		All (n=305)	Social Support	
			Available (n=263)	Unavailable (n=42)
Age	18-24	39 (13%)	33 (13%)	6 (14%)
	25-65	204 (67%)	183 (70%)	21 (50%)
	65+	62 (20%)	47 (18%)	15 (36%)
Gender	Female	199 (65%)	175 (67%)	24 (57%)
	Male	105 (34%)	87 (33%)	18 (43%)
Race	Black	92 (30%)	78 (30%)	14 (33%)
	White	183 (60%)	158 (60%)	25 (60%)
	Other	30 (10%)	27 (10%)	3 (7%)
Relationship status	Married	99 (32%)	90 (34%)	9 (21%)
	Single	92 (30%)	80 (30%)	12 (29%)
	In a relationship	50 (16%)	41 (16%)	9 (21%)
	Other (e.g., widowed)	64 (21%)	52 (20%)	12 (29%)
Educational attainment	High school or less	126 (41%)	109 (41%)	17 (40%)
	Associate degree or vocational training	79 (26%)	66 (25%)	13 (31%)
	Bachelor's degree or higher	100 (33%)	88 (33%)	12 (29%)
Employment status	Unemployed	33 (11%)	30 (11%)	3 (7%)
	Employed (full or part-time)	169 (55%)	146 (56%)	23 (55%)
	Student	19 (6%)	16 (6%)	3 (7%)
	Retired	84 (28%)	71 (27%)	13 (31%)
Income	$0-49k	148 (49%)	135 (51%)	13 (31%)
	$50-99K	102 (33%)	79 (30%)	23 (55%)
	$100k+	55 (18%)	49 (19%)	6 (14%)
Prior evacuation experience	No	56 (18%)	45 (17%)	11 (26%)
	Yes	249 (82%)	218 (83%)	31 (74%)
Persons in household	1 person	90 (30%)	76 (29%)	14 (33%)
	2-4 persons	183 (60%)	157 (60%)	26 (62%)
	5+ persons	32 (10%)	30 (11%)	2 (5%)

Accommodation Intentions

Asked where they would stay in the event of a future one-week evacuation, respondents with and without social support indicated they would stay in different types of accommodations. Table 5 shows the intended accommodations of respondents according to the range of their social support networks, i.e., the in-county, in-

state, or out-of-state location of the most distant family or friend who can provide them with a place to stay during an evacuation. Respondents with social support are most likely to stay family or friends (58%), however, respondents with out-of-state social support (61%) are more likely to stay with family or friends than respondents with in-county (42%) or in-state (49%) social support. However, respondents with only local, in-county social support are more likely to stay at hotels (42%) than respondents with more expansive social support networks. In contrast, respondents without social support are most likely to stay at hotels (60%) or public shelters (21%).

Table 5. Intended accommodations of respondents by range of social support network.

	Social Support		Range of Social Support Network		
Accommodation	**Unavailable**	**Available**	**In County[1]**	**In State**	**Out of State**
House of family/friend	0 (0.0%)	152 (57.8%)	8 (42.1%)	19 (48.7%)	125 (61.0%)
Hotel or motel	25 (59.5%)	75 (28.5%)	8 (42.1%)	10 (25.6%)	57 (27.8%)
Other (RV, 2nd home, etc.)	5 (11.9%)	15 (5.7%)	2 (10.5%)	6 (15.4%)	7 (3.4%)
Peer-to-peer rental	3 (7.1%)	16 (6.1%)	0 (0.0%)	2 (5.1%)	14 (6.8%)
Public shelter	9 (21.4%)	5 (1.9%)	1 (5.3%)	2 (5.1%)	2 (1.0%)
Overall	42 (100.0%)	263 (100%)	19 (100.0%)	39 (100.0%)	205 (100.0%)

[1]For comparison with prior research that reports in-county destinations, we refer to counties rather than parishes.

Table 5 also reveals that some respondents who have social support choose not to use it. Among 263 respondents with at least one family or friend with whom they can stay during an evacuation, 111 (42%) intend to stay in a hotel or other accommodations. Not shown in Table 5, 32 (12%) respondents plan to stay in a hotel or other accommodation at a destination where they could stay at the home of a friend or relative. These "locally supported" households have not been identified before in prior survey studies.

Table 6 shows the intended accommodations of respondents according to the size of their social support networks, i.e., the number of family and/or friends who can provide them with a place to stay during an evacuation. Respondents with larger social support networks are more likely to stay with family and friends: over 50% of respondents with social support networks of 1-2 persons intend to stay with these family and friends, while 100% of respondents with three persons in their social support networks intend to stay in these accommodations. In contrast, as reported in Table 5, most respondents without social support intend to stay in hotels or public shelters.

Table 6. Intended accommodations of respondents by size of social support network.

	Size of Social Support Network		
Accommodation	**1 Person**	**2 Persons**	**3 Persons**
House of family/friend	34 (50.7%)	85 (52.1%)	33 (100%)
Hotel or motel	22 (32.8%)	53 (32.5%)	0 (0%)
Other (RV, second home, etc.)	4 (6.0%)	11 (6.7%)	0 (0%)
Peer-to-peer rental	4 (6.0%)	12 (7.4%)	0 (0%)
Public shelter	3 (4.5%)	2 (1.2%)	0 (0%)
Total	67 (100%)	163 (100%)	33 (100%)

Destination Intentions

Table 7 shows the intended evacuation destinations of respondents according to the range of their social support networks. Among 305 respondents, 205 (67%) can travel out of state to stay with a family/friend, 39 (13%) can travel somewhere within the state of Louisiana, 19 (6%) can only access social support within their home parish, and 42 (14%) have nowhere to go for help from family/friends.

Significantly, and related to the preference of staying at the homes of family/friends, where respondents plan to evacuate relates to the range of their social support networks. Households with only in-county social support tend to remain within the county/parish (58%), households with in-state social support tend to evacuate within the state (49%), and households with out-of-state social support tend to evacuate to destinations in the neighboring states of Alabama, Mississippi, and Texas (85%). Importantly, unlike respondents with out-of-state support, respondents with no support (24%), in-county support (16%), and in-state support (13%) are more likely to not know where they would evacuate.

Table 7. Intended evacuation destinations by range of social support network.

	Social Support		Range of Social Support Network		
Evacuation Destination	**Unavailable**	**Available**	**In County**	**In State**	**Out of State**
In County	7 (16.7%)	14 (5.3%)	11 (57.9%)	1 (2.6%)	2 (1.0%)
In State	2 (4.8%)	40 (15.2%)	1 (5.3%)	19 (48.7%%)	20 (9.8%)
Out of state	23 (54.8%)	193 (73.4%)	4 (21.1%)	14 (35.9%%)	175 (85.4%)
Unknown	10 (23.8%)	16 (6.1%)	3 (15.8%)	5 (12.8%%)	8 (3.9%)
Total	42 (100%)	263 (100%)	19 (100%)	39 (100%)	205 (100%)

Table 7 also shows that respondents with local support often evacuate outside of their social support networks by planning to travel to out-of-state destinations where they intend to stay at a hotel or other accommodation. Among 39 respondents with in-state social support, 14 (36%) intend to evacuate outside Louisiana where they lack family/friends who can provide them with accommodations. Overall, most respondents plan to evacuate to an out-of-state destination (Figure 1).

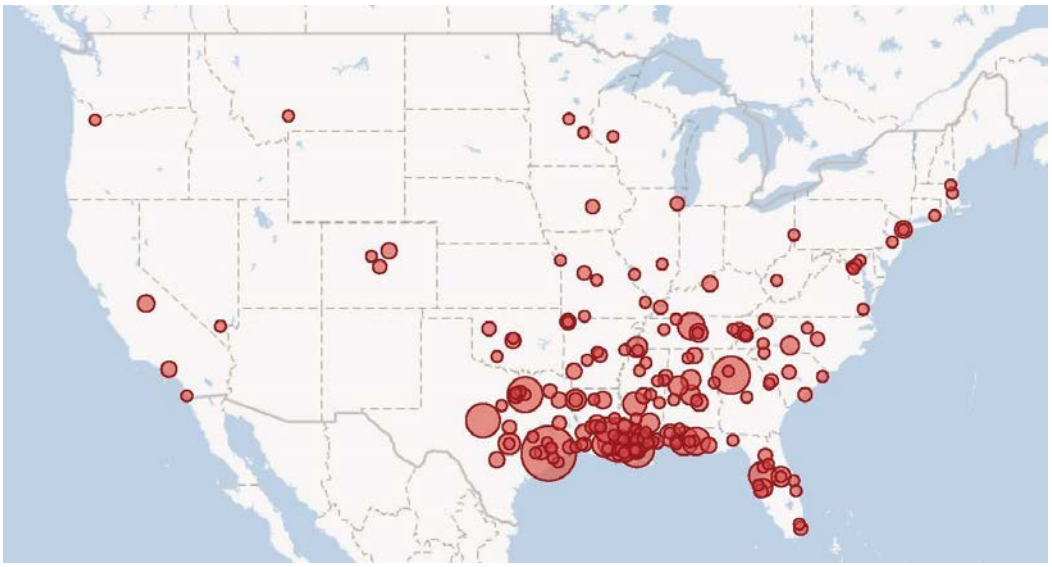

Figure 1. Intended destinations of survey respondents.

Table 8 shows the intended evacuation destinations of respondents according to the size of their social support networks. While out-of-state destinations are the most common among respondents with 1-3 family and/or friends who can provide them with a place to stay during an evacuation, respondents with more family/friends are more likely to evacuate out of state than respondents with smaller social support networks. Approximately 88% of respondents with 3 family/friends intend to travel out of state compared to 69% of respondents with one family/friend and 55% of respondents without social support.

Table 8. Intended evacuation destinations by size of social support network.

	Size of Social Support Network		
Evacuation Destination	**1 FF**	**2 FF**	**3 FF**
In County	6 (9.0%)	7 (4.3%)	1 (3.0%)
In State	11 (16.4%%)	27 (16.6%)	2 (6.1%%)
Out of State	46 (68.7%%)	118 (72.4%)	29 (87.9%%)
Unknown	4 (6.0%%)	11 (6.7%)	1 (3.0%%)
Total	67 (100%)	163 (100%)	33 (100%)

Decision-making Factors

Table 8 shows the factors that respondents consider when choosing an evacuation destination. Among the nine factors surveyed, respondents most often identified accommodation availability, destination distance, and financial

cost as important when deciding where to go during a future evacuation. However, respondents with social support (68%) are more likely to consider the availability of accommodations when choosing an evacuation destination than respondents without social support (43%). Furthermore, respondents with social support are more likely to consider the recommendations of family and friends (19%) than unsupported respondents (5%), as well as their familiarity with the destination (32%) compared to unsupported respondents (19%). In contrast, respondents without social support are more likely to consider cost (55%) and transportation (48%) to destinations than respondents with social support (49% and 38% respectively).

Table 8. Factors considered when choosing an evacuation destination.

	Social Support		Range of Social Support		
Factor	**Unavailable**	**Available**	**Local**	**State**	**Out of State**
Accommodations	18 (43%)	179 (68%)	10 (53%)	22 (56%)	119 (58%)
Distance	21 (50%)	151 (57%)	11 (58%)	24 (62%)	144 (70%)
Cost	23 (55%)	130 (49%)	12 (63%)	10 (26%)	77 (38%)
Transportation	20 (48%)	99 (38%)	7 (37%)	18 (46%)	71 (35%)
Traffic congestion	14 (33%)	96 (37%)	5 (26%)	16 (41%)	109 (53%)
Familiarity	8 (19%)	83 (32%)	5 (26%)	6 (15%)	38 (19%)
Family/friends advice	2 (5%)	49 (19%)	3 (16%)	5 (13%)	33 (16%)
Officials/media advice	4 (10%)	41 (16%)	3 (16%)	12 (31%)	67 (33%)

DISCUSSION

The preliminary survey results provide insight into the availability of social support among Greater New Orleans households and the relationship between social support, namely a place to stay with family and friends, and households' evacuation accommodation and destination intentions. The first of its kind, these results show that:

- Among survey respondents from Greater New Orleans (n=305), 263 (86%) report at least one friend or relative at whose home they can stay during an evacuation, however, 42 (14%) report no sources of social support.
- The ranges of social support networks vary among respondents (n=263): 19 (7%) report only friend/relative(s) inside their home parish, 39 (15%) report someone elsewhere in the state of Louisiana, and 205 (78%) report someone outside the state.
- The sizes of social support networks vary among respondents (n=263): 67 (22%) report one friend/relative with whom they can stay during an evacuation, 163 (53%) report two persons, and 33 (11%) report three persons.
- Respondents with social support are most likely to stay at the home of a friend or relative (58%), while respondents without social support are most likely to stay at a hotel (60%) or public shelter (21%). In contrast, 29% of respondents with social support intend to stay at a hotel and 2% intend to stay at a public shelter.
- Although they might stay with a friend or relative, 42% of respondents with social support intend to stay at a hotel, peer-to-peer rental, RV, public shelter, or other accommodation.
- Most respondents with and without social support intend to evacuate to out-of-state destinations, but respondents with social support are most likely to evacuate to in-parish, in-state, and out-of-state destinations where they can stay at the homes of family and friends.
- Respondents with social support are more likely to consider the availability of accommodations and recommendations of friends/relatives when choosing an evacuation destination than respondents without social support.

These results, by describing the availability, range, and size of households' social support networks, provide context to prior survey research that examines actual and intended evacuations destinations and accommodations (Adjei et al., 2022; Bierling et al., 2020; Huang et al., 2016; Lindell et al., 2011; Mitchell et al., 2017; Smith & McCarty, 2009; Wong et al., 2018; Wu et al., 2012). Importantly, the findings suggest that differences in social support networks may be better indicators of household vulnerability than demographic and other risk factors observed in previous studies (Adeola & Picou, 2017; Asfaw et al., 2019; Baker, 1991; Bolin & Kurtz, 2018; Wu

et al., 2012; Yabe & Ukkusuri, 2020).

By describing the friends/relatives who can provide households with accommodations during an evacuation, the preliminary results suggest that the range/geographic distribution and size of households' social support networks influences where they go and stay during an evacuation. Consequently, by improving our understanding of households' social support networks, we can better explain and predict where people go during an evacuation, their logistics requirements, and identify vulnerable groups who lack social support or the means to access social support during a large-scale evacuation.

Limitations of the present study include the non-representative sample of Greater New Orleans residents, biases introduced through the use of an online panel to administer the survey, and possible differences between respondents intended and actual response to an evacuation (Kang et al., 2007; Lindell et al., 2019). Future studies can address these limitations through different survey designs and recruitment procedures, as well as complementary methods, such as interviews, that can help explain the patterns of intentional and actual behavior observed through survey research. As described in the next section, future research can also explore the implications of these findings for the design of evacuation management systems.

Implications for Evacuation Management Systems

Information systems can support the management of large-scale evacuations at community and household levels. This study and future research can inform the design of such systems by describing and predicting household vulnerability and exposure to hurricane and evacuation-related hazards based on the availability and accessibility of households' social support. In addition to often-studied technologies, such as decision-support systems (DSS) for emergency managers (Davidson et al., 2020), this study suggests the need for systems that help households plan to access social support for likely evacuation scenarios, as well as seek assistance from government and non-government agencies (NGOs) when social support is unavailable or inaccessible during an evacuation.

At the community level, prior research focuses on evacuation and transportation modeling and simulation, and the design of DSS and intelligent transportation systems (ITS) for emergency managers and other decision-makers responsible for planning and managing evacuation and return-entry processes (Davidson et al., 2020; Iliopoulou et al., 2020; Murray-Tuite & Wolshon, 2013). As Lindell and Prater (2007a) explain, emergency managers in New Orleans and other hurricane-threatened areas depend on DSS for insight into "the behavior of the hurricane that is relevant to evacuation and the behavior of evacuees that is relevant to the hurricane" (p. 627). By providing insight into households' social support networks and evacuation destination and accommodation intentions, this work-in-progress paper and future research can inform models of evacuation behavior that, in turn, can inform the design of DSS that can guide emergency managers in evacuation planning, including the allocation and location of public shelters (Lindell & Prater, 2007a; Yang et al., 2019).

However, our findings also suggest opportunities for systems that support the discovery of vulnerable households that lack social support to connect these households with government agencies and/or NGOs poised to help during an evacuation. For instance, our preliminary results suggest that Greater New Orleans residents who are male, unmarried, and elderly are more likely to lack social support than other demographic groups. Designs might include social media listening and public information campaigns that target users who likely lack social support to direct them to web-based resources for obtaining transportation and accommodations ahead of a possible evacuation. In New Orleans, for example, city-assisted evacuation coordinates transportation out of the city using a system of pre-established pick-up areas and designated evacuation destinations with public shelters. Importantly, residents need to reach these pick-up points with the proper provisions and at the proper times. Future research can partner with community partners to co-design systems that identify and initiate communications with vulnerable households to effectively coordinate the use of such public transportation systems.

At the household level, insights from this study suggest the need for systems that support evacuation planning for different hurricane scenarios, particularly those in which a household may not be able to access accommodations from family or friends. This study finds that Greater New Orleans households have social support networks that vary in range and size, which suggests that the exposure of households' social support networks to hurricane hazards and evacuation orders will vary depending on the location of households' family and friends. Consequently, households may need to stay at a hotel or public shelter when social support is unavailable, as observed among the 14% of respondents who could not identify a friend or relative with whom they could stay during an evacuation, or inaccessible, such as when the path of a storm or road conditions restrict travel to available homes of friends and relatives.

As few households proactively plan for an evacuation (Vásquez et al., 2016), systems might support households in contingency planning for scenarios when they may need to stay in a hotel or other accommodations when social

support is available but inaccessible. Similar to DSSs emergency managers use to predict evacuation zones based on likely storm paths and intensities (Lindell et al., 2019), a system might help households plan where to go and stay based on the availability and accessibility of social support during likely hurricane scenarios. As DSS research has not focused on household use contexts, future work is required to understand households' evacuation planning needs and co-design and evaluate systems that can support destination, accommodations, and logistics planning ahead of future disasters.

CONCLUSION

This study reports preliminary findings from a survey administered in 2023 to investigate New Orleans households' social support networks: friends and relatives who can provide them with accommodations and other assistance during evacuations caused by hurricanes and other hazards. While most respondents report at least one relative or friend with whom they can stay during an evacuation, some respondents lack social support, and these respondents are most likely to stay at a hotel or public shelter during an evacuation. These findings and future research can improve understanding of the relationship between social support and evacuation behavior and inform the development of systems that can support community and household evacuation planning.

ABSTRACT

Wildfires are a growing threat to wildland-urban interface (WUI) communities. Globally over the last decade hundreds of wildfire related deaths have occurred along with hundreds of billions in economic losses. If the encroachment of fire into a community cannot be stopped, evacuation becomes necessary to save lives. In response to the increasing threat, WUI communities must properly prepare and implement an evacuation plan, as orchestrating an evacuation within a limited time frame is a complex challenge. While several fire and evacuation simulation tools have been developed to aid planning, a comprehensive methodology for constructing and assessing evacuation plans is still evolving. This article fills some of the current gaps with a simple six-step process to evaluate wildfire risk, individual evacuation zone traffic demand, and formulate a staged zone-based full evacuation plan. This methodology can be used for wildfire evacuation planning, evacuation plan management, and training.

Keywords:

Wildland urban interface, wildfire, evacuation planning, emergency management, simulation.

INTRODUCTION

A 'wildfire' can be defined as an unplanned vegetation fire produced by natural or human causes. Wildland urban interface (WUI) fires involve fire encroaching into populated communities causing loss of life and economic losses, including damage to property, infrastructure, and natural resources, as well ongoing concerns such as businesses and industries (Bento-Gonçalves et al., 2020; Schug et al., 2023). The development of the fire itself will be influenced by geography, weather patterns, and vegetation; the impact on affected buildings by construction materials/techniques and land use planning; while the capacity for communities to cope with an incident will be influenced by the resources available, the information available, and their ability to evacuate. These elements combine to produce the outcome in the context of planning effective mitigation and intervention efforts (i.e. emergency management and response).

Climate change has contributed to the increase of high-profile wildfires globally in recent years. For instance, extreme weather conditions contributed to the 2018 California wildfires, resulting in 100 deaths and an estimated $148.5 billion US dollars in economic losses, including damage to homes, businesses, and infrastructure (CAL Fire; Wang et al., 2021), while extreme heat promoted the 2019-2020 Australian bushfires resulting in an estimated $103 billion Australian dollars in losses and 33 deaths (Ogie et al., 2022). Over the decades, there is a tendency that more frequent and severe wildfires occur at many places around the globe, as illustrated in Figure 1. Figure 2 shows the tree loss by country using 2010 as a reference point. It is apparent that some countries have shown a dramatic loss, e.g. Portugal has a 39% loss, Sierra Leone a 33% loss, and Australia a 17% loss (Global

Forest Change). In response to the threat caused by the wildfire, it becomes a crucial requirement for all communities located at wildland urban interface to prepare for such a disastrous event. This, however, is challenging (Murray et al., 2023). As such events begin to encroach on occupied regions (only made more likely by the migration of people to the WUI), so the risk of exposure and the need for emergency response increases.

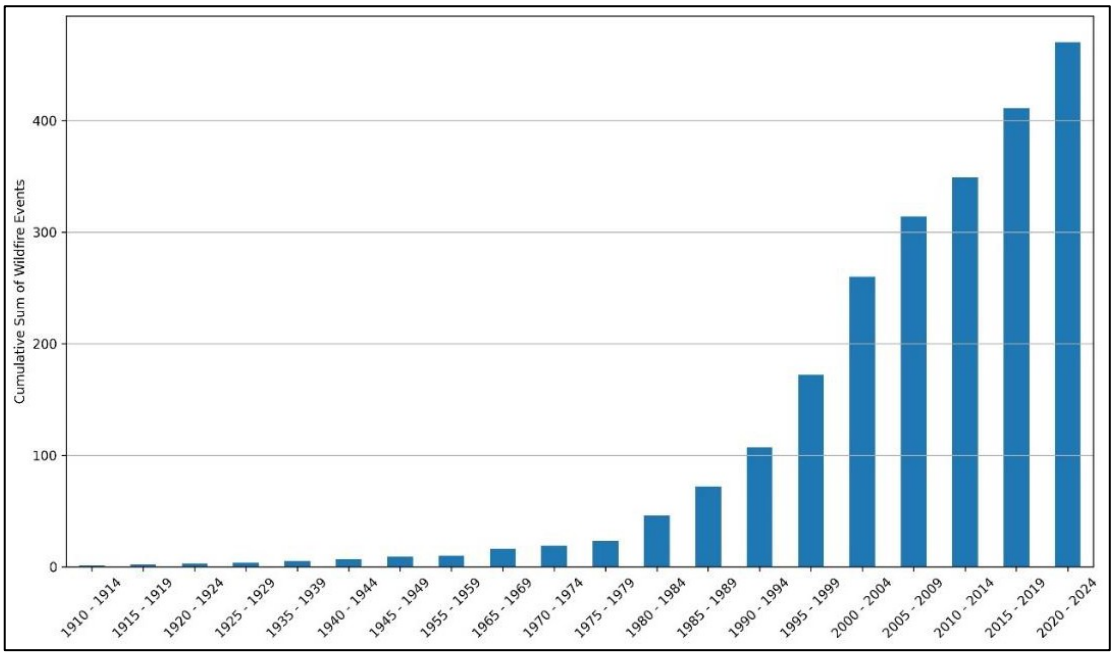

Figure 1: Occurrence of wildfire in five-year intervals. Data: (Global Forest Watch).

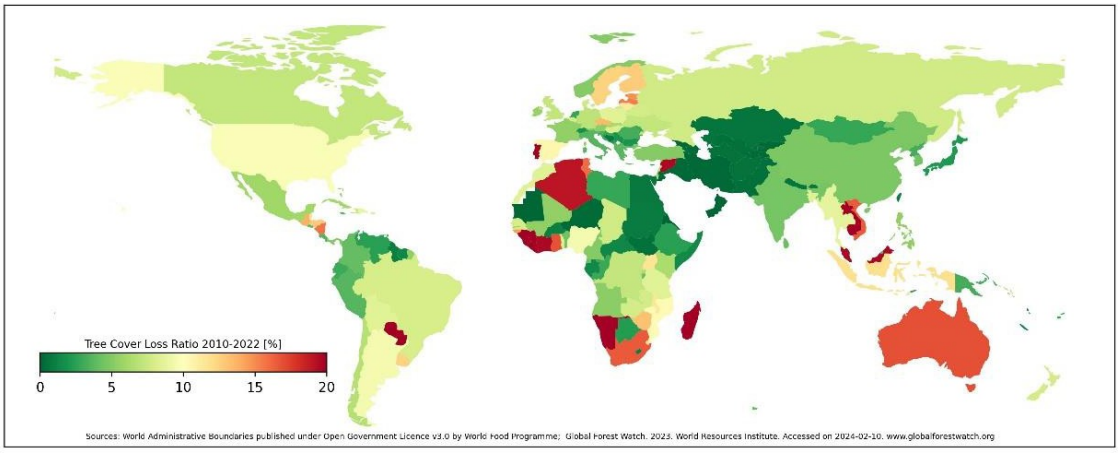

Figure 2. Tree loss due to wildfire between 2010-2022 using 2010 as reference point (Global Forest Watch).

The ability to carry out a large-scale evacuation is a key measure to safeguard communities when a fire threatens inhabited areas. It may be particularly important where mitigation measures have been ineffective and where real-time intervention cannot halt the progress of an oncoming fire front. Conducting such a large-scale evacuation requires a coordinated effort from multiple agencies and stakeholders, including emergency responders, local government officials, and community leaders to work together, taking into account all the relevant factors in evacuation planning and management. These factors include, but are not limited to, the nature of the fire threat (affected by the landscape, the vegetation, and the wind conditions affecting the movement of the fire front and therefore the time available for evacuation); the number, mobility and distribution of people to be evacuated; the availability of evacuation routes and target destinations; and the resources required for the evacuation (e.g., intervention, communication, vehicles and shelter etc.). Given the complex interaction between these factors and the importance of the evacuation performance (for both planning and emergency management), it is necessary to analyse the relationship between these factors.

- **The threat**: When a fire is detected, the direction and speed of fire spread, and its distance to the community combine to determine the fire risk, i.e., the level of threat posed to the community. The threat

also affects the range of the area to be evacuated and the available time for evacuation.

- **The evacuation demand**: The demographics, size, and distribution of the population within the community form the demand for evacuation. This demand is also affected by the layout and distribution of the community properties, including the residential streets within the community as well as the demographic and socioeconomic makeup of a community.
- **The routes for evacuation**: In most WUI communities, evacuation will need to be facilitated by the road network. That is, the evacuating population will need to leave the threated area via either familiar routes or designated evacuation routes through the road network to a place of safety. Thus, the layout and capacity of the road network, given their availability and use, will influence capacity and therefore the required evacuation time assuming demand is at a manageable level.
- **The resources required for the evacuation**: The resources required include fire intervention and traffic control, fire prevention and traffic control, the availability of vehicles for evacuation, and the notification system in place to convey the instructions to the residents (assuming that this affects the time to initiate evacuation along with preparatory activities).
- **The evacuation goal**: The availability of safe locations to accommodate the evacuees and their tools for transportation.

An effective evacuation plan for a community should be evidence-based, i.e. involve the assessment of threat level to different regions of the community (over time) and the effectiveness of different evacuation responses (e.g. including an attempt to balance the evacuation demand with the available routes and resources for evacuation), to increase the probability of a safe community evacuation.

The goal of developing this evacuation planning methodology is to take the above factors into account in planning or managing an evacuation, so that it can both minimise the risk of exposure to the fire threat, and stage the evacuation based on a zone-based division of the community, so that the resources are more effectively utilised and any plan put in place is more robustly tested. In other words, the evacuation plan should be designed to ensure that the risk of exposure to the fire threat is minimised, while also ensuring that the evacuation is carried out in a way that makes the best use of available resources. The plan is based on a zone division of the community given its layout, so that the evacuation can be designed, managed, and tested at the zonal level. It is recognized both that this methodology is draft in nature and broadly drawn given that the intention is that it might be generally applied. However, such methods are both uncommon and necessary both to encourage the appearance of evacuation models and structure their use.

QUANTIFYING PERFORMANCE

Ideally evacuation performance would account for all aspects of emergency management, including prevention, mitigation, preparedness, response, and recovery. Given the challenges posed in the collection and analyses of traditional outcomes and the significant variability of fire scenarios (e.g. making reliance on analytical derivations and empirical correlations much more challenging), wildfire evacuation modelling might be employed to quantify the interaction between the various elements and their consequences. Any model applied will inevitably contain multiple approximations and assumptions; however, coupled with subject matter expertise such efforts can reasonably assess the potential impact of certain factors, their interaction, and the sensitivity of the outcome to this interaction. That is, they might provide the means for communities, first responders, and emergency managers to define and explore certain ‘what-if’ scenarios. The use of modelling tools that consider traffic evacuation dynamics along with wildfire spread and pedestrian response might inform decision-makers about potential outcomes, vulnerabilities in their communities, and the most appropriate strategy to adopt (Ronchi et al., 2019; Kim et al., 2024).

There are a number of evacuation-related simulation platforms available (Ronchi et al., 2019; Intini et al., 2019), for instance, fire models (e.g. Spark, FARSITE, Prometheus, Phoenix, CAWFE, etc.), pedestrian models (e.g. EvacMod, FDS-Evac, Pathfinder, PedGo, Pedestrian Dynamics, JPS, etc.) and traffic models (e.g. OREMS, EVAQ, DYNA-SMART, AIMSUN, SUMO, TRANSIMS, VISSIM, etc.) that can be used to estimate evacuation outcomes. Most models simulate only one of the necessary features (i.e. fire, traffic, or pedestrian). There are several evacuation simulation tools available that attempt to capture the complexity of wildfire evacuation events – by including several aspects of the wildfire events including urbanEXODUS, Simtable, FLEET and WUI-NITY (Grajdura et al., 2022; Veeraswamy et al., 2018; Wahlqvist et al., 2021; Wildland Fire – Simtable; Fast Local Emergency Evacuation Times (FLEET); Genasys EVAC). These tools, amongst others that are emerging, would allow the practitioner to assess the evacuation of a community under different evacuation strategies and route availability – enabling the effectiveness and robustness of such strategies to be assessed. This is a pre-requisite for the methodology described below.

METHODOLOGY

The objective of the proposed evacuation planning methodology is to develop an effective evacuation plan for a threatened community with the aim for those individuals who need to evacuate, to do so safely and effectively. The method is based on a zone-based division of the region. By assessing fire risk and evaluating individual zone and full evacuation performance, the method provides guidance on constructing staged evacuation plans and applying evacuation simulations to select a plan based on performance metrics. It is important to note that this methodology is not tied to any specific modelling tool. However, it is essential to recognize that the development of this methodology imposes certain requirements on evacuation models. Specifically, these models must exhibit the flexibility necessary for effective evacuation planning and the capability to compare the performance of different evacuation plans using the proposed measures. Finally, this methodology can serve as training guidance in preparation for potential wildfire emergencies.

The methodology comprises six essential steps for analysing evacuation procedures and the metrics for selecting an effective plan. The first two are preparatory steps, which identify the geographical area for evacuation planning analysis and create a zone division of the area – the fundamental information for zone-based evacuation planning. Step 3 creates a simple estimate of exposure of different part of the area to the fire threat, based on the zone division. This step generates a rank of the zones with associated weight values, which will be used in the subsequent steps. This rank will be referenced for defining evacuation sequence of the full evacuation plans. And the weight values will be used in performance metric calculations for these plans, so that the fire risk is considered in identifying an effective plan. Step 4 defines three criteria for assessing the required safe evacuation times for the zones and Step 5 assesses the evacuation performance of individual zones through simulations according to these metrics. The outputs of these two steps are essential for determining the timing of the evacuation sequence in the last step. Step 6 (the last step) defines the components of staged full evacuation plans and suggests how to construct the plans using the outputs from previous steps. Step 6 utilises the results obtained from applying simulations to the plans and the proposed performance metrics to identify the final plan. These steps are outlined in detail below.

Step 1: Identify the location and range of the region to be considered for evacuation planning analysis.

The first step is to examine the target region that is susceptible to fire threats and identify the range of the area for evacuation planning or management analysis. Mapping platforms such as OpenStreetMap, Google Maps or Bing Maps can be used to examine the area, with consideration of the following criteria:

- The region should encompass the entire residential area and traffic network, inclusive of unimproved roads, relevant for evacuation analysis. Depending on the scale of evacuation planning, this could be a local community, a town, or even a city.
- The region should include evacuation objectives away from the threatened area. If the evacuation goal is not clearly defined, the region should cover a specific length (e.g., X kilometres) of the roads leading out of the populated area. Such a road segment defines a city exit within the region.

Step 2: Define evacuation group according to emergency management zone (EMZ).

For a large, populated community (e.g., a city), it might not be a credible strategy to order an evacuation of the whole population at the same time – especially if routes are limited and the community is densely populated. This is because the road network is seldom designed and developed with the aim to accommodate the surge of traffic demand from all residents. In practice, officials often divide such a large community into multiple emergency management zones (EMZs) so that the evacuation can be staged / managed at this level of resolution. While there are several factors (e.g., the population distribution, the layout of local road network) that can be considered in this process, the division of the area and the identification of the zone boundaries often follow political or geographical boundaries. This is primarily to facilitate the conveying of the message to people and their interpretation of the emergency management instructions. The development of this evacuation planning methodology is based on the zone division for the planning of emergency response – assuming the zone division is completed. The successive steps will assess the risk of exposure to the fire threat at different zones[1], and stage the evacuation of the zones to make an efficient use of the available road network capacity – assuming necessary resources such as notification and communication systems, and emergency management personals are in place to carry out the staged full evacuation plan.

[1] Zone and EMZ are interchangeable terms used throughout this paper.

Step 3: Assess fire risk to EMZs: Pre-Modelling Ranking.

To plan a staged evacuation for the EMZs, their exposure to the potential fire risk needs to be assessed first to prioritise their evacuation order. While there are many factors influencing the speed of the fire spread, range, intensity, and its subsequent impact on the community, here we propose a simple method to give a basic estimate of risk that can help structure the subsequence modelling. This simplified approach can be used when there is a lack of necessary information to perform a more detailed assessment of the fire risk (especially the spread of the fire itself). The approach should be enriched should both the information for fire modelling and fire simulation capability are available for fire risk assessment (Kalogeropoulos et al., 2023). This is beyond the scope of the description of this planning method.

When a fire is detected, or where there is a high risk of ignition at a nearby region with vegetation as fuel, the distance from the fire front to the EMZs can be used to assess the level of risk to which they are exposed. In general[2], the EMZs that are close to the fire, or the source of a potential fire should be ranked at the top in the evaluation order if the evacuation must be staged. To construct a fire risk factor for an EMZ that allows the comparison of the level of threat with the others, a normalised fire risk (FR_i) for the i^{th} EMZ based on the distance to a fire threat is defined as

$$FR_i(D_i) = \frac{\sum D_i}{D_i} \Big/ \sum \frac{\sum D_i}{D_i},$$

where D_i is the shortest distance from the fire front to the perimeter of each EMZ.

The method of assessing the fire risk to EMZs is illustrated using a hypothetical example shown in Figure 3. The community consists of four EMZs labelled from A to D. It is assumed that a fire starts at the top left corner of the region with a red arrow showing the possible propagation direction towards the community. Subject to the distance to the location of fire threat and the direction and speed of potential fire spread, the EMZs may be exposed to different levels of risk. In general, the closer to the fire front a community is when the fire propagation is detected, the higher the fire risk of the place will be. Thus, people living in this region should be evacuated with priority, and the distance can be used to construct a risk indicator (although other factors, such as weather and wind conditions or the geometry of the road network certainly also affect the potential risk at a given location).

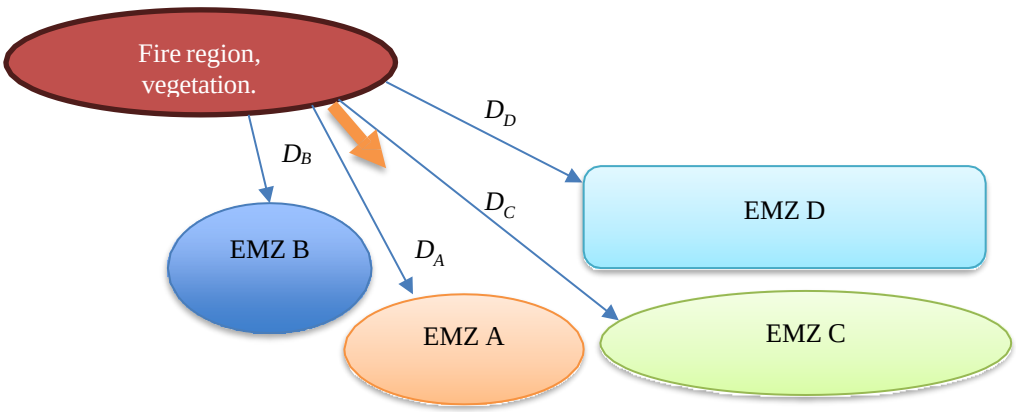

Figure 3. The relative location of EMZs and the fire.

Table 1 lists the values of D_i and the calculated value of FR_i for the four EMZs in the example. The closer an EMZ is to the fire, the higher the fire risk indicator is. For instance, EMZ C is four times further away to the fire than EMZ B, the risk value of EMZ B is about four times of that of EMZ C. Note that FR_i is a signal-factor risk indicator; it does not include the other potential influencing factors in the assessment of the fire risk to the EMZs. For example, equivalent vegetation type and distribution between the fire front and each region is assumed. Additionally, to be fair with the comparison of the fire risk using FR_i, it is also assumed that the EMZs are comparable in size, i.e., none of the EMZs is significantly larger or smaller than the others. If there is any EMZ that is significantly smaller than the others, it may be merged with a nearby EMZ which has similar D_i for planning analysis.

[2] For example, this might not be the case should there be a change of wind direction, or where there are measures to separate or protect the zones, so that some zones may not catch fire. Again, we are not trying to cover all the possibilities but the general concept.

Table 1. The calculation of fire risk based on distance to the source of fire risk.

	EMZ A	EMZ B	EMZ C	EMZ D
D_i (km)	4	1.5	6	4
FR_i	0.19	0.50	0.13	0.19

Step 4: Assess the evacuation performance of individual EMZs: Evacuation Assuming Ideal Management Conditions.

To create an effective staged and zone-based evacuation plan, the traffic demand from each zone and the expected duration of use are two key pieces of information for planning the evacuation and optimising route usage. To be able to estimate the information, this step defines three exit stages from their start location (households) to destination (final place of safety), which set the criteria for estimating the times for people to escape from the danger. Based on this definition, Step 5 introduces the method to estimate the information through simulations.

Unlike the traditional building evacuation planning, which normally includes a signal stage of evacuation to a place of safety, the evacuation route from residential areas to a final place of safety can be broadly divided into three sections, which correspond to three exit stages of the evacuation (see Figure 4 and an example illustrated in Figure 5). The first section includes roadways (primarily for local traffic) within EMZs connecting households and the nearest arteries in the city, which is normally located at the boundary of the corresponding EMZ. The location where the perimeter of the EMZs intersects with the main roads can be defined as **zone exit**. During this stage of evacuation, people who have decided to respond emerge from their homes, join the evacuation traffic follow on local roadways towards the main roads (i.e., zone exit). Progress will have been made once they have arrived at these main roads; however, they still need to continue driving along the main roads towards the boundary of the city and then the place of safety. They are still vulnerable, but less so than when they had first initiated movement.

The second section of the evacuation route is from the main roads within the city towards the city boundary. During this stage of evacuation, there will be merging flows from the same or other EMZs on the main roads. Therefore, people might not be able to drive at their desired speeds and may also experience congestion – depending on the population size/density, demand levels, route capacity and the conditions faced. The location where the perimeter of the city intersects with the main roads out of the city can be defined as the **city exit** (see Figure 5). When people pass the city exits, it usually means they have left the populated area. Therefore, less merging traffic from side roads will be expected, and people should therefore be able to drive at relatively higher speeds as they move further away from the city.

The last section of the evacuation route is normally from major arteries or freeway leaving the city towards the remote **regional exit** (see Figure 5) representing a place of safety, such as planned sheltering places or a remote location far away from the wildfire threat. If there are no planned sheltering places and people are heading towards their own elected destinations once they leave the city, then a location on the freeway that is relatively far away from the area being threatened can be defined as a regional exit for the modelling purpose.

In this step, it is required to perform a static analysis of the zone map including the traffic network. The goal is to identify the three types of exits and determine the evacuation route options to leave through the zone and city exits towards the final reginal exits. When planning the evacuation route for each zone, the consideration for route choice includes nearest, fastest (and route familiarity if the information is available) route towards assigned sheltering places. The planning should also consider the likely use of the roads by people in other zones. The insights gained from Step 4 serve as input for the subsequent evacuation performance analysis in the next two steps.

Step 5: Stress-Testing: individual zone evacuation analysis.

Before complex situations during a full evacuation (for instance, as a result of management or intervention) are assessed, it is essential to develop an understanding of the evacuation performance of individual zones. In essence, how each zone might perform should other zones be successfully delayed in their response. This step conducts a stress test of the response from each zone, given the routes they use, to inform the development of city-wide evacuation plan and the test outlined in Step 6. In the stress test, each zone is evacuated alone with instant response (to encourage the development of peak levels of congestion) and the route choice obtained in Step 4 under two traffic conditions:

1. **Zero background traffic** – representing the assumption that people in the EMZ have priority in the order of evacuation and the attempt to manage the background traffic is successful.
2. **Certain amount of background traffic** - representing the assumption that either (a) the attempt to manage the background traffic is partially successful or (b) the potential for interacting with evacuees

from other zones given they ignored previous instructions (here represented implicitly by a reduction in available route capacity).

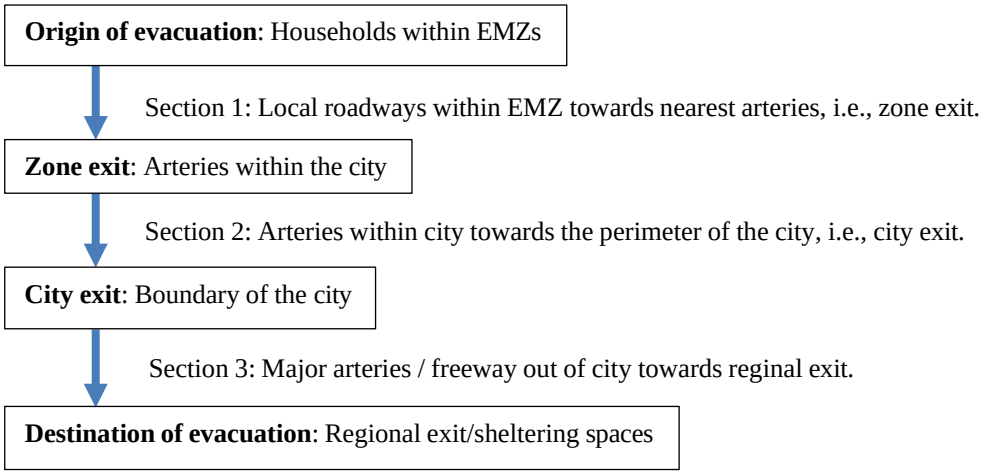

Figure 4. Three stages of the wildfire evacuation.

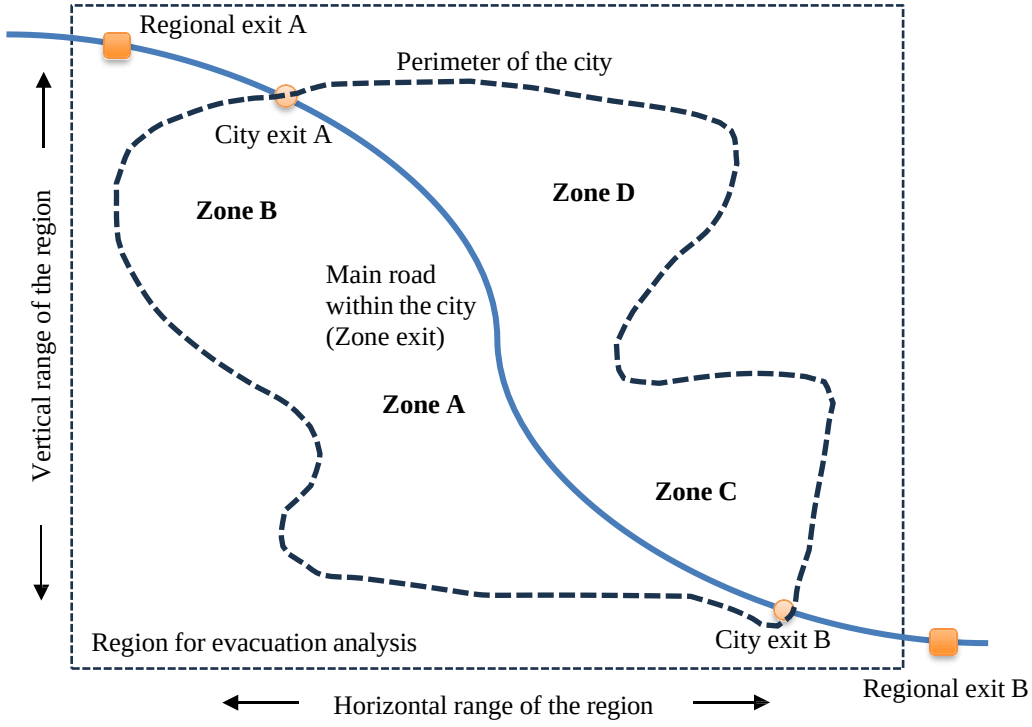

Figure 5. The range of the region for evacuation analysis and three types of exits.

Under the stress testing condition (i.e., instantaneous response / focus on response of individual zones), the simulation results produced from the first test traffic condition give an indication of the minimum time required to move the sub-population to safety, while the results produced from the second test traffic condition indicate a more representative estimate of the time required for the sub-population to evacuate the zone in general. The first time is useful for planning during an emergency in which a particular zone is facing an immediate threat especially in establishing locations of potential route congestion, while the second time is useful for making a city-wide evacuation plan reflecting more representative clearance times for each sub-population. Both might be used to prioritize zone evacuation and suggest design modifications to reduce sources of traffic congestion.

Corresponding to the three stages of evacuation outlined in Step 4, the evacuation performance of each zone has three indicators:

- Ez_{i0} - the time to clear the i^{th} zone alone.
- Ec_{i0} - the time for the subpopulation of the i^{th} zone alone to clear the city exits.

- Er_{i0} - the time for the subpopulation of the i^{th} zone alone to reach the regional exits.

Given these indicators are obtained without considering the interaction with the subpopulations in other zones, these form the baseline for comparison with the evacuation performance obtained from all EMZs evacuation analysis in next step. These indicators are also the bare minimum requirements for safe evacuation of the zones.

Step 6: All EMZs evacuation analysis in response to various potential fire threats.

The final step of developing a city-wide evacuation plan involves determining the order and timing of evacuations for the EMZs. This process considers the factors examined in all previous steps, including the zone divisions (Step 2) within the examined area (Step 1), fire risk assessment for each zone (Step 3), the three evacuation stages (Step 4), and the minimum requirement derived from stress-testing of individual zone (Step 5). A general approach for constructing effective evacuation plans involves:

- **EMZ evacuation sequence**: Define the EMZs evacuation sequence, with reference to the order of the fire risk from high to low, to stage the evacuation that allows those who are closer to the fire risk to leave with priority.
- **Timing Considerations:** Define the timing of the evacuation sequence, with reference to the times to clear the actively evacuating zone(s), and their times to clear city exits. The goal is to give the evacuating zone(s) sufficient time to clear while avoiding overloading the road network with traffic from multiple zones simultaneously or within a short period of time.
- **Route Planning**: Plan the use of route for the EMZs with reference to the availability of the regional exits (i.e., the location and capacity of the evacuation target), the road network connectivity and capacity, and the resources that can be deployed to manage the traffic. The goal is to efficiently utilise the capacity of the road network, while minimising the interaction between evacuation traffic from different zones to prevent bottlenecks and delays. The planning conducted in this step considers the collective traffic demand from multiple zones that may need evacuation within a limited time window. This differs from the route planning in Step 4, which focuses on individual zone traffic demand.

When considering various combinations of the first two components in the planning process (assuming an optimised route planning or a consistent basis), there are two extreme base plans that impact road capacity differently. The first one is to evacuate all EMZs simultaneously (i.e., without any delay gaps). The second one is to evacuate all EMZs strictly in sequence, with gaps set to each zone's clearance time down the line. The first one, which is equivalent to a stress test, exerts maximum pressure on the traffic network and may lead to significant congestion and delays. The second one, which minimises pressure on the traffic network, underutilises the road network's capacity, resulting in unnecessarily extended total evacuation time – in an attempt to manage road conditions. Therefore, these two base plans serve as boundaries for constructing other feasible evacuation strategies. The goal is then to strike an ideal balance between the planning components, while ensuring the safe and efficient evacuation of all residents.

Those feasible plans that strike a balance between evacuation efficiency and pressure on the traffic network involve intricate interaction among evacuating people from different zones. These evacuation plans can be assessed through computer models that represent corresponding evacuation scenarios. However, evaluating these plans based solely on total evacuation time does not fully address safety concerns. For instance, two plans - one accounting for fire risk to decide evacuation sequence and another ignoring it, might yield similar evacuation times. To address this, we propose a composite evacuation time, defined as the sum of the three zone-specific indicators corresponding to the three stages of evacuation, for each plan. This metric, coupled by the fire risk factors for the zones obtained in Step 3, is then used in the assessment of the simulation results to evaluate the effectiveness of evacuation plans.

Assuming a set of evacuation plans have been defined as P_j with the combination of evacuation sequence and timing of evacuations for the EMZs (and a consistent route planning). The performance metrics defined as composite evacuation times weighted by the fire risk factor for these plans are as follows:

- $\sum_i Ez_i(P_j) * FR_i$ - the composite evacuation time to clear the zones,
- $\sum_i Ec_i(P_j) * FR_i$ - the composite evacuation time to clear the city exits,
- $\sum_i Er_i(P_j) * FR_i$ - the composite evacuation time to reach the regional exits,

where $Ez_i(P_j)$, $Ec_i(P_j)$ and $Er_i(P_j)$ are the zone exit times, city exit times and reginal exit times of the corresponding zones within each of the plans. These exit times can be obtained through computer simulations that simulate the evacuation plans for the region.

Finally, the metrics are compared against the baseline defined as the composite evacuation time obtained through

individual zone evacuation analysis performed in Step 5 (as shown in Figure 6). The deviations (dz_j, dc_j and dr_j) from the baseline serve as reference for assessing plan effectiveness. The ultimate objective is to identify a plan that minimises deviations while ensuring safe evacuation. For instance, if the priority is to evacuate people from their zones to the main road first, then focus on minimising dz_j when choosing a plan. If the safe evacuation goal also involves clearing city exits and reaching reginal exits, consider minimising dc_j and dr_j as well in the decision-making process.

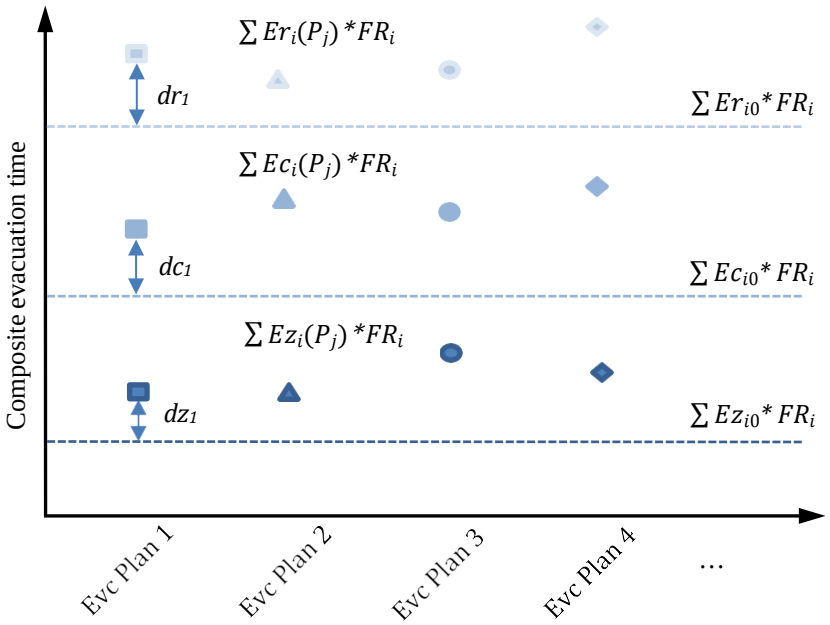

Figure 6. The performance metrics for evaluating the evacuation plans.

In Step 3 of the analysis, one fire condition is assumed. If there are multiple potential fire threats to be considered for the region, the above six-step evacuation planning analysis should be conducted for each of them. The analysis of the fire threat should also include the assessment of its impact on the availability of city exits, and regional escape routes. This information feed directly into route planning in the Step 5 and Step 6 analyses.

The above six-step evacuation planning considers the static status of the fire threat, i.e., the fire risk assessment is only based on its distance to the EMZs in the region. When a final plan is identified from the planning analysis, it should be compared against the projected development of the fire threat to assess the emergency level to further adjust the plan if necessary. The emergency level (EL) can be assessed through

$$EL = \frac{T_t * (1 + S_m)}{T_f}$$

where T_t is the total evacuation time from simulating the identified evacuation plan, S_m is a safety margin and T_f is the projected time for the fire to reach the perimeter of the community. T_f can be obtained through fire simulation, considering vegetation location, weather conditions and wind direction (i.e. direction of approach) etc.

If $EL < 1$, the emergency level is manageable since either the fire front is still far away, or it takes longer time than the required safe evacuation time of the community. The situation can be monitored to decide whether and when to issue an evacuation order.

If $EL \geq 1$, the emergency level is high and the fire can potentially be harmful to the evacuating people, especially to those EMZs ranked high in the fire risk assessment. An immediate response including evacuation should be considered.

LIMITATIONS AND DISCUSSIONS

This paper presents a planning methodology to develop evidence based and quantifiable evacuation strategies for WUI communities threatened by wildfires. This approach is based on the idea that computer models and calculations can be used to describe evacuation performance. As any model, the work presented here, is a

simplified representation of the complexities that can be expected in a 'real' incident and it should be noted that the approach selected has certain limitations; for example, it is proposed that Fire Risk can be represented in terms of Euclidian distance from an encroaching fire; however, other metrics (e.g., estimated travel times) might be equally or more representative. Further, how quickly a community needs to issue an evacuation order is determined by multiple factors (e.g., geography, vegetation, weather, wind, community layout, means of transportation, etc.) (Kalogeropoulos et al., 2023), the evacuation process involves heterogenous responses to evacuation alerts, and associated behavioural itineraries (Vaiciulyte et al., 2021). The inclusion of these two and other potential factors is a relatively minor task to complete and is left for future method development. The method shown is therefore presented to show a general application of evacuation model output and the types of insights that might be provided.

CONCLUSION

The evacuation of areas affected by wildfires is likely to become more commonplace and involved an increasing number of communities. Wildfire evacuation pose numerous challenges due to multiple factors and inherent uncertainties involved. Given this, the emergency plans might become more complex and sensitive to increasing numbers of variables. Coupled with the challenges with relying on historical data, the capacity to quantify evacuation performance will be increasingly important – to enhance design and improve between alternative community designs and emergency plans. Despite the existence of various evacuation models tailored for different scenarios, there remains a gap in applying these tools to plan effective response measures. To address this issue, this article has outlined a simple means by which such a quantitative assessment might be structured – a methodology that can be employed to further develop evacuation models and establish common performance metrics. As a work in progress, this method is still in development. We anticipate both further enhancement of the method with practical details and application scenarios that will demonstrate its applicability with the proposed measures.

It's a Machine Learning world: no future for Complex Event Processing?

Anne-Marie Barthe-Delanoë
IMT Mines Albi, University of Toulouse
anne-marie.barthe@mines-albi.fr

ABSTRACT

In 2010, Complex Event Processing was a groundbreaking approach for data processing for Early Warning Systems and Decision Support Systems in the crisis management domain. Although Machine Learning has eclipsed CEP in the ISCRAM community these last few years, these two approaches do not fulfil the same objectives. With this article, a quantitative analysis is made on papers related to these domains to understand the current trends and identify the next challenges the ISCRAM community should address. Combining CEP with ML can help to overcome the strong assumptions made towards the CEP rules this last decade, such as the availability of experts, structured data, etc. It is then recommended that the ISCRAM community explore the hybridisation of these approaches to improve the responsiveness in real time of EWS and DSS in crisis situations, emphasising the automatic, non-supervised generation of CEP rules.

Keywords

Complex Event Processing, Machine Learning, Early Warning, Decision Making, Trends.

INTRODUCTION

Early Warning Systems (EWS) (UNDRR, 2007) and Decision Support Systems (DSS) rely on data analysis and processing. In the context of EWS, it is crucial to identify, analyse and predict potential hazards and their outcomes. Similarly, in the context of DSS, valuable information must be extracted to support decision-making. Complex Event Processing (CEP) was a top trending event processing approach for data input for EWS and DSS under time-sensitive applications in the last decade, from financial fraud monitoring to crisis management. However, in crisis management, CEP now seems overshadowed, not to say replaced, by Machine Learning (ML) and all the artificial intelligence (AI) related disciplines despite its numerous strengths. For example, the last publications on CEP applications for EWS and DSS in the ISCRAM digital library were published a decade ago (Barthe-Delanoë et al., 2014; Kovordanyi et al., 2014; Pottebaum et al., 2011).

But is this a real trend or just a side effect of all the buzz about AI in the latest research projects and academic publications? Are these approaches exclusive or complementary for real-time data analytics for EWS and DSS in crisis management? Is there a future for CEP in this ML world? The research question is then: What are the current uses of CEP and ML to feed EWS and DSS, from a data analytics perspective?

To answer these questions, this position paper explores the relationship between CEP and ML approaches for data analytics in the context of information systems for crisis management. This paper will study the synergies, complementarities, and potential challenges of integrating ML and CEP for more effective EWS and DSS for crisis management. It will also focus on how the ISCRAM community deals with it now and which challenges they might address in the future.

This paper is structured as follows. First, a brief reminder of the characteristics of each approach is made. The second part will analyse the state-of-the-art in a significant academic publication database. The main takeaways of the analysis will then be addressed to the ISCRAM community in a third part to spark future discussions about efficiency in mining and analysing multiple flows of data in real-time to feed EWS and DSS, before concluding with insights for future research topics for the ISCRAM community.

DATA PROCESSING AND ANALYTICS

DSS and EWS are based on information from the field (real-time data), and historical information (capitalised knowledge). The need to feed these systems with data is facing many constraints: real-time data processing, historical data processing, and management of numerous data sources, sometimes competing, sometimes uncertain, and sometimes temporarily unavailable. The data may also be available in the form of a continuous, ordered flow over time (data stream) or in the form of a cloud of data that is not necessarily ordered. It will also be necessary to aggregate low-level data (e.g. calculating an average temperature over the last 5 minutes of collected data) or to match patterns (e.g. A happening before B and after C within a 10-hour time window). This allows for extracting the necessary information at the right level (regarding the stakeholders' needs) to be actioned for risk assessment, monitoring, forecasting, or any other purpose related to early warning or decision support. Two approaches are mainly used to achieve these data processing and analytics steps in a time-sensitive context: Complex Event Processing (CEP) and Machine Learning (ML).

Complex Event Processing

Event processing is a method of monitoring and analysing (processing) information flows (data) about things that happen (events) to draw a conclusion from them. Complex Event Processing (CEP) is a set of concepts and techniques for processing events in real-time and extracting information from event streams as they arrive (Etzion & Niblett, 2010).

The objective of CEP is to identify significant events (such as opportunities or threats) in real-time situations and respond to them as quickly as possible. These significant events are complex because they cannot be detected or observed directly; they must be identified by deduction, analysis and correlation of observed elementary events (Luckham, 2011). For example, the combination of events embedding the temperature measure of sensors located in various areas of a building can lead to emitting an early fire alert event, indicating an incipient fire as the temperatures are slowly increasing with no abrupt temperature changes. The low latency of real-time data processing (under 10 µs in the state-of-the-art CEP engines) combined with the ability to face high volumes of data makes CEP a top technology for the Internet of Things community (Lima et al., 2022; Shah et al., 2022).

On the technical side (see Figure 1), the CEP system relies on manually pre-defined business rules (implemented as event patterns, event filters, event aggregators, causality rules, timing rules, etc.) continuously executed by the CEP engine over the incoming data streams of events that feed the event cloud. If a rule is verified, then the resulting complex event is generated. The event streams are collected through subscriptions to various heterogeneous event sources: sensors, log files, social networks, reports, etc. The generated complex events can also be collected and processed to deduce other complex events.

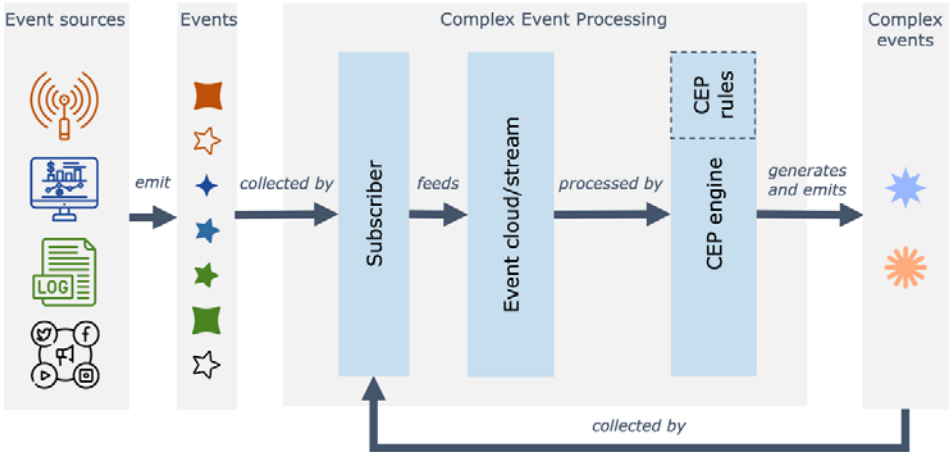

Figure 1. Principles of Complex Event Processing

It must be noted that the time dimension is natively part of the CEP system, allowing it to handle time frames (fixed or sliding) and the non-occurrence of an event. Moreover, CEP is not yet another expert system. CEP is not about decision-making as a standalone solution but about creating knowledge about a system in real-time (Fülöp et al., 2012). The generated complex events are consumed by EWS and DSS applications to feed their knowledge base, Common Operational Picture, and any component relying on situational awareness in a crisis management context, as shown by (Barthe-Delanoë et al., 2014; Kovordanyi et al., 2014; Pottebaum et al., 2011).

Machine Learning

Machine Learning (ML) was defined by (Samuel, 1959) and later by (Mitchell, 1997) as the field of study that enables computers to learn and improve from experience without being explicitly programmed. ML is a branch of Artificial Intelligence (AI) that aims to find the underlying relationships (i.e., models) between data. ML algorithms can analyse large volumes of data to identify patterns and trends that may raise potential opportunities and threats: detecting anomalies in a financial system, predicting failures in aircraft maintenance, identifying structural threats in a building, etc.

Technically, ML algorithms are trained, tested, and evaluated on historical data, split into a training set, a test set, and an evaluation set (see Figure 2). The outcome is a model called a predictor, which is then fed with new data and produces a prediction. The nature of the prediction depends on the type of the trained ML algorithm. It can be a discrete value, a series, a classification, a clustering, a probability, an association, etc.

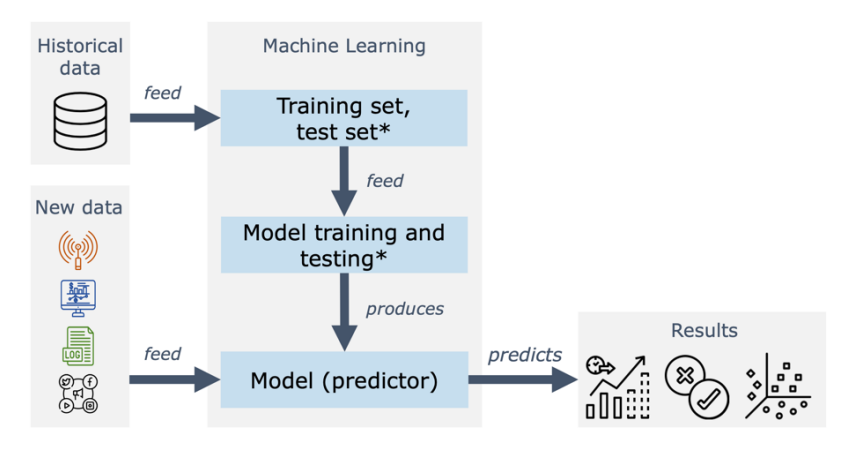

Figure 2. Principles of Machine Learning
(*evaluation step is often included with the test step)

ML can handle complex data better than classical data analytics approaches: datasets with many features and individuals; unstructured data (text, images, etc.); non-linear relationships among features. It can also make predictions, e.g. financial crisis prediction (Jaquart et al., 2021) and identification of disaster news using Natural Language Processing techniques (Chasseray et al., 2021; Domala et al., 2020).

Application to DSS and EWS

In EWS and DSS applications for crisis management, it is necessary to ensure the following requirements regarding the data analytics part: real-time detection of events and patterns of events, forecasting and prediction of the situation, low latency for timely decision-making, and scalability to handle large volumes of data.

Given the above characteristics of each of the CEP and ML approaches, a synthesis of their advantages and limitations is provided in Table 1.

Table 1. Advantages and limitations of CEP and ML for EWS and DSS (crisis management context)

Characteristics	CEP	ML
Real-time detection of events	Yes (real-time flow of data)	No
Real-time detection of patterns	Yes (use of predefined rules)	No
Forecasting and prediction	No	Yes (training on historical data)
Low latency	Yes (<10 µs)	Model dependent
Scalability	Yes (Big Data context)	Yes (Big Data context)

CEP is natively designed to detect events in real-time and complex patterns in huge data streams with low latency, making this approach suitable for time-sensitive applications. On the other hand, ML algorithms can uncover hidden patterns in historical data and make predictions about future events. They can also natively handle large volumes of data.

CEP, ML: WHERE ARE WE?

Overview of the Publication Trends

The first step of the inquiry about the position of CEP and ML in the literature is exploratory data analysis on the publications retrieved through six SCOPUS[1] queries, as shown in Table 2. These queries look for the presence of the CEP and ML approaches with a focus set on crisis management (queries *R1* and *R2*, respectively), on the DSS and EWS (queries *R3* and *R4*, respectively), and finally, on DSS and EWS for crisis management (queries *R5* and *R6*, respectively). The subject areas of all the queries were limited to the relevant ones, given the technical topic and the application domain (*dom*): computer science, engineering, mathematics, decision sciences, social sciences, business, management and accounting, energy, economics and finance.

Table 2. Set of SCOPUS queries

Req.	CEP	Req.	ML
R1	TITLE-ABS-KEY("event process*" AND ("cris* manag*" OR "emer* manag*"))	R2	TITLE-ABS-KEY ("machine learn*" AND ("cris* manag*" OR "emer* manag*"))
R3	TITLE-ABS-KEY("event process*" AND ("decision support*" OR "early warning*") AND system*)	R4	TITLE-ABS-KEY ("machine learn*" AND ("decision support*" OR "early warning*") AND system*)
R5	TITLE-ABS-KEY("event process*" AND ("decision support*" OR "early warning*") AND system* AND ("cris* manag*" OR "emer* manag*"))	R6	TITLE-ABS-KEY("machine learn*" AND ("decision support*" OR "early warning*") AND system* AND ("cris* manag*" OR "emer* manag*"))
dom	AND (LIMIT-TO (SUBJAREA , "COMP") OR LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "MATH") OR LIMIT-TO (SUBJAREA , "DECI") OR LIMIT-TO (SUBJAREA , "SOCI") OR LIMIT-TO (SUBJAREA , "BUSI") OR LIMIT-TO (SUBJAREA , "ENER") OR LIMIT-TO (SUBJAREA , "ECON"))		

From the raw results of these six queries[2] (before the screening of each paper), it can be observed (Table 3) that the literature is more extensive regarding ML than CEP, which is explained by the variety of techniques and tools that can be found under the umbrella of ML compared to CEP.

Table 3. Raw results of the SCOPUS queries

Req.	CEP	Req.	ML
R1	31 documents	R2	329 documents
R3	114 documents	R4	6,984 documents
R5	10 documents	R6	24 documents

The gathered results are then plotted (Figure 3) to observe the overall distribution of publications by year for each 2-uple of queries: R1 vs R2, R3 vs R4, and R5 vs R6. It must be noted that since 2024 is at its beginning (to date of this review), the 2024 figures cannot be interpreted as for the previous years. Also, some publications from late 2023 are not yet referenced. A few duplicates were found between queries results (Table 4).

In Figure 3, a first observation is that the distribution of CEP-related publications peaks in the early 2010s, then decreases and reaches an asymptote (between 1 or 2 publications per year in the 2020s). On the other end, the ML-related publications tend to increase over time since mid-2010s with an exponential growth in the 2020s. It appears that the naïve impression of CEP being overshadowed by ML in the academic literature is correct from a quantitative point of view, especially in the case of ML/CEP for DSS and EWS applications, without connection to a specific business domain. However, if the focus is set on DSS and EWS restricted to crisis management applications, the number of publications drops significantly and the ratio between CEP and ML publications per year is far less pronounced (average ratio of 1 per 6).

[1] The focus is set on the SCOPUS database since it references a wider range of publishers (contrary to ScienceDirect or IEEE Xplore), including the ISCRAM digital library.
[2] Data files are available upon request.

The 10 duplicate results between R1 and R3, R1 and R5, and R3 and R5 queries (focus on the CEP approach) are the same 10 documents resulting from the R5 query (CEP × DSS/EWS × crisis management). Half of these 10 documents are authored by the ISCRAM community (in ISCRAM conferences, journals, etc.). They represent 32% of the R1 and 8.7% of the R3 results. The 24 duplicates found between R2 and R4, R2 and R6, and R4 and R6 (focus on the ML approach) are the same documents as the 24 results of the R6 query (ML × DSS/EWS × crisis management). They represent almost 7.3% of the R2 and 0.34% of the R4 results. A few of these 24 publications were authored by the ISCRAM community, not necessarily within the ISCRAM conferences series. R3 and R4 share 7 results, while there is no overlap in R1 with R2 and R5 with R6.

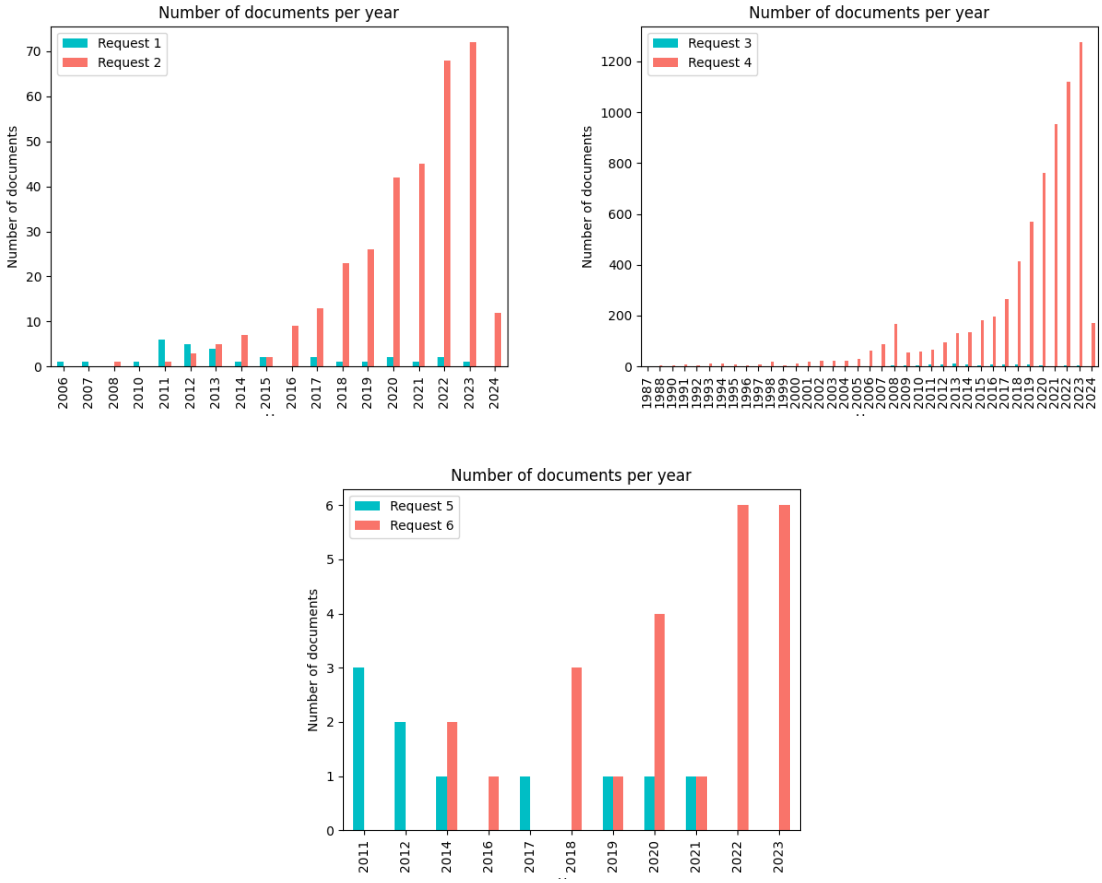

Figure 3. Distribution of the publications per year (R1 to R6 raw results)

Table 4. Duplicates between two queries raw results

Req.	R1	R2	R3	R4	R5
R2	0	-	-	-	-
R3	10	-	-	-	-
R4	-	24	7	-	-
R5	10	-	10	-	-
R6	-	24	-	24	0

The main outcomes of this quick quantitative exploratory data analysis are the following:

- ML is exponentially trending in DSS and EWS studies, exponentially overshadowing CEP for a decade.
- Within the crisis management application domain, the global ratio between CEP and ML publications is of 1 per 9 (R1 vs R2) up to 1 per 2.5 (R5 vs R6).

Deep Dive into the Research Topics

The previous findings show us that it will be more efficient to explore the topics of the publications retrieved by the R5 query and the R6 query to understand the use of CEP or ML for EWS and DSS in crisis management, as well as the seven results common to the R3 and R4 queries to understand the simultaneous presence of CEP and ML in these papers.

This section deep dives into the content of the retrieved documents. First, the relevance is checked by reading the title, abstract, introduction, and conclusion: publications outside the scope of this paper (data analytics to ultimately feed an EWS or a DSS) are not included in the analysis. Then, they are fully read to analyse the research proposal and results and, if applicable, the TRL (Technology Readiness Level) and the assumptions. These will help to understand the current trends found in the previous section, but also the gaps and the maturity level of the proposed solutions.

The results of the R5 query (Barthe-Delanoë et al., 2014; Braun et al., 2012; Fertier et al., 2020, 2021; Itria et al., 2017; Kovordanyi et al., 2012; Kraus et al., 2011; Mijović et al., 2011, 2019; Vranes et al., 2011) all show that the focus of these research works was on proving and demonstrating the integration of CEP components with other information system components (DSS, EWS, simulation tools, COP) within a crisis management context. Several information system architectures based on a hybrid ED-SOA (Event-Driven Service-Oriented Architecture) are also proposed to ensure the low coupling of these components. The proofs-of-concept and demonstrators presented in these publications are TRL 4 up to 6 by the end of the 2010s.

Out of the 24 results of query R6, 10 publications are excluded due to language constraints (despite automated translation efforts), being out of the scope of the study (e.g. wildlife activities) or having too few details about the processed data and/or the end use. The remaining 14 publications can be classified as follows, based on their authors' envisioned use:

- ML for DSS: emergency care triage (Rostam Niakan Kalhori, 2022), building structural assessment (Rahman et al., 2020), resources reallocation (Khouj et al., 2014, 2018), nuclear emergency management (Ionescu & Scheuermann, 2016), earthquake damage assessment (Ahadzadeh & Malek, 2021), contingency plans design (Kunikowski et al., 2020).
- ML for EWS: financial crisis (Zhao et al., 2023), citizen complaints (Zhang et al., 2023), flood forecast (Burrichter et al., 2023), building structural assessment (Kim et al., 2022).

These works all have a low TRL (evaluated at 3): the limitations and discussion sections show that the proofs-of-concept are still in their early stages. This can be explained by the recent technological hardware advances that made the wide use of ML algorithms possible. However, they all face the data input issue, either regarding the available volume, the available quality, or the available diversity of the data sources. Most of the authors underline the need for training, testing, and validating on (i) real data rather than on generated data and (ii) various datasets to overcome the overfitting bias.

Among the seven publications in common between the R3 query and R4 query results, one was recently retracted, and only two use both CEP and ML approaches. The works of (Bertoncelli et al., 2023; Sadanandan et al., 2022) aim to detect patterns in real-time data, using pre-defined CEP rules and historical data to learn data patterns with ML algorithms. Both CEP and ML are used concurrently rather than by hybridisation.

PAST AND CURRENT ISSUES

Integrating CEP in Information Systems Is A Mature Research Topic

It is interesting to note that despite a clear difference in the goal of each approach towards data processing and analytics, research on CEP has been almost abandoned in the information systems for crisis management domain since the late 2010s.

Given the findings in the previous section, it seems that this is mainly due to the maturity level of the research results (Barthe-Delanoë et al., 2014; Braun et al., 2012; Fertier et al., 2020, 2021; Itria et al., 2017; Kovordanyi et al., 2012; Kraus et al., 2011; Mijović et al., 2011, 2019; Vranes et al., 2011). The common topic of these papers was proving the benefits of integrating a CEP engine to feed an EWS or a DSS in a crisis management context with quite a high TRL. It means that they were ready for the next stage of development, which is production rather than research and proof.

However, while CEP has now been adopted as a powerful approach to analyze large volume of streaming data in real-time while operating with limited computational resources, a strong assumption was made in the publications

related to information systems for crisis management. It was assumed that the knowledge necessary to create and implement the CEP rules was available so that it was ready to use. The questions of sharing explicit knowledge, making tacit knowledge explicit, the availability of experts for knowledge gathering and CEP rules assessment, the volume of knowledge to deal with, etc., to create these CEP rules have not yet been addressed by the ISCRAM community.

Automatic Creation of CEP Rules

The SCOPUS query R7 (Table 5) looks for publications about the automatic generation of CEP rules without limit of time or application domain: 48 documents were retrieved, authored by the Computer Science community, who seized this question (Alakari et al., 2020; Margara et al., 2014; Mehdiyev et al., 2015) mainly in the context of physical/cyber intrusion detection, air quality monitoring, traffic monitoring.

Table 5. Set of SCOPUS queries and results

Req.	Content	Results
R7	TITLE-ABS-KEY("event process*" AND autom* W/5 rule*)	48 documents
R8	TITLE-ABS-KEY "event process*" AND "of thing*" AND autom* W/5 rule*)	14 documents

Among these 48 documents, 25% are related to the Internet of Things (IoT) and Web of Things (WoT) research areas (query R8). The distribution of the publications over time (Figure 4) shows that the question of the automatic creation of CEP rules is still an open issue and has been seized by the IoT and WoT communities in the last decade. This question has been on the roadmap of these research communities (Mehdiyev et al., 2015), among the first to adopt CEP in their software architectures.

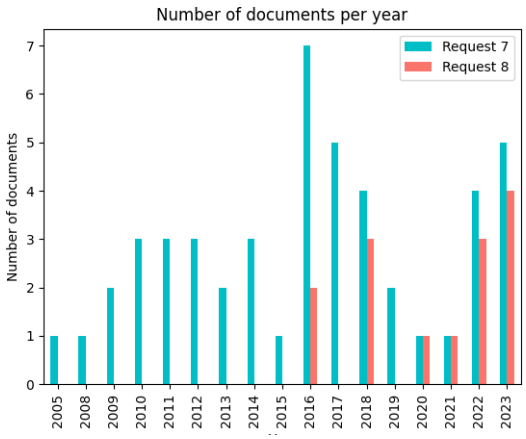

Figure 4. Distribution of the publications per year (R7 and R8)

Most of the papers propose using ML algorithms to generate CEP rules automatically: Deep Learning algorithms (Liu et al., 2022; Simsek et al., 2021; Simsek & Özdemir, 2018), classification algorithms (Kumar et al., 2023; Petersen et al., 2018; Sun et al., 2020), Principal Component Analysis (PCA) (Roldán-Gómez et al., 2023), time series shapelet (Li et al., 2019; Mousheimish et al., 2017). Only a few papers use approaches such as optimisation: evolutionary algorithms (Lv et al., 2022) or swarm algorithms (Bruns et al., 2023). All these research works focus on numerical and categorical data, mostly in a supervised training context.

CEP and ML are, in fact, complementary, given their features (see Table 1). CEP natively offers the processing of event flows in real time and enables patterns to be detected in real time, with limited computational resources. ML, on the other hand, makes it possible to exploit historical data to generate the CEP rules automatically (or as much as possible).

However, the results of the IoT and WoT communities may not be directly transposable to the field of crisis management (civil, humanitarian, agricultural, etc.). To prepare or to respond to a crisis, data are collected from various sources and in various types: numerical measures from sensors, text and images from social media (Coche et al., 2020; Power et al., 2022; Salemi et al., 2023) and from reports and press articles (Chasseray et al., 2021), speech (Cámbara et al., 2023), etc.

In other words, there is a significant challenge in processing structured and unstructured data when the CEP-ML solutions referenced above use datasets with numerical features (mostly) and categorical features.

Another key challenge is the learning part itself: most of the cited works use supervised algorithms, meaning their training datasets are labelled. In the context of crisis management, where the context is dynamic and the data sources volatile, the task of labelling datasets to train ML algorithms is unrealistic. It is then necessary to explore ways to perform CEP and ML hybridisation that rely on unsupervised learning algorithms.

CONCLUSION AND RECOMMENDATIONS

In this position paper, a short quantitative analysis was conducted on the papers related to CEP and ML for processing and analysing data to feed DSS and EWS. The naïve thought of CEP being overshadowed by the trending ML in the ISCRAM community is due to the maturity of the past research topics. However, the major issue of the automatic CEP rule creation was not addressed in the crisis management area. It is still an open issue, now seized by the Internet and Web of Things communities. They propose to use ML to deduce CEP rules, mainly using labelled datasets.

It is then recommended that the information systems for the crisis management community (particularly the ISCRAM community) focus on the potential of CEP in conjunction with ML. A hybrid approach may be the key to overcoming the challenges associated with automatic rule generation by exploiting the advantages of ML to process historical data and extract the necessary knowledge, whether explicit or tacit, whether from experts' interviews or written documents, images, etc.

It is crucial to address the assumptions related to the availability of knowledge and the resources required in the proposed solutions and to keep in mind the specific challenges faced by the crisis management domain compared to other application domains: the variety and the reliability of data sources; the availability of data sources and knowledge resources; structured, semi-structured and unstructured data; labelled and unlabeled data (to name a few).

A potential agenda for future research could lie in these four threads:

- Exploring methods to generate CEP rules from unsupervised ML algorithms automatically, trained on non-structured data;
- Optimizing CEP rules to balance accuracy, completeness, and efficiency considering the complexity and volatility of data sources;
- Adjusting CEP rules dynamically based on feedback from practitioners and end-users;
- Considering the ethical and societal implications of using ML-generated CEP rules such as privacy, transparency, bias, and fairness awareness (to name a few).

By investing in CEP-ML hybrid approaches adapted to the crisis management domain characteristics, DSS and EWS could significantly improve responsiveness and accuracy in crisis situations.

PROJECT SYNERGISE - increased safety and efficiency of first responder operations

ABSTRACT

SYNERGISE is an EU-funded research project aimed at enhancing the safety and efficiency of first responder operations through innovative technological solutions. With the evolving landscape of emergencies and disasters, the need for effective response strategies has become increasingly critical. SYNERGISE addresses this challenge by leveraging advanced technologies to empower first responders with enhanced capabilities and tools.

The project focuses on developing integrated robotic solutions and intelligent decision-support systems tailored to the needs of first responders. By harnessing the power of robotics, artificial intelligence, human-machine collaboration and data analytics, SYNERGISE aims to revolutionize the way emergency situations are managed and responded to.
Key objectives of the project include:

1. Designing and implementing robotic platforms capable of assisting first responders in various tasks, such as search and rescue, reconnaissance, and hazardous material/environment handling.
2. Developing intelligent decision-support systems that analyze real-time data from multiple sources to provide actionable insights and recommendations to first responders.
3. Enhancing collaboration and coordination among different response teams through advanced communication and information-sharing technologies.
4. Conducting rigorous testing and validation of the developed solutions in real-world scenarios to ensure their effectiveness and reliability.

Through collaborative efforts involving researchers, industry partners, and emergency response organizations, SYNERGISE aims to deliver impactful solutions that enhance the safety of first responders and improve the efficiency of their deployments. By embracing innovation and technology, SYNERGISE seeks to pave the way for a safer and more resilient future in emergency response operations.

DIGITAL EMERGENCY COMMUNICATION IN THE NORDIC COUNTRIES

ABSTRACT

During disasters and emergencies, reliable means of communication are of vital importance to life- saving efforts. This poster presents findings from DIGeMERGE, which is a research project on Digital Emergency Communication in four highly digitalized countries: Norway, Sweden, Finland, and Denmark. DIGeMERGE is funded by the CHANSE (Collaboration of Humanities and Social Sciences in Europe) call for projects on Transformations: Social and cultural dynamics in the digital age. The project consortium consists of the Peace Research Institute Oslo (PRIO), Malmö University in Sweden, the IT University of Copenhagen in Denmark, and the Centre for Machine Vision and Signal Analysis, University of Oulu in Finland.

The overarching objective of the DIGeMERGE project is to understand both the everyday practical challenges of emergency management digitalization and the deeper implications of these developments for the state-citizen relationship. The project pursues this objective by investigating challenges associated with new digital emergency communication tools and related debates about societal and individual responsibility, protection needs, vulnerability and rights in the four Nordic countries.

The governments of the Nordic countries highlight the need for information sharing, cooperative initiatives and technical innovation to improve emergency response capabilities and readiness, focusing on the adoption of cell broadcast alert systems and mobile broadband networks (3GPP, LTE, and 5G). There is also a strong attention to the need to set standards that provide smooth communication in cross-border emergencies and ensures interoperability across countries.

In the poster for ISCRAM, we will present a case study of the implementation of the cell broadcast emergency alert system in Norway, which is a new system designed as a digital supplement to the existing post-World War II air-raid typhoons or sirens. At least 2.2 million of Norway's 5.5 million people live too far away from the nearest siren to be able to hear it. In the latest test of the cell broadcast alert for mobile phones ("Nødvarsel på mobil"), approximately 90% of the population received the alert on their phone. Unlike the typhoons or sirens, which are operated by Norway's Civil Defence and were designed primarily for war-time emergencies, the cell broadcast alert system is operated by the police in peace-time and the Civil Defence in war-time. The Norwegian Police Directorate has developed a set of templates that consist of potential scenarios where they foresee the alert system to be put into use. The poster will present examples of these templates to show how the new technology is transforming the way authorities communicate with the public during emergencies, and will also give examples of reactions on social media to the use of the system in a real-life emergency - the extreme weather event "Hans" - illustrating the potential impact of this technological and organizational transformation on expectations about emergency management in Norway.

Development of a Responding Laboratory for the Collection of Data on Major Emergency Incidents

ABSTRACT

As part of the incident management process, it is necessary to collect data on the event, its course and how it is managed. This data can be used after the incident to continuously improve the entire incident management process. At the same time, it is necessary to be able to collect valid as well as precise data quickly during the incident and to present it appropriately for decision support to initiate measures in order to deal with the incident. The poster shows the development and the use of a laboratory that serves these purposes. The RespondingLab enables researchers to collect data during exercises or in real-life events, allowing them to evaluate processes and structures. The RespondingLab also serves as a kind of test bed for new technologies. For example, different sensors on drones and various options for visualizing the situation are currently being tested. To date, the laboratory has been used, for example, for the construction of a temporary bridge after a flood event. In this case, the laboratory provided 3D data of the terrain as well as live data on the bridge construction.

The RespondingLab is supplemented by a vehicle and a trailer so that the laboratory's technologies can be used flexible in different locations. The lab's sensors can be set up quickly, and they are just as quickly connected to each other via the lab's own ad hoc WLAN. The poster shows which sensors and technologies the laboratory uses to collect data and how this data can be analyzed. The poster is intended to give researchers an idea of how data from emergency incidents can be collected and analyzed in the field. This research method not only supports the improvement of processes and structures for first responders, but also the active provision of analyzed data during real emergency incidents.

Enhancing Emergency Preparedness in Mass Gatherings

ABSTRACT

This study emerges from a vital collaboration with the firefighters in France (i.e. Service Départemental d'Incendie et de Secours, SDIS), underscoring the critical role of emergency services in fighting fires, providing emergency assistance, and preventing accidents and disasters, particularly in the context of mass gatherings. The primary purpose of our research is to enhance preparedness and proactive response planning for medical emergencies during large-scale events through a sophisticated crowd simulation and analysis approach.

Our approach unfolds in two layers. The first layer, **modeling and assessment**, focuses on creating models of different urgency levels of projected scenarios, including their cascading effects. It aims to assess the agility and effectiveness of various emergency response strategies and their capability to mitigate such cascading phenomena. The second layer, **analysis, and decision-making**, is dedicated to identifying critical thresholds where medical responses might be overwhelmed. It seeks to optimize the allocation of medical resources and improve response times, ensuring agile and efficient emergency handling.

A practical application of our approach was demonstrated at a major music festival held on the former air base of Cambrai, France. We employed AnyLogic's pedestrian library and agent-based modeling to develop a crowd simulation that fulfills two expectations: visualizing and monitoring crowd flow within confined spaces and anticipating the impacts of current and future risks and their cascading effects on both the crowd and emergency responses.

Our outcomes to date reveal three significant capabilities of the simulation:

- Simulating normal crowd movement within a realistically scaled environment.
- Modeling low urgency emergency scenarios, allowing us to compute crucial metrics like crowd density and medical response time.
- Illustrating high urgency medical emergencies and their potential to incite secondary incidents, such as widespread panic, and examining how crowd movement patterns might create barriers or bottlenecks that impede emergency responses.

An ongoing effort is directed towards simulating how secondary incidents propagate through the crowd, affecting overall safety and the efficacy of response strategies. Regarding an outlook for future work, we aim to refine our simulation capabilities to encompass a broader spectrum of emergency scenarios and their complex interdependencies. This includes enhancing the model's accuracy in predicting cascading effects and integrating real-time data for dynamic scenario planning.

Community-Based Smart City Digital Twin Platform for Optimised DRM operations and Enhanced Community Disaster Resilience

ABSTRACT

PANTHEON is a project funded by the European Union's Horizon Europe programme, bringing together 17 partners from 9 different countries under the research theme Disaster-Resilient Society for Europe. The project started on 1 January 2023 and its planned durations is 36 months. The PANTHEON consortium aims to develop a community-based Smart City Digital Twin that facilitates disaster risk management operations while reducing vulnerability and strengthening community resilience.

The implementation of technologies is impossible without considering the context in which they will be deployed, thus the first year of the project has focused on the study of the PANTHEON ecosystem. As a first step, a risk mapping and assessment was carried out to identify the most relevant disasters in the two pilot cities: Athens and Vienna. This assessment includes both natural and man-made hazards. In addition, the regulatory framework was analysed in depth, including national civil protection plans and disaster management strategies for the two countries, as well as EU-wide directives and initiatives. On the social side, an assessment of the vulnerability and capacity of the community in the event of disasters has been carried out, with a particular focus on vulnerable groups such as the elderly, children or people with physical or mental disabilities. One of the outputs was the development of a set of indicators to assess community capacity and vulnerability. In addition, a series of recommendations were produced to involve the community, especially vulnerable groups, in decision-making on disaster management issues. From the technological viewpoint, the technical and scientific capabilities that exist to support disaster planning and management have been studied, something that has greatly assisted in the creation of a roadmap of technologies that PANTHEON intends to develop as well as their expected improvements.

These results, together with a participatory design process, have been the basis for conceptualising the idea of the PANTHEON system. Thus, taking advantage of the diversity of data sources available in a smart city, such as satellites, sensors, infrastructure data, traffic data, UAV data and community data, PANTHEON aims to be a system composed of two fundamental elements, both focused on the pre-disaster phase. On one hand, PANTHEON will provide a training platform to simulate disaster situations and train for complex and economically difficult scenarios whereas, on the other, a planning and early warning platform will be integrated to allow end-users optimise and improve resource management and disaster planning, with a special focus on cascading effects.

To test the usability and functionality of the PANTHEON system, four scenarios have been created that reflect the most important disasters in the two cities, as well as the most relevant tools for each scenario. The training platform will be tested by visualising and simulating an earthquake near Athens and a fire caused by a cyber-attack on a power plant in Vienna. The planning and early warning platform will be tested by visualising and simulating a forest fire near Athens and the propagation of a heat wave in Vienna.

Automated Integration of Humanitarian Data into Route Planning to support Disaster Response

ABSTRACT

During disaster events, humanitarian organisations often need to plan routes to deliver goods and services to affected areas, identify evacuation paths, and to determine the reachability of services by the population. Especially in the case of flooding, roads can become blocked and impassible, meaning that vehicles need to be redirected from the usually optimal route. To efficiently plan suitable routes during disaster events, a routing service must consider the constantly evolving condition of the road network by integrating data from different sources and organisations.
Existing services such as Google Maps do not offer such capabilities.

To fill this gap, a prototype system has been developed called the HeiGIT Disaster Portal [2], which acts as a data storage and a proxy to services such as Openrouteservice for Disaster Management [1]. Data relating to disaster events (such as flooded regions) can be added to the portal, which is then stored centrally for access by other users and services. When requests to openrouteservice are made through the portal, these data can be automatically included in the request as areas to be avoided without the user needing to manually draw them.

The newest set of developments includes an advanced routing algorithm, that supports extensive and intricate avoidance zones, which would normally slow down calculations or render them impossible. The algorithm combines the centralized storage with rapid pre-processing steps for routing graphs, thereby ensuring efficient routing and reachability analysis on complex avoidance data.

As an example, the HeiGIT Disaster Portal was used during the Anatolia earthquake in 2023. Data relating to closed border crossings and damaged road infrastructure were provided to the portal by humanitarian organisations, which were then used to avoid areas in routing requests.

In the future, the Disaster Portal will be extended to include automatic ingestion of data from sources such as the Copernicus Emergency Management Service [3], as well as providing access to additional services and operations.

Decision Support Systems for Public Authorities to Prepare and Manage Food Shortages

ABSTRACT

Crises such as the COVID pandemic and Russia's war of aggression against Ukraine have shown that food shortages are more likely than previously thought. In such a case, the state must maintain the population's food supply to avoid a crisis. This implies that the relevant authorities should be able to intervene in the food supply system in a directive manner. To do this, they need knowledge of the structures and capabilities of the food industry and perhaps even up-to-date operational information such as stock levels, supply and demand estimates and forecasts.

The disruptions in the food supply chain during COVID and the Russian-Ukrainian war have shown that cooperation and active communication between the responsible authorities and the food industry are essential for managing and solving problems. Instruments for such systematic cooperation do not currently exist in Germany. The events of recent years have shown that the authorities' crisis management of food supply problems is currently limited to manual data queries and spontaneous ad-hoc measures.

For this reason, the aim of the project “KRITIS-ENV” is to develop suitable cooperation and decision support systems. This is intended to improve the authorities' ability to act in the event of potential food supply shortages to make the food system more resilient.

To this end, the project will develop three tools. First, the development of a Risk Management and Communication System (RMCS) creates a standardised platform to facilitate and simplify management and communication between authorities and food industry companies. Second, the development of a decision support system and a database of information on the food supply in the form of a Geographical Information System (GIS) improves the transparency of the food system for the authorities and thus increase their ability to act and react. And third, contingency plans for selected scenarios provide a system of procedures and responsibilities to support appropriate action.

Methodically, a literature review and interviews will be used to define the requirements for the RMCS. For the GIS system, a comprehensive dataset of the German food supply system will be established. This database will provide the basis for a vulnerability analysis of the German food supply system which will determine the design of a GIS-based decision support system for food shortages. The derivation of several contingency plans will be done by practitioners accompanied by researchers. This Action Based Research setting will also result in a process blueprint for plan development.

To test the developed tools, we will specify a scenario in which we assume the closure of a large number of points of sale (e.g. due to staff shortage). For this, we develop a multi-objective optimization problem to select the optimal subset of POS to maximize food accessibility and (at the same time) efficiency of logistics operations.

The project is carried out in close cooperation with the Lower Saxony Ministry of Food, Agriculture and Consumer Protection, the software company Calpana and Kühne Logistics University. The project is expected to start on the 1st of March 2024.

TREEADS - Holistic Fire Management Ecosystem for Prevention, Detection, and Restoration of Environmental Disasters

ABSTRACT

Wildfires are a severe threat across Europe, causing significant environmental and economic damage. They are becoming more intense and widespread as a result of climate change, particular forestry practices, ecosystem deterioration, and rural depopulation. Longer fire seasons, more frequent fire events, an increase in fire-prone locations, and more extreme fire behaviour are all projected to enhance fire risk as a result of climate change. According to the European Forest Fire Information System (EFFIS), the wildfire season of 2022 was the second worst on record, in terms of burnt area (881 275 hectars) and number of fires [1]. The latest UNEP and GRID-Arendal report on wildfires foresees a global increase of extreme fire events by up to 14 percent by 2030 [2]. Extreme wildfire events, in addition to their devastating ecological impact, have an unparalleled social cost in terms of impacts on human health and life, as well as environmental and economic losses.

The TREEADS project addresses several major challenges that wildfires pose, including current technological and infrastructural restrictions and severe environmental, societal, and economic consequences [3]. The TREEADS fire management ecosystem will include various innovative technologies and systems covering all time-interconnected stages of wildfires (before, during, and after). Over 26 different technologies are optimized, developed, and validated in the implementation of TREEADS, including coordinated novel pilotless aircraft (multi-rotor and fixed wing) and satellite systems, an advanced analytical and modeling framework for fire prevention, detection, and response, forest and landscape restoration and an emerging set of fire protection and suppression technologies. Expected results are, among others, the minimization of the significant impacts caused by extreme fires and experience strengthening for end-users within a rich set of realistic scenarios via the project's training programme. In TREEADS, we focus our research, development, and integration efforts on delivering systems of high relevance and benefit to the relevant end-users and the forestry market while providing them, in turn, with an excellent opportunity to understand potential weaknesses or limitations of current technologies. The TREEADS tools and solutions are demonstrated and validated under actual operating conditions in eight complex pilot implementations in Taiwan and seven European countries: Austria, Norway, Spain, Italy, Romania, Greece, and Germany. The project is also carrying out a disciplined assessment of the impact of the developed technologies based on methods that consider both social and financial aspects (e.g., Social Return on Investment (S-ROI)).

Acknowledgment: TREEADS has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No. 101036926. The findings were published in several conferences such as RISE-SD2023, ICFFR-Coimbra and IAFSS2023.

ZKI Fire Monitoring Service of DLR

ABSTRACT

The "ZKI Fire Monitoring System" of the German Aerospace Center (DLR) is making new research methods in the field of satellite-based wildfire detection easily accessible to academics and practitioners alike. The system provides up-to-date wildfire information for Europe and other pre-selected areas. Aiming at monitoring burnt areas and their spatial development in near-real time, a fully automated approach was developed (Nolde et al., 2020, Nolde et al., 2021) and implemented in a thematic processing chain. The "ZKI Fire Monitoring System" is operated by the Center for Satellite Based Crisis Information (ZKI) of DLR. To achieve several updates per day, mid-resolution satellite data are used. The daily research products show the perimeters of burnt areas, processed minutes after satellite imagery becomes available. Detected areas are iteratively and automatically refined over a period of 10 days as new satellite data becomes available. This enables continuous improvement of the derived fire perimeters by minimizing the influence of disturbing factors such as cloud cover, smoke plumes and shadows. Beside the burnt area perimeter, other attributes such as the fire severity, the area affected, as well as the exact detection times are included in the data. It is therefore possible to track the evolution of each burnt area in space and time.

The aim of the "ZKI Fire Monitoring System" is to provide burnt area analysis in near-real time, complementing existing services in Europe. The comparison and combination of different approaches, methods and sensors is vital for new scientific achievements and progress in this topic.

In addition to the processing component a public web application was developed (https://services.zki.dlr.de/fire/) to ease fast and interactive analysis and exploration of the generated research data products. In a first step the burnt area data is published as standardized OGC web service by the Earth Observation Center (EOC) Geoservice (Dengler et al., 2013; https://geoservice.dlr.de/) and afterwards integrated in a dedicated frontend user interface. There the detected wildfires can be shown on a dynamic web map, built with DLR's Environmental and Crisis Information Systems (UKIS) software components for geoscientific data visualization (Muehlbauer, n.d.; https://github.com/dlr-eoc/ukis-frontend-libraries). The web services themselves can be integrated in other geographical information systems as well. This makes it especially easy for researchers and practitioners to access the data and use it for a more detailed situational awareness overview in their own information systems.

Factors for Volunteer User Satisfaction and System Success in Warning Apps

ABSTRACT

The success of information systems in human computer interaction builds on the user's satisfaction with the technology or application. Warning and emergency response systems provide alerts and instruction to specific groups of individuals. As an emergency response system, it is not designed to improve productivity or quality of life in regular use cases, but it applies to exceptional cases – emergencies – only. In our work, we investigate this application area using a warning app as part of a fire detection system in which volunteer helpers are automatically alarmed based on the measurements of a sensor network. The primary goal of this socio-technical system is to support the protection of historical buildings, whereas individual benefits are secondary and realized through the collaboration in the protection of valuable assets. Consequently, user satisfaction must be viewed form a different perspective: While classical user satisfaction in information system success, technology acceptance or human computer interaction builds on the ease of use and benefits created by using a technology or information system, satisfaction in emergency response must consider how users perceive their safety and trust in the system and if the system's purpose itself corresponds to the user's aim: the protection of the building and assets inside.

The presented study is part of the BRAWA[1] project. We present findings from a study comprising three parts, a screening study on a variety of items and psychological variables, a main study based on the BRAWA app including an in-app questionnaire and a post questionnaire on experiences and ratings with 79 participants. Each participant received three alerts during a period of two weeks, informing the recipient about a potential fire in the building and the task to investigate the area. One set of participants additionally received reminders between the second and third alert on the purpose and functionality of the app. Another set received additional graphical aids illustrating the probability of the potential fire. A third set received more detailed information on potential causes for the fire based on measurements from the sensor network. Three preregistered hypotheses[2] investigated the relationship of reminders, graphical aids, and the amount of information on the perception and reaction of participants to the alerts.

In our findings we show that the Protective Action Decision Model (PADM) is a fitting model to explain user satisfaction and system's success in the context of emergency warning systems. We draw conclusions on the hypotheses and formulate suggestions for future app designs in this domain, e.g. that graphical aids increase the trustworthiness of information. Our findings will be submitted to the International Journal of Human-Computer Interaction. We want to present them as poster on the ISCRAM 2024 conference to engage with practitioners and experts in crisis management and information system design and discuss further insights into system developments.

Seismic Variables: Impact of Distance and Azimuth on Landslide Forecasting

ABSTRACT

In recent years, machine learning (ML) methods have gained popularity for predicting landslides following earthquakes, replacing traditional statistical or numerical simulation approaches. Most ML studies in this field relied on the Peak Ground Acceleration (PGA) to predict the landslides. Yet, the accuracy of PGA-based models can be compromised due to the limited availability of near-source observations and spatial information regarding seismic faults. This limitation can result in significant discrepancies between the accumulated PGA and the actual ground shaking, which cannot be overlooked. This study introduces a novel approach that utilizes ML models based on two seismic features: the distance and azimuth to the epicenter. The ML model using the distance and azimuth to the epicenter performs better than the model using PGA in terms of accuracy as well as actual prediction results. The findings indicate that these models exhibit superior performance in predicting the spatial distribution of landslides resulting from seismic events, compared to models relying solely on PGA. Furthermore, considering their computational efficiency and cost-effectiveness, the ML models utilizing distance and azimuth to the epicenter as inputs could be used as an alternative to PGA-based models for evaluating the impact of co-seismic landslides. Particularly, these models prove advantageous in near real-time scenarios and settings that require high spatial resolution.

Prototyping data-driven disaster mapping for multiple roles

ABSTRACT

Working on analog situation and crisis maps for major incidents is still common practice in Germany. Analog situation maps are updated manually. This is time-consuming and prone to errors. The time delay between receiving information and issuing commands is estimated to be over 90 minutes in some cases (cf. Lamers 2016[1]). It is not possible to work synchronously on a common situation picture regardless of location. The fact that more and more data is available also means that we find ourselves in a kind of unstructured jungle of information. This flood of data can only be quickly perceived and prioritized by one person to a limited extent.

Although there are attempts to convert these situation and crisis maps into a digital form, this usually only results in a simple 1:1 transfer of the analog map without exploiting the opportunities and possibilities of digital systems. The result is a digital system that enables location-independent and cross-device work but offers little added value in its handling compared to the analog form, although the available data (e.g. sensors, cameras, weather data, traffic data) is constantly increasing and can make a positive contribution to the interpretation of the situation map using artificial intelligence. Supporting applications with artificial intelligence, on the other hand, can quickly evaluate this data and alert the user to specific information in the event of anomalies.

In the SPELL research project, funded by the German Federal Ministry for economic affairs and climate action, the German Red Cross as a disaster response organization has the task of mediating between practice and development to communicate practical requirements and technological innovation opportunities between all parties involved.

In order to communicate these needs and innovation opportunities in a way that is understandable to all those involved, we at the German Red Cross are developing a visual design prototype of a practical and user-friendly digital situation map. Our guiding principle: as much recognition value as necessary, as much innovation as possible. The focus here is on the role-based networking of all management levels and emergency responders (e.g. political decision-makers, command staff, control center, ...) and the integration of AI services via the SPELL platform.

The demonstrator is based on familiar structures and symbols known from the situation map display. This recognition value is essential to ensure intuitive operation of the system by those involved, without the need for extensive training, and thus to achieve acceptance in practical applications. The demonstrator shows various applications of artificial intelligence developed as part of the SPELL

project and available to the operational and command staff.

The demonstrator allows access to the situation map by various levels of command. The views and applications adapt to the individual needs and access rights of the users.
