Command & Control Studies 1
WiP Papers
Institutional amnesia during large crisis: Effects of poor documentation; Erik A.M. Borglund[1]; Kjell Lagerström[1]; [1]Mid Sweden University 2
Civil Protection in Europe: Towards a Unified Command System? Update on knowledge-sharing work and future actions; Jean Paul Monet[1]; Anaïs Saint-Jonsson[2]; Sergio Pirone[3]; Marc Castelnou Ribau[4]; Stephane Poyau[5]; Marc Dumas[1]; Miguel Cruz[6]; Tony Johansson[7]; Christoph Lamers[8]; Christos Lampris[9]; Pierre Schaller[10]; [1]Bouches-du-Rhône Fire Dpt; [2]Aix-Marseille University; [3]Regional Forest FireFighters Corp, Piedmont; [4]Catalonia Fire & Rescue Service; [5]Landes Fire Dpt, [6]Emergency and Civil Protection National Directorate, Portugal; [7]Södertörn Fire & Rescue Service; [8]Joint Competence Centre for Civil Protection NRW; [9]National Fire Service, Greece; [10]National Fire Service, France 10
Unified command? Preliminary findings from a situation awareness experiment; Jeroen Wolbers[1]; [1]LeidenUniversity 26
Collaborative Evaluation: Mapping Socio-Technical Patterns in an Emergency Exercise; Kjetil Rustenberg[1]; Kristine Steen-Tveit[1]; Bjørn Erik Munkvold[1]; Jaziar Radianti[1]; [1]Center for Integrated Emergency Management, University of Agder 35
Geographic Information Science (GIS) for Crisis Management 48
CoRe Papers
QuakeSet: A Dataset and Low-Resource Models to Monitor Earthquakes through Sentinel-1; Daniele Rege Cambrin[1]; Paolo Garza[1]; [1]Politecnico Di Torino 49
Volunteers in Crisis and Emergency Management 61
CoRe Papers
Managing volunteers in disaster situations - an overview of models for decision-makers; Florentina Hager[1]; Melanie Reuter-Oppermann[1]; [1]University of Twente 62
Improving emergency and disaster response management through bidirectional communication between citizens and decision-makers – A field test on the coordination of spontaneous volunteers; Michael Holzhüter[1]; Hans Betke[1]; Alina Fröhlich[1]; Michael Klafft[1,2]; [1]Fraunhofer Institute for Open Communication Systems; [2]Jade Hochshule 79
WiP Papers
The coordination and leadership in first aid ad-hoc immediate responder groups: a work-in-progress; Wilhelm Brodin[1]; Erik Prytz[1]; Carl-Oscar Jonson[1]; [1]Linköping University 97

Selection of rural villages as volunteer centers for emergency response; Niki Matinrad[1]; Tobias A. Granberg[1]; [1]Linköping University 108

Civilian-Military Integration in Ukrainian Defense Supply Chain; Myroslava Kushnir[1]; Anna Nagurney[2]; Renata Konrad[3]; [1]Ukrainian Catholic University; [2]UMass Amherst; [3]Worcester Polytechnic Institute 119

Usability and Universal Design of ICT for Emergency Management 131

CoRe Papers

Contextualizing Effective Use of Health Information Systems in Humanitarian Setting: The role of Transparent Interaction; Marta Maria Vila-Pozo[1]; [1]University of Oslo 132

WiP Papers

Avoiding "metal astray": experience evaluation of virtual reality training for melting furnace operators.; Jo Dugstad Wake[1]; Frode Guribye[2]; [1]NORCE; [2]University of Bergen 145

First Evaluation of the Usability and Usefulness of the PROACTIVE App; Laura Petersen[1]; Natasha McCrone[1]; Grigore Havârneanu[1]; Garik Markarian[1]; [1]UIC; [2]Rinisoft; [1]UIC; [2]Rinisoft..... 156

Integrated Wildfire Risk Management 166

CoRe Papers

Uncertainty in Forest Fire Management; Nikola Tietze[1]; Thomas Kox[1]; Till Büser[1]; Lars Gerhold[1]; [1]Freie University Berlin; [2]Weizenbaum Institute; [2]Weizenbaum Institute; [3];Technische Universitaet Braunschweig 167

WiP Papers

Networks for Integrated Wildfire Management: A Social Network Analysis Approach; Diogo Vallim[1]; Amalia Giannakopoulou[1]; Anna Coco Schmid[1]; David Struthers[1]; Efthymios Altsitsiadis[1]; Isabel Froes[1]; [1]Copenhagen Business School 176

Wildfire Evacuation: Social Resilience and Local Community Response..... 192

CoRe Papers

Evacuation modelling for community resilience: An Australian perspective; Dhirendra Singh[1]; Hanna Grzybowska[1]; Leorey Marquez[1]; Vincent Lemiale[1]; [1]CSIRO's Data61 193

Wildfire Evacuation Challenges in Multi-ethnic Communities: An Information Communication Perspective; Meng Duo[1]; Jun Hu[1]; Anying Chen[2]; Zhetao Fang[3]; [1]Beijing Normal University; [2]Jinan University; [3]China People's Police University..... 206

IT Solutions for Crisis Management..... 216

CoRe Papers

Drone Swarm for Post-Wildfire Hot Spot Detection: Technology Assessment and PoC Demonstrator; Micha Sende[1]; Christian Raffelsberger[1]; Samira Hayat[1]; Armin Köfler[2]; Alexander Almer[2]; [1]Lakeside Labs; [2]JOANNEUM RESEARCH..... 217

WiP Papers

Chatbot Based Public Sensoring to improve Situational Awareness; Hans Betke[1]; Thomas Kox[2]; Sascha Peitzsch[1]; Johannes Boldt[3]; Dustin Reimann[1]; [1]Fraunhofer FOKUS; [2]Weizenbaum Institute; [3]Martin Luther University Halle-Wittenberg 229

Modular Multi-Platform Interface to Enhance the Situational Awareness of the First Responders; Xabier Oregui[1]; Izar Azpiroz[1]; Veronica Ruiz[2]; Blanca Larraga[2]; Alvaro Gutierrez[2]; Igor G. Olaizola[1]; [1]Vicomtech

Foundation BRTA; [2]Universidad Politechnica de Madrid 242

Long-Range Human Detection in Drone Camera Images; Joris Heemskerk[1]; Tina Mioch[1]; Henry Maathuis[1]; Huib Aldewereld[1]; [1]University of Applied Sciences Utrecht 253

From Data to Action: A Graph-Based Approach for Decision Support in Civil Protection Operations Planning; Sabine Janzen[1]; Natalie Gdanitz[1]; Merlit Kirchhöfer[2]; Tobias Spanke[2]; Wolfgang Maass[1]; [1]German Research Center for AI, Saarbruecken; [2]Federal Agency for Technical Relief, Bonn 266

Adapting PLUM: Earthquake Early Warning with Node-Level Processing in New Zealand; Chanthujan Chandrakumar[1]; Marion Lara Tan[1]; Caroline Holden[2]; Max T. Stephens[3]; Raj Prasanna[1]; [1]Joint Centre for Disaster Research, Massey University; [2]SeismoCity Ltd.; [3]University of Auckland 275

A Study on The Frequency Characteristics of Typhoon Landing in Guangdong, China Based on Machine Learning Methods; Chenning Pan[1]; Xiaoyong Ni[1]; Ruoxi Lai[1]; Dafeng Ma[1]; Xifan Shen[1]; [1]Beijing Normal University 289

Improved satellite-based emergency mapping through automated triggering of processes; Martin Mühlbauer[1]; Monika Friedemann[1]; Johanna Roll[1]; Torsten Riedlinger[1]; Fabian Henkel[1]; Lucas Angermann[1]; Mathias Böck[1]; Tobias Kaminski[1]; Kayla Barginda[1]; [1]German Aerospace Center 305

SILVANUS Dashboard for Wildfire Management; Dominika Grunwald[1]; Marcin Wawrzyniak[1]; Marcin Przybyszewski[1]; Emil Gatial[2]; Zoltan Balogh[2]; Sepideh Hassankhani-Dolatabadi[2]; [1]ITTI Sp.zo.o., Poznań, Poland; [2]Slovak Academy of Sciences 314

Risk Communication and Community Engagement 327

CoRe Papers

Correlation Analysis of the Terrorist Attacks and Social Attributes in The Gulf States; Ting Liu[1]; Xiaoyong Ni[1]; Miaohan Shu[1]; Dafeng Ma[1]; Jiawei Sun[1]; [1]Beijing Normal University 328

Understanding Crisis Preparedness: Insights from Personal Values, Beliefs, Social Norms, and Personal Norms; Felix Burger[1]; Jasmin Haunschild[1]; Christian Reuter[1]; [1]Technical University of Darmstadt 345

WiP Papers

Engaging the Public in Forest Fire Awareness through a Mobile Application; Emil Gatial[1]; Zoltán Balogh[1]; Sepideh Hassankhani Dolatabadi[1]; Mariana Soledad Molina[2]; Timo Kasig[2]; Kayvan Yousefi Mojir[3]; Marcin Wawrzyniak[4]; Dominika Grunwald[4]; Marcin Przybyszewski[4]; [1]Slovak Academy of Sciences; [2]Massive Dynamic, Sweden; [3]University of Borås, Sweden; [4]ITTI Sp. z o.o. , Poland 360

Towards a Taxonomy for Conversational Agents in Disaster Management; Johannes Göbel[1]; Hans Betke[2]; Stefan Sackmann[1]; [1]Martin-Luther-University Halle-Wittenberg; [2]Fraunhofer FOKUS 373

Tweeting Through the Flood: Application of BERT Topic Modeling for a Comparative Flood Communication Analysis; Christin Salley[1]; Nathan Fox[1]; Alyssa Schubert[1]; [1]Michigan Institute for Data Science 384

Broadcasting Resilience: Developing Wildfire Readiness Through Student-Driven Radio Programs; Jose Azevedo[1]; Susana Neves[1]; Ivone Neiva Santos[1]; [1]University of Porto 395

Social Media for Crisis Management 401

CoRe Papers

Semantically Enriched Cross-Lingual Sentence Embeddings for Crisis-related Social Media Texts; Rabindra Lamsal[1]; Maria Rodriguez Read[1]; Shanika Karunasekera[1]; [1]The University of Melbourne 402

Image-text crisis tweet categorization: a caption-based approach; Badreddine Farah[1]; Guillaume

Cleuziou[1]; Cécile Gracianne[2]; Adel Hafiane[1]; Anaïs Halftermeyer[1]; Raphaël Canals[1]; [1]University of Orleans; [2]BRGM France 414

Enhancing Emergency Post Classification through Image Information Amplification via Large Language Models; Pablo Giaccaglia[1]; Carlo Alberto Bono[1]; Barbara Pernicis[1]; [1]Politecnico di Milano 426

Monitoring Critical Infrastructure Facilities During Disasters Using Large Language Models; Abdul Wahab Ziaullah[1]; Ferda Ofli[1]; Muhammad Imran[1]; [1]Hamad Bin Khalifa University, Doha, Qatar 439

Empowering Crisis Response Efforts: A Novel Approach to Geolocating Social Media Images for Enhanced Situational Awareness; Hafiz Budi Firmansyah[1]; Jose Luis Fernandez-Marquez[1]; Mehmet Oguz Mulayim[2]; Jorge Gomes[3]; Joao Ribeiro[3]; Valerio Lorini[4]; [1]University of Geneva; [2]Spanish National Research Council; [3]VOST Europe Santarem, Portugal; [4]Joint Research Center, European Commission Ispra, Italy 453

WiP Papers

Social Media Analysis in Sudden Onset Disasters and its Usefulness for Decision Makers - A Scoping Review; Francesca Müller[1]; Sylvia Bach[1]; Frank Fiedrich [1]; [1]University of Wuppertal 467

Utilizing Social Media and Crowdsourcing for Crisis Management and Communication: proposing an Integrative Framework; Kees Boersma[1]; Nathan Clark[1]; Robert Larruina[1]; Emmeline Roeloffs[1] 482

Effectiveness of Emergency Response to Typhoons: Lessons Learned from Historical Typhoon Disasters in Zhuhai, China; Ting Liu[1]; Xiaoyong Ni[1]; Jiawei Sun[1]; Ziyi Peng[1]; [1]Beijing Normal University 493

Forced Displacement Situation Awareness with Large Language Models: Ukrainian Refugees in Poland Case Study; Brian Tomaszewski[1]; Nataliya Shakhovska[2]; Harley Emery[3]; Paweł Śniatała[4]; [1]Rochester Institute of Technology; [2]Lviv Polytechnic National University; [3]University of Maryland; [4]Poznan University of Technology 508

Crisis[2]Sum: An Exploratory Study on Disaster Summarization from Multiple Streams; Philipp Seeberger[1]; Korbinian Riedhammer[1]; [1]Technische Hochschule Nuernberg 523

Can User Characteristics Predict Norm Adherence on Social Media? Exploring User-Centric Misinformation Interventions; Shangde Gao[1]; Yan Wang[1]; [1]University of Florida 544

M-CATNAT: A Multimodal dataset toanalyze French tweets duringnatural disasters; Badreddine Farah[1]; Omar El Bachyr[1]; Guillaume Cleuziou[1]; Anaïs Lefeuvre-Halftermeyer[1]; Cécile Gracianne[2]; Samuel Auclair[2]; Adel Hafiane[1]; Raphael Canals[1]; [1]University of Orleans; [2]BRGM France 555

Impact-driven Emergency and Crisis Management 567

CoRe Papers

State of Knowledge Management among German fire fighters; Andreas Schultz[1]; Fabian Dotzki[1]; Iryna Mozgova[1]; [1]Paderborn University 568

WiP Papers

Cascading supply chain disruption: impact on water industry during COVID-19; Lijo John[1]; Wojciech Piotrowicz[1]; Aino Ruggiero[2]; [1]Birla Institute of Technology Pilani-Dubai Campus; [2]Hanken School of Economics, Helsinki 583

Assessing Infrastructure Resilience in Small Islands: Methodology Proposal; Fabiane A. Acordes[1]; Sylvia Bach[1]; Frank Fiedrich[1]; Frank Sill Torres[2]; [1]University of Wuppertal; [2]German Aerospace Center 591

A Study on The Heterogeneity of Tropical Cyclone Vulnerability Functions in Different Provinces along The Coastal Areas in China; Chenning Pan[1]; Xiaoyong Ni[1]; Xifan Shen[1]; Ziyi Peng[1]; [1]Beijing Normal University 602

Crisis Response and Management of Public Administrations: Forgotten Tales; Yannic Schulte[1]; Malte Schönefeld[1]; Patricia M. Schütte[1]; Frank Fiedrich[1]; [1]University of Wuppertal 617

Uncovering Impact of Innovation: Continuous Stakeholder Engagement through Scenario-based Systems Engineering; Jens Pottebaum[1]; Marcel Ebel[1]; Iris Gräßler[1]; [1]Paderborn University 626

Disaster Public Health and Healthcare Informatics 638

CoRe Papers

Accounting for systemic risk in analysis of crisis scenarios; Jose J. Gonzalez[1]; Reem Abbas[2]; Sigurd Paulsen[3]; [1]University of Agder, Norway; [2]Auckland University of Technology; [3]Dept. of Organization, Crisis Management and Information Security, Kristiansand municipality, Norway..... 639

Perceiving and Behaving in a Crisis: Developing a Multi-Functional Crisis Information Platform for Psychosocial Situations (CIP-PS); Sebastian Sterl[1]; Andreas Billig[2]; Franck William Taffo[2]; David Svoboda[2]; Lars Gerhold[1]; [1]Technische Universitaet Braunschweig; [2]Fraunhofer Institute for Open Communication Systems 654

Designing Information Flow with Diverse Community Health Workers to Improve Public Health Situational Awareness During COVID-19; Temitayo Okusanya[1]; Jane Gresser[2]; Michael Stevenson[3]; Ajay Kumar[4]; Zeno Franco[1]; Md Romael Haque[2]; [1]Medical College of Wisconsin; [2]Marquette University; [3]University of Wisconsin-Madison; [4]University of Muenster 672

Psychosocial Aspects of the 2021 Flood Disaster in Anonymous District, Germany: Strains, Resources, and the Role of Social Media; Francesca Müller[1]; Marvin Kubitza[1]; Frank Fiedrich[1]; [1]University of Wuppertal 687

Visions for Future Crisis Management 699

WiP Papers

Technology Enhanced Actual Situation Awareness Model for Dog-Handlers working with Search and Rescue Dogs; Stella Polikarpus[1]; Kristine Steen-Tveit[2]; Ana María Aldea Reyes[3]; Marta Burgos González[3]; Susana Izquierdo Funcia[3]; Graham Edgar[4]; [1]Estonian Academy of Security Sciences; [2]University of Agder; [3]Spanish School of Rescue and Detection with Dogs; [4]University of Gloucestshire 700

Exploring the roles and challenges of disruptive technologies for emergency management in Aotearoa New Zealand; Lukas Kroher[1]; Marion Lara Tan[2]; Raj Prasanna[2]; [1]Otto-Friedrich University Bamberg; [2]Massey University 709

Vision for Emergency Management: Conceptualizing Mission-Critical Ecosystems; Jaziar Radianti[1]; [1]University of Agder 721

Bridging Gaps, Building Futures: How DIREKTION Innovates for Global Disaster Resilience; Juliane Schlierkamp[1]; Eileen Murphy[2]; Louise Vos[3]; [1]Fraunhofer INT; [2]Trilateral Research; [3]TNO..... 734

Pre-disaster Training for Firefighters Using Augmented Reality: Hologram Characteristics; Stella Polikarpus[1]; Reet Kasepalu[1]; Kärt Reitel[1]; [1]Estonian Academy of Security Sciences 744

Information Systems in Humanitarian Operations 757

WiP Papers

Navigating the Digital Technology Behavior for the Distribution of Humanitarian Cash-Based Assistance: Aid Recipients Experience; Amin Maghsoudi[1]; Abdelsalam Hamid Abakar[1,2]; [1]Hanken School of Economics; [2]A'Sharqiyah University 758

Analytical Modeling and Simulation 767

CoRe Papers

Possibility of Suppressing Fire-spread in the Event of a Large Earthquake by Greening and Demolishing Vacant Houses; Toshihiro Osaragi[1]; Asuka Harada[1]; Takuya Oki[1]; Yoho Sakamoto[1]; [1]Tokyo Institute of Technology 767

Enabling Information Transmission in Low-Throughput Wireless Channels for Aerial Disaster Monitoring Systems; Julian Zobel[1]; Ralf Steinmetz[1]; [1]Technical University of Darmstadt..... 785

WiP Papers

Location and allocation of primary and backup shelters in transboundary disasters; Oscar Rodriguez-Espindola[1]; Pavel Albores[1]; Dolores Edwiges Luna-Reyes[2]; Juan Antonio Diaz-Garcia[2]; Sergio Picazo-Vela[2]; [1]Aston Business School; [2]Universidad de las Americas Puebla..... 801

Using Optimization Modelling to Determine Locations for Aerial Firefighting Resources Based on Wildfire Risk Data; Viktor Sköld Gustafsson[1]; Tobias Andersson Granberg[1]; Martin Waldemarsson[1]; [1]Linköping University 813

Towards a repository for datasets of mass casualty incidents; Florentina Hager[1]; Melanie Reuter-Oppermann[1]; [1]University of Twente 822

Cascading Effects of Critical Infrastructures in a Flood Scenario: A Case Study in the City of Cologne; Moritz Schneider[1]; Peter Priesmeier[2]; Alexander Fekete[2]; Daniel Lichte[1]; Frank Fiedrich[3]; [1]German Aerospace Center; [2]Cologne University of Applied Sciences; [3]University of Wuppertal..... 834

Homophily in opinion networks affects collective risk perception in heterogeneous populations; Francesca Giardini[1]; Daniele Vilone[2]; Lorenzo Zino[3]; Ming Cao[1]; [1]University of Groningen, The Netherlands; [2]National Research Council, Rome, Italy; [3]Politechnico di Torino 843

Sensitivity Analysis of a Road Clearing and Relief Supplies Distribution Model for Vancouver Island in the Event of a Cascadia Megathrust Earthquake; Ronald Pelot[1]; Pranitha Vattoni[1]; Luana Souza Almeida[1]; Floris Goerlandt[1]; [1]Dalhousie University, Halifax, Canada 852

Open Track 870

CoRe Papers

R²DN – Integrating Databases about Natural Disasters; Jose Verissimo Pereira[1]; Marcos Borges[1]; [1]Universidade Federal do Rio de Janeiro..... 871

The Role of Digitalization During Supply Chain Disruptions: Lessons from the Experiences of Family-Owned Austrian Firms During the COVID-19 Pandemic; Deepak Khazanchi[1]; Reinhard Bernsteiner[2]; [1]University of Nebraska Omaha; [2]Management Center Innsbruck Austria 888

Comparative Analysis of Strategies for National Food Stockpiling: A Case Study of Germany and Switzerland; Katharina Eberhardt[1]; Simon Stieler[1]; Florian Klaus Kaiser[1]; Frank Schultmann[1]; [1]Karlsruhe Institute of Technology..... 898

Empirical Investigation of Values Affected by AI Systems for Fire Services; Tina Mioch[1,2]; Huib Aldewereld[1]; Mark A. Neerincx[2]; [1]Delft University of Technology; [2]University of Applied Sciences Utrecht 912

WiP Papers

Introducing WALKER – Safeguarding Cultural Heritage through Evacuation Run Maps; Tobias Hellmund[1]; Jürgen Moßgraber[1]; Jürgen Reuter[1]; Susanne Rißmann[2]; Hermann Bayer[3]; Stefan Deschermeier[3]; [1]Fraunhofer IOSB; [2]Bayerische Verwaltung der staatlichen Schlösser; [3]Kreisfeuerwehrverband München e.V. 924

The Utility of Community Resilience Models for the Prevention of Online Violence; Dante Della Vella[1];

Hoang Long Nguyen[1]; Rajendra Akerkar[1]; [1]Vestlandsforsking 931

Scoping Review: Digitalisation in the organisational culture of safety and security agencies; Thomas Kox[1]; Patricia Schütte[2]; Sebastian Rohwedder[1]; Till Büser[1]; [1]Weizenbaum Institute; [2]Bergische Universitaet Wuppertal 942

Human Values for Responsible Decision-Support for Fire Services; Tina Mioch[1,2]; Huib Aldewereld[1]; Mark A. Neerincx[2]; [1]Delft University of Technology; [2]University of Applied Sciences Utrecht 952

Inter-professional simulator training for reliable ship-helicopter interactions; Thomas Lübcke[1]; Hendrik Wilhelm[2]; Oda Schliebusch-Jacob[1]; Tim Kreter[2]; Tanja Martini[3]; Torsten Gerlach[3]; [1]German Maritime Search and Rescue Service; [2]Witten/Herdecke University; [3]German Aerospace Center 961

User-tailored visualization of simulation and sensor data for efficient crisis management; Nils Winter[1,4]; Michael Monteforte[1,3]; Fabian Müller[1,2]; Ines Rohrbach[1,3]; Philipp Hertweck[1,4]; Till Martini[1,2]; [1]Fraunhofer SIRIOS, Berlin, Germany; [2]Fraunhofer EMI, Freiburg, Germany; [3]Fraunhofe IVI, Dresden, Germany; [4]Fraunhofer IOSB, Karlsruhe, Germany 972

Strategies for Crisis-Responsive Governance: Automated Anomaly Identification in Public Services; Hakan Unveren[1]; Ayesh A. Lehyeh[1]; Duygu Pamukcu[2]; Christopher W. Zobel[3]; [1]University of Vermont; [2]HEC Montreal; [3]Virginia Tech 981

Scenario planning to enable foresight in crisis management; Marte Luesink[1,2]; Jeroen Wolbers[1]; Menno van Duin[1]; Sanneke Kuipers[2]; [1]Nederlands Instituut Publieke Veiligheid; [2]LeidenUniversity 995

One System to Connect them All - A Core System for Realizing Integrated Command and Control Research; Björn Johansson[1]; Jesper Tordenlid[2]; Jonas Lundberg[1]; Jens Alfredson[3]; [1]Linköping University; [2]Combitech AB; [3]Saab AB, Aeronautics 1004

Towards training network resilience to maintain disaster recovery expertise; Paul Savignac[1]; Eva Petitdemange[1]; Christopher Zobel[2]; Nicolas Cellier[1]; Robert Weiss[2]; Matthieu Lauras[1]; [1]Centre de Genie Industriel, IMT MINES ALBI, Universite de Toulouse; [2]Virginia Tech 1015

Barriers against data sharing for Disaster Risk Reduction (DRR) at borders; Anouck Adrot[1]; Lola Brunet[1]; Henri Isaac[1]; [1]Université Paris-Dauphine, Université PSL, CNRS, DRM 1025

End-user perspective on the results and impact of European projects: a case of failure to innovate; Maaike van de Vorst[1]; Kenny Meesters[2]; Bert Brugghemans[3]; [1]APB Campus Vesta; [2]Tilburg University; [3]Brandweerzone Antwerpen 1037

Knowledge on demand: the future of decision support systems?; Yohann Chasseray[1]; Aurélie Congès[1]; Audrey Fertier[1]; Anne-Marie Barthe-Delanoë[1]; [1]IMT Mines Albi, Universite de Toulouse.. 1050

Future AI in crisis management: Proposing a bio-inspired, neuro-symbolic architecture; Aurélie Montarnal[1]; Frédérick Bénaben[1]; Rob Grace[2]; Grégoire Borst[3]; Paul Gaborit[1]; [1]IMT Mines Albi; [2]Texas Tech University; [3]LaPsyDE - UMR CNRS 8240, Université Paris Cite 1061

Envisioning the Future of Emergency Management focused on Artificial Intelligence; Ana-Gabriela Núñez[1]; Patricia Quiroz-Palma[2]; M.Carmen Penadés[3]; Otto Parra[1]; Oscar Alvear[1]; [1]Universidad de Cuenca; [2]Universidad Laica Eloy Alfaro de Manabi; [3]Universitat Politecnica de Valencia, Spain 1072

Evacuation Social Support Among New Orleans Households: Implications for Evacuation Management Systems; Rob Grace[1]; Hyeong Suk Na[2]; [1]Texas Tech University; [2]University of Missouri 1084

WUI-PEM: Wildfire Phased Zone Evacuation Methodology; Hui Xie[1]; Michael Kinsey[1]; Steve Gwynne[1]; Max

Kinateder[2]; Paul Geoerg[3]; Roy Thun[4]; [1]Movement Strategies; [2]NRC Canada; [3]Vereinigung zur Förderung des Deutschen Brandschutzes e.V., Germany; [4]GHD, USA 1096

It's a Machine Learning world: no future for Complex Event Processing?; Anne-Marie Barthe-Delanoë[1]; [1]IMT Mines Albi, University of Toulouse 1107

Demonstrations 1151

ISCRAM 2024: Embracing the Crisis Management Lifecycle

The conference follows a pracademic approach and will be jointly hosted by the European Research Center for Information Systems (ERCIS) Competence Center for Crisis Management at the University of Münster and the State Fire Service Institute North Rhine-Westphalia, Germany. As seen and discussed in the ISCRAM community in recent years, the need of "pracademics" became essential to facilitate and further increase high-quality research on information systems in crisis management (CM) and response. Thus, it appeared as a logical consequence to join forces from both the practitioner and scientific communities to promote the ISCRAM mission. The "pracademic approach" is considered for all relevant conference elements, such as a balanced keynote lineup or practitioner-friendly contributions (e.g. practitioner talks instead of practitioner papers).

Besides, the conference theme takes a process-centric view on crisis management: "Embracing the Crisis Management Lifecycle". The theme emphasizes a holistic and integrated process view of crisis management to overcome isolated considerations of crisis management lifecycle phases and showcase how important well-structured and clearly defined roles, tasks and processes are to supporting communication and collaboration between involved actors.

The ISCRAM 2024 Proceedings include two types of papers: Completed Research (CoRe) and Work in Progress (WiP) Papers. CoRe papers are longer in length and describe completed research studies. Only CoRe papers were candidates for the Best Research Paper or Best Student Paper awards. WiP papers are shorter and meant to describe preliminary or more focused research findings. Both paper types (CoRe and WiP) underwent a rigorous peer-review process to determine the papers included in these proceedings and archived in the ISCRAM digital library.

In total, 31 CoRe papers were submitted and 27 were accepted. Two out of the four rejected papers got recommended for a resubmission as WiP. The overall acceptance rate for the CoRe papers at the conference was 87%. Besides, 96 WiP papers were submitted and 66 got accepted. The overall acceptance rate for the WiP papers at the conference was 69%.

Besides, practitioners' contributions are documented as abstracts of the new practitioner talks track as well as project symposium abstracts. Practitioner talks are peer reviewed to high ISCRAM standards and their presentations were similar in length to CoRe paper presentations. In total, seven practitioner talks were submitted and accepted.

The program is completed with eight workshops, ten posters and two demonstrations. On top of that, a Project Research Symposium under the topic: "Fostering collaboration: Bridging Academia and Practice through ongoing Projects and Opportunities for Future Research". The project symposium is designed to foster interactions between academia and practitioners by showcasing funded research projects, both ongoing and completed, encouraging discussions about future research ideas and finding synergies. In total, nine projects were accepted. The project symposium presentations were limited to seven minutes each, followed by a world-café format.

Five criteria (relevance, significance, originality, validity, and clarity) were used to review all types of ISCRAM papers by at least two regular and one meta review. Papers were submitted to one of fifteen tracks, which included:

- Command & Control Studies

- Geographic Information Science (GIS) for Crisis Management
- Volunteers in Crisis and Emergency Management
- Usability and Universal Design of ICT for Emergency Management
- Integrated Wildfire Risk Management
- Wildfire Evacuation: Social Resilience and Local Community Response
- IT Solutions for Crisis Management
- Risk Communication and Community Engagement
- Social Media for Crisis Management
- Impact-driven Emergency and Crisis Management
- Disaster Public Health & Healthcare Informatics
- Visions for Future Crisis Management
- Information Systems in Humanitarian Operations
- Analytical Modeling and Simulation
- Open Track

All authors in these proceedings have agreed to the ISCRAM 2024 Proceedings Copyright Agreement. This copyright agreement and use license state that an author retains copyright. It also permits any user – for any non-commercial purpose, including unlimited classroom and distance learning use – to download, print out, extract, archive, distribute and make derivative works of an article published in the ISCRAM 2024 Proceedings, if appropriate credit is given to the authors, the source of the work, and all derivative works are placed under the same license.

We would like to recognize the efforts of the Organizing Committee and Program Committee (track chairs and reviewers) for making the ISCRAM 2024 conference possible. We also thank the ISCRAM board, our partners, and sponsors for their significant support of the conference. Lastly, we sincerely thank the authors and speakers who shared their work at ISCRAM 2024. We thank you all for your service to the ISCRAM community over the past year and look forward to the next ISCRAM world conference in Halifax, Canada.

Program Committee

Program Chairs

Dr. Michael Middelhoff, University of Münster, Germany
Prof. Dr. Ir. Kees Boersma, Vrije Universiteit Amsterdam, Netherlands
Matthias Kalthöner, State Fire Service Institute North Rhine-Westphalia, Germany

Workshop Chairs

Dr. Christoph Lamers, Joint Competence Center for Civil Protection, Germany
Johannes Ponge, M.Sc., University of Münster, Germany
Prof. Jaziar Radianti, University of Agder, Norway

Practitioner Talks Chairs

Nicola Rupp, Deutsches Rettungsrobotik Zentrum e.V., Germany
Bart van Leeuwen, Netage B.V. and Amsterdam-Amstelland FD, Netherlands
Dr. Christoph Lamers, Joint Competence Center for Civil Protection, Germany

Doctoral Colloquium Chairs

Prof. Dr. Melanie Reuter-Oppermann, University of Twente, Netherlands
Prof. Dr. Stefan Klein, University of Münster, Germany
Prof. Dr. Mark Haselkorn, University of Washington, USA

Demonstration and Poster Chairs

Dr. Sandra Wissing, FH Münster, Germany
Dr. Monika Rode, State Fire Service Institute North Rhine-Westphalia
Prof. Dr. Apoorva Chauhan, Concordia University of Edmonton, Canada

Project Symposium

Dr. Chiara Fonio, ICONS Innovation Strategies, Italy
Dr. Alexander Rösner, Federal Agency for Technical Relief, Germany
Dr. Monika Rode, State Fire Service Institute North Rhine-Westphalia, Germany
Dr. Adam Widera, University of Münster, Germany

Awards Committee Chair

Filippo SanFilippo, University of Agder, Norway

Organizing Committee

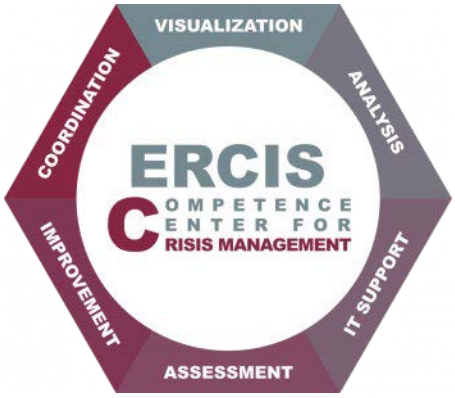
Conference Chairs

Berthold Penkert, State Fire Service Institute North Rhine-Westphalia, Germany
Prof. Dr.-Ing. Bernd Hellingrath, University of Münster, Germany
Dr. Monika Rode, State Fire Service Institute North Rhine-Westphalia, Germany
Dr. Adam Widera, University of Münster, Germany

Publicity and Communication Chairs

Stephanie Albiero, MA Int.Sec., United Nations Office for Project Services, USA
Sebastian Henke, M.Sc., University of Münster, Germany

Proceedings Chair



Anirudh Ravi, University of Münster, Germany

Conference Local Management and Logistics

Carmen Sicking, University of Münster, Germany

Workshops

1. Workshop: Remote Crowdsourcing and Participatory Local Mapping for Disaster Management

Oliver Fritz, HeiGIT gGmbH
Anne Schauß, HeiGIT gGmbH
Marcel Reinmuth, HeiGIT gGmbH

The workshop, led by HeiGIT, focuses on addressing the challenges of accessing and capturing spatial insights throughout the disaster management cycle. Participants will explore the Sketch Map Tool and CrowdMap, open-source tools designed to collect and map local knowledge and interpret imagery through participatory mapping approaches. Through hands-on sessions and discussions, attendees will learn how these tools can engage local communities and remote volunteers to provide valuable data, contributing to more effective disaster management practices. The workshop provides a platform for sharing experiences and discussing opportunities and challenges in integrating crowdsourcing and participatory mapping into disaster management strategies.

2. Workshop: Devising Assessment and Mitigation of Systemic Risks with Strategy Mapping with a Participant Group

Jose J. Gonzalez, University of Agder
Sigurd Paulsen, Crisis Manager at Kristiansand Municipality, Norway

In our interconnected society, risks create cascading effects across sectors, forming a complex system with interdependent outcomes. Involving practitioners and experts is crucial for effective systemic risk assessment and management. A strategy mapping method, originally developed for complex projects in the 1990s, has been extended to address systemic risks in societal resilience and pandemics, notably applied to Covid-19.

3. Workshop: Using Bomb Shelters in the 21st Century?

Jaziar Radianti, University of Agder
Terje Gjøsæter, University of Agder
Stella Polikarpus, Estonian Academy of Security Sciences
Priit Laaniste, Estonian Academy of Security Sciences and Estonian Ministry of the Interior

The workshop examines the importance of utilizing bomb shelters in contemporary times, acknowledging insights from the conflict in Ukraine and the historical neglect of shelter maintenance since the Cold War. It delves into the potential of new technologies in warning the public about attacks while addressing associated security risks. Through discussions on information management, public training, and warning systems, participants aim to compile a thorough list of research topics pertinent to the modern utilization of bomb shelters, considering evolving societal expectations and the role of social media in crisis communication.

4. Workshop: Measuring Stress Levels in Critical Systems for Monitoring and Response

Michiel Rhoen, Veiligheidsregio Utrecht
Luuk Vink, Veiligheidsregio Utrecht

The Dutch Safety Regions utilize data streams to monitor stress levels and risk indicators across essential systems, enabling measurement of relative stress levels, real-time crisis response support, and long-term trend analysis. Emphasis is placed on both crisis response systems and

everyday societal continuity essentials such as telecommunications, power, sewers, and water management. The goal of the workshop is to present examples of data usage for stress measurement in critical systems across different time periods, solicit feedback for the development of a real-time risk monitor, and promote collaboration between first responders, data scientists, and experts in critical systems.

5. Workshop: Using Emergency Response Data to Connect Practice and Science

Amy Matser, Netherlands Institute for Public Safety
Guido Legemaate, Safety Region of Amsterdam – Amstelland
Vera Oosterveen, Netherlands Institute for Public Safety
Michiel Rhoen, Veiligheidsregio Utrecht (VRU, Safety Region Utrecht), Netherlands
Rob Peters, Utrecht University of Applied Scientific Research

The workshop explores the utilization of emergency response data for both practice and scientific research, bridging the gap between operational needs and academic inquiry. By aligning with the ISCRAM 2024 theme of embracing the crisis management lifecycle, the workshop aims to extend understanding beyond traditional boundaries. Drawing from over a decade of experience in the Netherlands, participants will delve into real projects, discussing success criteria and methods to meet scientific standards while upholding the quality of emergency response systems. Through interactive sessions, attendees will collaboratively develop research proposals focusing on key themes such as cross-border interoperability, event management, resilience, crisis communication, floods, and infectious agent spread.

6. Workshop: Cascading Effects in Complex Health Networks

Stefan Schauer, AIT Austrian Institute of Technology
Manuel Egger, AIT Austrian Institute of Technology

The workshop focuses on critical infrastructures and entities essential for maintaining societal functions, highlighting the interdependence and complexity of these systems, particularly in domains like healthcare. With increasing digitalization, cybersecurity becomes paramount, especially in sectors like healthcare, which are prime targets for adversaries. The workshop aims to provide a holistic understanding of cyber-physical systems and their interdependencies to enhance risk and resilience management in critical domains.

7. Workshop: Capability Gaps in Fire Fighting – how to proceed

Juliane Schlierkamp, Fraunhofer INT
Maike Overmeyer, Fraunhofer INT
Jean-Paul Monet, Bouches-du-Rhône Fire Department
David Martín, Pau Costa Foundation

The workshop, facilitated by the DIREKTION and FIRELOGUE projects, aims to foster collaboration and innovation in firefighting by bringing together practitioners and solution innovators. Designed for both industry experts and emergency responders, it provides a platform to discuss challenges, share insights, and explore solutions in wildfire risk management. Participants can expect lively discussions, knowledge exchange, and opportunities to shape the future of firefighting through collaboration and research-driven innovation.

8. Workshop: Netcentric Crisis Management – a Dutch approach and its challenges

Steven van Campen, Trimension
Willem Treurniet, Netherlands Institute for Public Safety – NIPV
Arthur van Lohuijzen, Trimension

The workshop, led by experts from the Netherlands Institute of Public Safety (NIPV) and Trimension, focuses on Netcentric Crisis Management (NCM) as a method to enhance information management and coordination during crises. Aimed at emergency responders, academics, researchers, and policymakers, it offers interactive sessions to discuss experiences, principles, implementation challenges, and future developments of NCM. Participants engage in cross-organizational knowledge exchange and exploration of innovative information management processes and tools to enrich NCM practices.

Netcentric Crisis Management
Insights gathered during a workshop on the ISCRAM2024 conference

How do you facilitate collaboration between involved actors during a crisis? How do you help them to overcome isolated considerations? How to effectively manage a complex network, stimulating shared situational awareness? All these questions underline that in many ways crisis management is network management. Over the past 20 years, emergency services, government, healthcare and critical infrastructure organisations in the Netherlands have co-created Netcentric Crisis Management (NCM); a method by which information management effectively supports decision making and coordination during crises.

During the ISCRAM2024 conference, NCM-experts of the Netherlands Institute of Public Safety (NIPV) and Trimension hosted a workshop in which the basic principles of NCM together with its impact were explained, the steps and challenges for implementation presented and the fits and non-fits of these were discussed in round-table sessions. The findings from both sessions are documented in this report and shared afterwards with the participants.

Set-up of the workshop

The workshop was aimed at emergency response practitioners, academics, researchers and policy makers with a specific interest in information management and netcentric operations to improve crisis management. The main aim was to discover further possibilities for NCM, obtain feedback from the international conference audience and discover state-of-the-art information management processes, systems and tools to further enrich NCM. The workshop consisted of two interactive round-table sessions of 90 minutes each. Participants were encouraged to attend both sessions and were mixed in smaller, multidisciplinary groups, thereby stimulating a cross-organisational exchange of knowledge, challenges and experiences.

The first session consisted of:

- An introduction to the workshops program, what NCM is, its history and basic principles, combined with practical uses of NCM during crisis situations.
- A first round-table session aimed at the questions: Do you recognise similar problems with information and crisis management in your region or sector? How do you cope with them? Would NCM fit your organisation's culture and processes?
- A short recapitulation of the most interesting results per table.
- The second session was focussed on implementing NCM, the challenges and potential developments and consisted of:

- A presentation on how NCM can be implemented in organisations and in networks from practical experience and the challenges and potential developments still ahead.
- Second round table session aimed at the questions: Do you recognise the presented implementation challenges? How could an implementation of NCM be successful in your country or organisation and which challenges do you foresee? What further developments or improvements do you suggest?
- A short recapitulation of the most interesting results per table.

Participants were split in two groups. The organisers provided canvases for both sessions, to document the findings in each round-table group.

Results from Session 1:
Question 1: Do you recognise the presented issues and challenges in information and crisis management in your own professional environment? If so, how?

Table 1	**Table 2**
Norway • Responsibilities: take responsibility vs. Handing over vs. Putting down • Covid-pandemic: Innovative risk method management with strict responsibilities; how emergency services are connected with each other: • Issues with data sharing due to national security concerns, therefore, specific mapping of information for chosen emergency service units. **Netherlands** • Train accident: Reaching out to relatives of casualties; who is responsible for accident?; privacy regulations are blocking sometimes • Limburg-south: Healthcare support & supporting infrastructures and including them into information sharing for measuring systems, detection systems for analysing **Italy** • (De-)centralised system for disaster management • Dealing with the amount of untrained volunteers **Germany** • Decentralised disaster management	1. Train for network centric -> high barrier (Netherlands) 2. No shared system (Norway + Catalonia) 3. Organisational boundaries (Norway + Catalonia) 4. Reluctance to share info (Belgium + Norway + Catalonia) • Passive = easier • No shared training + professional culture • 5. Hierarchy + professional culture (Catalonia) • Masculine culture 6. C&C tension between tactical and strategic level (Netherlands + Belgium + Norway) 7. Security + confidentiality (Netherlands + Belgium + Norway) • Different meaning of what a COP is

• Data protection law • • No army support	

Question 2: How could an implementation of NCM be successful in your country or organisation, and which challenges do you foresee?

Table 1	Table 2
• Strategy mapping1 • Exercises • IT-solutions • Trust building • Using social media	4. Trust building -> train together, swift trust -> see others act prof. -> legitimate by law -> expectation management 5. More women in emergency response + retaining women + train both masculine and feminine leadership styles 7. Wink wink nudge nudge; open up information in C&C -> case by case • Shared goal finding + prevent institutional crisis • Split between Command&Control and Info management processes

Question 3: Would NCM fit your culture and processes? If so, how?

Table 1	Table 2
• Networks: Bringing "emerging services" together with first responders • Sense-making: Every helping hand has to feel their support value • Common Operational Picture: IT solution(s) and merging them • For Command&Control: Single or multiple command posts	• Norway: Striving to get there • Belgium: First single agency + national agreement • Catalonia: Emergency services work together but reluctance at non-emergency services

Results from Session 2

Question 1: Do you recognise the presented implementation challenges?

Table 1	Table 2
• Belgium: Cultural issues o Languages o Organisations not talking to each other o People not talking to each other • Norway: Budget cuts • Germany: Reasonable service- blueprint for emergency service units; supply chain management similarities with multiple self-centric goals; issues with "global optimum"-goal reaching multi-facetted	• Cultural/political elements o Drivers/Barriers vary between cultures considerably • Limited time/resources to participate • Complexity of network collaboration o Roles regime with different types of knowledge o Need for power brokers, with the right connections and ability to execute o Identifying right mix of individuals

problems (legally, organisation, IT-solutions) • • Generally: Lack of imagination and bad experiences on implementing innovations	

Question 2: How could an implementation of NCM be successful in your country or organisation, and which challenges do you foresee?

Table 1	Table 2
• Case specific network building o In parallel "service blueprint" -> collaboration building o Table top session/exercises about responsibilities • Knowing your mandate (silos are important, yet blocking information transfer between disciplines)	• Norway: Success for those who embrace innovation succeed; challenge how to convince those that have not tried it, reluctance to change; change is often considered a burden • Spain: Success by bottom up + top down approach; need for approval and practitioner support; challenge: constant work due to political changes • Italy: Challenge in rigidity to change, resulting in reliance on legacy systems • Germany: Success needs not only change for management but also process for iteration; challenges in lack of digitalisation and no concept for "stay live phase"

Question 3: What further developments or advices for NCM do you suggest?

Table 1	Table 2
• Community driven design • Service blueprint with all included (all recognise) (e.g. top level C&C) • Ambassadors to show/share added value/liaison and information managers to share info • Look at UN's cluster approach • Enforce 1 system and 1 method for an entire region/country • Scientific' proof NCM works (very hard; via exercises?; ambassadors) • • Interoperability for technology & humans & procedures	• Assign roles to organisations, across all sizes of organisations • Eliminate knowledge silos o Embrace AI o Generate documents/scripts • • Gathering of relevant data o Leverage lessons learned systematically • The value of strategy-mapping

What stands out

Session 1 question 1: Do you recognise the presented issues and challenges in information and crisis management in your own professional environment? If so, how?

In response to this question the participants identified a variety of issues and challenges regarding NCM. One of the most primitive ones is the need for a system to work with. Not all countries have such a system in which they can work together with other partners during crises. Another challenge is that all parties working with the system need to be trained in the concept of NCM and the usage of the supporting system. Both the creation of systems as well as the training of professionals require a substantial amount of resources, which countries might not have or are not willing to invest. Concerns about data protection and national security as well as the fact that regulations might not be suitable yet, also form a barrier against the implementation of NCM. If laws would need to be changed, this would take up a lot of time. The general and/or professional culture can create challenges as well. Hierarchical structures present in the culture might inhibit good cooperation and professionals might be reluctant to share information. An additional challenge is how to divide the responsibilities amongst the variety of actors. Consensus is needed on who does what at which time and how to work together. This consensus can be difficult to accomplish. The degree of decentralisation is also a challenge in some countries. Decentralisation often means that a lot of small organisations need to work together. This makes it more difficult to come to an agreement with all parties to implement NCM, have well-trained professionals in all organisations involved in the crisis response and divide responsibilities between all parties.

Session 1 question 2: How do you cope with these issues and challenges?

The participants came up with a variety of coping strategies to tackle the issues and challenges they identified in the previous question. One of those coping strategies is to build trust amongst the various actors involved in the crisis response. An effective way to do so is to train and exercise together but a gentle nudge in the right direction can, at times, also do the trick. Another coping strategy is to identify common goals. When parties find out that NCM could be an asset to their as well as other parties' current operations, this can provide an incentive to start implementing it. In the case of culture being an issue for a country, the inclusion of more feminine command/leadership styles and separating command and control from information management could act as a way of coping. Participants see added value in IT-solutions and social media to improve information management.

Session 1 question 3: Would NCM fit your culture and processes? If so, how?

Most participants see the added value for an NCM-like method of information management, as quick and reliable information gathering and most important processing (preventing an information overload) is a main topic in crisis management all around Europe. Some countries have NCM-like systems and procedures in place, primarily in the Nordics. The main challenge in whether the Dutch NCM approach would fit in other countries originate in the cultural differences between the Dutch emergency services and those in other countries, and in the fact that the Netherlands has a law in place (i.e. the 2008 Safety regions act) in which shared information management processes are enforced.

Session 2 question 1: Do you recognise the presented implementation challenges?

The participants identified various challenges that come with the implementation of NCM. One of those challenges relates to culture and politics. For instance, there could be a lack of communication between organisations and/or people, a language barrier or political reasons restricting the enforcement of effective information sharing. Another challenge are the limited resources available for the implementation of NCM. A lack of collaboration between organisations and people as well as not knowing the right people, might also inhibit the implementation of NCM. Other challenges with regards to the implementation of NCM are a lack of imagination (how might this work for me in practice?) and bad experiences with past attempts to innovate or digitalise within first responder

organisations.

Session 2 question 2: How could an implementation of NCM be successful in your country or organisation, and which challenges do you foresee?

Participants mentioned that there are several ways they could see NCM become a success. One of those ways is through collaborating and exercising with other crisis response organisations, dividing responsibilities amongst them, and to keep on trying despite the challenging road ahead. Challenges that the different countries foresee in the implementation of NCM are the reliance on legacy systems, that other crisis response organisations need to be convinced to change, constant work due to political changes, a lack of or reluctance to digitalisation for crises-critical processes and a lack of trust in others in order to share information openly and speedily

Session 2 question 3: What further developments or advices for NCM do you suggest?

Several advices were gathered, which can be summarised by valuing a single system and process for all involved, in further researching the added value (and pitfalls) of increasing data-driven information management and the use of artificial intelligence, and developing network management skills (e.g. strategy mapping). Furthermore, an interest for more academic proof in the added value of NCM was recommended.

Project Symposium

The primary objective of the Symposium is to facilitate dialogue between academia and practitioners by featuring presentations and discussions on funded research projects (both ongoing and completed) and research ideas for future projects. It aims to explore promising collaboration opportunities spanning various disciplines and domains, including crisis management, assessing and mapping risks and impacts, risk and crisis communication, humanitarian logistics, AI in crisis management, socio-technical innovations, crisis management infrastructures, pandemic management, natural hazards, risks and climate change, science and policy for disaster risk management.

Each presenter delivered a 7-minute pitch in the plenary session (80 min) on, inter alia, ongoing projects, projects outcomes, overall impact and exploitation of projects' results, methodology, stakeholder involvement, existing gaps in current research, ideas for future collaboration between researchers and practitioners, etc. The pitches were followed by structured discussions (60 min). Presenters were stationed at designated tables, using a "world café style" arrangement. Audience members divided themselves among these presenter tables. This setup allowed for discussions between presenters and audience members, fostering idea exchange. The audience rotated to the next table every 10 minutes to ensure dynamic engagement throughout the session. In the following all presenters and the project abstracts (max 400 words) are listed.

BeLife: Knowledge Transfer as the Foundation of Holistic Crisis Management in the BeLIFE Project

Dr. Naomi Shulman
Technische Universität Braunschweig

The BeLIFE project, funded by the German Federal Ministry of Education and Research (BMBF), adopts a holistic approach to knowledge transfer, promoting crisis management as a continuous, proactive, and anticipatory process. BeLIFE began in October 2023 and will run for four years. It accompanies the second phase of five regional German projects, also funded by the BMBF, which are implementing solutions to prevalent issues in civil protection. These solutions respond to potential scenarios such as flooding, blackouts, and crowd panic. The five projects' planned measures seek to heighten actors' resilience and their ability to act, educate the population at large, and improve crisis planning and communication.

As the accompanying research project, BeLIFE addresses the demands of effective knowledge transfer on multiple levels and for various audiences: First, it creates an infrastructure designed to facilitate knowledge exchange between the five civil-protection projects, thus establishing an overarching knowledge space that enables each project to benefit from the others' insights into central issues and challenges. Second, it adopts the meta-perspective of sociotechnical systems to analyze how the various social and technical components of crisis management in the five projects interact and what implications this has for future crisis management, both for facilitating dialogue between researchers and practitioners and for ensuring sustainable approaches to crises. Third, BeLIFE transfers this knowledge gained from both scholarship and practice to decisionmakers and to the general population: It provides immersive insights into potential crisis scenarios at the Futures Security Lab, located at the Einstein Center Digital Future across from the German Bundestag, and disseminates key learnings from the five projects in an interactive traveling exhibit.

Ultimately, the aims of BeLIFE speak to multiple symposium topics. The project emphasizes that effective knowledge transfer, by promoting exchange between the various actors involved in crisis scenarios, is a vital aspect of the crisis management lifecycle. Moreover, it takes a holistic view of this lifecycle, demonstrating the necessary links between anticipatory planning, proactive response, and critical reflection.

The meta-perspective of sociotechnical systems as an interdisciplinary basis for knowledge transfer also prompts further avenues of inquiry. Future projects could examine how the various dimensions of knowledge transfer can help to anticipate and address challenges that arise when technical innovations encounter social needs and expectations. Such projects could focus, for instance, on how to optimize knowledge transfer between diverse actors to promote a nuanced, transparent, and responsible use of artificial intelligence in civil protection.

CREXDATA: Critical Action Planning over Extreme-Scale Data

Dr.-Ing. Jens Pottebaum
Paderborn University

Emergency management and critical action planning call for timely and accurate decision making in several, diverse applications with the goal to optimize economic, societal, or environmental impacts. Weather and health emergencies and maritime applications collect live streams of extreme scale data that reach high speeds and volumes and possess highly volatile statistical properties, incorporating uncertainties and diverse modalities through a multitude of sources. The vision of CREXDATA (https://crexdata.eu/) is to develop a generic platform for real-time critical situation management including flexible action planning and agile decision making over data of extreme scale and complexity. To achieve its vision, CREXDATA will develop a next generation Prediction-as-a-Service (PaaS) system where action planners will easily register their multimodal data stream sources and compute resource federations and graphically design predictive analytics workflows. The project will develop the algorithmic apparatus, software architectures and tools for federated predictive analytics and forecasting under uncertainty.

The purpose of the envisioned framework is to boost proactive decision making providing highly accurate and transparent short- and long-term forecasts, explainable via advanced visual analytics and accurate, real-time, augmented reality facilities. Three use cases will be used to evaluate project results: enabling authorities and first responders to act proactively in the event of weather-induced emergencies, predicting hazardous situations like potential vessel collisions at sea, and mitigating pandemic outbreaks and developing non-pharmaceutical means of treating patients. Collaborative experience will strengthen the CREXDATA project, involving 15 institutions with emergency management stakeholders in Germany, Austria and Finland. The consortium builds upon results of preceding projects like ANYWHERE, enabling impact assessments in extreme weather situation based on Multi-Hazard Early Warning System. Data from the meteorology domain like weather sensor data, nowcasts and forecasts is integrated with local data streamed from stationary and mobile sensor systems like rescue robotics.

The CREXDATA consortium will contribute knowledge along the entire chain from data processing across such extreme data up to visualization of actionable information subsuming explicit notions of uncertainty. Use case range from map-based decision support views for high level command posts to Augmented Reality tools for tactical commanders in the field. The CREXDATA architecture will incorporate ten exploitable assets based on cutting edge research, which will significantly outperform the current state of practice in respective fields. The CREXDATA project works within the greater ecosystem of HORIZON EUROPE projects that contribute to the Digital Europe Programme.

DigCBA: Digital Cash Based Assistance

Dr. Hossein Baharmand
University of Agder

DigCBA (https://digcba.uia.no/) contributes to the responsible use of digital cash-based assistance (CBA) in refugee crisis through the design, development and evaluation of evidence-based frameworks to support policy makers with the selection and use of the most suitable digital technology for delivering CBA to refugees. Digital technology, including mobile money, electronic vouchers, electronic cash, and recently blockchain-based transfers, is transforming CBA with the potential to increase access to financial resources and services during times of crisis while increasing the effectiveness and efficiency of assistance. While academic research on technology aspects of CBA is rare, the growing interest on CBA in practice has stimulated the need among CBA actors to explore using digital technology where FEASIBLE in terms of (i) contextual characteristics (e.g. data infrastructure conditions in target locations) and refugees' preference, technology access and digital literacy; and (ii) the relative readiness and acceptance of main CBA actors to adopt, implement and use the technology in target locations. The responsible use of digital CBA entails ensuring policy makers at humanitarian organizations (HOs), non-governmental organizations (NGOs), and donors make informed decisions about the use of digital technology in CBA while accounting for the contextual characteristics of the target community, and the technology readiness of involved actors. Specifically, the project takes a stakeholder-centered approach addressing the needs of beneficiaries, HOs, international and local NGOs, donors, and business partners. The project is coordinated by the University of Agder (Norway), in collaboration with NTNU, Hanken School of Economics, University Münster/ERCIS Competence Center for Crisis Management (Germany), and Makerere University Business School (Uganda). A reference group of CBA actors secures close interaction with policy makers targeted by DigCBA. The project consists of an interdisciplinary team of humanitarian operations researchers with focus on ICT, supply chain management, information systems and organization studies.

DIREKTION: Disaster Resilience Knowledge Network

Juliane Schlierkamp
Fraunhofer INT

The increasing frequency and severity of global crises, from natural disasters exacerbated by climate change to the multifaceted challenges posed by rapid technological advancements and societal shifts, necessitates a paradigm shift in disaster response and management strategies. The DIREKTION project (https://www.fire-in.eu/direktion), launched as part of the European Union's Horizon Europe initiative under the specific call HORIZON-CL3-2022-SSRI-01, aims to improve public safety and resilience against disasters. It does so by combining advanced technologies and new strategies to better manage emergencies and protect communities. DIREKTION seeks to address the critical need for an adaptive, resilient, and efficient crisis management framework that can navigate the complexities of modern disasters. It emphasizes the development of a comprehensive system that leverages the latest in research and technology while fostering collaboration across disciplines and sectors. This project underscores the potential of interdisciplinary efforts to create solutions that are not only technologically advanced but also inclusive and sustainable. This abstract outlines DIREKTION's core objectives: to harness and integrate cutting-edge technologies and methodologies to improve crisis prediction, management, and recovery processes. The project aims to innovate in areas such as real-time data analytics, communication technologies, and decision-support systems, ensuring that responses to crises are more coordinated, timely, and effective. Furthermore, DIREKTION places a significant emphasis on environmental sustainability and social responsibility, aiming to develop solutions that mitigate the impacts of disasters on communities while promoting resilience and adaptation. The methodology encompasses a blend of quantitative and qualitative research approaches, including case studies, simulations, and participatory design workshops, to ensure that the solutions developed are grounded in real-world needs and scenarios. This comprehensive approach ensures that DIREKTION's outcomes are not only theoretically sound but also practically viable and adaptable to various contexts and challenges. Anticipated outcomes of the DIREKTION project include the development of a framework for capability-driven innovation management, enhanced tools for situational awareness, and innovative strategies for community engagement and resilience building. By bridging the gap between technological innovation and societal needs, DIREKTION aims to contributing to safer, more resilient societies. In conclusion, the DIREKTION project represents a critical step forward in the quest for more effective, efficient, and equitable disaster management solutions. By aligning with Horizon Europe's vision for civil security and societal resilience, DIREKTION not only addresses the immediate challenges posed by modern crises but also lays the groundwork for future innovations in the field.

iProcureSecurity: Pre-Commercial Procurement of Innovative Triage Management Systems Strengthening Resilience and Interoperability of Emergency Medical Services

Dr. Zeynep Sofuoglu
Izmir Democracy University Medical Faculty Department of Public Health

Emergency Medical Services (EMS) in Europe are characterized by a heterogeneous landscape with diverse organizational setups, technology standards, coordination mechanisms and actors. This is the result of different historical and institutional contexts. However, these EMS are united by the common aim of providing timely care to casualties of sudden and life-threatening emergencies or disasters in cross-border settings and international humanitarian missions. Fostering the response capacities and increasing the cooperation of the Emergency Medical Services Systems is of decisive importance for strengthening the resilience of European societies.

During the prior iProcureSecurity Coordination and Support Action (CSA) project, many EMS were involved to identify, evaluate, and prioritize future challenges and needs. The creation of an interoperable, flexible triage management system supported by modern technologies was among the most requested solutions in the context of security-related scenarios.

This iProcureSecurity Pre-Commercial Procurement (PCP, https://www.iprocuresecurity.eu/) project is a result of those intense participatory processes. The action will lead to an innovative triage management system that supports the EMS on the field in the management of the Mass Casualty Incidents (MCIs). The envisaged solution will be extremely flexible and interoperable, to adapt to the different procurers' needs.

Overall, the iProcureSecurity PCP Solution aims to: (a) Fully digitalize the triage management operations on the field and provide guidance and support to the EMS practitioners; (b) Facilitate the communication and the information sharing among EMS on the field and external stakeholders. (c) Facilitate the decision-making process of the actors involved, by proving them with key information in real time, as well as with alerting and notification systems.

Following the EC Guidelines on PCP, through a competitive series of design, prototype and pilot steps, the iProcureSecurity PCP will contract suppliers to deliver the creation and deployment of the envisaged triage management system.

LINKS Strengthening links between technologies and society for European disaster resilience

Prof. Dr. Ir. Kees Boersma
Vrije University Amsterdam

Decades of research and experience have demonstrated the positive impacts of an all-of-society approach for involving members of the population in disaster risk management (DRM). In recent years, EU funding calls (e.g. H2020 and Horizon Europe) and projects for research into societal resilience, have also placed increasing emphasis on the importance of inclusive engagement with different stakeholders in DRM, including formal authorities and response organisations, businesses and private actors, and (spontaneous) volunteers and citizens, and researchers. Such broad-based participation from society requires rethinking of organisational routines and processes in crisis management, as well as innovative approaches for communication and engagement with citizens including the most vulnerable. It requires time, trust, and finding new ways to dialogue between stakeholders, both in researcher and practice.

This pitch focus on the experience and outcomes from the H2020 project LINKS (https://links-project.eu/), which concluded in 2023. The project examined the ways in which social media and crowdsourcing could be used to enhance DRM efforts in various hazardous environments. Overall, the project produced valuable lessons learned for involving and collaborating with crisis management practitioners (and other stakeholders) in research, including concrete examples of exploitation and impact of project outcomes on practitioner organisations. The pitch will also discuss how the project outcomes fed into ongoing initiatives between researchers and practitioners in projects such as the Horizon project SYNERGIES, and provide some suggestions for strengthening future research collaborations between these stakeholders.

RESCUE-MATE (1): New approaches to dynamic situational awareness and emergency responders support

Luisa Knoche
Federal Agency for Technical Relief

Storm surges are a natural hazard that is expected to increase in frequency and severity in the coming decades due to climate change. The RESCUE-MATE project (https://www.rescue-mate.de/), which is funded by the Federal Ministry of Education and Research, will address the scenario of a storm surge in Hamburg with a water level exceeding 7 meters above sea level. This could result in flooding of large parts of the port and districts close to it. All available relevant data sources must be integrated when dealing with severe storm surges due to the limited information typically available. This includes all data collected by emergency services via control centers and on site, data from sensors on site such as traffic cameras, terminal cameras, and environmental sensors, as well as all relevant information from existing systems. Additionally, information from citizens on social networks may also be considered. By collecting all of this information, it is possible to make a comprehensive assessment of the situation and derive more efficient and effective assistance. The project aims to automate, accelerate, and enrich the flow of information between authorities, emergency services, and aid organizations. Additionally, it aims to automatically collect and evaluate relevant information for assessing the situation and process it for different target groups. The project aims to develop an open, decentralized, and secure AI and data platform for situation and decision support. The platform will enable effective information exchange and generate digital twins as images of the situation on the ground, without replacing existing systems. The platform integrates public data sources and new sensor technology developed in the project, making them available to the different stakeholders.

The project addresses especially, but not only, the ISCRAM topics AI in Crisis Management and Risk and Crisis Communication. The AI-powered RESCUE-MATE system analyses available data to provide first responders with relevant, summarized information and prevent them from being overwhelmed by data. The exchange of data between organizations involved in disaster response is one of the platform's main objective.

RESCUE-MATE is set to conclude in 2027. However, further research is required to investigate short-term simulations of hazardous events and their impacts. By providing probable scenarios, emergency responder organizations can take necessary anticipatory measures, such as issuing evacuation orders and constructing flood barriers

RESCUE-MATE (2): Digital Twins and Analytical Modeling for Crisis Management: Enhancing Situation Awareness in Urban Environments

Dr. Bita Vogler
HafenCity Universität Hamburg (HCU)

As the impacts of climate change intensify, cities like Hamburg face increasing risks from natural disasters such as storm surges. In response, the RESCUE-MATE project (https://www.rescue-mate.de/), conducted within the Digital City Science (DCS) chair at HafenCity University Hamburg (HCU), integrates cutting-edge technologies, particularly Digital Twins in the Urban Space and Analytical Modeling and Simulation, to enhance crisis management strategies.

Digital Twins offer a revolutionary approach to understanding and responding to urban crises. By creating virtual replicas of physical environments, Digital Twins enable real-time monitoring, analysis, and prediction of crisis scenarios. In the context of RESCUE-MATE, Digital Twins serve as dynamic representations of vulnerable areas, infrastructure, and population density, facilitating proactive decision-making and resource allocation.

Analytical Modeling and Simulation further augment crisis management capabilities by providing insights into the potential impacts of various scenarios. Leveraging advanced algorithms and data analytics techniques, analytical models can simulate the behavior of complex systems under different conditions, allowing authorities to anticipate outcomes and plan accordingly. In RESCUE-MATE, these models enable authorities to assess the effectiveness of evacuation plans, infrastructure resilience, and resource distribution strategies, ultimately enhancing preparedness and response efforts and they can gain unprecedented insights into crisis scenarios, enabling proactive and effective responses to mitigate risks and protect lives and infrastructure.

At the conference, we propose to present the findings and methodologies developed within RESCUE-MATE Project in DSC, focusing on the role of Digital Twins and Analytical Modeling in urban crisis management. We will demonstrate how these technologies enable authorities to visualize, analyze, and simulate crisis scenarios, providing valuable insights for decision-makers and first responders and showcasing case studies and real-world examples from the RESCUE-MATE project. Additionally, we will discuss the challenges and opportunities associated with implementing these technologies, as well as future directions for research and development in the field of urban crisis management.

In summary, our conference proposal seeks to showcase the transformative potential of Digital Twins and Analytical Modeling in enhancing situation awareness and crisis response capabilities in urban environments conducted within the Digital City Science chair at HCU. We look forward to sharing our insights and collaborating with fellow researchers and practitioners in the field.

SUNRISE: Strategies and Technologies for Resilient CIs in Europe

Stefan Schauer
AIT Austrian Institute of Technology

European societies and economies depend on the reliable provision of vital services. Such vital services are delivered through Critical Infrastructures (CIs) which include basic supply networks (water, electricity), networks of information and communication services, social services (e.g., care of children or elderly), as well as complex networks of essential supply to the population (e.g., medical supply, food supply). This means that European CIs must be resilient, i.e., able to accommodate constantly changing risks and recover quickly from expected or unexpected disruptions. However, infrastructure systems and their components are interdependent. If a disruption or failure occurs in one system, it can spread to other systems and subsequently amplify the impact of a disruption many times and impact further systems.

The COVID-19 pandemic has highlighted the importance of the continuity of these vital services and has shown the need to work together for the common good. It has proven that a pandemic is not only a health crisis that disrupts CIs but underlines the extremely important link between the resilience of these CIs and our societies. The economic crisis caused by the pandemic also provides a unique opportunity to jointly 'build back better' with the focus on sustainability and green recovery.

In this context, the SUNRISE project (https://sunrise-europe.eu/) facilitates active collaboration of CIs across Europe to share best practices and jointly tackle future pandemics. Therefore, SUNRISE aims to identify pandemic-specific vital services and CIs, their dependencies, risks, cascading effects, and effective measures to tackle them at European level. This will be done by developing a comprehensive strategy for ensure the availability, security, robustness and resilience of European CIs. Further, four innovative tools are developed that include solutions for risk-based access control, resource demand prediction and management, cyber-physical resilience, and remote infrastructure inspection to improve trustworthiness, cost-effectiveness, climate-friendliness, and continuity of pandemic-specific vital services in Europe.

SUNRISE pilots the results in operational environments of the CIs while tackling some of their biggest pain points exposed by the current pandemic, promoting the approach across Europe to ensure a united front and future resilience of CIs. Overall, the SUNRISE project carefully considers legal, ethical, societal, economic, and climate aspects, ensuring that the results address not only the needs of the CIs, but also those of our society.

SUNRISE has a special focus on pandemics, but the general approaches and strategies developed in the project could also be transferred to and applied in other domains. For example, when looking at natural and technological (NaTech) disasters, it would also be necessary to integrate different points of view into one assessment and to explicitly take into account their cascading effects. With todays' interlinked and thus highly sensitive supply chains, the direct and indirect effects of such a disaster on society and social life are also an important part that needs to be considered.

ISCRAM 2024 Best Paper Awards

Awards Committee Chair: Filippo SanFilippo, University of Agder, Norway

Awards Committee: Jaziar Radianti, University of Agder; Rob Grace, Texas Tech University

Best CoRe Paper Award

Understanding Crisis Preparedness: Insights from Personal Values, Beliefs, Social Norms, and Personal Norms

Authors: Felix Burger and Jasmin Haunschild

Best CoRe Paper Nominees:

- Accounting for systemic risk in analysis of crisis scenarios, Jose J. Gonzalez, Reem Abbas and Sigurd Paulsen
- Enabling Information Transmission in Low-Throughput Wireless Channels for Aerial Disaster Monitoring Systems, Julian Zobel and Ralf Steinmetz
- Psychosocial Aspects of the 2021 Flood Disaster in Anonymous District, Germany: Strains, Resources, and the Role of Social Media, Francesca Müller, Marvin Kubitza and Fiedrich Frank

Best Student Paper Award

Adapting PLUM: Earthquake Early Warning with Node-Level Processing in New Zealand

Authors: Chanthujan Chandrakumar, Marion Lara Tan, Caroline Holden, Max T. Stephens and Raj Prasanna

Best Student Paper Nominees:

- Using Optimization Modelling to Determine Locations for Aerial Firefighting Resources Based on Wildfire Risk Data, Viktor Sköld Gustafsson, Tobias Andersson Granberg and Martin Waldemarsson
- Human Values for Responsible Decision-Support for Fire Services, Tina Mioch, Huib Aldewereld and Mark A. Neerincx
- Engaging the Public in Forest Fire Awareness through a Mobile Application, Emil Gatial, Zoltán Balogh, Sepideh Hassankhani Dolatabadi, Mariana Soledad Molina, Timo Kasig, Kayvan Yousefi Mojir, Marcin Wawrzyniak, Dominika Grunwald and Marcin Przybyszewski

Best WiP Paper Award

Selection of rural villages as volunteer centers for emergency response

Authors: Niki Matinrad and Tobias A. Granberg

Best WiP Paper Nominees:

- Utilizing Social Media and Crowdsourcing for Crisis Management and Communication: proposing an Integrative Framework, Kees Boersma, Nathan Clark, Robert Larruina and Emmeline Roeloffs
- SILVANUS Dashboard for Wildfire Management, Dominika Grunwald, Marcin Wawrzyniak, Marcin Przybyszewski, Emil Gatial, Zoltan Balogh and Sepideh Hassankhani-Dolatabadi
- Navigating the Digital Technology Behavior for the Distribution of Humanitarian Cash-Based Assistance: Aid Recipients Experience, Amin Maghsoudi and Abdelsalam Hamid Abakar
- Tweeting Through the Flood: Application of BERT Topic Modeling for a Comparative Flood Communication Analysis, Christin Salley, Nathan Fox and Alyssa Schubert

Best Reviewer Award

Katrina Petersen, Public Safety Communication Europe

Practitioner Track

Track Chairs

Nicola Rupp, Deutsches Rettungsrobotik Zentrum e.V.

Bart van Leeuwen, Owner at Netage B.V., Amsterdam-Amstelland FD

Christoph Lamers, Joint Competence Center for Civil Protection

Following the ISCRAM tradition and the conference vision, crisis management practitioners are invited to present their work in the practitioner track. Unlike other tracks, which require a CoRe- or WiP-paper for presentation, ISCRAM 2024 is adopting a novel approach informed by feedback from practitioner communities. We encourage practitioners to share their experiences, realities, and insights on current ISCRAM challenges and solutions through talks, without the need for paper submissions. This initiative aims to facilitate the sharing of pertinent ISCRAM topics and foster stronger collaboration between academics and practitioners. The submitted and accepted practitioner talk abstracts are listed in the following section.

Optimizing the deployment and use of new technologies in Search and Rescue: A recap from recent missions

Harris Georgiou
Hellenic Rescue Team of Attica (HRTA)
harris@xgeorgio.info

Alexis Vlachopoulos
Hellenic Rescue Team of Attica (HRTA)
nosailor01@gmail.com

Anastasia Andriopoulou
Hellenic Rescue Team of Attica (HRTA)
aandriop2@gmail.com

In Search and Rescue (SAR) operations, the First Responders (FR) are called upon to act in a wide range of environments, conditions and limitations, associated to both external and internal factors. Weather, location, access, infrastructure, travel time, are only some of these external factors, while team's readiness level, organization, skill level and experience, toolkits available, are some of the most important internal factors. For Urban Search and Rescue (USAR) the most critical factor, besides FR safety, is speed. Every USAR mission is an effort against time, beginning as a speed race during the first few hours after the disaster event and gradually becoming a marathon run as the hotzone gets cleared in a more focused way. In this presentation, four recent Search and Rescue (SAR) deployments of our team in 2023 are briefly presented as baseline for contextualizing the challenge of designing the next generation of assets and tools for the field operations. Namely: (a) earthquake in Turkey-Syria, (b) train crash in central Greece, (c) wildfires in Greece, (d) floods in central Greece. Lack of preparedness, coordination and poor perimeter monitoring is, as expected, a major factor in large-scale disasters. Specific differences in task prioritization and speed are evident between small-scale events like train accidents and large-scale events like devastating earthquakes, leading to corresponding changes in the deployment or even the planning phases of a SAR mission. Citizens and spontaneous volunteers are important assets often overlooked. The "last mile gap" and changes in First Aid / medical response are also crucial factors that emerge more evidently as the scale of the disaster increases. In the non-operational context, a few important guidelines and good practices can be proposed for SAR-related R&D projects. Specifically, several limitations and hindering factors in developing new technologies may work counter-productively, often very early on while in design or prototyping phases. These include very limited or no provision budget-wise for full IPR protection of the developed technologies, the low Technology Readiness Level (TRL) expectancy, limited focus to standardization and interoperability outcomes, as well as the inherently limited / highly specialized FR "market" for these products and tools. Based on the experience from DRS cluster projects of EU Horizon H2020 in recent years, important guidelines and good practices can be formulated in relation to expectation management for both FRs and technical partners, early end-user involvement in all the phase and extensive field trials throughout the projects' lifetime.

How unmanned systems empowered civilian command systems and strategic response: 15 years of lessons learnt in wildfires fight

Jean-Paul Monet
Lieutenant-colonel of Bouches-du-Rhône Fire Department (BDRFD),
Marseille, France
jean-paul.monet@orange.fr

Eric Rodriguez
Lieutenant-colonel of BDRFD, division chief
Marseille, France

Emmanuel Dombre
Emeritus CNRS research director, LIRMM, Department of Montpellier University
Montpellier, France

Marc Dumas
Lieutenant-colonel of BDRFD, Assistant chief officer for operations,
Marseille, France

For many years, military, security and safety services have been experiencing and finally using unmanned systems. The presentation's aim is to describe a short history of these robots and depict how are there employed today, in the field of civil safety, peculiarly in wildfire fight. After more than 15 years' experience of aerial imagery use, and many ground robotics trials, Bouches-du-Rhône fire department's unmanned tools team can be now share lessons learnt, in this very special context. Furthermore, authors eventually explain how this new deal implies some changes to integrate it in the incident command system processes and in decision making.

About ground robotics (UGVs) Counter Improvised Explosive Devices crews were the first to acknowledge these unusual tools. After 90ies, solutions of ruggedized, versatileand multi terrain, robots progressively emerge. Unmanned Ground Vehicles (UGVs), and this generation of tools move from C-IED missions towards CBRNe sector market, then recently in generic fire fighting and Oil and gas domains. Right now, wildfires applications revealed poor benefits, mainly due to water supply difficulties, and accessibility issues. However, some real specific cases will be reported.

About drones (UAVs)

On another hand, large employment of Unmanned Aerial Vehicles (UAVs) during Afghanistan and Middle East conflicts definitely consolidates concept and machines and allowed to develop interfaces and sensors for military uses. In the same time, in another world, leisure domain, huge number of inventors created -most frequently in their own garage! - all over the word, the large family of light drones. Nowadays, allclasses of UAVs are now fully employed, in tourism, industry, sensitive area survey, natural disaster fighting and law enforcement missions. More in our focus, Civil Protectiontroops, all over the world currently use all range of UGVs and UAVs, especially in wildfire fight. Mediterranean wildfires experiences will be reported: achievements and doubts linked to several constraints.

The conclusion will depict how the update of the command-and-control structures is paramount to increase the performance by using these tools, and how incident commanders' behavior and thinking has been influenced.

Opportunities And Challenges Raised By Introducing Robotic Systems Into The Crisis Management Process

Ivana Kruijff-Korbayová
German Rescue Robotics Center
Ivana.kruijff@rettungsrobotik.de

Firefighters and other first responders often operate in partially known and uncertain situations involving high risk due to, e.g., instability of afected structures; presence of potentially explosive or other known and unknown hazardous materials; changing situation dynamics, such as unexpected fire spread due to radiant heat transfer. This is particularly the case in medium- to large-scale incidents, such as major fires, floods or earthquakes. To reduce the danger to first responders and extend their operational capabilities, disaster response missions are increasingly supported by rescue robots, i.e. unmanned air, ground or water vehicles. Remote reconnaissance and search by robots carrying visual, thermal and other sensors enables better situation assessment and therefore better mission plannning. Remote physical operations, such as firefighting, ventilation, manipulation or heavy load transport help reduce human risk exposure. While rescue robots unarguably offer great potential benefits for mission safety and efficiency, integrating them into firstresponse teams also gives rise to various challenges. Based on practical experience from a variety of field tests and real deployments carried out with and by practioners (mostly firefighters) this talk will highlight some of the implications that the use of robots as part of incident response has on the roles, tasks and processes. In particular, (what) new roles are needed in connection to operating robots; (how) the tasks done by robots need to be reflected in mission tactics, in some cases entailing radical changes; (how) robot-teams need to be incorporated into the command structure; (what) data collected by robots needs to be transmitted and processed to derive actionable information to be presented at the right time and in the right amount to the right people; (how) data/information pull and push need to be reclected in the decision making processes. While the focus is on the (first) response phase, the need for and availabilityof data/information also needs to be taken into account in the preparedeness and recovery phases. I hope that the talk will indicate open research questions and inspire collaboration.

Engaging end users in security research

Tiina Ristmäe
THW
SYNERGISE Coordinator
Tiina.ristmaee@thw.de

Evangelos Sdongos
ASTRIAL GmbH
SYNERGISE Technical and Scientific Coordinator
e.sdongos@astrial.de

End-user involvement in security research is paramount for ensuring the effectiveness, relevance, and practical applicability of research outcomes in real-world emergency response scenarios. This abstract delves into the significance of engaging end users, such as emergency responders (ER), (from government agencies, community organizations etc.) throughout the research process in civil protection.

The culture of knowledge exchange and mutual learning has been actively practiced in the EU research project SYNERGISE. SYNERGISE develops complex technology solutions for increasing the emergency responder's safety and improving the efficiency of disaster management. In SYNERGISE project emergency responders are engaged in the research process, the scientific organisations learn about deployments and the challenges ER face during their rescue operations. To bring these different worlds together is a challenge but only the mutual learning process can bring the desired results of the research.

SYNERGISE project is user led and user oriented with defined process of user involvement. The developed technologies have to support ERs work during missions, so it is natural that ER will provide the framework of their rescue operations (scenarios, use cases, end user requirements etc.) Regular exchange between technology developers and end users is also foreseen during the prototype's development phase, in that way the connection and exchange stays alive throughout the project life time. In the validation activities at the final stage of the project end users play a crucial role – they need to evaluate the technology performance outside labs and if the systems are usable and useful during their work. Training follows these actions otherwise it wouldn't be possible to test the technologies in the field conditions.

Disaster Response by Using Location Data in Japan

Yasuhiro Soshino
Disaster Management Research Institute
Japanese Red Cross College of Nursing
y-soshino@jrcdmri.redcross.ac.jp

Masahiro Nemoto
Japanese Red Cross Hokkaido College of Nursing
nemoto@rchokkaido-cn.ac.jp

1. Background

Past disasters such as the 2011 Great East Japan Earthquake and Tsunami and the recent 2024 Noto Peninsula Earthquake revealed the challenges in identifying the passable roads, the isolated areas, and the non-officially designated shelters. To cope with these challenges, in 2018, Japanese Red Cross Kumamoto Hospital started to discuss the application of people's flow data with Agoop Corp. In the 20202 Kumamoto Floods Response, people's flow data provided by Agoop Corp. were utilized in the relief team's decision making for a rapid assessment.

2. A Field Test on the Tsunami Evacuation Monitoring

Based on this experience, the Japanese Red Cross Disaster Management Research Institute started the collaborationwiththe Agoop. Following the announcement of the damage estimation of the earthquake along withthe Chishima and Japan Trenches, the authors conducted the joint field test on the real-time tsunami evacuation during the evacuation drill in Nemuro-City, Hokkaido. In the test, the participants were asked to install a smartphone application for sharing the location with their consents while the personal data were anonymous. The collected data was analyzed to show (1) the quick identification of the evacuation sites, (2) monitoring of the evacuationstatusof the participants. The resultsof the analysiswere shown on twomonitors at the disaster response headquarters so that the local authorities and relief agencies could understand the evacuation status. In addition, after the evacuation, the participants reflected their evacuation behaviors by watching the results shown in the monitors.

3. The 2024 Noto Peninsula Earthquake Response

The recent 2024 Noto Peninsula Earthquake causedthe severe damage in infrastructure such as road, tunnels, water supply and drainage. The authors and Agoop Corp. jointly startedthe remote assessment of the disaster affected areas. By using the location data of the smartphones in the disaster affected areas, the unpassable roads were identified. In addition, the data identified a lot of isolated areas in Noto Peninsula due to the landslides. Furthermore, the people's gatherings to the non-official evacuationcentres, which localauthorities did not recognize them, were identified. The information was shared with the Japanese Red Cross and other medical relief teams, and the local authority in the disaster affected areas to support relief activities.

4. Conclusion

Application of people's flow data were effective in the rapid assessment in emergencies. For the effective and smooth application of the data, building up the information sharing system is crucial.

Institutional amnesia during large crisis: Effects of poor documentation

Erik A.M. Borglund
Mid Sweden University
erik.borglund@miun.se

Kjell Lagerström
Mid Sweden University
kjell.lagerstrom@gmail.com

ABSTRACT

In this "work in progress" research, we attempt to understand and explore the effects of inadequate documentation during crises. We have studied the work of three different organizations during the first six months of the Covid-19 pandemic and have been able to ascertain that almost no official documents from the organizations' crisis management teams can be found. The consequences of inadequate documentation resulted in challenges when learning from mistakes, difficulties in real-time learning, and a lack of understanding regarding the rationa le behind the decisions made. This institutional amnesia is problematic for many reasons and needs to be further studied. The next step in our research will be to study information culture and try to understand the effect of this amnesia on resilience.

Keywords

Crisis management, Covid-19, Documents, Institutional amnesia, Records.

INTRODUCTION

During large crises, command and control (C2) work is meticulously documented in various forms. These documents and records, some of which are more fragile and temporal while others are rather legally required, play a pivotal role in creating the common operational picture (COP) (Borglund, 2020). Documents and records in crisis management play a large role in creating the common operational picture (Borglund et al., 2014; Borglund, 2011). However, there are numerous instances where the absence of documents obstructs understanding of what transpired during and after a crisis, emphasizing the critical need for comprehensive documentation.

For example, when the Corona Commission, a large national assessment and review of how the Swedish government had managed Covid-19, presented their first report, much of the criticism was based on the absence of documents (Statens offentliga utredningar, 2022a, 2022b). The most severe criticism of the Swedish government was a) a lack of proper document management within the Swedish Government Office, b) difficulties accessing public records produced by the Swedish Government Office. The Corona Commission implicitly criticized the Swedish Government Office for having a very poor document and record management function during the management of the pandemic. However, there were other large crises that occurred before Covid-19 that were also criticized for poor documentation. In 2014, a large forest fire took place in Västmanland County, where 37,000 acres of forest were on fire. The fire lasted for many weeks and identified several weaknesses in the Swedish emergency management system. In the aftermath of the forest fire, one severe criticism was the absence of documentation from the authorities involved (Skogsbrandsutredningen, 2015). For example, during the forest fire, hundreds of volunteers were helping the authorities with different tasks, but in the official records there was little evidence of these activities (Sperens, 2016). In 2018, Sweden had a very dry summer and several large forest fires challenged the Swedish emergency management system, and even if authorities had improved the documentation of their activities, the lack of proper documentation was once again criticized (Statens offentliga utredningar, 2019). In the reports on the fire in 2014 and the fires in 2018 (Skogsbrandsutredningen, 2015; Statens offentliga utredningar, 2019), it is obvious that the review and assessment of how the authorities acted during the crisis could not rely on the evidential value that public records bring. The review rather relied on interviews with

people involved and their memories about what happened, instead of evidential records of the activities that took place. Noticeable is that we see evidence of activities that not are recorded at all. Lack of documentation makes it difficult to improve crisis management in the future. One area where we lack experience is understanding how information sharing worked and shared situation awareness took place in a large crisis so that challenges could be detected, and a system developed.

In this paper we investigate how authorities in the public sector fail to document their work in a command and control setting during a large crisis. The research question that guides this research is*: "What challenges arise from inadequate document management capacity during a large crisis?* This is ongoing research, and this paper presents the first findings from the work.

The paper is organized as follows. First, an overview of document management during crises is presented together with the concept of institutional amnesia. This is followed by the research method that was applied , after which the preliminary results are presented, followed by a discussion and a tentative outline for the continuation of this research.

DOCUMENT MANAGEMENT AND RECORDS MANAGEMENT DURING CRISIS

The Swedish emergency management system is complex and divided into a local, regional, and national level (Myndigheten för samhällsskydd och beredskap, 2014). There are three general principles that should guide the Swedish emergency management work:

• *The principle of responsibility means that actors retain their ordinary responsibilities in situations of crisis and disaster. This principle also includes a responsibility to support other involved parties as necessary.*

• *The principle of proximity means that crises and disasters should be managed as close as possible to those primarily concerned.*

• *The principle of similarity states that the methods and structures used in crisis and disaster management should be similar to those used under normal circumstances.*

(Krisinformation.se, 2024)

In Sweden, current recordkeeping and archival management is not separated as it is in many other countries. This is based on what constitutes the democratic openness in Sweden. The Swedish openness is based on the Swedish Constitution, the Freedom of the Press Act, which declares that all citizens have free access to public records. The Swedish Archival Act makes the Freedom of the Press Act more operational, and it states that the archive consists of all the records that are a result of a public authority's activity and business. These two legislations make it possible for everyone to access and thereby understand public authorities and their business, which is very important for Swedish democracy. Public records are evidence of activities and make it possible to understand what happened afterwards. The Swedish national legislation regulates that public business should be documented, and based on the principle of similarity, public authorities involved in crisis management should act consistently, regardless of whether there is a crisis or not.

These principles indicate that authorities should maintain consistent actions during a large crisis. According to Thomassen (2001, p. 376), records are important, *"Without records, no assessment can be made of whether individuals, private organisations and public organisations have actually carried out the actions and transactions that they had to execute, or whether the actions and transactions made meet the criteria of efficiency, legitimacy or the principles of good governance, and whether they have done things which they were not supposed to do."*

Records are evidence of the past, and during challenging situations, e.g., during a large crisis, such evidence could be extremely important as a way of producing new knowledge. In 2021, the Corona Commission, presented their first report. In the report document and records management during the Covid-19 pandemic was identified as almost non-existent.

During a large crisis, authorities usually organize into some version of a C2-setting, frequently in the form of an emergency operation center, to manage the upcoming situation.

INSTITUTIONAL AMNESIA

Other researchers have studied the effect of absent documentation in public organizations. Not only Swedish authorities have identified memory loss in organizations. Pollitt (2000) argued that organizational learning is frequently discussed, but the organizational forgetting is rarely mentioned. Many argue that the archives are the memory of the past and the archives provide organizations and culture with a lasting memory (Brothman, 2001). Therefore it is strange that the modern society with its information technology cannot provide a memory that

lasts (Pollitt, 2000). According to Pollitt (2000, p. 8), some of the underlying reasons for the institutional memory loss are the following:

"…/

1. An increasing rate of organizational re-structuring, leading to a higher proportion of relatively 'new' organizations, which rapidly lose touch with the records and personnel of their organizational 'ancestors'.

2. Rapid shifts in the media in which records are held, first from paper ('the files') to electronic media, and then from one kind of software to another. With each shift, some of the past is, for a variety of reasons, likely to be lost.

3. The decline of the concept of public service as a permanent career, leading to a higher proportion of public servants with only transient experience of their organizations.

4. The popularity of ideas of unceasing, radical change. These include some of the most fashionable improvement techniques in the public sector, such as re-engineering and benchmarking. These systems of ideas include suggestions that the past is no longer relevant, or even that to look back is defeatist and dangerous.

/…"

In the work by Borglund (2020) the management of records during crisis very much relied on the discretion of individuals. Some records were necessary to keep for legal reasons, but a rather large amount of information created during large crises were never documented and kept for future use.

T he impact of memory, relevant to crisis management, can be summarized as follows, according to Pollitt (2000, pp. 13-14):

1. The learning from mistakes is rare, and organizations tend to re-try things that failed 5–10 years ago.
2. Using fashionable solutions increases vulnerability.
3. Using other organizations' solutions to move away from certain trajectories but without knowing if the solution works.
4. Lack in capacity to understand the knowledge value amongst "long-serving staff".
5. Inconsistencies and discontinuities in dealing with citizens/service users. From a crisis management perspective 1–4 are very relevant and therefore institutional amnesia should be avoided.

METHOD

Our research uses a qualitative research approach (Myers, 2009). The research can be a seen as a case study (Lee, 1989) where we have aimed to understand how the Covid-19 pandemic was managed by one municipality, one region and one county administrative board during the first six months of the pandemic. Additionally, we sought to understand and further scrutinize document management and the document management role specific to the management of the Covid-19 pandemic in one region in Sweden. The data collection has primarily focused on studying the public records registered as created or received by these three authorities. We decided to collect records related to C2 organization in the three studied organizations from when WHO declared Covid-19 a pandemic on March 11, 2020, and the six months following. The selection of these three authorities was defined as expedient selection (Hartman, 1998), where selection was meant to be able contribute to the answer of the research question. The region is a responsible for many tasks, but primarily for medical service within the region. The country administrative board is a government authority in a region that serves as link between people, municipalities, the government and central authorities. Furthermore, the county administrative board is responsible for crisis management collaboration within the region 's borders, while the municipality is responsible for crisis management collaboration within the municipality 's borders.

The three organizations studied had all activated their crisis organization, i.e., they organized according to the recommendations from MSB (The Swedish Civil Contingencies Agency).

We conducted a search for data within the registers of public records generated by the crisis organization at the regional level, the county administrative board, and a specific municipality. In each case, we focused on posts, records, or files that were tagged with metadata labels such as "crisis", "operation picture", or "crisis organization". We searched the public records registers to find the original records. We also conducted further investigations within the three organizations to understand if other records and documents could be received.

INITIAL FINDINGS

We started by searching the official registers of the three authorities. As all documents made and received from a public authority's business should be part of the authority's archives, finding the documents produced during the crisis management organisation in the authority's official register should be possible.

Municipality

In the official register of the municipality, there was only one record related to the municipality's crisis management during Covid-19, primarily related to the COP. We also used other search strings, but it did not result in any additionalofficial documents. We then asked the municipality for a manual search, and they provided six different closed records. One record could consist of one or several documents. The municipality replied with six records labelled the crisis management board (*Krisledningsnämnd* in Swedish). The reply from the head of security of the municipality did not provide us with any physical documents to study, only a list of six records. What documents these records contained was not clear. The municipality studied has a catalogue of all processes and documents that can be incorporated into these processes. The catalogue regulates how to deal with the documents, including preservation time, etc. All risk and crisis management documents in the studied municipality should be preserved for three years. Therefore, it is strange that for the first six months of Covid-19, there are only six records.

County Administrative Board

The county administrative board is an important authority in the Swedish crisis management system. There are twenty-one country administrative boards, and their tasks during larger crisis are:

- Collaborate within the county and with neighboring counties.
- Coordinate activities and information among municipalities, regions, and authorities during a crisis.
- Direct and prioritize state and international reinforcement resources based on government decisions.
- Implement preventive measures to prevent societal disruptions.

A search in the official register of the county administrative board during the first six month of Covid-19 resulted in six records with some relevance to the crisis management organizations.

Region

In the region, during a crisis, an emergency management board is activated with the task of governing the region during a ciris. As with the municipality, we searched for documents in the official register. The result was a total of 5 records containing "common operational picture", out of which some were irreleva nt. It was not possible to further investigate the relevance and the presence of documents within those records in the official register.

In a consultant report from KPMG (KPMG, 2021) the work of the entire region during the first month of Covid-19 was evaluated. In the report it is obvious that the region with its subdivisions had regular meetings related to Covid-19. Some parts of the region organized into a staff organization. The KPMG report also indicated that through there was a lack of documentation of decisions, KPMG were able to analyze more than 400 nonregistered documents such as minutes, decision logs, and memorandums.

Secret or Not Secret Documents

One possible explanation for the absence of documents from the first six month of the Covid-19 pandemic is that the documents that do exist have been secret. However, if they were secret, they should be listed in the registers. In Swedish legislation it is stated that records with a secret content must be registered, where you should find the date, the register number, who created the record, and what it is about (Larsson, 2019). This means that if the three authorities classified their records from the crisis organization and their common operation picture as secret, it should still be possible to find the records when searched for.

A NATIONAL DOCUMENTATION TASK

In connection with the first wave of the coronavirus pandemic, the National Archives urged government agencies to preserve documents containing information about the pandemic (Riksarkivet, 2020). The following points were

highlighted:

• Improving the preservation of documents such as internal communication, including emails, meeting notes, and information for employees.

• Ensuring that relevant information from government websites and social media is preserved.

In 2023, the National Archives issued a general recommendation encouraging government agencies and other entities to expand the preservation of societal information during crises. It is worth noting that the National Archives considers crises as disruptions similar to the Swedish Civil Contingencies Agency (See in page 5-6 Riksarkivet, 2023).

DISCUSSION OF THE COLLECTED DATA

While it is too early to draw any definitive conclusions, it is obvious that the criticism raised after the forest fires in 2014 and 2018 was not only relevant for the management of forest fire crisis. During the Covid -19 pandemic, thousands of people died in Sweden, which makes it clear that it was a large crisis. Why is it so difficult to find documents and records from a large crisis? At this stage we have only scratched the surface, but based on previous research (Borglund, 2017; Borglund, 2020; Holmström, 2017), the way documents are created is a possible explanation, and the lack of adequate system support to manage the created documents over time is another. Whiteboards are important in the documentation of common operation pictures, but a whiteboard and large flip chart sheets are also difficult to preserve. In the temporal location of the crisis management, the systems available are not designed to capture the records and documents created. However, it is notable that in a nother study where an organization did not establish any temporal crisis organization (like an emergency operation center) due to the need to work from home, they found that the documentation was greatly improved by working as normal (Borglund et al., 2021). Could the explanation in poor documentation be found in how the work is done?

What Challenges Arise From Inadequate Document Management Capacity During a Large Crisis?

Naturally, many challenges arise when very few documents from C2 work is found. Argyris and Schön (1974) presented Espoused Theory and a Theory-in-Use. Espoused Theory is about the theories a person believes he or she follows. But we apply the concept from (Argyris & Schön, 1974) as a concept where espoused theory is also about the action or activities a person believes he or she has done. Theory in use, however, refers to the theories a person actually uses or follows. The lack of documents from a crisis makes it almost impossible for external or internal auditors to assess how the organizations actually worked. The story, or the narrative, from the crisis, comes from the memories of the people involved. The evaluation of the forest fire in Sweden 2014, 2018 (Myndigheten för samhällsskydd och beredskap, 2016; Skogsbrandsutredningen, 2015; Statens offentliga utredningar, 2019) and the evaluation of Covid-19 in Sweden (Statens offentliga utredningar, 2022a, 2022b) a **l** indicate that the narrative of the actions comes from the memories of the people involved. I.e. the actual action and activities (theory in use) cannot be evaluated.

Another problem caused by inadequate document management during crisis is that it becomes a challenge to learn. In the double loop learning presented by Argyris and Schön (1978), documents can be important in the analysis of the results that are the effect of certain actions and assumptions. The double loop learning is visualized in fig 1.

During the winter of 2024, a large traffic incident occurred on E22 in Skåne where 1,000 vehicles were stuck on the highway due to snow for up to 50 hours. In a recently published report from this incident a lack of documentation was identified also in this case, which made it impossible for authorities to understand the situation and to share the situation awareness with other authorities. This in turn resulted in the absence of a common operational picture which caused a delay for all decisions needed (Capgemeni & Länsstyrelsen Skåne, 2024).

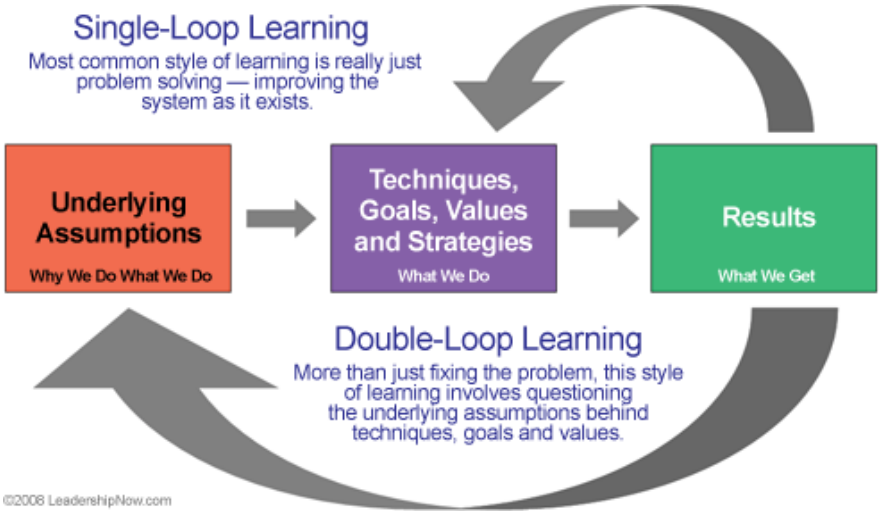

Figure 1. Double loop learning.

Category of Crisis and Its Temporality

Not all crises are the same, and an important difference between them is the need to manage the core of the crisis. In a forest fire, the problem is the fire itself, the crisis is a result of the fire. During the Covid-19 pandemic the problem was the virus. These rather obvious differences in crisis categories also affect the time frame in which the crisis management is taking place. The mentioned forest fires in Sweden in 2014, and 2018 required crisis management for a period of weeks, whereas the Covid-19 pandemic required support for years. This difference in temporality is bound to affect the documentation practice during a crisis. None of the actors involved in these crises realized that the absence of documents was an issue, nor that a poor document management should not be accepted.(Myndigheten för samhällsskydd och beredskap, 2016; Skogsbrandsutredningen, 2015; Statens offentliga utredningar, 2019, 2022a, 2022b).

CONCLUDING REMARKS

One of the most significant issues stemming from the absence of documents and records is the inability to learn from past mistakes, thereby minimizing the risk of repeating unsuccessful solutions. However, documents a lso play a crucial role in understanding the common operational picture at a given time, and the shared understanding of the situation that formed the basis for specific decisions. During command and control work , information sharing is crucial to establish a shared understanding of the ongoing situation (Sonnenwald, 2006). Effective information sharing can also result in a shared situation awareness (Chubala et al., 2023). To be able to improve the information sharing and work with a common operational picture, documents can play an important role.

There can be many explanations for the lack of documentation from the crisis management in the three studied organizations. One explanation is lack of time, and stressful work situations for the staff in the C2 setting. However, when examining the principle of similarity, it suggests that the methods and structures employed in crisis and disaster management should closely resemble those used in normal circumstances. In normal circumstances activities in public authorities are documented and registered. We believe that many of the activities during the first six months of the pandemic in the studied authorities was documented but never registered.

The next phase of this research involves delving deeper into the information culture within organizations to gain a better understanding of why documents and records are not being kept, organized, and made readily accessible. Additionally, we will assess the quality of existing evaluations of large crises. However, can we truly draw meaningful conclusions without sufficient documentation and records?

ABSTRACT

In the context of climate change, increasing disaster severity and extension, the paper suggests to DGECHO, agency managing the European civil protection mechanism, an improvement for joint operations command-and-control practices. It constitutes an update of Monet et al. (2020) paper, enhancing the work progresses in terms of analysis, applicability, monitoring and training.

In this perspective, the work of the authors is completely dedicated to the improvement of interoperability when different (national) civil protection forces work together, to respond to emergencies or disasters. Building on

theoretical comparative studies, this opinion paper now relies on an interoperability monitoring tool and consolidates the ways on defining the future for an "European Command System", proposing innovative operational practices by associating knowledge exchange and operational training.

Actually, the presentation will depict how to organize a training strategy at European level, alternating international and regional courses, to pave the way for future harmonization.

Keywords

Crisis Management; Civil Protection; Incident; Command and Control System; Interoperability; European Union

INTRODUCTION

The aim of this paper is to propose elements of a "new governance in operations" for European civil protection. To avoid any misunderstanding on the term governance, the authors specify that the present work does not tackle the whole domain of civil protection policies. This presentation is focused on a small part of these public policies, dealing with disaster response management and associated training.

All the years, from 2016 onwards, gave many occasions to activate at large scale the EU Civil Protection Mechanism (EUCPM): floods, hurricane, earthquakes, and wildfires. Climate change and the increasing occurrence of natural risks reveal a need and the opportunity to develop a European command and control framework (Maestracci, 2013). For more than 15 years, authors, who are in a predominant majority responders, have been working in this field of international mutual aid for civil protection. This paper's purpose is to provide inputs for the further empowerment of the EUCPM.

The area of large incidents and disaster management is frequently evoked by academics (Topper and Lagadec, 2013; Dufès and Ratinaud, 2014, Wybo and Latiers, 2003), but slightly targeting incident management practices. Many collaborative EU funded projects (FP7, H2020, and Horizon Europe) related to disaster research topics are contributory too, but totally focused on innovation, mainly technique one. Even if some research exists, "real" field incident management topic remains in Europe a kind of grey zone.

Today more than ever, in a changing risk landscape, and after many destabilizing incidents (terrorism in France and Belgium; wildfires in Portugal, Spain, France, Sweden, and Greece; flood and storms), empowerment of the European civil protection mechanism is essential. And clearly under the leadership of the Directorate-General for European Civil Protection and Humanitarian Aid of the European Commission (DGECHO).

Under pressure of climate change and wildfires geographical area extension, civil protection forces and fire departments have, right away, to respond to the risk of hyper violent fire behavior (e.g. extreme wildfires events: Tedim, Xanthopoulos et al., 2018), and natural disasters due to extreme meteorological conditions. While incident management is sometimes a sovereignty issue, or perceived as it, authors suggestion is conceived as an intermediary stage towards harmonization. Hence, in this transitional period, effort is dedicated to the crucial interoperability increase. For this purpose, national systems are preserved, and suggested to be customized in a kind of "international hybridization", to be better compliant when the European civil protection mechanism is activated.

The following paper presents ongoing works, written by knowledgeable practitioners of civil protection, aiming to provide insights and opinions, to support dealing with current global trends and the reality of "terrain response". As very challenging events (Maureen Essen et al. 2022), wildfires, due to their extension and intensity, could play in this evolution, the peculiar role they already performed in some fire-prone countries (USA, Australia, Portugal, France…) in fostering command and control enhancements, further extended to all hazard management, as Rowley and others authors explain for American incident command system (ICS).

The document is organized in five parts: built on lessons learnt study and real EUCPM activations, it presents an interoperability monitoring tool supporting the evaluation of the cooperation. After a quick presentation of existing systems, the work identifies by comparison the possible contributions that each could make to new European operating modes. And eventually provides some pathways to share the knowledge and organizing training and exercising in the EU.

Finally, in a nutshell, this transitional proposal, expecting a leveraging effect, opens the way for the EU towards establishing a sui generis harmonized operational command and control system (ECS), which would be interoperable with the other major pre-existing global ones, without being enslaved to them.

TERMINOLOGY

Definitions

To clarify the paper vocabulary, we must first reach an agreement on some basic terminology, which unfortunately is not yet harmonized across the world. After discussing terminology, we will present our ideas on proceedings.

We could start with the terms "crisis" and "crisis management" themselves: these words, initially meaning situations in which decision bodies lose control and their ability to act, have over time been stripped of their original meanings and now are more generally used to mean big incidents and incident management. Big incidents are not necessarily crises in the original sense, and a misbalance between available and needed means is not enough to create an actual crisis. However, random or quick evolution, lack of decisions, emergence of power struggles, and other signals of weakness need to be tackled in order to avoid crisis occurrence. In order to characterize these issues, and because no classification system exists in Europe, the US classification of incidents (see below Table 1.) could be used or slightly adapted to provide harmonization at an international level.

Table 1 : US Incident classification

	"Definition"	**Example**
Type I	Huge incident	i.e. large on shore pollution lasting weeks P>500
Type II	Big incident	i.e. Bushfire lasting 3 days P<500
Type III	Important incident	i.e. Railway crash lasting one day with multiple assets
Type IV	First level of incident implying transfer of command	i.e. structure fire
Type V	Small usual mission dealt by one or two assets.	i.e. Emergency Medical Service mission with one ambulance

What shall we call LEMA? LEMA is the European acronym for Local Emergency Management Authority. Nowadays it is frequently used in a broad sense, meaning all local incident managing activities. In our proposal, we use the term LEMA in its original sense, to refer to an elected (or non-elected) single person authority, who is a policy maker in charge of the strategy above the Incident Commander. To draw comparisons, UK uses "Competent Authority" and US ICS "Authority Having Jurisdiction".

What is an ICP? Incident Command Post (ICP) or Field Command Post (FCP), interchangeably, is remarkably close to US terminology. This term is our favourite to describe "site headquarters' ' preferred to **OSOCC which** was initially set by UNOCHA, in UNDAC/INSARAG guidelines. Meaning On-Site Operations Coordination Centre (UNOCHA Field Handbook, 2018), this wording has been surprisingly corrupted by the term "virtual OSOCC" (1998), which describes a shared assessment IT tool. Introducing *de facto c*onfusion which might be a permanent source of misunderstanding, we suggest not using this term, and favour ICP instead.

What about the so-called Standard Operating Procedures (SOPs)? While this acronym is trendy in Europe, with different understandings, (in total absence of an harmonization framework) we propose to clarify it by introducing a distinction. We suggest using STPs for *Standard Technical Procedures* and SCCPs for *Standard Command and Control Procedures*; both constituting SOPs (cf. Figure 7.)

STPs: as all EUCPM participant states have a great reservoir of skills relating to civil protection techniques, there is an opportunity to share and exchange. Currently technical practices are not regulated by any EU or other standard, so it's now impossible to have standardized training on these practices.

SCCPs: As it has been said, there is a real need to empower EUCPM through a "European Command System" (ECS), giving harmonized command and control methods at the international level in the EU. All these practices are gathered under SCCPs acronym.

Eventually, this paper has included a Glossary for all abbreviation used, in the last part of the paper

CONTEXT, LESSONS LEARNT AND PROBLEMATIC

Large and violent wildfires in Greece (2007, 2018, 2021, 2023), Portugal (2016, 2017), Spain (2012, 2015, 2019) France (2003, 2016, 2019, 2022), Sweden (2018), Australia (2019), South Africa, Canada (2023) and California (2018), gave in the last decade several opportunities to witness climate change consequences. These events also demonstrated a real need for a larger commitment of EU practitioners, to increase the quality of European civil protection mutual support. And the recent cases of EUCP mechanism activation (2018, 2021, 2022, 2023) including floods in Belgium and Germany (2021), and France (end of 2023 to 2024) demonstrated the increasing need for field experts and very experienced responders.

The Swedish 2018 fires gave another perspective on emergency management in a "non-fire prone country", using NATO guidance to deal with the unusual situation. Actually, the Kårböle-Ljusdal fire Incident command post followed the NATO standard organization (cf. below: "NATO framework"), with a large Incident Management Team, driven by an Incident Commander, responsible for decisions, ground tactics and management. The latter was permanently reporting to the local policy maker (Province Governor), in charge of strategy, and in contact with national authorities. In this case, despite the larger EUCPM activation of its history (20 years), and the involvement of eight countries in response to support Sweden, DG ECHO constituted only a very agile structure of coordination in the host country at national HQ. And that was valuable, a kind of "proof of concept", which allowed all kinds of wildfires modules sent, to be adequately involved in the fight, and additionally, the Swedish C2S demonstrated its adaptability in efficiently integrating the foreigner experts.

Greek fires in 2021 and 2023, demonstrated a real integration of European forces by pre-positioning of some other European resources and the repartition of large and diverse involvement of EU wildfires modules and assets.

Facing all these cases, we must admit that there is a great reservoir of data in the study of these cases. Some lessons learnt and seasonal reports have been written, notably by European Commission bodies (San-Miguel-Ayanz et al., 2023), but rarely dealing with command-and-control issues.

Regardless of the cases, the **same problematic arose**: if at ground level all foreigner strike teams and platoons are integrated with relevancy by "missional assignments" in the fight to the disaster, it remains the question about the interoperability for the officers and experts, that can neither understand clearly the host nation command and control practices, nor been properly integrated in the incident management team, to provide a support at the level of their expertise.

INTEROPERABILITY MONITORING TOOL

Principle

Authors propose and use a matrixial interoperability evaluation tool which offers a simple and user-friendly framework for evaluating and enhancing teamwork to prepare for and respond to joint civil protection operations.

The tool can be used to document in a structured manner the lessons learned in the aftermath of disaster response. Alternatively, it can be used at any time to monitor existing cooperative activities (e.g., cross-border operations) to check and identify areas for improvement, building a kind of "pathway toward interoperability".

Inspired by an US[1] radio communication monitoring tool (SAFECOM program), this interoperability evaluation tool (Monet, Mannaioni et al., 2018) was initially developed, by adding others criteria, at national level to meets satisfying two aims:

- Address all aspects of national interagency civil protection operations: policy and guidance, training and communication, and command and control practices.
- Assess and score each criterium and create a combined score using weights reflecting the decided relative importance of each.

The structure of this tool was slightly modified to reflect international operations and used to assess interoperability in a 2018 European Civil Protection Mechanism (EUCPM) wildfire operation in Sweden involving both Swedish and French responders.

This work has been finalized under the auspices of a EU funded project (Monet et al. 2023)

[1] Department of Homeland Security, 2004

Depiction

The structure of the matrixial interoperability evaluation tool, dedicated for assessing a joint operation which relies on the use of the table above to assign an Evaluation Level of 1 – 5 for each interoperability component, defining 5 as the best ranking.

- Governance
- Standardized Operational Procedures (SOPs)
- Data Technologies
- Voice Technologies
- Training and Exercises
- Language
- Operations

A Component Score is calculated for each component by multiplying its Evaluation Level by a Component Weight. An Overall Score is then calculated by adding up the seven interoperability components.

It was judged that the first four components, Governance, SOPs, Data and Voice Technologies, are considered of equal importance. Training and Exercises as well as Language skills are viewed deemed as being twice as important as the first four components. Finally, the Operations component was judged to be four times as important as the first four components.

All these Component weights ensure a maximum overall Score of 100. The Overall Score is supposed to rank the performance of the cooperation of civil protection forces at incident management level.

To give a score on the efficiency of interoperability, policy makers or responders can use this innovative and simple tool themselves to improve their joint operation, identifying the way(s) of improvement. The Table 2 below presents the tool.

Table 2. Evaluation components and levels

Interoperability component	Evaluation level				
	1	**2**	**3**	**4**	**5**
Governance	National agencies working separately	No formal joint work between national agencies	Occasional bilateral or multilateral formal group for join work and missions	Multilateral agreement (s) for join work and missions	Specific bilateral agreement (s) for join work and missions
SOPs	Harmonized national SOPs	National SOPs to receive international aid	Regional SOPs	Multilateral SOPs	Specific bilateral SOPs
Data Technologies	Manual files swap	Bilateral files exchange via commercial software	Sharing by a dedicated ad hoc interface App	One-way sharing with standards-based software	Two-way sharing
Voice Technologies	Swap radio	Gateway	Shared channels	Proprietary channels system	Bi or multilateral standards-based sharing systems
Training	National unified training doctrine	National full-scale exercises	Cross bordered training and exercise	Regional training and exercising	Multilateral training and exercising
Language Skills	Use of interpreters and/or immediate translation tools (e.g., I.A., smartphones)	Basic use of third language (A)	Independent use of third language (B)	Proficient use of third language (C)	Use of host country language
Operations	Teams working separately with limited communication	Teams working together with formalized (briefing, radio) communications	Teams achieved being integrated in the local command system	International teams taking roles in local ICS	Same incident command system

Summary

These last four years, the tool was applied by authors to some real cases of EUCPM activation, and after Modex (Modular exercises, EUCPM field trainings). Even if it highlighted several criteria's room for improvement, one of them, significantly always appearing with a low score, was C2S practices.

STATE OF THE ART IN COMMAND-AND-CONTROL PRACTICES

US ICS system

In the 1970's, the Incident Command System (**ICS)** was developed by the US Forest Service to manage forest fires and other natural hazards, and it was quickly recognized as an efficient inter-agency control system. After the terrorist attacks of 11 September, following an *ad hoc* decision of the federal government, the concept rapidly and widely spread throughout the United States. Now largely used there in its "All Hazards Management" version, ICS today involves thousands of civil servants, foresters, police officers, fire fighters and elected officials who constitute more than 15 regional teams. At the highest level, responding to the largest incidents known as Type I, these "Incident Management Teams" (see IMT, Figure 1.), are constituted with 50 specialists on 24/7 duty.

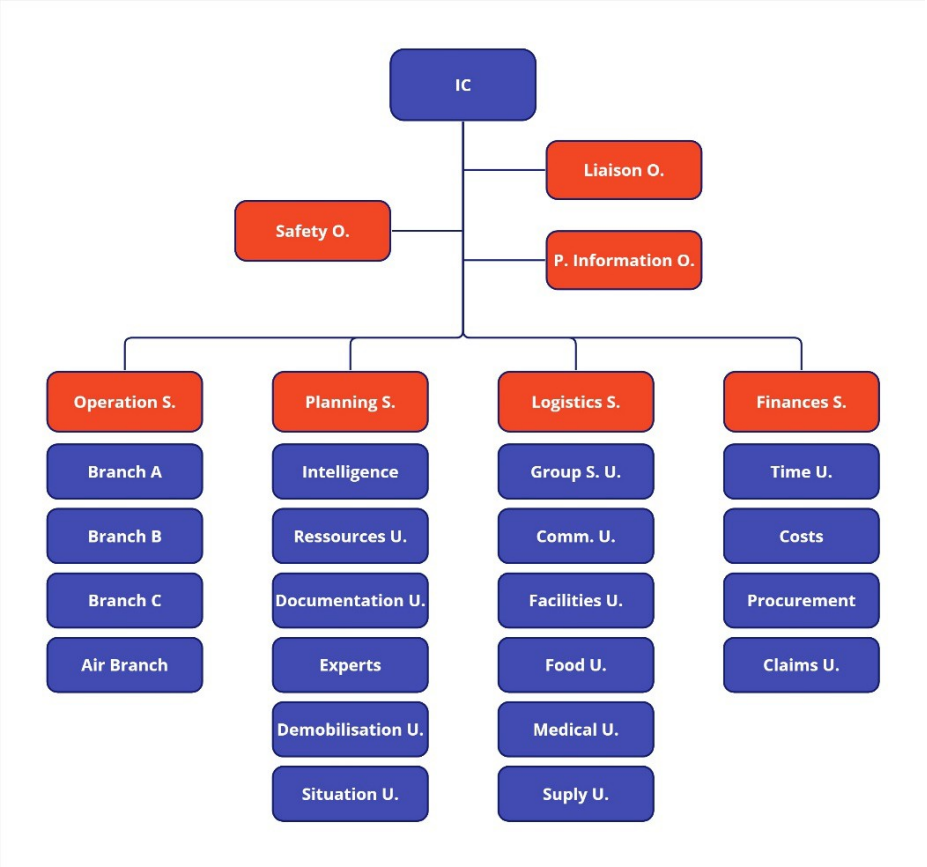

Figure 1. IMT

Today ICS is disseminated all over the world, with some adaptations. However, in France less than 20 fire officers are acquainted with this system. After being trained through the IS-420 Incident Management Team course (an intermediary rank in the ICS training program which starts from IS-100 to IS-800), a few of them participated in exercises in California and Australia. Some Spanish provincial foresters and Norwegian fire fighters are now implementing the US ICS directly. The fire service of Catalonia (GRAF, Grup d'Actuacions Forestal) is also influenced by ICS, especially in the practice of use of fire, which has been incorporated with a deep and extensive expertise in fires behavior.

One of the most interesting adaptations is the Australian system, AIIMS (for Australasian Inter-Service Incident Management System), more used as Command Control and Coordination system (C3S), in powerful headquarters, as example in New South Wales state.

In the U.S. the FEMA (Federal Emergency Management Agency, www.fema.gov) is responsible, through its National Incident Management System, for organizing, teaching and training of this doctrine. In general, the position of this agency towards teaching and giving public information can be an inspiration at the European level.

The World Health Organization (WHO) has also set up an ICS-related system, WHE, (WHO Health Emergencies, 2016). WHE is a very close system, not allowing for much sectoral adaptation (quite copy and paste). Some industrial companies, especially in oil and gas, have also directly adapted ICS for their crisis management, for example Total Offshore and LyondellBasell (U.S. National Incident Management System presentation, 2017).

UN Organization

The United Nations Office for the Coordination of Humanitarian Affairs (UNOCHA) framework United (Field Handbook, 2018) has, from its creation, been inspired as well by ICS. Although its field command post is called "On-Site Operational Control Centre" (OSOCC), it is not a real command and control system, but instead highly inspired by humanitarian activities. The main theme in UN field organizations is coordination (Figure 2.). So UNOCHA, is now in charge of managing a large certification system (International Search and Rescue Advisory Groups - INSARAG), and responsible for international aid, that is more focused on search and rescue and humanitarian aid.

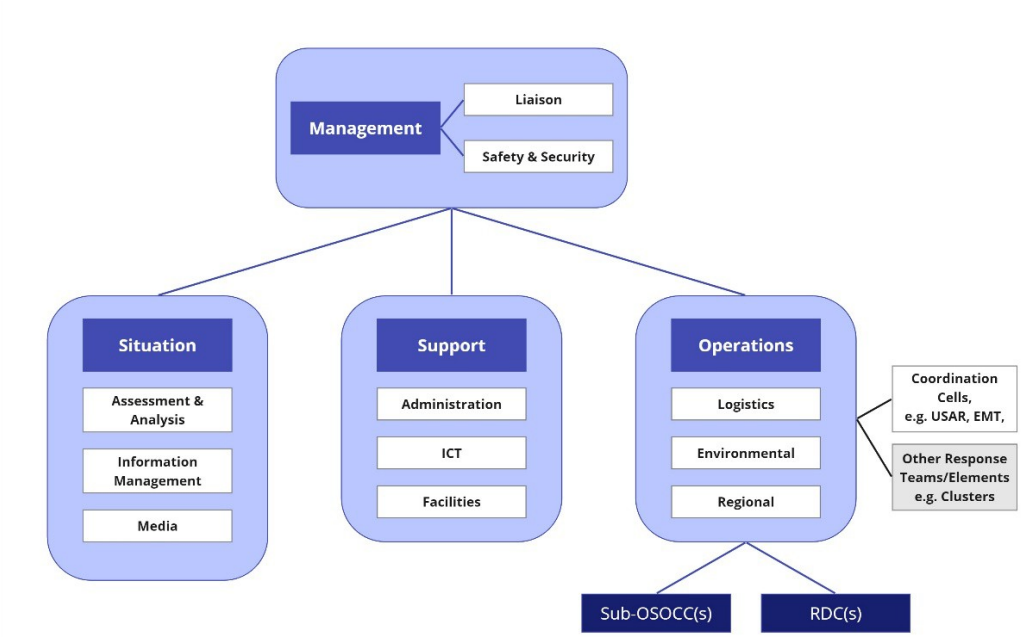

Figure 2. UN coordination

The OSOCC is a rapid response tool that provides a platform for the coordination of international response activities in the immediate aftermath of a sudden-onset emergency or a rapid change in a complex emergency. It is at the same time both a methodology and a physical location for on-site emergency response coordination. The OSOCC is designed to work in support of the Government of the affected country and is a tool promoted and supported by the UNOCHA to carry out its mandate of coordination and information management in emergency response, particularly at the field level.

Through its guidelines, the OSOCC enables the concept to be utilized by other organizations, agencies and teams, when responding to emergencies, including Governments, international and regional response organizations. It is a concept that can be internalized entirely by national emergency management structures who are in the lead of coordinating the assistance to populations affected by emergencies in their countries.

The OSOCC Guidelines are designed to provide direction on establishing, managing, working within and interacting with an OSOCC. The Guidelines are composed of three parts. Part I provides the foundation on which the OSOCC concept is built and the humanitarian context in which it operates. Part II presents guidance on how to implement the OSOCC system components, i.e., the Virtual OSOCC (VOSOCC), the Reception Departure Centre (RDC), the OSOCC facility, sub-OSOCCs and other coordination cells, and provides links to other more detailed guidance notes and resources. Part III is an annex of tools for practical use during OSOCC operations

The OSOCC is generally structured into four functions, each of which may be composed of multiple cells. The basic OSOCC structure is illustrated below; however, not all functions or cells may be needed in every situation.

French System, GOC.

In France, the GOC (standing for Gestion Opérationelle et Commandement) system has provided a unique and harmonized command system since the 1990's.
It manages four levels of command based upon progressive field transfers of command. Training program comprises five levels: level 1 is taught to all firefighters, it's not a commanding level. Level 2 (truck leader) is the first level of incident command used to deal with the majority (more than 50 %) of French fire service missions, tackled with a single resource. Levels 3 to 5 employ several ranks of officers, from team (group) leader to senior incident commander. Deployment of an Incident Command Post (ICP) starts at Level 4. Built as a decision tool for the incident commander, the ICP is staffed (one staff chief, four sections: operations, planning, resources & logistics, intelligence) with up to 12 persons; 20 in an interagency context. In this type of incident management team, the Incident Commander has a direct command on Sector Chiefs, whose number is usually between two and four (see Figure 3).

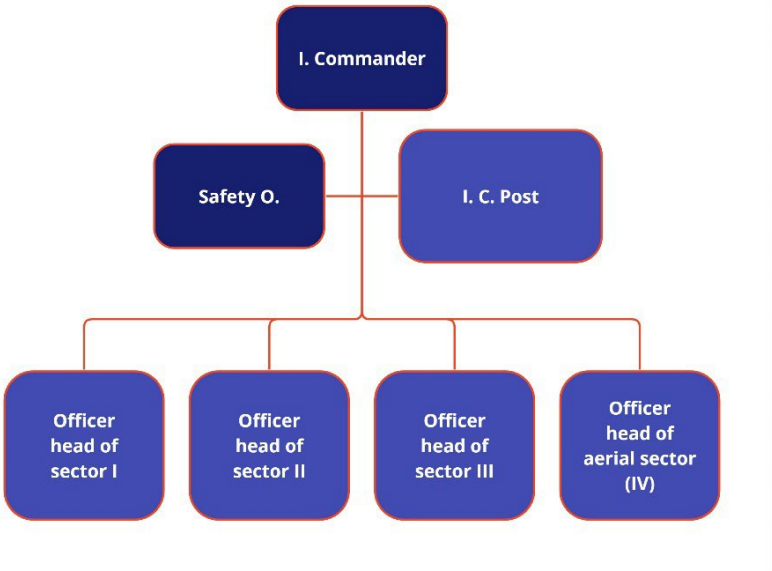

Figure 3. French GOC chart

This system has also been integrated by several countries of Africa, and Portugal and Spain (some provinces)

German System, DV 100.

Rather similar is the German system described in the set of regulations "Dienstvorschrift (DV) 100 - Führung und Leitung im Einsatz" (Service Regulation 100 - Command and Control in Operations) developed in the late 1970's after a major wildland fire and modified in the late 1990's. It combines the principle of sectorization with an incident command organized into functional sections. In most German states, an administrative crisis committee meets in parallel to the operational incident command in the event of major emergencies, both under the auspices of a political decision maker.

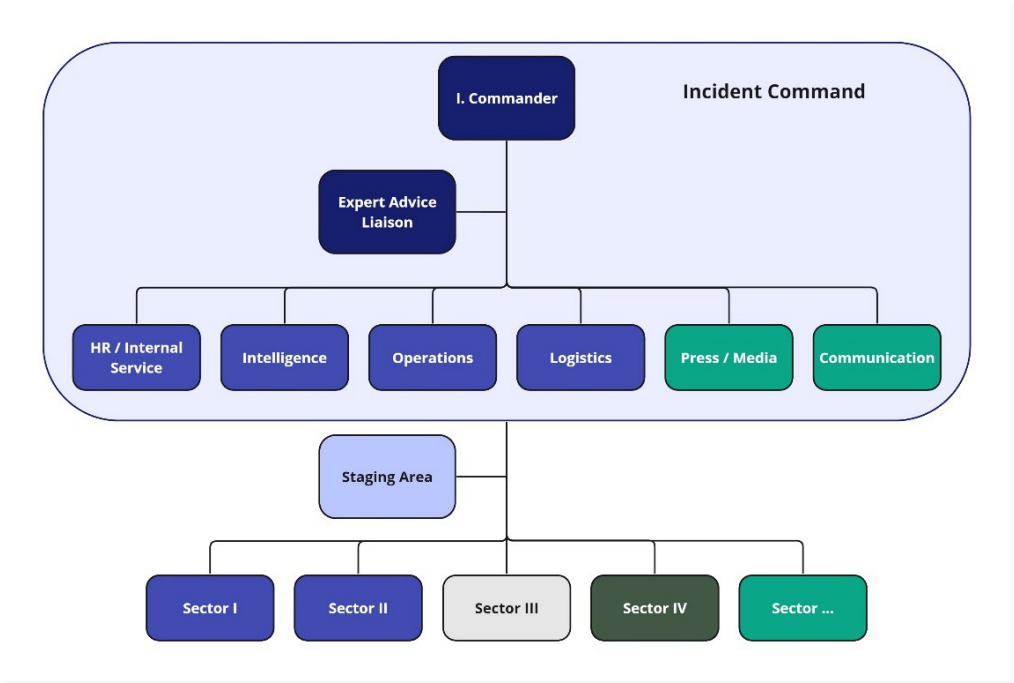

Figure 4. German GOC chart

NATO Framework.

Due to "*centric operations, demanding closer cooperation among more dispersed forces, the importance of interoperable C2 grows exponentially. Forces that expect to operate together must at least be able to communicate with each other via both voice and data formats, even though they are not yet equipped.*" (Barry, 2003). Indeed, for years, command and control has been considered by NATO strategists as the "*most crucial medium for interoperability*". Eventually, NATO shifted in 2017 toward a new command and control structure, but it's interesting to note that this structure is based on a constellation of separate international headquarters split in the different member states.

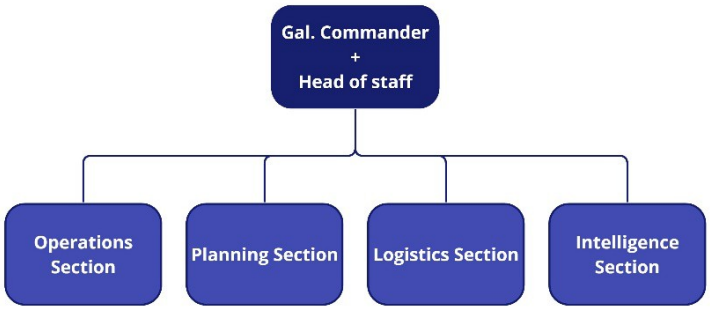

Figure 5. NATO basic chart

In the field, NATO is working with a very classical organization, close to a generic ICS. The four main functions (Figure 4.) are represented here in the scheme above: operations, planning, intelligence, and logistics. In many NATO operations, planning is done far from the field of operations, in a distant and secure headquarters.

The cited case in Sweden (Figure 5. below, 2018) provided a very interesting implementation of this framework, managed by a large incident management team (90 – 100 officers).

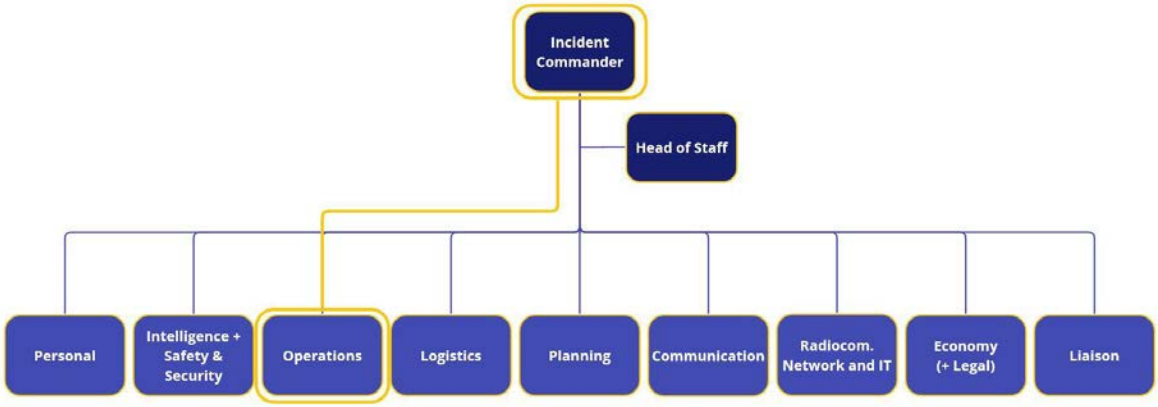

Figure 6. NATO / Swedish chart

After this quick overview of the existing landscape, two main concerns obviously appear: which relevant elements from these systems can be transferred to EUCPM with added value? And how to harmonize?

COMPARISON AND FINDINGS

To answer to the problematic mentioned at the end of the third chapter, we identified three critical issues:

- To manage very mature but not harmonized national civil protection systems, in all participant states;
- To be interoperable in and through the member states, some of them very small, respecting existing systems and implying a transition in the format of incident management when international aid is asked;
- Being compatible with UNOCHA teams and INSARAG standards, and others systems ICS, NATO, WHO and ISO 22320 compliant. But, fully independent from other international C2 systems, which can be sometimes considered as using “hegemonic practices”.

The idea developed here is not to copy and paste any system, but to develop, organize, implement and teach at EU level an ad hoc command system, ECS, tailor made for EU nations and disasters. It was foreseen since our 2018 works, but now somehow consolidated by our experimental training and new studies.

Comparison on the General Organization of the Command Framework

In all observed systems, the position of IC (incident commander) and its hierarchic relationship to LEMA plays a pivotal role. However, in some countries (Croatia for example), there is no clear differentiation between these two positions.

The connection with sectors or branches (generally 3) is sometimes done in a variable manner, but the recognition of a sectorization of the incident field is permanent and mandatory. Even if very dependent on national aerial laws and standards, the aerial sector appears to be fundamental for safety issues, in case of EUCPM activation. This sector is not developed in all countries' systems (only in GOC and ICS).

The existence of an Incident Command Post (or Field Command Post) is consolidated. Its internal organization is variable, but the common sections of quite all systems are:

- Operation
- Planning
- Resources

Alternatively, we find in the ICPs optional ones:

- Communication
- Intelligence
- Security
- Safety
- Coordination/liaison
- Finance-administration.

Safety and communication, frequently managed by single person positions besides the IC are also very dependent on command-and-control national culture. If these two functions seem to be a point of convergence, regardless of the nation, they are probably on the verge of turning into a function rather than a single officer duty. Other observed single positions (not ICP section) are: security (police), IT and radiocommunication, liaison officers.

Findings and Proposal

For large incidents, and activation of international European aid, the added value of this EU system could be in providing and establishing an interoperable framework of art of command, adaptable at state and at European level, considering national command systems and history.

This is the reason why we consider as “strongly suggested” the sections: **operations, logistics and planning**.

The single positions of **safety officer and communication** are at least recommended.

The **sectorization**, either geographical or missional, and aerial sector if the operation encompasses aircrafts, is also our recommendation.

Eventually, we identified a common “backbone” of command-and-control functions (Figure 6.)

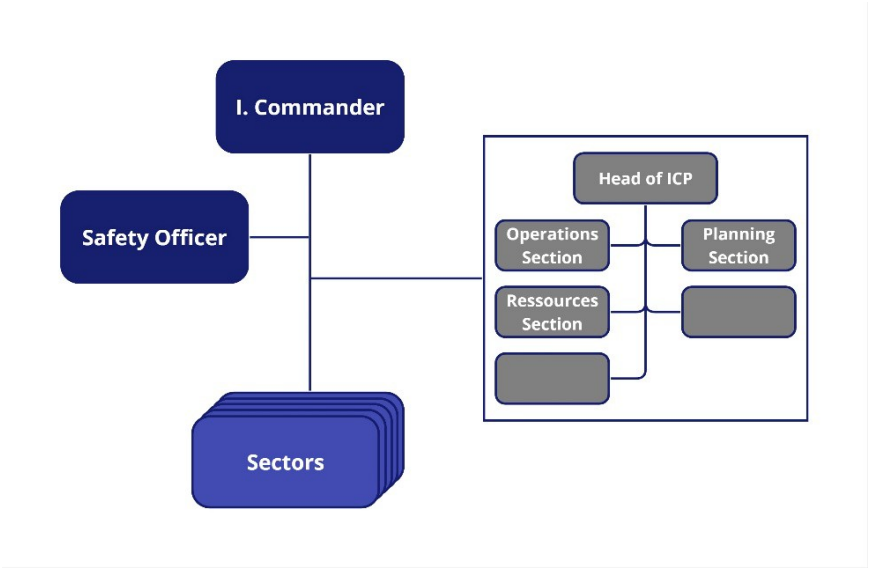

Figure 7. Commonalities

The proposed European Command System is, in evidence, a long-term solution. It must be expanded upon from this skeleton onwards. Rather than standardization, DG ECHO might establish guidance and recommendation to be acknowledged by practitioners.

Additionally, it is highlighted that in this way of construction the proposal is ISO 22-320 compatible, fulfilling the requirements listed at the beginning of the section.

What is nowadays lacking is a reliable inventory of all European participant states' command and control systems. That could support the authors to validate their study.

SHARING KNOWLEDGE

Since 2001 DG ECHO has organized EUCPM training for Member States. Renewed at the end of 2023, and reinforced by “knowledge network” website, this framework is now enriched by many courses. It also distinguishes clearly between the courses for responders and those dedicated to civil servants or staff persons.

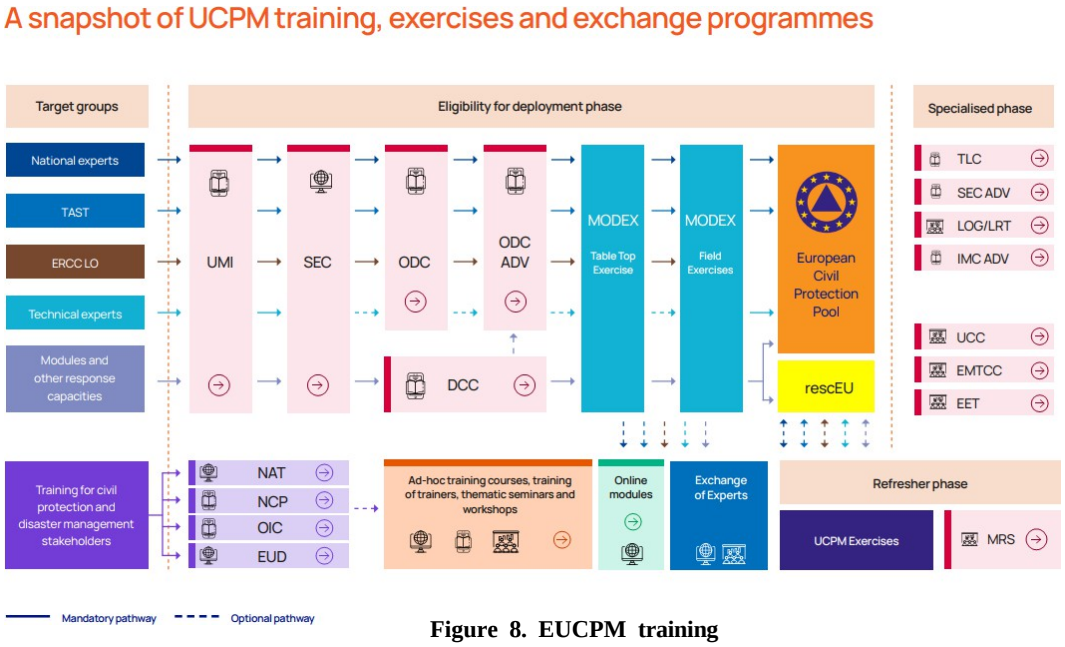

Figure 8. EUCPM training

The authors' suggestion is that DG ECHO would need to set, manage, and teach a "new command and control framework", or at least share the knowledge of the international C2 systems used within Europe, to increase our civil protection interoperability.

Finally, the authors propose to simply use the already existing training program (EU Brochure, 2023 & fig.7), and link these proposed trainings (see below) with On site Deployment Courses (ODC in the scheme).

Experimental Trainings

Several experimental European courses were organized in Aix-en-Provence, at national wildfire school (ECASC) France, in the context of European project called *"Network of European hubs for civil protection and crisis management"* (Ecorys, 2020), and in the Green deal project FIRE-RES (April 2024).
Gathering 40 trainees from 20 different countries, these trainings were organized at the French fire service facility's virtual reality simulator, involving a complete incident management team (15 to 20 players). This serious game provided a unique opportunity to organize some trials and experiments, as described below.

Methodology:

During experimental courses we highlighted that at least in Europe, command and control systems are comparable and some common points may be underlined.

The aim of this experimental training was to establish and drive an incident management team on a big incident and to deal with the arrival of – at least – two EU modules.

Exercise Incident Command and Control: The management of the training proposed a fixed command framework (IC + 3-4 sectors + ICP, cf. Figure 6.). But otherwise, the organization and staffing of the Incident Command Post was fully adaptable to each Incident Commander (i.e. to each nation receiving UCPM aid).

We only had a small "sample" of countries to lead this Incident Command System simulation: Italy, France, Sweden, Croatia, Portugal and Greece. However, all attendees were involved in ICP functions or single officer positions (safety, public info. officer, liaison officer …), giving a unique opportunity to test full international (Austria, Belgium, Poland, Croatia, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Israel, Italy, Netherlands, Norway, Portugal, Slovakia, Spain, Sweden) interoperability. This experiment demonstrated that EU participant states are able to cooperate efficiently in a command-and-control system. It also

confirmed the incident management commonalities existing between all participant states. This common framework could obviously constitute the backbone of a future European command and control system.

Modules and Experts Involvement:

This structured, common command and control system is actually very helpful to optimize involvement of EU modules. To manage module national specificities and logistics, a very obvious methodology (more than 9 times tested in the experimental courses) emerged at the end of these trainings: the Chief of Module needs to be directly involved within a sector, while a Liaison Officer needs to stay assigned to the ICP, in order to be the permanent representative of the module (logistics, capabilities, safety, etc …). This best practice is now beginning to be shared at EU level, even if it is not a mandatory procedure. Additionally, testing international cooperation within a unique incident management team in real/simulated conditions proved its feasibility and constitutes a very promising input for the future embedding of EU experts into the host nation incident management team.

This small-scale experience, more empirical than scientific, constitutes a demonstration of our theory on this parcel of interoperability and gives arguments and a possible form for future EU trainings.

CONCLUSION

We have imagined a doctrinal framework, totally dedicated to civil protection, based on guidelines developed in this paper. Effective, interoperable, respectful of sovereignties, this system could match with the needs and wishes of the EU for its citizens, and promote solidarity between the EU and non-European regions.

Of course, this proposal is anchored in experience rather than on scientific research. Further studies could be performed to confirm and consolidate this proposal. What is nowadays lacking is a reliable inventory of all European participant states' command and control systems. That could help to validate our assumption on the “common backbone”, and to clearly differentiate civil protection operations from humanitarian ones.

This work faces a paradoxical time context: after being hampered by Covid, its immediacy has been triggered by the climate change effect since 2021. Regarding usual experience with instructing, training and exercising efforts, it could take years to begin to fully use the new approach in operational situations. The first evaluation feedback is foreseen to be available after five years.

The European Commission has to determine how to organize the development of an improved EUCPM. How to concern and involve national civil protection, fire and EM services structures? What will be the role of national Fire and civil protection academies? How to let this European Command System knowledge percolate towards national levels? All these key points need to be solved if we really want to improve the interoperability of the participant states and the efficiency of EUCPM, to give European citizens the safety they deserve.

GLOSSARY

C2 Command and control

C2S Command and control system

Unified command? Preliminary findings from a situation awareness experiment

Jeroen Wolbers
Leiden University
j.j.wolbers@fgga.leidenuniv.nl

ABSTRACT

This study investigates high-pressure decision-making in fire response operations, with a particular focus on the cognitive abilities of incident commanders. It builds upon the naturalistic decision-making approach, emphasizing the pivotal role of situational awareness in decision-making. While existing studies predominantly concentrate on individual decision-makers, this study shifts attention to the collaborative dynamics within incident command teams. Through computer-based experiments, it explores the impact of interdependence between fireground commanders on situational awareness, challenging the presumed benefits of teamwork. Counterintuitive results question the conventional wisdom regarding the advantages of having a second pair of eyes. The experiment's findings indicate that commanders operating alone achieve the highest situational awareness scores, suggesting that organizing periodic moments of consultation works better than operating in pairs during response operations. This study provides insights into the intricate interplay of interdependence and situational awareness during high-pressured decision-making.

Keywords

Situational awareness, decision-making, command & control, experiments, fire department.

INTRODUCTION

Try to imagine a fire engine rushing to the incident scene, blue light flashes, sirens, and rapid commands uttered by the crew commander to his team. While squeezing through heavy traffic, crews put on their gear, getting ready to battle a raging fire. Probably one of the key concerns on the mind of the engine commander and his crew is getting a bearing of what they will run into. A sense of awareness and vigilance. Not only will this aid in the rapid rescue of victims, it is also imperative to safeguard the lives of the crew. When the fire crew arrives on-scene and rushes onto the fire ground, they will need to carry out a rapid risk assessment and take critical decisions that will likely determine the difference between life and death.

Such tense situations of high-pressured decision-making have attracted the attention of academics. The classic work of Klein et al. (1986; 2010) on rapid decision-making on the fireground marked the beginning of a fruitful line of research. The study departed from the classic idea of rational, stepwise decision-making and instead stressed the key role of experience by which decision-makers interpret regularities in the environment. Traditional decision models did not take into account the critical role of experience to assess operational settings, as they often relied on students participating in decision-making experiments. Instead, Klein et al. (1986) forwarded a naturalistic approach, in which decision-making is closely connected to the environment, in which previous experiences and expertise plays a major role in guiding the decision-making. It was found that experts are able to read regularities in the environment on which they develop heuristics or rules of thumb, which function as cognitive shortcuts that enable rapid decision-making based on recognition (Klein et al., 2010).

As the naturalistic decision-making school gained footing, many studies on incident command teams followed suit, focusing on the cognitive abilities of the commander (Boehm, 2018), such as situational awareness (Endsley, 1995), sensemaking (Barton et al., 2015; Barton & Sutcliffe, 2009), intuition and mental simulation (Klein et al., 2010). Other studies documented the sequential order of decision processes (Cohen-Hatton et al., 2015; Groenendaal & Helsloot, 2016). This resulted in a renewed understanding of the decision-making process, in which a different sequence of decision phases is identified, which departs from the logical stepwise order seen in normative models (Cohen-Hatton et al., 2015). In these models phases like situation assessment, plan formation, and plan execution are identified as important phases in the decision process (Cohen-Hatton et al., 2015). Initial

results support the idea that in high-(time) pressured situations decision-making is primary guided by expertise as decision-makers skip plan formulation. It is also found that goal-directed training can aid decision-makers to switch to more deliberate refection in action (Cohen-Hatton et al., 2015). Taking the time to question perspectives and renewing one's situational awareness remains a key challenge in time pressured environments.

If one thing stands out from this line of research is that most studies focus on the cognitive abilities of the individual decision-maker. Given the attractiveness of the role of the commander in this setting, this is understandable, but also is a limitation that warrants our attention. There are important empirical and theoretical limitations to this focus. A key concern is that the individual decision-maker is often biased and is prone to make intuitive errors (Kahnemann & Klein, 2009). Moreover, a range of studies point to the importance of *shared* and *distributed* sensemaking (Barton, et al., 2015; Wolbers, 2022), *collective mind* (Weick & Roberts, 1993), and *dynamic delegation* (Klein et al., 2006). Indeed, in many operations a commander is not alone, but part of a hierarchy with multiple lines of command. As incidents turn more complex, multiple commanders work in parallel and interact with each other. Therefore, it is time to take distributed command into account more elaborately.

This study explores the impact of collaboration between commanders on situational awareness. Does it help to organize backup for a commander that is operating in a dynamic and chaotic scene? The question is posed: *what is the influence of different types of interdependence between fireground commanders on situational awareness in a fire response operation?* In order to answer this question, the concepts of situational awareness and interdependence are discussed and later operationalized in the methodology. The design and execution of the computer-based experiments offers an innovative way to study the role of teamwork in command and control studies. This study offers counter-intuitive results that question the benefits of teamwork for reaching a high level of situational awareness.

FROM SITUATIONAL AWARENESS TO SYNCHRONIZED DECISION-MAKING

Command & control is a key process in incident response operations that determines what actions response organizations need to take. There are multiple studies that map what incident commanders do when they take command (Njå & Rake, 2009). These studies show that incident commanders usually focus on problem solving and are operating within narrow time horizons. Njå & Rake (2009) note that command strategies were often reactive and interestingly, that very few commanders turn to giving commands. Most of the incident commanders were found to give very few commands (Groenendaal & Helsloot, 2016). Instead, commanders are busy with developing situational awareness in order to monitor the work of others and intervene only when absolutely necessary.

Studies into incident command tend to use a naturalistic decision-making approach (NDM). NDM centers its focus on the proficient decision maker, who operates within bounded rationality. The NDM framework comprises two primary components: situation assessment and mental simulation, both of which are context-specific and rooted in experience. The RPD model, as proposed by Klein et al. (1986), draws upon research spanning diverse domains, including (wildland) fireground command, military battle planning, critical care nursing, ship and flight deck operations, and chess tournaments (Njå & Rake, 2009). In essence, the RPD model depicts decision-making as a sequential process, where proficient decision makers assess the situation and choose an action based on their expertise. The model involves continuous monitoring of deployed actions, and incorporates feedback loops to account for the effects of actions taken. Additionally, mental simulations in the RPD model facilitate feed-forward loops, enabling a proactive approach to decision making.

In contrast to the naturalistic decision-making (NDM) approach, the heuristics and biases (HB) approach points out that humans are often inconsistency and reach different conclusions based on similar information (Tversky & Kahneman, 1974). Tversky & Kahnemann (1974) argued that human judgment is often flawed due to unconscious bias. The naturalistic and HB are often pivoted against each other in terms of influence of expertise. When integrating the insights from both approaches, Kahnemann & Klein (2009) conclude that the quality of intuitive judgment relies on the predictability of the environment and the individual's opportunity to learn the regularities of that environment. Both agreed that situational awareness formed the ground on which decisions were made (Kahnemann & Klein, 2009).

Assessing the environment thus plays an important role in decision-making processes, which points to a key role for situational awareness. This is corroborated by studies that investigate the sequential order of decision-making process, who point out that the step of situation assessment is leading in decision processes (Cohen-Hatton et al., 2015). According to Endsley (1995: 36), *'situation awareness is the perception of the elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future'*. This definition identifies three levels of situational awareness: (1) perception of elements in the environment, (2) comprehension of the meaning of those elements, (3) and the projection of a future state.

Whereas most often situational awareness is frequently measured on the individual level, a range of studies has explored team-level dynamics (Artman & Garbis, 1998). These studies point out that teams play a key role the quality and direction of decision-making (Salas et al., 2017). For instance, Stanton et al. (2017) discuss the role of distributed awareness in dynamic systems and explain that each actor holds their own situational awareness, which may be very different from others. While large disparities may emerge between actors, they note that it is not always necessary to share a similar level of situation awareness, as commanders may have different roles or focus. In that sense, team situational awareness may be understood as a dynamic, fluctuating process, binding agents together on a moment-by-moment basis (Treurniet & Wolbers, 2021). Similarly, Salas et al. (1995) argue that team situational awareness is comprised of a cyclic process that oscillates between individual and team level awareness. On a slightly different note, Shu & Furuta (2005) point out that the required awareness depends on the intensity of a collaboration, and introduce the concept of mutual awareness. Mutual awareness describes the situation where two actors interact intensively for the completion of a task. Therefore, in order to understand the required level of situation awareness, it is necessary to look into the intensity of different forms of collaboration.

In order to find out whether different forms of collaboration impact the level of situational awareness, the concept of '*interdependence'* is helpful. This concept from organization theory lays the foundation for what type of coordination and sensemaking can be achieved in organizing processes (Weick, 1993; Wolbers & Boersma, 2013; Wolbers et al., 2018). Thompson (1967) identifies three forms of interdependence: *pooled*, *sequential* and *reciprocal*. Pooled interdependence refers to arrangements were a task is split among actors that work independently with no flow of work between them, requiring little contact. Sequential interdependence occurs when actors rely on one-directional pathways that contain predictable workflows, which are often codified into plans. The idea of a conveyer belt in a factory comes to mind, to describe a situation where one step is required in order to a colleague to take a next step. Finally, reciprocal interdependence describes the situation where actors work back and forth and mutually adjust their actions.

These three types of interdependence are crucial in the setting of crisis management, as they describe how the composition of, and interaction between command teams may influence distributed sensemaking (Schakel & Wolbers, 2021; Wolbers, 2022). How mutual interdependencies influence cognition is described by Weick et al. (2005), who notes how each type of interdependence is tied to a specific type of cognition. Pooled interdependence is associated with automatic cognition through stereotypes, as actors are not in the position to communicate directly, but have a share sense of how a task should be completed. Discussions on collective mind also describe such a type of meta-cognition (Weick & Roberts, 1993). Sequential interdependence is often tied to heuristic cognition associated with memorized if–then rules, which builds upon the sequential order between work processes. We can recognize this type of recognition in the naturalistic decision-making school, discussing heuristics as a way to codify the expertise of decision-makers in dynamic situations. Reciprocal interdependence involves a more controlled type of cognition based on doubt, inquiry, and argumentation, which emerges from the continuous interaction between decision-makers. Indeed, reciprocal interdependence is time intensive, but also important as actors are able to question and doubt dominant frame that develop in a response operation (Barton et al., 2015). By engaging in this type of controlled cognition actors are able challenge existing frames and able to prevent a collapse of sensemaking (Weick, 1993). These studies show the key role that the different types of interdependence may play in influencing the cognitive abilities of incident commanders.

METHODS

In this study, we measured the impact of different types of interdependence (pooled, sequential and reciprocal) on the level of situational awareness of fire ground commanders. We have created a 1,5h scenario in a virtual reality environment of a complex fire in a storage facility that commanders were asked to watch. The commanders cannot walk around in the computer simulated environment themselves, but have to watch 5 extracted video fragments in which the incident response simulation unfolded, in order to show each commander exactly the same information. The commanders are asked to answer 15 probe questions after each video in order to measure their level of situational awareness. In order to determine the effect of the type of interdependence, we have randomly assigned the commanders into three corresponding groups. We designed these manipulations according to the concepts of pooled, sequential, and reciprocal interdependence (Thomson, 1967). The control group engaged in pooled interdependence, which meant that subjects viewed the videos completely independent (alone). In the manipulation of sequential interdependence, subjects were asked to work together, but were only able to update each other after watching a video, just before answering the questions. In the manipulation representing reciprocal interdependence, the subjects were allowed to engage in full, continuous consultation while watching the videos. In this way, we were able to simulate the three different types of interdependence in the experiment.

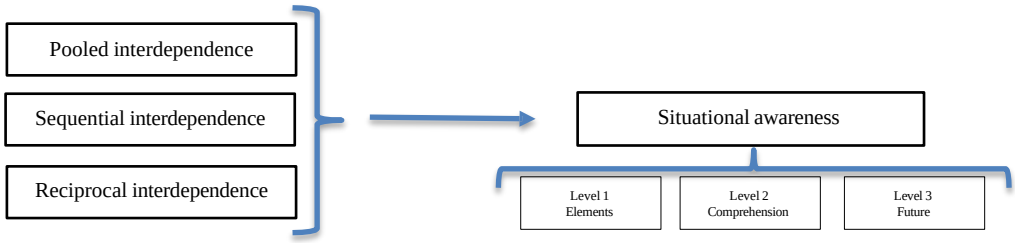

Figure 1. Conceptual design of the experiment

We measured situational awareness according to the QATA methodology, as described in Edgar et al. (2018). In this method, probes are presented to the subjects in the form of visual cues, situation reports, or radio messages. Subjects are presented with relevant and irrelevant probes during the videos, and depending on the manipulation group they are in, are able to discuss their assessment with another commander. The QATA methodology uses a confirm or deny format, as subjects can select that questions are true or false. To measure situational awareness, we formulated 75 probe questions. Each video contained 15 questions, 5 corresponding with each level of situational awareness: level 1) perception of elements, level 2) comprehension of the coherence between the elements, and level 3) future projection. We used the same set of probes and questions throughout the entire incident across all subjects. Subject were asked to state whether a probe was true or false, and how confident they were about each answer on a 5-point Likert scale. Examples of the probe questions are: *'there are people in front of the print shop that make access to the launderette difficult'* [level 1]; '*since the color of the smoke has changed, the situation in the Laundromat is deteriorating'* [level 2], '*heat affected IBCs behind the building pose a risk for a rapidly developing fire'* [level 3].

Participants

112 fire commanders volunteered for this study and provided informed consent for their participation. They were drawn from a representative sample covering all 25 safety regions in the Netherlands. The sample included 103 males and 9 females. The average age was 45 years. The participants were randomly assigned in three groups on the basis of whether they were to engage in pooled, sequential or reciprocal interdependence during the experiment. The participants were not informed there were three different groups. Each participant was briefed on the procedure and gave informed consent for their participation.

We determined the minimal number of participants in advance, by conducting a G-power effect size calculation. To find a large effect size, we required 21 participants in each group, with 3 groups manipulations, this means 63 participants. To find a medium effect size, we required 52 participants in each group, with 3 group manipulations, so 156 participants. We concluded that we needed a sample of at least 52 participants up to 156 participants to measure a medium effect size. In total, 112 commanders participated in the experiment, with 44 in pooled, 34 in the sequential group, and 34 in the reciprocal group. Previous operational experience was assessed in a questionnaire leading up to the experiment that identified how long participants had served in the role of on-scene commander. The mean overall command experience was 9.33 years.

Equipment

The experiment was designed by making use of the software XVR Simulation. The XVR Platform provides all fire departments in the Netherlands with computed-based scenario training. Trainees are immersed in a controllable situation, which is repeatable and measurable. Similar research with support of simulations exists, such as C3 fire (Johansson et al., 2003) and FireChief (Omodei & Wearing, 1995). XVR is step forward in this sense, as it provides the subject with an immersive realistic 3D view of the incident scenario. This paper builds on successful experiences with XVR software in the Firemind and FireFront research projects (Thoelen et al., 2020; Polikarpus et al., 2022). The scenario was designed from scratch, for which we made use of fire department experts, and scenario trainers in a safety region in the Netherlands. We consulted with these experts to make sure to develop a scenario that is realistic for fire-fighters, which contain cues that they would also encounter in a real-live situation, such as the of the spread and intensity of the fire, color of the smoke, fire hoses, fire engines, and other emergency services. We created a 5 separate videos from the 1st person perspective of our avatar walking through the incident, as the scenario unfolded.

The subjects watched the videos on the Labvanced platform, which we used to build online experiments. The platform was used to build, record and share online experiments directly in the browser. It also enabled multi-user studies, in which two subjects perform a task together and the system waits for them to complete the task together before moving forward. In this way, we made sure participants watched the same videos and answered the questions at the same time. We asked the participants to conduct the experiment on their home desktop, in order to provide a calm environment. The subjects in the sequential and reciprocal interdependence groups stayed in

contact with each other through a video call on Microsoft Teams in a separate desktop window, which enabled them to interact with each other throughout the scenario. This channel was recorded and continuously monitored by two research assistants to check for disturbances or technological problems. Before the experiment was launched, two research assistants checked in with respondents to check the setup, ensure a quiet environment, and explain the logic of the experiment based on a predefined procedure with fixed talking points. As a result of this monitoring, the data of one participant was deleted due to technical problems with the microphone.

It is important to recognize a few limitations of this setup as the commanders cannot 'seek' information as they normally would do during an incident as they watch pre-recorded videos, are not inside an operational setting itself, and do not continuously see their real-life counterparts. This was accounted for in the setup by showing prerecorded conversations with virtual role players, and information that reached commanders through visual cues, pager notifications, and radio messages. The advantage of this setup is that we were able to create exactly the same operational environment for all participants, the downside is that participants could not adjust it.

Nature of the Scenario

The scenario depicts a complex fire in an industrial warehouse building with several compartments, housing a laundry, garage, car repair shop, and a printshop. The fire starts in the garage, but soon spreads to the laundry and car repair shop. As the fire and smoke grow in intensity, a hidden XTC-lab in the back of the laundry catches fire and explodes. A fire fighter is reported missing and part of the building collapses. In this way, the scenario starts relatively simple, but as the videos progress increases in terms of complexity. Cues are offered to the subjects that hint to an XTC lab inside one of the compartments, before and after the collapse, such as reports of interference with electrical wiring, blue barrels, and chemical equipment. There are multiple fire department processes that needs to be arranged simultaneously (asking for additional engines to provide water, scaling up the operation, and deciding on the entry tactics). In that way, we simulate a growing cognitive load for the commanders.

The first video covers the initial reconnaissance walk as the commanders arrive for the first time. It shows an industrial complex on fire, with smoke pillowing from multiple windows. The second video shows the initial attack by fire crews, in which there is an escalation of the fire/smoke propulsion, which leads up to the question whether or not to ventilate. The third video shows the situation directly after the explosion, in which the north side of the building has collapsed and possible persons missing. Here we also introduce the XTC barrels for the first time. The fourth video shows the XTC lab in detail and the fire escalating in other parts of the premises, so that the subjects have to choose between focusing on the XTC lab, or focusing on the fire that is developing in other parts of the building. At the end of the fifth video, the fire fighter that is reported missing is found and the fire is contained by the crews on site.

RESULTS

The first results of the experiment indicate significant differences between the pooled, sequential and reciprocal interdependence, both at the combined situational awareness (across levels), and in particular at the second SA level (comprehension). A score ranges from 0 - 100 and means that the subject has a good overview of that percentage of the cues. That means that a score of 100% is not realistic, as subjects are not expected to remember all cues, but discriminate important and less important cues. The score does give an impression of the scope of situational awareness, not so much whether crucial signals are missed or not. All groups appear to be relatively capable of building up an adequate level of situational awareness.

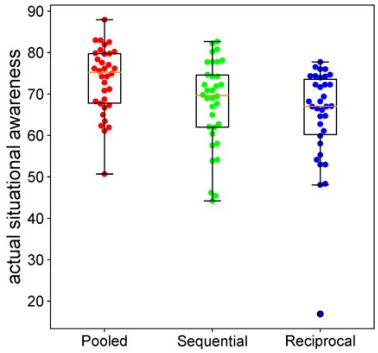

Figure 3. Actual Situational Awareness

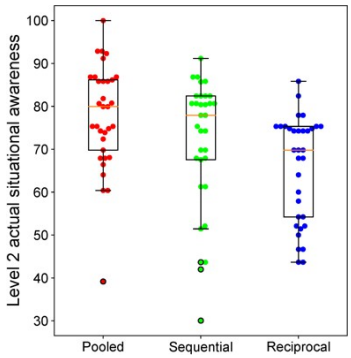

Figure 4. Level 2 ASA

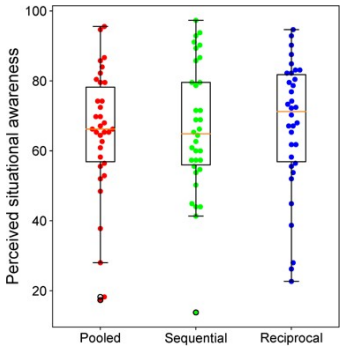

Figure 5. Perceived Situational Awareness

The analysis offers two important statistically significant results on the measure of overall actual situational awareness (ASA) and level 2 situational awareness (L2ASA). A Kruksal Wallis non-parametric test was conducted to test whether the medians of the different groups are equal. The Kruksal Wallis was found to be most fitting to the dataset, as it does not assume a normal distribution, in contrast to a regular one-way ANOVA. In a Kruksal Wallis test the is data reorganized based on a ranking.

For overall situational awareness (ASA), the Kruksal Wallis test showed that individual exploration of the scene significantly affects the level of situational awareness, compared to actors that engage in continuous collaboration: $H(2) = 20.92$, $p = .004$. Commanders exploring the scene alone based on pooled interdependence (*Mdn* = 73.26), or engaging in a form of sequential interdependence (*Mdn* = 69.64), scored significantly higher than commanders engaging in reciprocal interdependence (*Mdn* = 67.03).

For level 2 situational awareness (L2ASA) that focuses on the comprehension of the meaning of elements in a scenario (i.e. overview of the situation), results show that engaging in individual exploration significantly affects the level of situational awareness: $H(2) = 22.29$, $p = .002$. Here, commanders engaging in a form of sequential interdependence (*Mdn* = 76.63), score higher than in exploring the scene individually in pooled interdependence (*Mdn* = 75.33), and scored a significantly higher than commanders engaging in reciprocal interdependence (*Mdn* = 69.81).

These results indicate that the subjects in the pooled interdependence group had a higher situational awareness score than the subjects engaging in periodic or continuous consultation. In comparison, the subjects engaging in continuous consultation (reciprocal interdependence) have the lowest scores on average. In Figure 5, the perceived situational awareness (PSA) is indicated, of which the scores are not significant and are dispersed across the plot. This could suggest that subjects may find it difficult to make a valid assessment of their own situational awareness.

CONCLUSION

The results of this experiment indicate that when commanders engage in continuous conversation during a response operation, it limits their situational awareness. Commanders that take in cues on their own, score significantly higher than commanders working in teams. This is an important result that shows that having two pair of eyes does not always result in a better situational awareness.

It is important to note that this study concentrates on situational awareness, whereas this is not the only aspect at stake during a response operation. The required decisions, interaction with other crews and emergency services, may very well warrant the help of other commanders. It is unlikely that a commander will be in the position to develop situational awareness all by him/herself during the entire incident. These results of this study also provide valuable lessons for shared incident command. If a second commander is called towards the scene, he or she has the most positive contribution if he/she takes in the situation before coming into contact with the other commander. During a response operation, it works better to organize periodic moments of consultation, compared to operating in pairs. That makes it important to make process agreements in command teams on how commanders will collaborate, when to separate, and when meet up again. Although commanders are of course not able to spot all cues, engaging in continuous joint exploration is also not the solution. A good assignment for a second commander could be to focus on noticing abnormal signals that he or she feels have not been picked up by the other commander(s). By distributing tasks in this way, the mental load during high-intensity decision-making can be reduced. This makes the assignment of the second commander twofold: 1) mapping the situation independently of other commanders; 2) find out what the perception of the other commander is, in order to complement and challenge existing beliefs. As such, these findings have important implications for the development of the command tactics and situational awareness in situations of high-pressured decision-making.

ABSTRACT

Evaluating both exercises and real events can be challenging. This is especially evident in full-scale exercises, where a wide range of organizations must collaborate to solve a common problem. Information sharing, use of technology, and role understanding can be particularly challenging. In this article, we illustrate how academia can meaningfully engage in conducting and executing a comprehensive Emergency Exercise, ensuring that insights from prior research are evident from the outset. We employ a method where we co-create a Socio-Technical Network map together with practitioners. The method provides results that help visualize the complexity generated by large-scale collaboration, fostering involvement and engagement from both researchers and practitioners. Through this mapping, we gained valuable insights into barriers to Team Situation Awareness, technological possibilities and limitations, and a better understanding of various roles and their information needs.

Keywords

Full-scale exercises, collaborative evaluation, Team Situation Awareness, socio-technical network mapping

INTRODUCTION

Crises and unforeseen events are a part of reality. The frequency of these events can be related to contextual elements such as population density, climate change, and migration but also deliberate actions like terror and cyber-attacks (McCreight, 2023). A key feature is that these elements contain surprise (Deverell & Olsson, 2009). The wicked nature of a crisis challenges society to take relevant and adequate preparatory measures (Edzen, 2014; Owen et al., 2018), and handling crises demands various organizations to interact. Both defined emergency response organizations and organizations that do not usually handle crises must cooperate and form a new, temporary organization where cross-organizational collaboration is essential (Roud & Gausdal, 2019; Roud et al., 2021; Van Haperen, 2001). However, conducting exercises that prepare for collaboration in handling real events can be complex and challenging to achieve within the conditions that organizations typically operate under. There is an academic debate about the usefulness of full-scale exercises, which can be costly in terms of time and resources (Roud et al., 2021; Sørensen, 2017). Some have questioned the effectiveness of such exercises regarding individual learning outcomes (Berlin & Carlström, 2015; Borell & Eriksson, 2013). Previous studies also pinpoint the importance of differentiating between exercises focusing on individual skills and exercises focusing on collaboration and systems which prioritize the process to ensure effective collaboration (Roud et al., 2021). In the latter, elements such as information flow, communication channels, establishment of structures, and cross-organizational work beyond what one typically performs are central. A social-technical pattern within emergency

management describes the integrated systems of human behavior and technology that impact the response. It acknowledges that effective emergency management encompasses not solely technical components like technology, infrastructure, and protocols, but also social aspects such as individual situation awareness (SA) and Team Situation Awareness (TSA) (Endsley, 1995; Endsley, 2020). TSA is SA distributed across organizations, involving shared awareness of protocols, goals, and situational information (Sorensen & Stanton, 2011). Understanding patterns is essential for designing and implementing effective emergency management strategies that address both the technical and social aspects of the response.

Collaboration between academia and practice is essential for addressing these issues, but Davenport (1998) argues that this can be challenging. Academic research findings can be diffuse, or their points are already known by practitioners (Davenport, 1998). Furthermore, academia can be seen as an actor that tends to problematize rather than come up with solutions related to real-life problems. This means the practice fields may be reluctant to involve academia in their projects. This perspective can also be valid in exercise planning and execution.

This research aims to address the issue of effective collaboration and effective evaluation of full-scale exercises, something that requires a shared understanding of the social-technical patterns including both organizational-specific and shared information needs. We draw from experiences participating in a full-scale exercise that simulated a collision between two vessels in the waters off the coast of Southern Norway. This incident required a coordinated response effort from various emergency response organizations, municipalities, and volunteers. To approach these challenges this paper attempts to answer the Research Question (RQ): *How can the co-creation of Socio-Technical Network maps aid collaboration and understanding between researchers and practitioners during emergency exercises?* We used a Socio-Technical Network (STN) approach to initiate the work to uncover communication patterns and barriers to TSA. We mapped communication pathways, information technology in use, and plans and procedures in detail from the moment of the collision until the various organizations had initiated their work phase, in collaboration with practitioners as a part of the data collection. We argue that this approach is fruitful and provides a common understanding of the situation, making the evaluation work effectively. The data collection was conducted through participatory observations and qualitative, in-depth interviews with relevant stakeholders.

Considering the importance of TSA elements and Shared Mental Models (SMM), we seek to identify factors that strengthen collaboration and those that weaken it. SMM is further explained in the Theories section.

Identified elements of improvement from evaluation of the exercise will be part of the next planned full-scale exercise in which the authors will participate (Figure 1). Thus, we have the opportunity to follow up results and further validate our methodical approach.

BACKGROUND

The field of exercise methodology encompasses a wide range of approaches, and extensive literature exists discussing the efficacy of exercises in relation to real crisis management (Berlin & Carlström, 2015; Roud & Gausdal, 2019; Roud et al., 2021; Roud & Schmied, 2020; Sørensen, 2017). A common denominator among methodological approaches is that exercises aim to prepare the various actors to face real crises (Borell & Eriksson, 2013; McCreight, 2023). In crisis management, there are typically four or five stages or phases including preparedness, response, recovery, and mitigation. Some models also include prevention as a distinct phase (Coppola, 2006; McCreight, 2023). Prevention means actively taking measures to prevent crises and undesired events from occurring. Exercises are part of organizations' preparations for crises and undesired events, where exercises and training are included along with their plans and guidelines on how organizations can best ensure the best possible outcome. In Norway, different organizations have a high level of autonomy, which influences the amount of time and resources they dedicate to preparing for hypothetical scenarios. This includes scenarios based on risk analysis of past events. For instance, municipalities have varying degrees of available resources and personnel with specific roles related to exercises and preparations for undesired events. In larger municipalities, there are dedicated personnel with full-time positions related to crisis management. In comparison, crisis management may comprise only a limited role in smaller municipalities associated with personnel with completely different daily tasks. Also, within the established emergency response organizations, such as fire departments, police, and ambulance services, there is a high degree of autonomy. In addition, it is challenging to conduct satisfactory evaluations of emergency management exercises, as it also requires personnel to step out of their daily tasks, which can be costly and must be prioritized by the individual organizations (Steen-Tveit, 2020). Overall, this can challenge the opportunities for large-scale training.

In evaluation reports after major events in Norway, it is repeatedly pointed out that organizations struggle to learn from real events and exercises (Henriksen, 2022). Information sharing, TSA, and role understanding are recurring challenges. Despite identifying problem areas, the different organizations do not absorb the lessons, and it does not lead to real changes in behavior (Borell & Eriksson, 2013; DSB, 2020; Halvorsen, 2021; Henriksen, 2022;

Sønderland, 2012). In such cases, individuals or organizations continue to follow the same approach without critically examining or adjusting their methods, missing the opportunity for deeper learning and improvement that the events and exercises could provide (Deverell & Olsson, 2009; Roud et al., 2021). In the context of exercises, it is challenging to facilitate information sharing across organizational boundaries (Roud & Schmied, 2020). The established emergency response organizations have plans that ensure early sharing of important information so that each actor can have as accurate an understanding as possible of what they are responding to as early as possible. In Norway these are called Triple alert procedures (Steen-Tveit & Munkvold, 2021).

The procedure is anchored at the national level and has a historical basis in the unfortunate handling of a terrorist incident in 2013 (DSB, 2014). In this incident, the police knew that they were responding to an active knife stabbing while other emergency responders responded to what they believed was a bus accident. Procedures aimed at ensuring early similar situational understanding only apply to the collaboration between the fire department, ambulance service, and the police, as well as The Norwegian Joint Rescue Coordination Centres (NJRCC) and in some cases, the road traffic control center. In Norway, a collaborative model is used, where there are expectations that crises are handled by all relevant organizations in cooperation. Even if responsibility is not explicitly documented in procedures, the organization that normally has responsibility for a subject area or a geographical area should, as far as possible, assume this responsibility also in a crisis. This means that a cooperative response operation often becomes much larger than the established emergency response organizations, requiring planning and training for a sometimes very large, interdisciplinary, and cross-sectoral new organization.

THEORETICAL PERSPECTIVES

Team Situation Awareness (TSA) and Distributed Situation Awareness (DSA)

Theories on Situation Awareness (SA) are frequently used in emergency management, exercises, and evaluations following real-life events (DSB, 2020; Halvorsen, 2021). Shared situational understanding is essential when multiple actors interact and collaborate, but it can be challenging to achieve. Although reports have identified a lack of situational understanding as a challenge, barriers to obtaining shared situational awareness persist. Sharing relevant information and understanding the workflow processes within collaborating organizations are particularly challenging.

Endsley's 1995 SA model sheds light on SA as an individual, cognitive phenomenon and as a part of teamwork (Endsley, 1995). The theories for TSA refer to factors that promote shared situational understanding in collaborative teams. Central to successful collaboration is the sharing of information and familiarity among team members and building and maintaining SMM (Endsley, 2020; Endsley & Robertson, 2000). Mental models relate to internalized knowledge stored as schemas in long-term memory at an individual level. SMM relate to mental models being a product of collaboration and familiarity with the actors one collaborates with (Salas et al., 2015; Salas et al., 2005). With SMM, each team member can more easily understand the actions, needs, and future actions of other team members (Salas et al., 2005; Stout et al., 2017). A high degree of TSA is achieved when the team knows each other's needs and supports each other by sharing information and considering other members when performing an action (Endsley, 2020).

Stanton et al. recognize Endsley's theories regarding both individual and Team SA but emphasize the interaction between humans and technology. According to DSA (Distributed Situation Awareness) theory, SA is not primarily a cognitive phenomenon but an emerging phenomenon resulting from the interaction between both human and non-human actors in collaboration (Salmon, 2016; Stanton et al., 2006; Stanton et al., 2018). DSA can be characterized by the collective understanding of a situation among individuals or teams operating in a distributed environment. It involves sharing relevant information and knowledge to establish a common awareness of the situation. This shared awareness facilitates effective team coordination and allows synchronized actions and resource allocation across distributed entities. In DSA theory, it is argued that SA exists at a systems level and can be viewed as an emergent feature of collaborative systems (Salmon et al., 2017).

There is an ongoing debate about whether Stanton et al.'s perspectives contribute a new theoretical perspective or if this is part of Endsley's described Distribution of Situational Awareness. In this paper, we choose to utilize perspectives from both theories and believe that they complement each other at a higher level (Endsley, 2015; Salmon et al., 2008).

SCENARIO DESCRIPTION

Large-scale exercises aimed at testing collaboration at the local system level are a recurring event in Norway, occurring annually and in multiple locations. In the exercise used in this article, a maritime incident was simulated. The scenario involved a collision between two medium-sized vessels in the archipelago area between two

municipalities in southern Norway. One vessel had 71 persons on board, while the other had 31 persons, totaling 102 actors who played the roles of shipwreck victims. The exercise commenced at 09:18 AM when one of the vessels sent out a MAYDAY distress call, which was intercepted by the Coastal Radio. The message reported a collision, water ingress in one vessel causing it to list and risk sinking, and smoke and fire onboard the other vessel. The message was immediately relayed to the NJRCC, who initiated the notification of police, fire brigade, and healthcare services in the relevant municipalities. Notification of emergency responders geographically linked to the incident follows national Search and Rescue (SAR) standard operating procedures (SOP). These procedures have similar wording and layouts to ensure an early common situational understanding among emergency responders.

Local tactical teams were then notified to respond to the scene, and a common radio frequency was established for coordination. Different emergency response organizations have independent responsibilities to alert other necessary resources, as specified in written SOPs available to operators. For instance, the Emergency Medical Communication Center (EMCC) is responsible for alerting ambulances and doctors in municipal duty rosters and keeping nearby hospitals informed. The police are responsible for leading local operations and also for notifying municipalities, volunteer organizations, and others who may have responsibilities related to handling the incident.

In the early stages of the operation, it was decided that the vessels would prioritize going to two different ports in each municipality. The land-based aspect of the incident had to be coordinated as both the same and as two separate incidents. Two centers for evacuees and relatives were established, and there was a need for information from local actors, such as the press, at both locations. However, only one of the vessels made it to port. For the other vessel, it was simulated that it sank, and passengers came ashore on various islets and rocks.

Overall, the scenario ensured that a relevant selection of actors that one would normally expect in a real scenario was notified and had the opportunity to practice cooperation and communication. There was also relevant stress on the technical structures, including intensive use of the Norwegian Critical Communication Network (NCCN), which was pushed close to its maximum capacity.

The exercise concluded at 1:00 PM. Individual organizations sporadically evaluated it through Hot Wash sessions, but none took the initiative for a larger, cross-organizational evaluation. We, as researchers, distributed a Survey and gathered input from observers.

METHODOLOGY AND DATA COLLECTION

Prior to the exercise, as researchers, we were engaged by the exercise committee to work with them to develop clear exercise objectives that could be followed throughout the exercise and evaluated afterwards. Figure 1 shows how we were engaged throughout the exercise.

The exercise objectives were the result of a workshop held beforehand, as well as a tabletop exercise focusing on identifying whether each organization's plans and procedures aligned with those of the other collaborating organizations. The exercise objectives are shown in Table 1.

Table 1. Exercise objectives

Goal #	Description
Overall goal 1:	Conduct the exercise with unified contingency plans, wherein participating organizations collaborate towards common objectives and optimal resource utilization across agencies.
Overall goal 2:	Ensure that the rescue service always has the necessary information to create a team situational awareness.
Overall goal 3:	Ensure coordinated media and information services at all levels to provide correct information at the right time.
Overall goal 4:	Optimize resource utilization by leading, coordinating, and supporting rescue resources at strategic, operational, and tactical levels.

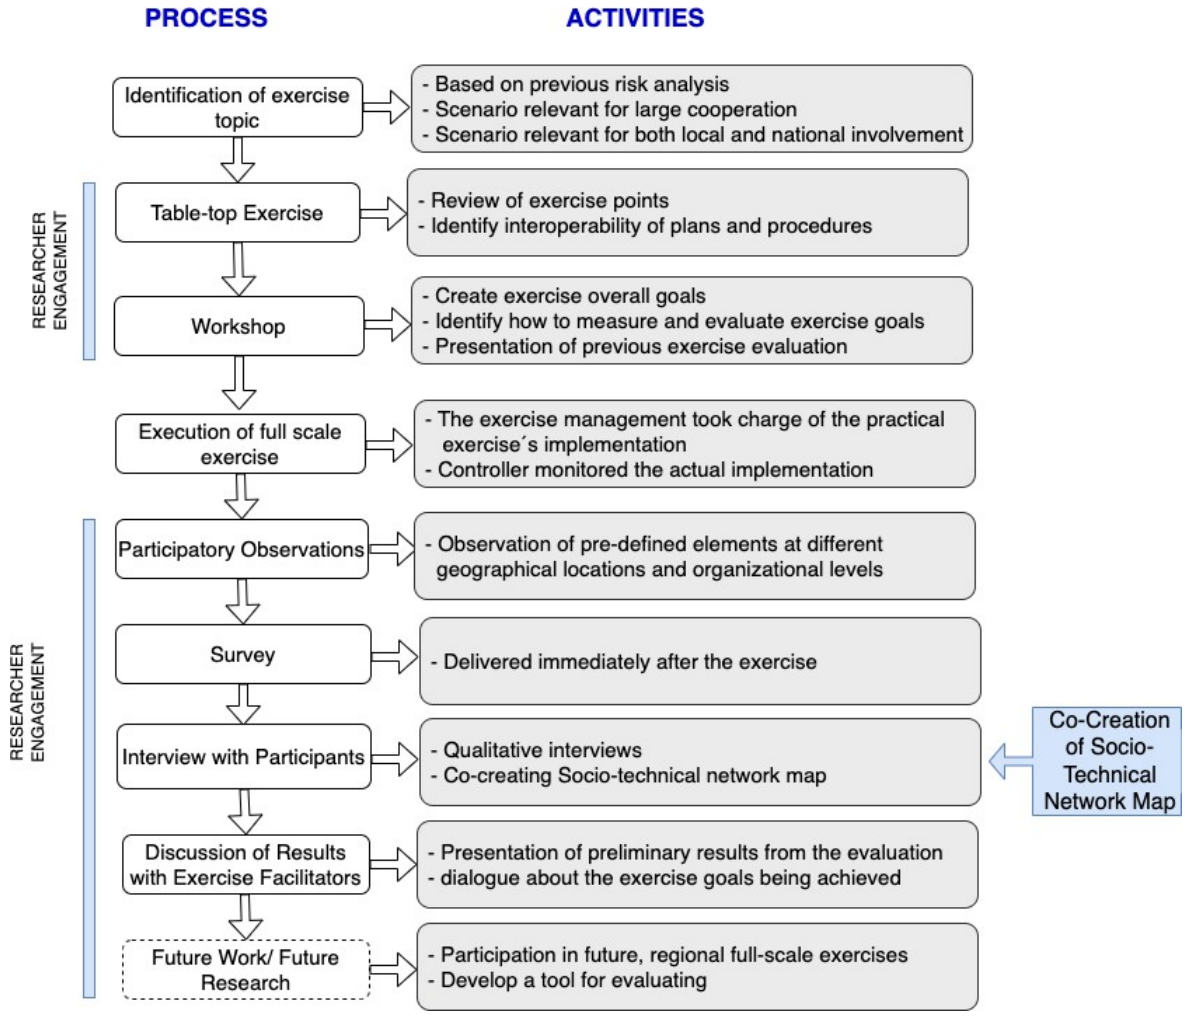

Figure 1. Researcher engagement in exercise

Data from the exercise was collected in four different ways: 1) A total of seven individuals, including three of the authors of this study observed the exercise at various geographical locations. At predefined times, observations related to the exercise objectives were recorded, using an observation guide to direct attention towards predefined elements and minimize observer bias; 2) Following the exercise, a survey was distributed to approximately 200 respondents, of whom 154 responded. The survey contained both closed and open-ended questions; 3) Selected findings from both observations and the survey are now being followed up with qualitative interviews. At the time of writing this article, a total of 13 interviews have been conducted. The interviews follow an interview guide aimed at clarifying respondents' role understanding, use of information systems, information sharing and communication, and experiences with evaluation and learning from exercises and real events. The length of each interview varies from 50 minutes to 150 minutes; 4) Before the interviews, we mapped the notification sequences, information systems in use, communication channels, and SOPs using MindManager[1]. This commercial mind-mapping software allows users to visualize information in mind maps and flowcharts. Together with the respondents, we enriched the initial mapping and co-created a network map that visualizes how information flows and how it is supported or not supported by adequate technical solutions and SOPs, thus supporting or creating barriers to TSA. Figure 2 shows the initial mapping of notification sequence, and Figure 3 shows initial notification with communications relations to VHF Maritime channels and the NCCN. Note that the original mapping is done in Norwegian. In this article, the figures demonstrate our methodical approach, but details have been removed for security and confidentiality reasons.

[1] https://www.mindmanager.com/en/

Socio-Technical Network (STN) Mapping

To approach an evaluation of whether the overall goals were achieved (Table 1), we, together with the respondents, have conducted an STN mapping as a part of our qualitative interviews (Figure 1). The mapping is delimited in time from the exercise's inception until the notification phase was over and the various organizations began the work phase. To gain an overview and to map information patterns and identify how information technology supported the human actors' SA, our mapping aims to identify both the human and the technical, or non-human, actors. Our approach is inspired by Salmon et al.'s (2017) approach to representing DSA, and also the Delphi method (Linstone & Turoff, 1975) where the "informed judgements" and expert opinions from practitioners are highly valued (Linstone & Turoff, 1975; Plotnick et al., 2011). The use of Social-technical network analysis in connection with emergency management is not uncommon. As an example, Houghton et al. (2006) seeks to elucidate and categorize archetypal networks in Command&Control networks. It suggests that social network analyses can be a valuable part of general studies of command and control. Mapping social networks along with other elements of an information system seems timely. In this article, we consciously call our approach a STN-mapping to clearly emphasize a connection between human and non-human actors, procedures, and communication pathways, and to clarify a distinction between Mapping and Analysis. Our mapping is a part of our analysis, but not an analysis on its own. In social networks, the relationship and/or flow of communication between human actors as individuals and groups and non-human actors such as computers and other data processing devices are plotted as connections between entities (Houghton et al., 2006).

Our STN mapping serves as a valuable tool in an interview situation. Collaboration between practitioners and researchers is essential, and input from practitioners can immediately be translated into a product recognizable to the practitioner and usable by the researcher to clarify what actually transpired. Thus, both parties have ownership of the end product. As a premise, only respondents in the interview were allowed to comment on the parts of the mapping they were involved in. Any objections or comments of others were noted and discussed with the relevant parties. The idea of the researcher being fully objective is an obsolete idea, at least from an interpretivist understanding of epistemology (Klein & Myers, 1999; Wynn Jr & Williams, 2012). An interview situation involving a researcher and a respondent represents an asymmetric power relationship, where the researcher holds a position where (s)he both leads the dialogue and interprets the information that emerges. Our method alleviates this asymmetry and the product we co-create functions as a boundary object (Star, 1989).

PRELIMINARY RESULTS AND DISCUSSION

In our analysis, we observe that the initial resource notification worked well in the very first sequence (Figure 2). In this part of the notification process, a SOP regularly drilled by established emergency response organizations was used. The SOP is well-known among all personnel and is rooted in national guidelines. However, as the complexity of the incident increased, the established emergency response organizations encountered increasing challenges in continuing resource notification. In cases where automated responses managed the notification, the process itself was unproblematic. However, when operators had to manually notify using, for example, call lists, there were failures in the notification process. For instance, the EMCC conducted macro alerts via the emergency network, where predefined NCCN macros alerted all healthcare resources considered relevant within the municipal boundaries in a cascading operation. This included hospitals closest to the incident site. Operators could verify that the alert had been sent and the call received without verbal confirmation over the communication system. However, organizations responsible for notifying volunteer organizations depended on operators physically calling each organization, providing relevant information, confirming receipt of the mission, and their deployment. In the exercise, we observed that this process did not function as intended. Some operators reported that they were overwhelmed with incoming calls, and that their organization's internal information needed in some cases forced personnel to prioritize this over following protocol. The STN network mapping clearly highlighted the causes of certain functions becoming bottlenecks in the flow of information. Here, we identified issues that challenged the overall exercise goals 1 and 2 (Table 1), such as organizations that were not present on the NCCN and, therefore, omitted from the information loop (Figure 3).

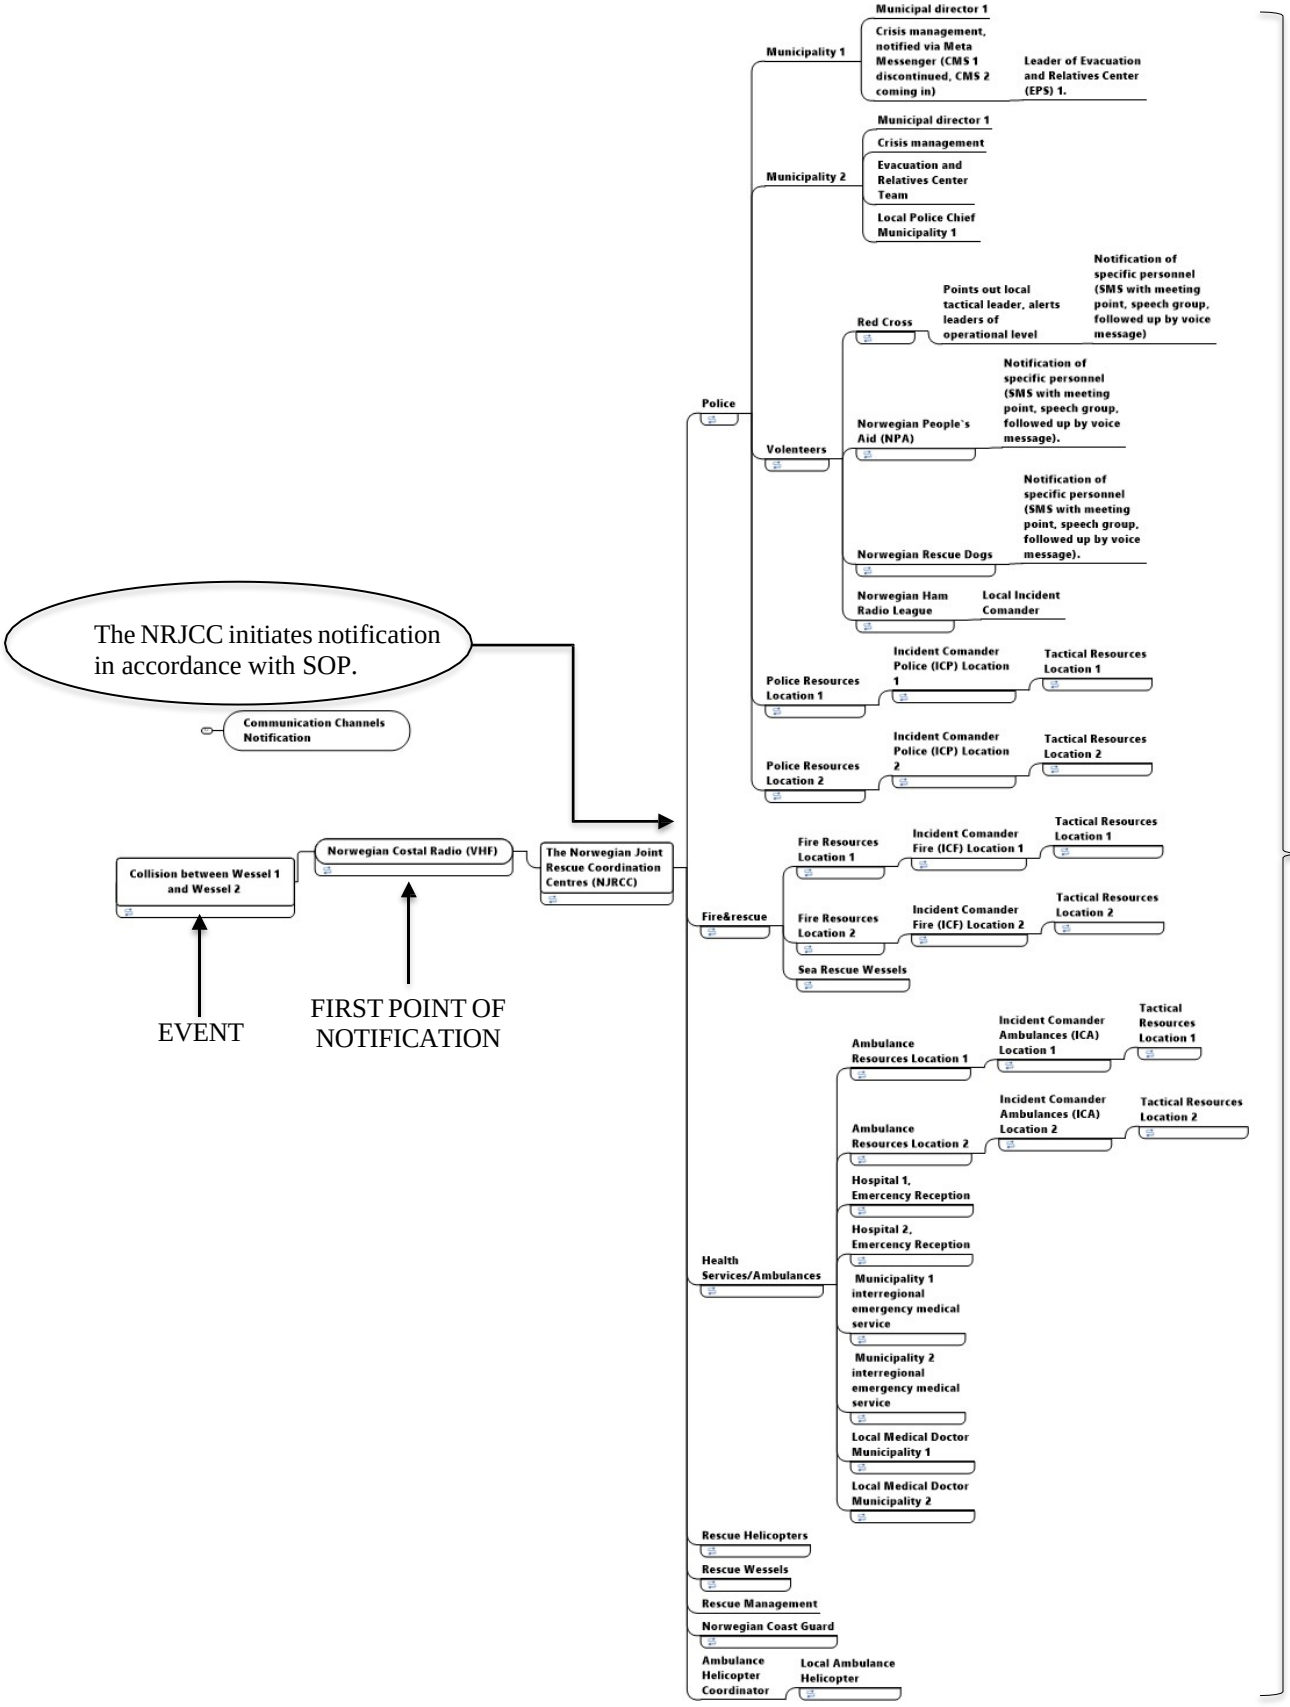

Figure 2. Socio-Technical Network (STN) Mapping of alerting phase without communications relations

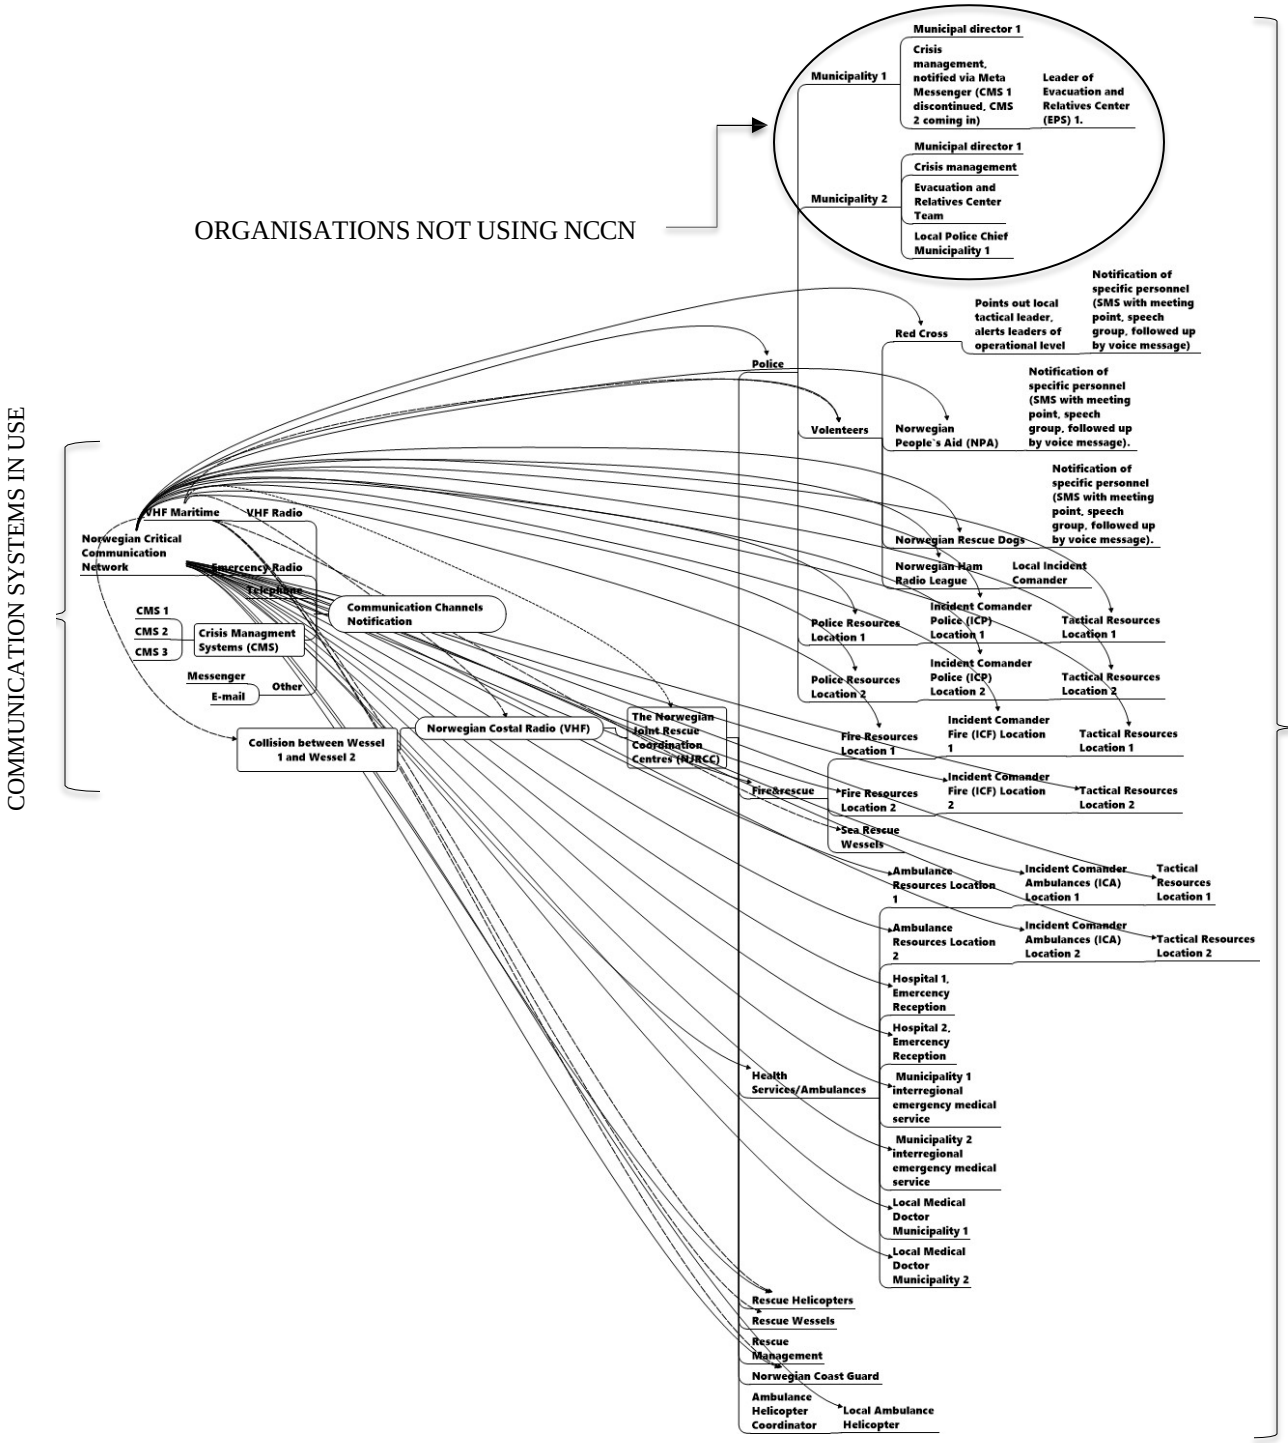

Figure 3. Socio-Technical Network (STN) Mapping with communications relations

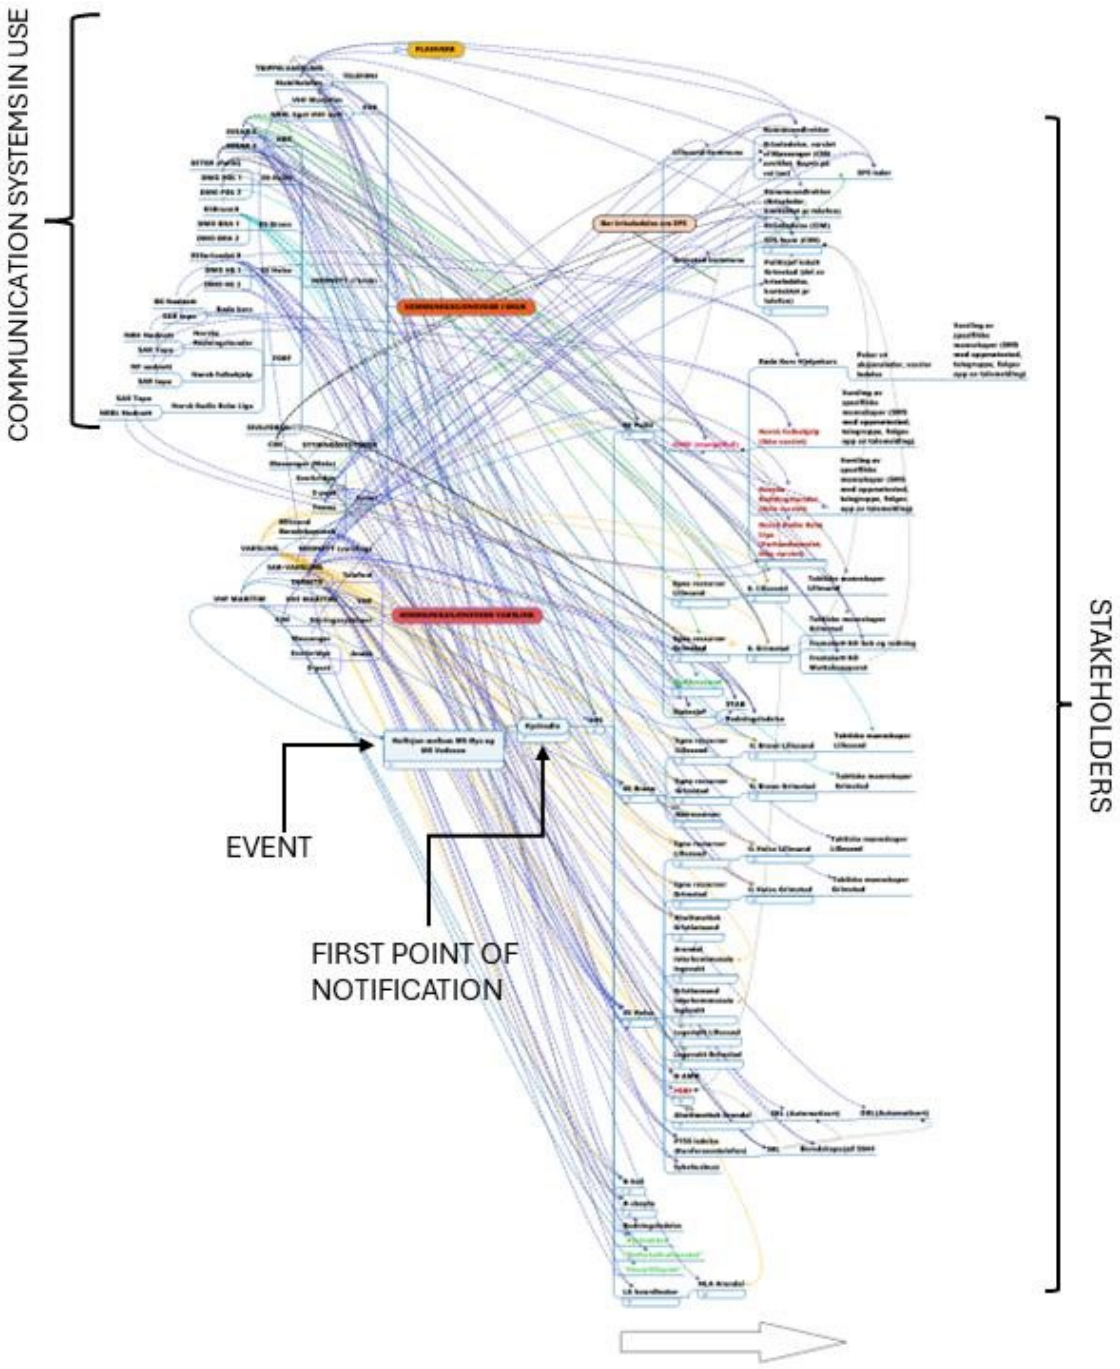

Figure 4. Socio-Technical Network (STN) Mapping full-blown from actual exercise

The mapping effectively illustrates the diversity of information systems operational during the exercise and to what extent they supported or hindered the achievement of a high level of TSA within the collaboration (Figure 4). In the initial alerting phase, eight different communication systems were in use, none of them overlapped. Consequently, interoperability posed a challenge, particularly affecting organizations unfamiliar with emergency network radios. This also challenged overall exercise goal 2 since it hampered the rescue service in getting necessary information to create TSA (Table 1).

An important function of the NCCN is the ability to set up different call groups or "digital rooms." It is possible to set up several call groups, both agency-specific and cross-organizational, during one emergency operation (Tveit et al., 2022). We observed that the NCCN structure was challenged as the number of call groups increased as the exercise progressed. Initially, agencies were notified by phone, and tactical teams were alerted in their own agency-specific call groups. They were then moved to a common call group in the very first part of the response phase. When the first resources arrived at the scenes, there were six active call groups across multiple base stations. As the operational phase progressed, this number grew to twelve call groups, with only one base station.

Additionally, several tactical teams communicated directly using direct mode communication, (i.e., communication from terminal to terminal, bypassing a common base station which releases network capacity). This fragmentation of communication pathways and information channels meant no single common location where all involved actors could expect to receive important information relevant to the collaboration.

The mapping also revealed deficiencies in the procedures used by the actors, demonstrating how, in some cases, procedures had to be abandoned because they were not practically applicable in the real world. As such, the mapping serves to operationalize procedures further by identifying why they did not function satisfactorily. For example, the procedure supporting municipal employees in establishing centers for evacuees and relatives required registration of evacuees in two ways, both in an Excel spreadsheet and in a separate system. However, the separate system had usability issues, such as the end-user receiving no information or confirmation that entered personal data was sent and received by the appropriate party. Additionally, evacuees could enter their information into this system by scanning an available QR code. This led to people being double-registered or not registered at all, without those on the front lines having oversight. The solution was to abandon the entire system and enter patient data into an Excel spreadsheet, which was then emailed to the central police. Another example was that, at one point, there were challenges associated with disseminating information from the centers for evacuees and relatives to other relevant stakeholders. Initially, there were no apparent reasons for this beyond the high workload of the centre's personnel. As completing the STN-map progressed, the issue became visually and explicitly apparent, leading to further exploration and contact with the center's leader. In dialogue with them, it emerged that they were receiving conflicting instructions about where they should be located, and at one point, the leader was ordered by the on-site police to relocate to the reception site where the involved vessel was arriving. With that, the contact point other organizations utilized to reach the center also disappeared, compromising the flow of information.

The collaboration process with practitioners to develop a STN map provides a thorough and objective illumination of potential barriers to Team Situational Awareness. In the co-creation process, we highlighted the complexity that extensive collaboration entails, including diverse roles, inter-organizational work across sectors, and various communication technologies with varying degrees of interoperability. The mapping also identified organizations that fell outside the majority, thus risking missing crucial information and consequently having a lower level of TSA.

We have presented our findings, illuminated through the mapping, to exercise leaders and leaders from the involved organizations. The feedback has been positive, and there is a plan for greater involvement in the next exercise to be implemented.

Both data collection and analysis processes in this type of study are demanding. As two researchers have a practitioner background, we quickly gained access to organizations where insight is typically hard to obtain. An example is that two of the researchers have a national personal security clearance that includes exposure to classified and sensitive information. This placed us in a dual role where, on the one hand, we gained rapid access to unrestricted information, while on the other hand, we individually and personally had to take responsibility for not exposing data that should not be disclosed. The solution to this is to collaborate closely with leaders from the various organizations, ensuring redundancy in the control of the information exposed for scientific purposes.

CONCLUSION AND FUTURE WORK

If academia is to be involved in such exercises as we describe, we find it highly beneficial to have early involvement. By being able to shape the wording of the exercise objectives and anchor them in the real problems experienced by the collaboration, we found that the entire process of ensuring that the various actors were involved in the exercise with the same focus, as well as the evaluation work, became much easier. We see the value of having a presence in the field of practice and approaching experts from various disciplines with a certain humility. The interaction between academia and practice can be highly fruitful and valuable. Still, it can easily be compromised if there are questions about ulterior motives or if trust between researchers and practitioners is undermined. Using a simple STN mapping, as demonstrated in this article, provides an element of objectivity. The map serves as a boundary object between practitioners with experience from exercises and real events, and us as researchers. The collaboration in recreating what actually happened, how it happened, and what support each actor received from other actors, technology, or predefined procedures allows for a good and candid dialogue between practice and academia, which we argue is valuable. The network mapping effectively visualized the complexity of some of the roles that needed to be fulfilled (Figure 4). In some cases, this visualization led to a demystification of acknowledging mistakes. Some actors were surprised to see how they were part of such a large interaction with other actors and technology. The findings can be used to refine the use of technology, with the understanding that TSA is necessary for the cooperation to achieve its goals when working together in a collaborative, large, fragmented, and temporary organization. We expect that a visualization similar to the one we

have conducted will strengthen and develop the SMM of the involved actors. Preliminary feedback suggests that the co-creation of the STN map and early researcher involvement have already contributed to a greater understanding of participants' roles, the information needs of collaborating organizations, and technological possibilities and limitations.

In our future research we will further develop and test a tool for evaluating post-exercise measures. We will also seek to identify Information Trading Zones (ITZ) within the various communication structures, and thus further validate a preliminary framework introduced in (Rustenberg et al., 2024). ITZ in the context of Emergency Management can be defined as a space where various actors "trade" their ideas about the relevance of available crisis information (Boersma et al., 2014; Boersma et al., 2012). Central to this is identifying barriers to the involved stakeholders' and organizations' ability to develop and maintain TSA. The STN mapping described in this paper will be further developed to visualize how the information trading during the exercise actually occurred and the limitations and potential of the Information Systems in use.

QuakeSet: A Dataset and Low-Resource Models to Monitor Earthquakes through Sentinel-1

Daniele Rege Cambrin*

daniele.regecambrin@polito.it

Paolo Garza
Politecnico di Torino
paolo.garza@polito.it

ABSTRACT

Earthquake monitoring is necessary to promptly identify the affected areas, the severity of the events, and, finally, to estimate damages and plan the actions needed for the restoration process. The use of seismic stations to monitor the strength and origin of earthquakes is limited when dealing with remote areas (we cannot have global capillary coverage). Identification and analysis of all affected areas is mandatory to support areas not monitored by traditional stations. Using social media images in crisis management has proven effective in various situations. However, they are still limited by the possibility of using communication infrastructures in case of an earthquake and by the presence of people in the area. Moreover, social media images and messages cannot be used to estimate the actual severity of earthquakes and their characteristics effectively. The employment of satellites to monitor changes around the globe grants the possibility of exploiting instrumentation that is not limited by the visible spectrum, the presence of land infrastructures, and people in the affected areas. In this work, we propose a new dataset composed of images taken from Sentinel-1 and a new series of tasks to help monitor earthquakes from a new detailed view. Coupled with the data, we provide a series of traditional machine learning and deep learning models as baselines to assess the effectiveness of ML-based models in earthquake analysis.

INTRODUCTION

The application of modern machine learning and deep learning solutions to remote sensing is strictly linked to data availability. Thanks to the launch of Landsat-8 (Wulder et al., 2019), MODIS (Justice et al., 2002), and Sentinel missions (Main-Knorn et al., 2017; Torres et al., 2012), general-purpose datasets were released in recent years (Helber et al., 2019; Sumbul et al., 2019; Y. Wang et al., 2022). Emergency management can benefit from these solutions. However, only a few datasets of satellite imagery were publicly released for a limited number of emergency management tasks (e.g., flood detection (Bonafilia et al., 2020) and burned areas delineation (Cambrin et al., 2023)). Ad-hoc image datasets are unavailable for many emergency management tasks. Among the others, public datasets of satellite imagery tailored to training machine learning models for earthquake analysis have not been released to our knowledge.

Earthquake monitoring is mainly based on seismometers that actively record seismic waves to detect, understand the strength, and identify the origin of these events. However, we cannot have global capillary coverage using this instrumentation. Conversely, satellite instruments have a broader view over the globe. Hence, they can help reach remote places worldwide and understand which areas were affected by the earthquakes without sending people to assess the damages and without using seismometers. Tasks such as identifying affected areas and estimating magnitude can be solved offline by collecting satellite images and then applying machine learning models in a data center. Alternatively, the inference can be made directly onboard the satellites using low-resource models, avoiding storing large amounts of data and enabling the possibility of transmitting only a few significant information (e.g.,

*corresponding author

coordinates of the damaged area, the estimated magnitude, etc). This raises another crucial challenge linked to the resource availability of the used systems: employing a large model requires computational resources unavailable on board. Creating an accurate model is not the only requirement. Low resource consumption is mandatory, and memory, CPU, and energy must be used effectively.

In this context, we propose a new dataset of more than a hundred earthquakes around the Earth, containing thousands of tri-temporal samples of the same event using Sentinel-1 data and ISC annotations. Moreover, we assess the effectiveness of shallow and deep learning models to solve tasks related to earthquake monitoring.

Our contributions can be summarized as follows:

- We propose a series of tasks to analyze earthquake-affected areas that can be solved by applying machine learning solutions to Sentinel-1 data.
- We evaluate a series of deep learning and shallow machine learning solutions in a subset of the proposed tasks.
- We pose the tasks as a balance between performance and resource consumption to democratize the proposed solutions and make feasible the application to low-resource devices.
- We publicly release a collection composed of tri-temporal time-series images, allowing the possibility to analyze time-related changes.

For reproducibility, we released the code for the experiments at https://anonymous.4open.science/r/quakeset-4D73/. The dataset is available at https://zenodo.org/records/10423411 to allow the community to experiment with it. Both code and data are released anonymously to comply with the double-blind review process.

RELATED WORKS

Image Processing through Deep Learning

The rise of convolutional neural networks and, more recently, vision transformers significantly improved the capability of processing images. The great data availability and the use of pre-trained neural networks posed deep learning models as state-of-the-art solutions in computer vision over classical machine learning models in benchmark datasets like ImageNet (Deng et al., 2009). The increasing performance of these models is often linked to the increased computational costs at training time and in inference (Xie et al., 2021). Dealing with real-time constraints or low-resource devices poses the challenge of balancing accuracy with resource consumption. Developing specific deep learning models like MobileNets (Howard et al., 2017; Sandler et al., 2018) or MobileViTs Mehta and Rastegari, 2021, 2022 were strictly linked to these constraints. Other solutions were designed in different fashions, including the possibility of employing less accurate real-time versions or the heavier and best-performing ones (Z. Liu et al., 2022; W. Wang et al., 2021; Woo et al., 2023; Xie et al., 2021). Finally, the effectiveness of the deep learning models in computer vision is highly impacted by data availability. Without ad hoc collections of images, the results decrease rapidly when considering domains for which tailored datasets are unavailable or limited.

Image Processing and Deep Learning in Crisis Management

Using textual information to analyze the evolution of ongoing emergencies has proven effective with the solutions proposed in the Incident Stream (McCreadie et al., 2019) and Crisis Facts (McCreadie et al., 2023) tracks of TREC. Although, also the analysis of images taken from social media has proven to be effective in the identification of areas affected by fires (Daly & Thom, 2016), earthquakes, hurricanes, and typhoons (Alam et al., 2017; Nguyen et al., 2017). The training of deep convolutional neural networks grants improved results over traditional techniques like Bag-Of-Visual-Words (Nguyen et al., 2017). The release of Incidents1M (Weber et al., 2022) with around a million images of 43 incidents granted the possibility to pre-train vision transformers and finetune existing pre-trained ones (Long et al., 2023). The significant drawback of all existing solutions is that they rely on social media and RGB images. RGB images can limit the comprehension of certain aspects of the events due to the limitations of the visible spectrum. For instance, using the infrared spectrum in Sentinel-2 helps monitor green areas (Drusch et al., 2012), being vegetation more sensitive to these frequencies. Moreover, using social media data also excludes the possibility of reaching sites with limited human presence or low-quality or damaged communications since they rely on information people send over social media. For these reasons, we propose to use satellite data, specifically Sentinel-1 images.

Machine Learning in Remote Sensing

The advancement of neural networks greatly benefits applications in the remote sensing field (Yuan et al., 2020; X. X. Zhu et al., 2017). The networks designed for RGB images have proven adaptable to other spectral bands like infrared and ultra blue. An extensive series of classical computer vision tasks, such as image classification and segmentation, were adapted to the remote sensing domain. The BigEarthNet (Sumbul et al., 2019) and EuroSAT (Helber et al., 2019) datasets pose the problem of landcover detection as an image classification one. The Seaships dataset (Shao et al., 2018) analyzes an object detection problem, while CaBuAr (Cambrin et al., 2023) analyzes a semantic segmentation problem in the burned area identification context. In addition to the extra spectral bands per image, in many cases, these datasets contain spatiotemporal information granting the possibility of solving tasks like change detection, which aims to find in supervised or unsupervised way the difference between two samples of the same spatial area taken at two different timestamps (Asokan & Anitha, 2019). The WHU dataset (Ji et al., 2018) deals with this challenge for urban planning.

Machine Learning in Seismology

There is an increasing interest in applying machine learning and deep learning in the seismology field (Chandrakumar et al., 2023). The current machine-learning solutions were mainly applied to earthquake seismic waves (P-waves and S-waves) to detect an earthquake in real-time. Machine learning was also applied to distinguish between earthquakes and microtremors (H. Liu et al., 2022) and to phase picking (Mousavi et al., 2020; W. Zhu et al., 2022). Current solutions involve convolution neural networks (Khan & Kwon, 2022; W. Zhu et al., 2022), generative adversarial networks (H. Liu et al., 2022), and transformers (Mousavi et al., 2020) applied to seismic waves. Sentinel-1 imagery has already been tested in earthquake analysis without involving automatic systems (Funning & Garcia, 2019). Specifically, the reported manual analysis highlights the feasibility of earthquake detection using Sentinel-1 data. The authors of Funning and Garcia, 2019 managed to identify approximately 70% of considered earthquakes. Compared to the manual analysis, we do not need to apply preprocessing steps for water bodies or atmospheric correction, and, more importantly, we propose completely automated ML-based approaches. Nevertheless, manual analysis in Funning and Garcia, 2019 involves correlation, which fails to understand non-linear relationships in data, while in our study, we employed many non-linear estimators. Moreover, we collected a time series of images to overcome the possible limitation of single image analysis, opening the possibility of leveraging changes instead of simply analyzing the content of single post-event images. Another difference is that we propose automatic solutions to analyze earthquakes from Sentinel-1 images instead of employing waves or manual solutions. Finally, we address several tasks, including detection and magnitude estimation.

SOURCES DESCRIPTION

In this section, we present the sources of our dataset, which includes Sentinel-1 GRD products and ground truth annotations from the International Seismological Centre (ISC).

Sentinel-1 mission

Sentinel-1 (Torres et al., 2012), with its Synthetic Aperture Radar (SAR), proved its effectiveness in a wide range of applications, and it is well suited for monitoring land changes due to its high revisit time and the capacity to see through clouds. It uses a single C-band operating at a center frequency of 5.405 GHz. SAR supports different acquisition modes in single and dual polarization: Stripmap (SM), Interferometric Wide swath (IW), Extra-Wide swath (EW), and Wave (WV). IW mode is mainly employed in land areas, WV in open oceans, EW in coastal areas, and SM for small islands. This work focused on land earthquakes, so we employed the IW mode, which provides VV and VH polarizations. Sentinel-1 products are available in four different formats: Level-0 Raw, Level-1 Ground Range Detected (GRD), Level-1 Single Look Complex (SLC), and Level-2 Ocean (OCN). We employed the Level-1 GRD products at two resolutions: 10 × 10 (high) and 40 × 40 (medium). To get all possible information, we kept only high-resolution samples.

ISC Bulletin

The International Seismological Centre (ISC) provides access to a database of all known and suspected earthquakes from more than 130 seismological agencies around the world (Willemann & Storchak, 2001). The ISC Bulletin ("International Seismological Centre (2023), On-line Bulletin", 2023) contains data from 1900 to the present (2023-11-19). The Reviewed ISC Bulletin, manually checked by ISC analysts and relocated (when there is sufficient data), is typically 24 months behind real-time and is currently up to 2021-11-01. The review procedure is applied to

all earthquakes with unknown magnitude or greater than 3.5. The procedure ensures the hypocenters are coherent with the origin region and that any regional and magnitude data are not missing. According to ISC, around 20% of the entire database is reviewed. The bulletin provides various information regarding each earthquake, such as hypocenter (Bonda´r & Storchak, 2011), the timestamp of the event, and magnitude (Di Giacomo & Storchak, 2016). Using this information, we can select an area of interest, know when to sample data related or not related to earthquakes, and try to understand different aspects of the events. The magnitude scale employed in this analysis and the ones directly provided by ISC is the mb scale, which can be used for medium entity earthquakes without encountering saturated values (Howell Jr, 1981). The following section describes how we use them to create tri-temporal time-series and ground truth annotations.

DATASET

Table 1. Dataset Summary

Earthquakes	155
Temporal window	2018-2021
Image channels	2 (VV and VH)
Area size	$20km \times 20km$
Temporal difference	1-13 days
Time series length	3
Patch size	512 × 512
Magnitudes	> 4 mb

We collected the epicenters of all earthquakes from 2018 until 2021 that were reviewed by ISC. We kept the ones defined as *known* events. We retained only the earthquakes that could create some visible effects, filtering the ones with mb magnitude greater than 4. We queried the Copernicus system of the European Space Agency to collect samples from Sentinel-1. For each epicenter longitude-latitude coordinates (E_{lg}, E_{lt}), we collected the area from $(E_{lg} - 0.1, E_{lt} + 0.1)$ to $(E_{lg} + 0.1, E_{lt} - 0.1)$. This creates an area around the epicenter of $\approx 20km \times 20km$. We have also constrained the image selection to IW mode samples. We collected two samples for each earthquake, one before (we call it "pre-event") and one after (we call it "post-event") the event. Since the revisit time of Sentinel-1 is 12 days, we created a temporal window of 13 days before and 13 days after the earthquake. We then selected the two images temporally nearest the event, excluding the day of the incident. We have excluded epicenters for which we do not have all the two samples. Furthermore, we collected an extra sample of the same area in a temporal window from 25 days before to 13 days before the earthquake, selecting the furthest day from the "pre-event" sample to avoid excessive similarities (we call it "neutral"). The availability of the third image for each earthquake helps balance the data distribution when considering the tasks based on the bitemporal time series in the following section.

Figure 1 depicts the four temporal windows considered for each earthquake. To summarize, three Sentinel-1 images are collected for each earthquake: one in the post-event, one in the pre-event, and one in the neutral temporal window.

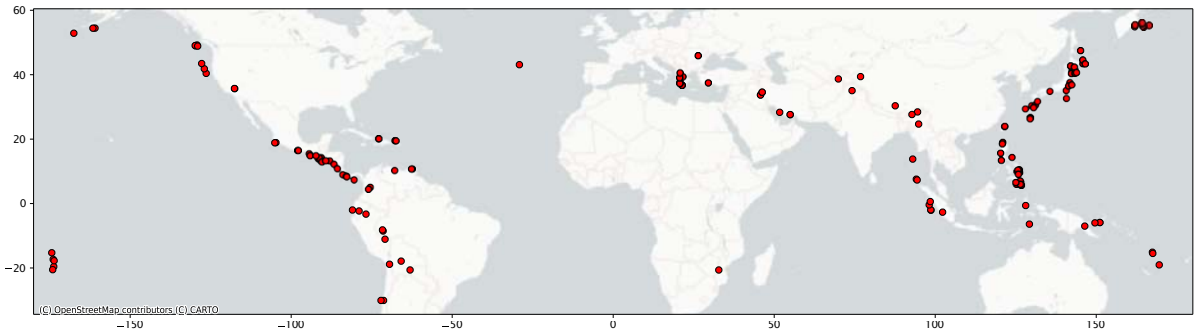
Figure 1. Temporal windows of collected samples

Each sample was preprocessed using SAR backscatter with the sigma0 ellipsoid coefficient. In this way, we collected 155 different events. For each earthquake, we provide three images (neutral, pre-event, post-event), the magnitude expressed in mb, the epicenter coordinates, and the depth (used to identify the hypocenter), when available.

In Figure 2, it is possible to see geographical distribution around the globe. Americas, East Asia, and Oceania are best represented, while Africa has the fewest samples. The identified epicenters cover coastal areas, hinterlands, and islands.

In Figure 3a, you can see the distribution of the magnitudes. We collected sufficient samples to approximate the distribution using a normal with $\mu = 5.64$, $\sigma = 0.44$. The collected values can be considered non-saturated

according to Howell Jr, 1981, which poses the upper limit of the scale to $mb_{sat} \approx 8.1$.



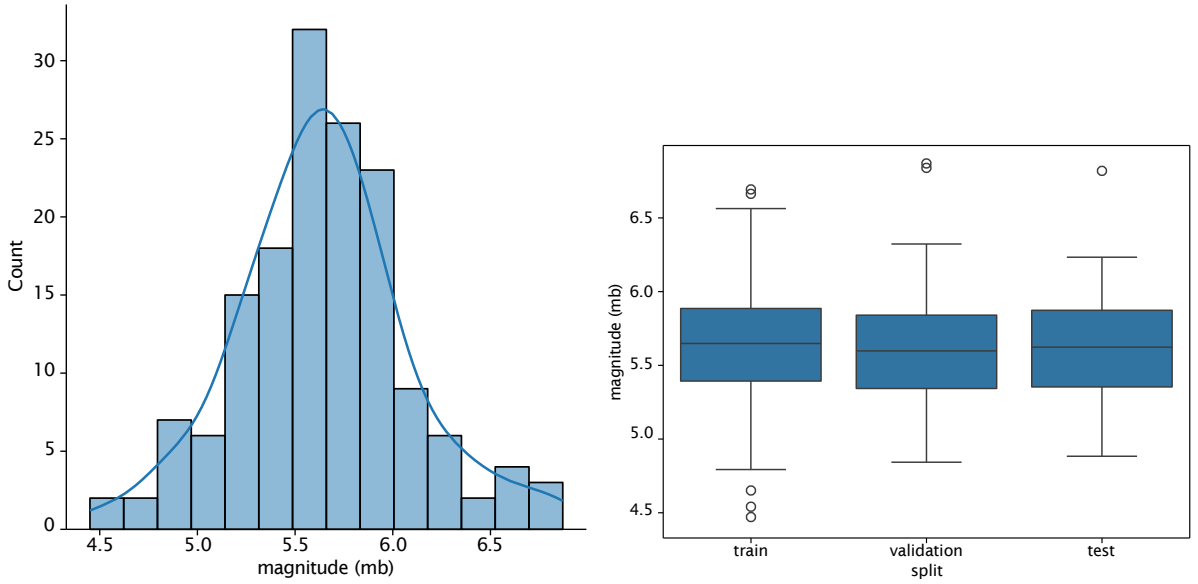


Figure 2. Earthquakes epicenters around the globe

We patched the samples from the center to obtain images of size 512 × 512 × 2, which are more tractable by machine learning models. In this way, we created 1906 patches. We reported a dataset summary in Table 1, highlighting the main features.

(a) Magnitudes distribution

(b) Magnitude distribution over splits

Figure 3. Magnitude distributions

Train, Validation and Test Splits

To create representative splits, we divided the dataset into 70%-15%-15% sets for train, validation, and testing, respectively. We decided to create the splits according to the distribution of the magnitudes. All the images (neutral, pre-event, and post-event) associated with the same earthquake event are in the same set/split. We sample from the original dataset with a uniform distribution. We evaluated the magnitude distribution using the two-sample Kolmogorov-Smirnov test to ensure similar distributions between train-validation and train-test. We obtain a p-value of 0.985 between train-validation and 0.995 between train-test sets. The obtained distributions in Figure 3b highlight the similarities between the three sets in terms of quantiles.

Tasks

Several tasks related to earthquake monitoring can be solved using the data we collected, and we are sharing. Among the others, we suggest using our data to handle the following emergency earthquake-related tasks:

1. Earthquake detection with bitemporal image time series
2. Magnitude regression with bitemporal image time series

3. Hypocenter or epicenter regression with bitemporal image time series
4. Change detection with bitemporal image time series
5. Earthquake detection with a single image
6. Magnitude regression with a single image
7. Hypocenter or epicenter regression with a single image

In the following, we formalize each type of task regardless of the input image time series size (the input can be either a single image or a time series composed of two consecutive images).

Earthquake Detection

The earthquake detection tasks (Tasks 1 and 5) can be formulated as follows. We have a set of time-series T, where each time-series $T_s \in \mathrm{T}$ is composed of N images, with $N \leq 2$, of size $W \times H \times C$ related to the same spatial area S at timesteps $\{T_1, \ldots, T_N\}$ and a ground truth value $G_t \in \{0, 1\}$ (where 1 indicate S was affected by an earthquake, 0 otherwise). Given a training dataset D_{tr}, composed of a set of pairs (T_s, G_t), we train a machine learning model
M. Given a test dataset D_{ts}, composed of a set of T_s, we can predict G_t for each sample T_s using M. This can be framed as a supervised classification task.

Magnitude Regression

The magnitude regression tasks (Tasks 2 and 6) can be formulated as follows. We have a set of time-series T, where each time-series $T_s \in \mathrm{T}$ is composed of N images, with $N \leq 2$, of size $W \times H \times C$ related to the same spatial area S at different timesteps $\{T_1, \ldots, T_N\}$ and a ground truth value $G_t \in \{0 \ldots M_m\}$ (where M_m is the maximum value for the given magnitude scale). Given a training dataset D_{tr}, composed of a set of pairs (T_s, G_t), we train a machine learning model M. Given a test dataset D_{ts}, composed of a set of T_s, we can regress G_t for each sample T_s using
M. This regression task is a supervised one.

Epicenter or Hypocenter Regression

The Epicenter or Hypocenter regression tasks (Tasks 3 and 7) can be formulated as follows. We have a set of time-series T, where each time-series $T_s \in \mathrm{T}$ is composed of N images, with $N \leq 2$, of size $W \times H \times C$ related to the same spatial area S at different timesteps $\{T_1, \ldots, T_N\}$ and a ground truth composed by the coordinates (x, y, d) (where x and y are the epicenter coordinates and d is the depth of the hypocenter) and a binary label $G_t \in \{0, 1\}$ (1 if the area S contains the hypocenter of the earthquake, otherwise 0). Given a training dataset D_{tr}, composed of a set of tuples (T_s, G_t, x, y, d), we train a machine learning model M. Given a test dataset D_{ts}, composed of a set of T_s, we can predict (G_t, x, y, d) for each sample T_s using M. If S is affected by an earthquake but does not contain the hypocenter, it should recognize that the tuple (x, y, d) cannot be determined. The task is supervised and combines classification (presence or absence of the epicenter) and regression (coordinates of the hypocenter).

Change Detection

Change detection (Task 4) can be formulated as follows. We have a set of time-series T, where each time-series $T_s \in \mathrm{T}$ is composed of 2 images of size $W \times H \times C$ related to the same spatial area S at different timesteps $\{T_1, T_2\}$. We want to generate a binary mask M_b of size $W \times H$ for each T_s. The value 1 indicates the pixel is affected by a substantial change; otherwise, it is set to 0. The task is an unsupervised semantic segmentation task. Given a training dataset D_{tr}, composed of a set of T_s, we train a machine learning model M. Given a test dataset D_{ts}, composed of a set of T_s, we can generate M_b for each sample T_s using M.

The previous formulations are general, and the mentioned tasks can be solved using single images (degenerate time series) or bi-temporal time series composed of two images.

EXPERIMENTS

In this section, we present the results obtained for a subset of the proposed tasks, which are Tasks 1, 2, 5 and 6. We have solved the most promising tasks to evaluate the quality of the collected data and the feasibility of the more relevant proposed tasks.

We employed four deep-learning models designed for low-resource devices: MobileNetV2 (Sandler et al., 2018) and ConvNextV2-Atto (Woo et al., 2023), which are convolutional neural networks (CNN), and MiT-B0 (Xie

et al., 2021) and MobileViTV2-1.0 (Mehta & Rastegari, 2022), which are vision transformers (ViT). We also considered some classical shallow learning models: Support Vector Machines (SVM) with 3rd-grade polynomial and Radial Basis Function kernels and Random Forest (RF). We have chosen these solutions because SVMs can exploit non-linear relations, while RFs, being an ensemble, are more robust.

Experimental Settings

This section reports all settings for the employed models and the input datasets.

Input data

Single Image. In this setting, the input data is a collection of single images (i.e., a collection of degenerate time series, each one composed of a single image). We use all the post-event images (as representative of areas already affected by an earthquake) and all the pre-event ones (as representative of areas unaffected by an earthquake). This corresponds to a balanced distribution of the two classes under analysis (affected/unaffected by an earthquake). In this setting, we do not consider the neutral images (see Figure 1). Each image has shape 512 × 512 × 2.

Bi-temporal Time Series. This second setting considers as input a collection of bitemporal time series of images. When dealing with bitemporal time series of images, we use samples of shape 512 × 512 × 4 concatenating the two components of the time series of shape 512 × 512 × 2 along the channel axis (this approach allows using machine learning models not designed for time series). Each time series is related to a specific earthquake and comprises a pre-event and a post-event image (example of affected area class object) or a neutral and a pre-event sample (example of unaffected area class object). This ensures a balanced distribution of positive and negative examples for the two classes.

Models

Deep Learning Models. We trained convolutional neural networks for six epochs while vision transformers for ten epochs. This was done due to the slower learning of transformers. The batch size is 16. We used an AdamW optimizer with a cosine-annealing learning rate scheduler with a warmup of 0.1 of the total training steps. The learning rate starts from 0.0001 for CNNs and from 0.001 for ViTs. All models are initialized without any pre-trained weights. The loss is Mean Squared Error (MSE) for regression tasks and Cross-Entropy loss for classification.

Shallow Models. We trained the Support Vector Machines with 3rd-degree polynomial and RBF kernels. Due to the high number of features, we applied PCA before using classical models. In this way, the size of the features of each sample is reduced to ≈ 2000.

Metrics

We analyzed the results in terms of accuracy for classification tasks since the class distribution is balanced (≈ 50% of positive and negative samples). Accuracy is defined as:

$$Accuracy = \frac{CC}{N} \tag{1}$$

where CC is the number of samples predicted correctly, and N is the number of samples we asked for a prediction.

We analyzed the results regarding Mean Absolute Error (MAE) for the regression tasks. Still, we also evaluated the accuracy in identifying the occurrence of an earthquake thresholding the predicted magnitude (if magnitude < 1, then no earthquake occurred; otherwise, an event affected the area). Mean Absolute Error is defined as:

$$\text{MAE} = \frac{1}{N} \sum_{i}^{N} |y_i - \hat{y}_i| \tag{2}$$

where N is the number of samples, y_i is the ground truth magnitude, and $\hat{y}_i$ is the predicted magnitude for the ith sample.

We are also interested in the resource consumption of the presented models, so we report the number of parameters for deep learning models, inference time in seconds, and Mega Floating Points Operation Per seconds (MFLOPs) computed on an Intel(R) Core(TM) i9-10980XE CPU.

Earthquake Detection with Bitemporal Time Series

We report in Table 2 the results for Task 1. The Random Forest Classifier is the best shallow model in terms of accuracy, providing reasonably high accuracy with a few FLOPs.

Regarding deep learning models, MobileViTV2 struggles to compete with the others, obtaining −20% accuracy and 2× FLOPs compared to Mit-B0. The best accuracy results are obtained by the CNNs, which are also less resource-hungry than transformers. MobileNet achieves the best result (94.72%) with fewer FLOPs than the other deep learning models. The differences between this model and the RFC classifier regarding FLOPs and accuracy are evident. Hence, deep learning models are needed to achieve high accuracy values at the cost of a more elevated resource consumption (two orders of magnitude more FLOPs than RFC). However, we notice that the "smallest" model (fewer parameters) of each deep learning category performs better than the "bigger" model of the same category. Specifically, MobileNetV2 (CNN) is more accurate than ConvNextV2 (CNN) and MiT-B0 (ViT) is more accurate than MobileVitV2 (ViT). Hence, smaller and less resource-demanding deep learning models are better for solving this task.

Table 2. Performance of models for earthquake detection with bitemporal time-series

Model	Params	Accuracy ↑	Time (s) ↓	MFLOPs ↓
SVC (RBF kernel)	-	0.6341	0.3640	1.0486
SVC (Poly kernel)	-	0.5440	0.3138	1.0486
RFC	-	0.7241	0.3130	1.0508
MobileNetV2 (CNN)	2.2M	0.9472	0.1109	207.5949
MiT-B0 (ViT)	3.4M	0.8865	0.0909	430.7062
ConvNextV2 (CNN)	3.7M	0.9374	0.1003	373.7727
MobileViTV2 (ViT)	4.9M	0.6536	0.1746	964.5956

Magnitude Regression with Bitemporal Time Series

In Table 3, we report the results obtained for Task 2. Classical solutions like Support Vector Regressors and Random Forest Regressors struggle to compete with deep learning models. In this case, the SVR with RBF kernel gets the best results in terms of accuracy among shallow machine learning models, despite RFR being the best in MAE. This means SVR can better distinguish between positive and negative samples, while RFR tends to approximate the magnitude better. Another critical factor is the accuracies of the shallow models, which are all near 0.5, being generally incapable of making distinctions between the classes.

Deep learning models are also more accurate (in terms of accuracy and MAE) for this task. Deep learning models provide higher accuracies and MAEs, distinguishing affected and unaffected areas. MiT-B0, which achieves worse MAE than CNNs (ConvNextV2 and MobileNetV2), gets an accuracy comparable to ConvNextV2 and MobileNetV2. Hence, Mit-B0, ConvNext, and MobileNet have the same ability to distinguish between earthquake-affected/unaffected areas. However, ConvNextV2 and MobileNetV2 estimate the magnitude values better. The performances of MobileViTV2 are not as satisfactory as the other deep-learning models. Similarly to the previous task, MobileNetV2 obtains the best performance under all metrics among the deep learning models despite being the "smallest" deep learning model. Furthermore, MobileNetV2 (CNN) is again more accurate (accuracy) and precise (MAE) than ConvNextV2 (CNN), and MiT-B0 (ViT) is more accurate and precise than MobileVitV2 (ViT). Hence, smaller and less resource-demanding deep learning models are also better for solving this task.

Table 3. Performance of models for magnitude regression with bitemporal time-series

Model	Params	MAE ↓	Accuracy ↑	Time (s) ↓	MFLOPs ↓
SVR (RBF kernel)	-	2.2368	0.5519	0.3640	1.0486
SVR (Poly kernel)	-	2.6015	0.5440	0.3138	1.0486
RFR	-	1.9930	0.5440	0.3130	1.0508
MobileNetV2 (CNN)	2.2M	0.5456	0.9374	0.1109	207.5949
MiT-B0 (ViT)	3.4M	0.8496	0.9276	0.0909	430.7062
ConvNextV2 (CNN)	3.7M	0.6494	0.9315	0.1003	373.7727
MobileViTV2 (ViT)	4.9M	1.7612	0.7378	0.1746	964.5956

Earthquake Detection with a Single Image

Table 4 reports the results for Task 5. It shows the models struggle to discriminate between areas affected by earthquakes and the non-affected ones. The benefits in reducing the computation costs compared to the models trained on bitemporal input data are evident only for shallow models (≈ 0.5× FLOPs than bitemporal settings), while the deep learning models gain is not worth the decrease in terms of accuracy (compare Table 4 with Table 2).

The best shallow model to solve Task 5 is SVC with RBF kernel, which achieves 0.60 of accuracy in a few FLOPs. Transformers get worse results than this model (−6% in the worst case). MobileNetV2 provides the best results (with +10% than SVC with RBF kernel), followed by ConvNextV2.

MobileNetV2 with single images achieves −24% in terms of accuracy than bitemporal settings (95%), and the results are comparable to those of Random Forest (RFC) with bitemporal input data (72%).

A consistent performance decrease using only one image was expected, as shown in the manual analysis of interferograms of Funning and Garcia, 2019 in which the authors highlighted that earthquake detection is feasible by looking at the differences between the two phases.

Table 4. Performance of models for earthquake detection with a single image

Model	Params	Accuracy ↑	Time (s) ↓	MFLOPs ↓
SVC (RBF kernel)	-	0.6047	0.1488	0.524288
SVC (Poly kernel)	-	0.5440	0.1472	0.524288
RFC	-	0.5186	0.1655	0.526554
MobileNetV2 (CNN)	2.2M	0.7104	0.0862	203.3172
MiT-B0 (ViT)	3.4M	0.5440	0.0710	424.8801
ConvNextV2 (CNN)	3.7M	0.6419	0.0609	370.8897
MobileViTV2 (ViT)	4.9M	0.5988	0.1171	960.3690

Magnitude Regression with a Single Image

The results in Table 5 for Task 6 show, as expected from the previous experiments, that the models are not well capable of identifying affected areas using one single image. We can conclude from the reported accuracies that this is common for both shallow and deep learning models.

The differences between the used models in terms of MAE and accuracy are less evident than before. Shallow models align with previous performances for Task 2. Conversely, deep learning models decrease their mean performance of −30% in terms of accuracy and +1.3 in MAE compared to the bitemporal setting.

MobileNetV2 gets the best results in terms of MAE but does not perform well in distinguishing between affected and unaffected areas. The decrease in accuracy compared to Task 5 is −16%. ConvNextV2 has the best accuracy, while MiT-B0 is the most balanced solution in both metrics. MobileViTV2 struggles to compete with shallow models in both metrics, too.

Table 5. Performance of models for magnitude regression with a single image

Model	Params	MAE ↓	Accuracy ↑	Time ↓	MFLOPs ↓
SVR (RBF kernel)	-	2.4088	0.5519	0.1488	0.524288
SVR (Poly kernel)	-	2.5960	0.5440	0.1472	0.524288
RFR	-	2.6204	0.5440	0.1655	0.526554
MobileNetV2 (CNN)	2.2M	2.1595	0.5734	0.0862	203.3172
MiT-B0 (ViT)	3.4M	2.1821	0.5832	0.0710	424.8801
ConvNextV2 (CNN)	3.7M	2.2353	0.5851	0.0609	370.8897

Preliminary Integration of a Global Seismic Hazard Map

The integration of the right in-domain information could be beneficial in addressing the proposed tasks. In our preliminary assessment, we evaluated the effectiveness of integrating a global seismic hazard map (Johnson et al.,

2023) as input. Specifically, we performed preliminary experiments by adding an extra channel associated with the seismic hazard information to the bi-temporal images. According to the preliminary results, this additional information does not provide any benefits in earthquake detection and magnitude regression. In the future, we will investigate other in-domain sources as well as other ways of integrating domain-specific information in the training of the models.

LIMITATIONS

The study employed only visual features without any external knowledge. Including other historical features and employing domain knowledge (e.g., geophysics, optics, and earth sciences) could strengthen the results on more complex tasks like hypocenter regression, which could benefit from extra information like geological plaques.

We employed single images and bi-temporal time series, although a longer time series could be investigated to include more historical information about the analyzed areas.

CONCLUSION AND FUTURE DIRECTIONS

Our experiments show the possibility of exploiting machine learning techniques to understand earthquakes using the visual components collected by the SAR instrument with satisfactory results.

We explored the usage of Sentinel-1 imagery, which is easily available to the public and for which there were studies proving effectiveness, although a different source (e.g., from drones and airplanes) or multi-source approach could be employed to adopt less expensive instrumentation.

We employed low-resource solutions (which are generally "small" models in terms of parameters) to show the unnecessary need for complex and bigger models. Results show that smaller deep-learning models are more accurate and precise than the bigger ones, contrasting expectations. Designing ad-hoc low-resource networks is an underexplored direction that should be addressed in remote sensing and hazard management.

In future works, we plan to investigate the remaining proposed tasks, the design of new ad-hoc low-resource models, and the inclusion of in-domain knowledge.

ABSTRACT

Volunteers are a valuable resource in disaster management. Yet to be useful, decision-makers need to manage this resource properly. However, managing volunteers differs from managing traditional work forces in multiple aspects: volunteers can spontaneously decide to offer their help, may have different skills and preferences for different tasks and can leave the system at any time. Several models for optimising volunteer management in disaster scenarios have been presented in the past. To provide an overview of existing approaches, this article provides a structured literature review, discusses the challenges of integrating these models into decision support systems and identifies future research directions. In total, 31 articles were identified, of which more than half were published in the last five years. Most authors addressed the issue of assigning volunteers to tasks, while little attention was paid to predicting the number of volunteers and optimising the composition of volunteer teams.

Keywords

Volunteers, decision support, disaster management, operational research, literature review

INTRODUCTION

When a disaster strikes, many different resources, such as medical or technical equipment and human resources, need to be available as quickly as possible. Thereby volunteers can play a significant role. For instance, according to a study conducted by the Fritz Institute in Indonesia after the 2004 tsunami, 90% of the survivors surveyed reported being rescued by volunteers (Fritz Institute 2005). If volunteers had their own sovereign nation, it would rank as the second most populous country in the world with its economy being one of the ten largest in the world (Salamon et al. 2011).

There are several definitions of volunteers. Most of them have in common that volunteers do not work for a salary but for free or only receive remuneration in the form of food and are not obliged to volunteer (Sampson 2006). Among volunteers, a second distinction is made in terms of affiliation. While some volunteers belong to an organisation such as the Red Cross, where they may receive training or similar, people may also decide to volunteer spontaneously, especially after a disaster. Therefore, these volunteers are sometimes referred to as "spontaneous" volunteers. However, this term implies that volunteers with affiliation are not spontaneous. Hence, we agree with Daddoust et al. (2021) that they should rather be called "unaffiliated emergent" volunteers. However, to be consistent with the literature, we will refer to these volunteers as spontaneous volunteers (SV). For a more detailed discussion on the definition of volunteers and SV, we refer the reader to Sampson (2006) and Paciarotti and Cesaroni (2020).

SV can be a useful resource in the aftermath of a disaster. They may be quickly available (Daddoust et al. 2021) and provide additional work force and possibly also additional skills (L. Fernandez et al. 2006) for little to no cost (Daddoust et al. 2021). Even without specialised skills, they can take on simple tasks such as making sandbags in the event of flooding or distributing food to relieve the burden on emergency management staff allowing them to focus on more specialised activities (Sauer et al. 2014).

*corresponding author

However, with a lack of an underlying organisation that exists for affiliated volunteers, the deployment of SV can also pose "serious issues and risks" (L. S. Fernandez et al. 2006). In the worst case, they can even cause additional problems after a disaster (L. Fernandez et al. 2006, S.-Q. Chen and Bai 2023) by obstructing or interfering with emergency response personnel and/or putting themselves or the victims in danger by acting according to what they think is necessary (Whittaker et al. 2015). Despite all the risks associated with the involvement of SV, it is also not an option not to involve them in disaster relief when they are available. Forgoing this additional labour force means a loss of resources, which can also distort the public perception of disaster response (L. Fernandez et al. 2006). In addition, the rejection of SV can also reduce future willingness to volunteer (Falasca, Zobel, and Fetter 2009, Daddoust et al. 2021). Hence, emergency managers should be prepared to manage volunteers in order to utilise their potential as efficiently as possible while avoiding additional risks and threads. According to research, organisations should have a centralised system to administer SV and assign tasks to them individually or in groups (L. Fernandez et al. 2006). Such systems should be able to respond to changing situations during disasters and be applied dynamically "in an on-going process", as well as anticipate needs (L. Fernandez et al. 2006).

Models developed in the field of operations research can provide decision-makers with a solution for the management of volunteers and the most efficient use of their workforce. For practical application, integrating these models into decision support systems (DSS) is important to facilitate the decision-making process. This review aims to provide an overview of existing models for the management of SV in disaster situations. The objective of this work is twofold: on the one hand, we aim to point out gaps and future directions for volunteer management in disasters. On the other hand, we want to facilitate the design of future DSS by providing an overview of the models and the data requirements that such a system should fulfil. In this work, we focus on physical volunteers who do not (only) collect data, but "offer their workforce and support at the disaster response sides within their range" (Betke 2018). In addition, we only consider volunteers in disaster situations and exclude regular emergency situations.

The remainder of this paper is structured as follows: In the next section, we provide an overview of the related literature. We then describe the methodology for the structured literature review and present the results, including an outlook on future research topics, before concluding the paper with a summary.

RELATED LITERATURE

The problem of labour scheduling has been extensively studied in the past (Van Den Bergh et al. 2013). Although volunteers can be understood as a type of labour, some assumptions made in traditional labour allocation (TLA) do not necessarily apply to voluntary labour allocation (VLA) (Sampson 2006). Following the most common definitions presented in the previous section, volunteers generally do not receive compensation, except perhaps per diems. Therefore, the overall goal shifts from minimising labour costs to maximising the tasks completed (Krstikj et al. 2021). Another key difference between TLA and VLA is the reliability of the workforce. Without significant remuneration or an employment contract, volunteers have no obligation to be available for work (Whittaker et al. 2015). Especially when dissatisfied with the assigned tasks or the amount of idle time, volunteers may decide to withdraw their help (Garcia et al. 2018). These particular characteristics inherent in the management of SV have led to extensive research into the psychological, motivational, and demographic aspects of volunteering (Einolf 2018). However, despite this general interest, the management of SV has received very little attention in the field of operational research (Sampson 2006).

The additional capacity of human resources provided by volunteers can be particularly valuable during disasters. Emergency response in disaster situations differs in various aspects from everyday emergency response (Altay and Green 2006) and poses its own unique challenges. Several articles have already been published analysing the existing literature in the field of Operational Research (OR)/Management Science (MS) addressing these challenges. One of the first reviews was written by Altay and Green (2006), who reviewed the literature up to 2004. This review was followed by several other reviews, including Galindo and Batta (2013), Özdamar and Ertem (2015), Kovacs and Moshtari (2019) or more recently Farahani et al. (2020). Despite their broad focus on various aspects of disaster management, none of the reviews explicitly addresses volunteer management. This gap in the literature is partially addressed by Ozdemir et al. (2022), who conduct a structured literature review focusing on volunteer location, allocation, and assignment. However, as the articles reviewed are limited to one of the three tasks mentioned, they only cover a subset of the decisions faced by emergency managers.

In addition to the literature in the field of OR/MS, the issue of volunteer management has also received attention in the field of information systems, particularly in association with the design of DSS. To guide the development of a DSS, L. S. Fernandez et al. (2006) recommend a system-based approach. For an in-depth evaluation of Volunteer Management Systems (VMS), Schonbock et al. (2016) develop a reference model and conduct a detailed comparison of seven distinct VMS. In a broader context, Betke et al. (2023) introduce a taxonomy that provides a comprehensive overview of these systems, facilitating their classification and selection based on relevant characteristics.

Apart from articles generally supporting the design of DSS, several authors have also contributed to the development of such systems. Among others, Fajardo and Oppus (2010), Rauchecker and Schryen (2018), Razali et al. (2019) and Patrisina et al. (2021) outline approaches to building DSS in the context of disaster management. A comprehensive documentation of the entire design approach is provided by Lindner, Betke, et al. (2017), Lindner, Kuehnel, et al. (2018) and Betke (2018). With a focus on agent-based simulation, Lindner, Betke, et al. (2017) identify 25 relevant attributes of spontaneous unaffiliated volunteers. Building on this work, Lindner, Kuehnel, et al. (2018) present a conceptual model for simulating volunteer behaviour, demonstrated in an artefact in Betke (2018).

Despite the strong interconnection between these two fields, there is a limited body of literature addressing the integration of OR/MS models into DSS. Conversely, the information system literature tends to concentrate on the technical implementation of DSS, neglecting the exploration of models guiding specific decisions.

Our distinctive contribution lies in a systematic literature review providing a comprehensive overview of existing models designed to enhance decision-making regarding volunteers in disaster situations, with a particular focus on their integration into DSS. Furthermore, our review extends the scope of Ozdemir et al. (2022) beyond location, allocation, and task assignment to encompass all potential aspects decision-makers might encounter in volunteer management pre- and post-disaster. We also include models designed for slow-onset disasters, and consider the actions taken during these events as part of the post-disaster phase.

METHODOLOGY

To provide an accurate overview of the currently existing literature, we conducted a systematic literature review and present the results according to PRISMA 2020 (Page et al. 2021). We searched two databases, Scopus, and Web of Science, using the following query to search by title, abstract and keywords: *volunteer* AND (disaster* OR crisis*) AND (optimi* OR alloc* OR quanti*)* and restricted the language to English. This query led to 365 results in Scopus, and 249 results in Web of Science. Additionally, to obtain a complete list of articles related to volunteer management within the field of OR/MS, we performed a second search in Web of Science with a more general query: *volunteer* AND (disaster* OR crisis*)* and restricted the results to those articles linked to the category of "Operations Research and Management", again considering only publications written in English. This search yielded to 43 hits. We then removed 227 duplicates as well as notes and editorials, conference reviews, books, and book chapters. Eventually, 397 articles remained for screening. After reviewing titles and abstracts, we excluded papers that did not focus on volunteer management in disasters, leaving 80 publications for further screening. Out of these, five publications could not be retrieved and were therefore excluded. During the full-text screening, we included all articles that addressed decision-making related to volunteers in disaster situations, while excluding those related to non-disaster situations, such as regular emergency scenarios, or that lacked a model supporting volunteer-related decisions. Furthermore, we opted to exclude the paper authored by Gutjahr and Viswanath (2020) due to its lack of consideration of the characteristics of volunteers highlighted in the previous section. Although their assumption might be valid in certain scenarios, decision-makers adhering to such assumptions could alternatively use models developed for general work assignment problems. Based on the 29 papers initially selected, we conducted a forward and backward search to ensure the inclusion of all relevant papers. In this process, we identified two additional articles, for which we also performed a forward and backward search, where, however, no other relevant articles where identified. A visual representation of the workflow is outlined in Figure 1.

Similar to other fields of disaster management, such as casualty management (Farahani et al. 2020), the potential of volunteer management has only recently gained attention. Despite the limited number of publications, interest has remained constant with a few publications per year. Figure 2 depicts the timely distribution of the articles.

The diversity of fields related to volunteer management is also reflected in the number of different journals and proceedings in which the articles were published. In total, the 31 articles were published in 24 different journals and proceedings, ranging from OR-related journals such as the European Journal of Operational Research to journals and conferences more closely related to computer science such as the International Journal of Advanced Computer Science and Applications.

Based on the questions addressed in the articles, we have identified seven different decision areas for emergency management. These fields include predicting the number of SV needed, hiring/admitting volunteers, training volunteers to acquire new skills, pairing volunteers, locating them in different geographical areas, and allocating them to tasks and queues. Figure 3 shows the distribution[1]. The most studied area is the assignment of volunteers to tasks, with more than half of the selected articles addressing this aspect. Some papers propose an approach to the hiring/admission of volunteers, their location and allocation to queues. The aspects of prediction, training, and pairing, however, are hardly addressed in the literature. Table 1 provides a brief overview of the selected articles.

[1]Note that some articles refer to two areas and are therefore counted twice.

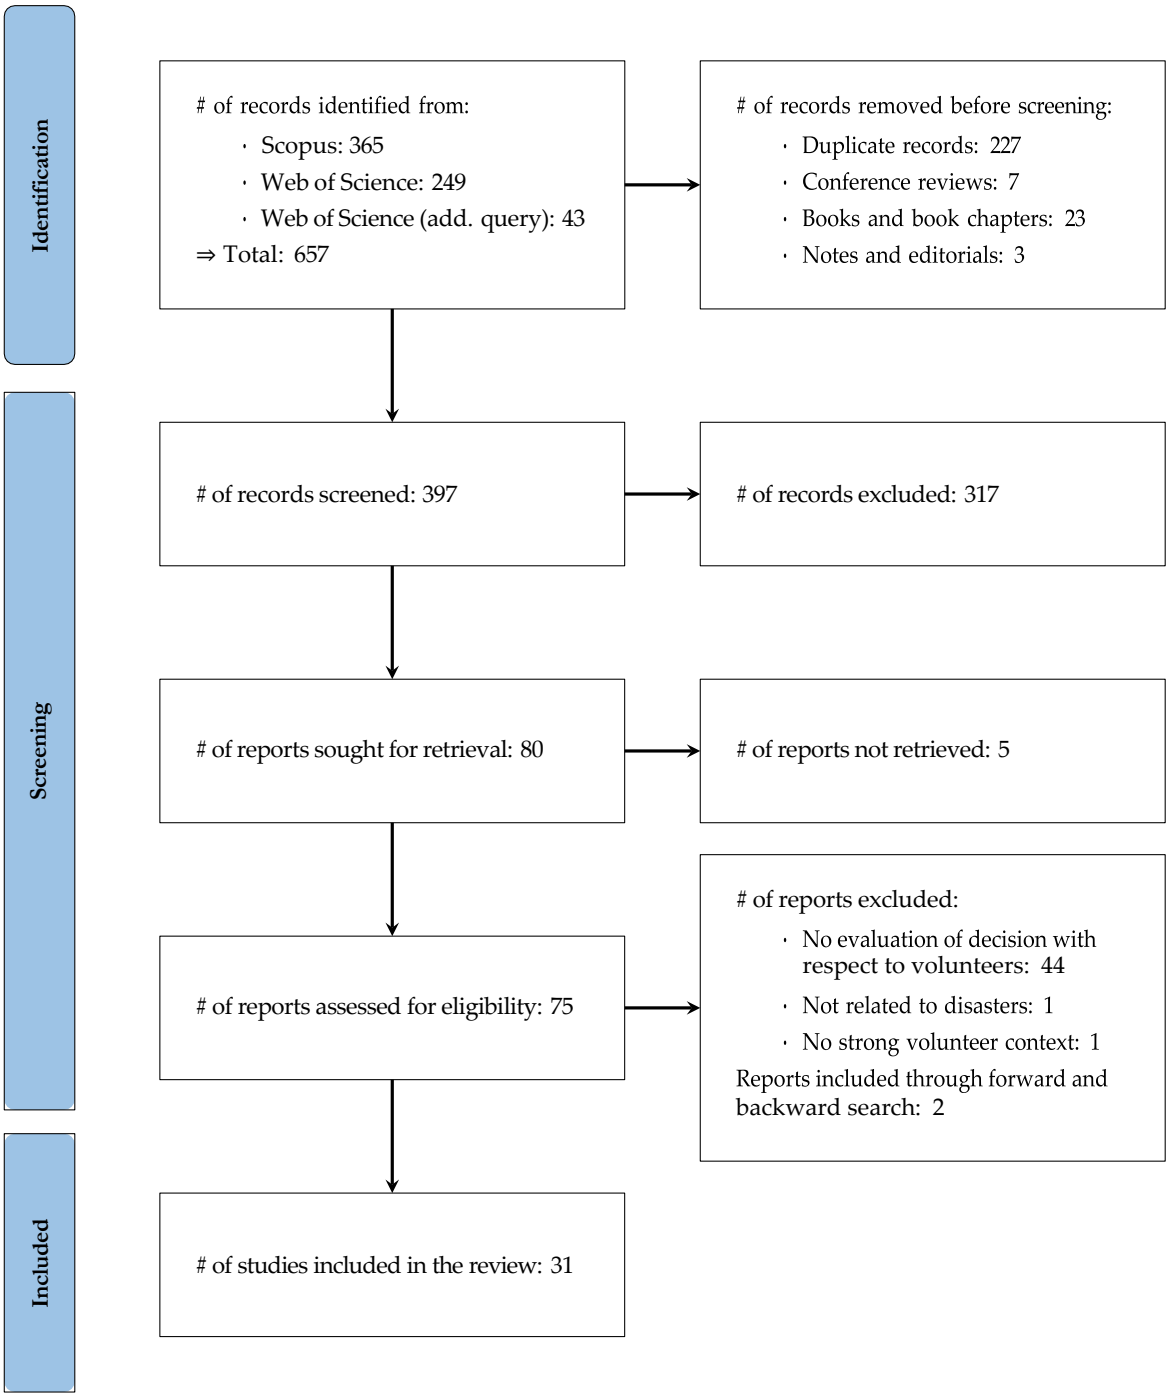

Figure 1. Review process mapped to PRISMA 2020 (following Page et al. 2021)

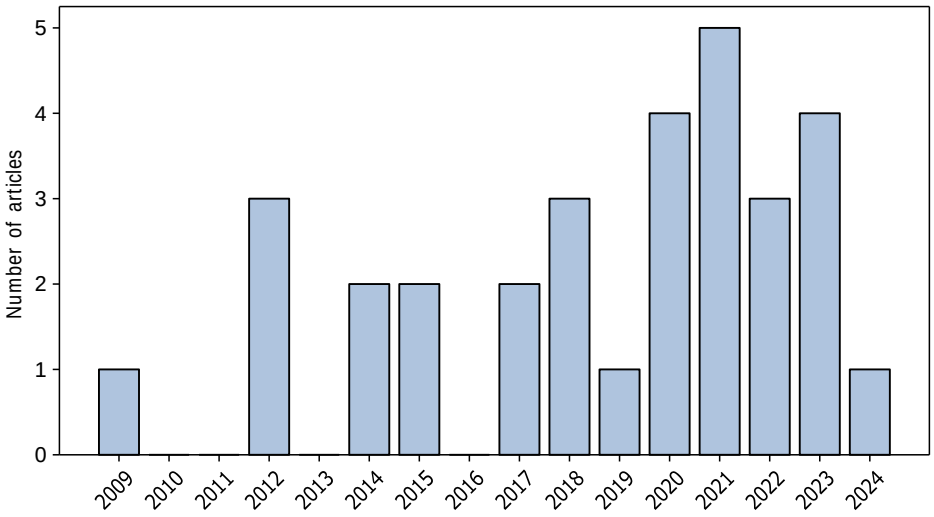

Figure 2. Timely distribution of papers

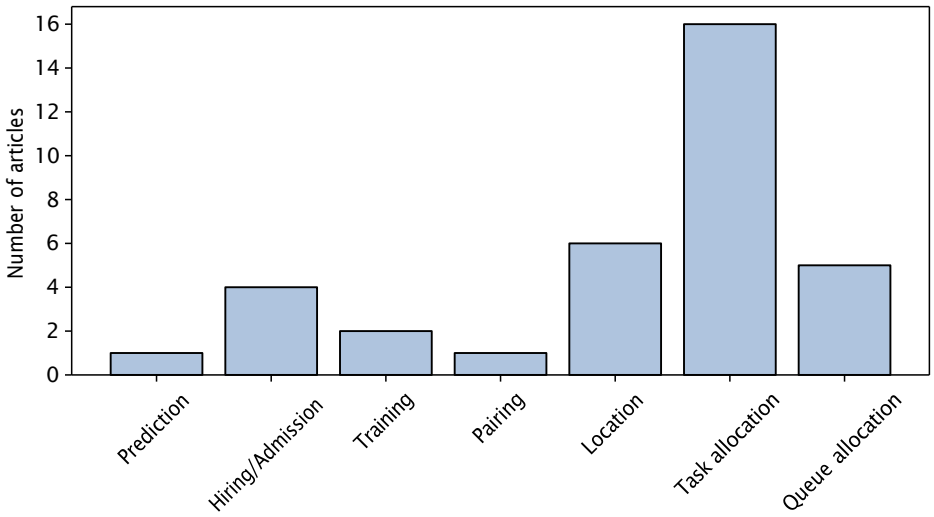

Figure 3. Emergency management decisions

The columns in "Major Decision" identify the key emergency management decisions as introduced above. The columns in section "Objective" specify the modelling objectives, which correspond to the objective functions for mathematical models and the primary evaluation metrics for other methods such as simulations. The column "Preprocessing" indicates whether the authors suggest data transformation actions. These actions can either facilitate data collection (e.g. to derive the demand at a particular location) or be necessary for the model (e.g. to calculate certain metrics). The applied methodologies are detailed in the "Methodology" section. A more extensive review of the papers follows in the next section.

RESULTS

Prediction

To manage volunteers efficiently and avoid a scenario where too many volunteers are deployed and hinder emergency response, emergency managers may first be interested in estimating the number of volunteers required. Prediction models can be useful to support this estimation. S.-Q. Chen and Bai (2023) address this problem and present an approach using machine learning models to predict the damage and derive the number of required volunteers. However, a significant limitation of this model for decision-makers is the focus on typhoons. Additionally, the model was only trained on data from the Philippines, so it is questionable to what extent this kind of model can be applied to a wider range of disasters around the world. Moreover, the authors are not very transparent about their final model parameters, limiting their article's relevance for practitioners. Despite these limitations, the approach described in the article can serve as a guideline for the development of similar prediction models for other types of disasters.

Hiring and Admission

Once the emergency managers can estimate the number of volunteers required, decisions must be made on how many and which volunteers to "hire" or to admit/reject. This problem has been addressed in several papers. At a higher level, Kebriyaii et al. (2021) present a linear optimisation model with the objective of minimising the total costs of the supply chain and casualty management. In addition to the costs of facility location, transportation and inventory, these costs also include the costs of volunteer deployment, e.g. per diem. Although this model does not exclusively focus on volunteers, but rather incorporates them in the general model, it can support emergency managers at a higher decision level.

On a more individual level, Moug et al. (2023) provide a linear mathematical model to decide which volunteers to hire for evacuating people. They propose a two-stage model in which the decision of which volunteer to hire is made before the disaster hits, while the demand for evacuation rides is only known after the disaster has hit. Thereby, the objective is to minimise the costs associated with hiring volunteers and the expected travel costs. The authors present several approaches to solve this rather general model, allowing a practical implementation in a DSS.

Rather than focusing on the cost, but instead on the time required to fulfil "orders", Urrea et al. (2019) present a model to support emergency managers in deciding whether they should allow for congestion in different ranges of supply and demand. Although the authors consider a charity warehouse belonging to a faith-based organisation in their article, we believe that the assumptions regarding volunteers can be translated to SV. Their contribution is twofold, addressing both the question of allowing for congestion and team composition. The presented approach can be useful for emergency managers to determine the optimal number of volunteers per task, especially in spatially restricted areas.

The question of whether SV willing to work should be admitted or rejected upon arrival is addressed by Zayas-Caba´n et al. (2020). The authors analyse a queuing model with the goal of minimising the holding costs for customers, which are assumed to be linearly related to the queue length, the holding costs for volunteers (e.g. costs for equipment and food), and the rejection costs for volunteers. In their model, volunteer managers first have to decide whether a volunteer is admitted. If this is the case, the volunteer is then assigned to one of the queues and can be reassigned at any time. The model is formulated as a continuous-time Markov decision process to solve these questions optimally. While this approach could be implemented in a DSS to provide the optimal answer depending on a given state, i.e. the number of volunteers and "customers" in the system, the authors are aware that in a disaster situation simple policies might be more practical. Therefore, they propose heuristic admission policies to decide whether volunteers should be admitted. While one of the policies only requires the current number of volunteers in the system, the authors also propose more advanced policies that additionally consider the expected workload.

Addressing the problem of hiring and admitting volunteers from very different angles, the presented models can support emergency managers at various levels of decision-making both before and after the disaster has hit. From a cost perspective, the model presented by Kebriyaii et al. (2021) could be integrated into financial decision support tools, as they require several financial metrics as input. In addition to financial metrics, the model presented by Moug et al. (2023) also requires information about the geographic location of potential drivers and evacuees needing a ride. To collect this information, databases of potential volunteers, people requiring help, and geographical information systems can support emergency managers in the decision process. To decide on a level of congestion based on the model presented by Urrea et al. (2019), decision-makers require up-to-date estimates of demand, availability of volunteers and current volunteers in the system, as well as average service times depending on the volunteers' skill level and pairing. Linking this model to sensor data can support the model's accuracy with respect to the real-life representation and thus improve decisions. The same applies to the model presented by Zayas-Caba´n

et al. (2020). Moreover, the heuristic policies proposed by the authors require not only data to tune the model, but also the constant monitoring of certain metrics. In addition to the number of volunteers currently in the system, the more advanced policies further require an estimate of the current workload. To keep track of these numbers, especially with multiple queues and sites, monitoring and tracking systems could assist emergency managers to continuously evaluate these metrics and adjust their policies.

Training

Acknowledging the different skills of volunteers and the possibility of training volunteers, especially when considering longer-lasting tasks such as reconstruction work, represents another potential decision point. In our review, we identified two articles addressing this aspect. In the earlier article, Lassiter, Alwahishie, et al. (2014) propose a linear optimisation model in which volunteers with different skill levels have to be assigned to different tasks requiring different skill levels. While some volunteers already have some skills, emergency managers may also decide to train volunteers to acquire new skills. This, however, limits the efficiency of volunteers during their training, affecting the tasks completed for a particular skill level and therefore the future number of tasks for a particular skill. It also influences the future availability of skilled volunteers and hence their dissatisfaction if these skills are not used. A similar approach is presented in Lassiter, Khademi, et al. (2015). While their model differs slightly in the way of how they deal with skill mismatch, the assumptions regarding training are similar.

Both papers propose a solution for emergency managers to consider the medium-term decision on volunteer training. Since both models need an estimate of the skills required for tasks over a longer horizon as well as an overview of the current skills of volunteers, applications collecting this data could support the usage of these models by providing an up-to-date database.

Teaming

Some tasks in disaster response should be carried out in teams. Surprisingly, little research has been performed on this topic. As introduced above, Urrea et al. (2019) address the question of the optimal team composition in their model for a charity warehouse. The authors differentiate between two levels of experience, "experienced" and "inexperienced", and consider various options of pairing. They show that depending on the level of congestion, demand and available volunteers, different pairing options are preferable to fulfil as many orders as possible.

This model can serve as an initial guideline for emergency managers to decide on how to form teams for specific tasks. However, it is limited to teams of two, which may be applicable for certain tasks such as order-picking but may not be a suitable team size for other tasks.

Location

When volunteers are needed at different sites, emergency managers first face the decision to locate the volunteers. A classic model for this task is presented by Pielorz and Lampert (2016). They adapt a facility location model to minimise the number of volunteers needed, with the restriction that each demand point is covered by a minimum number of volunteers reaching that location within a certain threshold. Although the model is relatively general, it allows emergency managers to analyse the influence of different parameters, such as the required number of volunteers per demand point, on the spatial distribution of volunteers. The authors then extended the case study (Pielorz, Prandtstetter, et al. 2017) and replaced the previously used "flying distance" with a more realistic "driving distance". Although this study does not provide any additions to the mathematical model itself, it gives insights into the differences in locating volunteers when different distance metrics are used.

Krstikj et al. (2021) propose a method to distribute volunteers equitably across neighbourhoods depending on an index reflecting marginalisation. They first suggest an approach to calculate a marginalisation index before presenting a heuristic approach to support the allocation of volunteers to neighbourhoods. Although their case study is based on a pandemic situation and therefore focuses particularly on elderly citizens requiring help, the model can also be adapted to other disaster situations.

A solution approach to match individual volunteers with victims is proposed in the article by Yang et al. (2020). The authors present a heuristic multi-agent reinforcement learning scheduling algorithm to minimise the total time (distance) while ensuring that at least one volunteer rescues each victim. Zhong et al. (2023) propose to use civilian vehicles for evacuation. The authors present a prototype for a constraint-based recommender system that matches volunteers with a suitable vehicle and people who need to be evacuated to a shelter based on constraints on vehicle type and experience, with the objective of minimising the total evacuation time. A similar problem is addressed by Arai et al. (2012). In the suggested approach, volunteers can propose "bids" on disabled persons to help, with the

costs of the bids depending on distance and health status. Using a linear optimisation model, the bids resulting in the minimum overall costs are then selected so that each disabled person is rescued.

The above-mentioned papers propose very different approaches for the spatial allocation of volunteers, ranging from heuristics to linear programming and reinforcement learning. To address the need of up-to-date input data, Yang et al. (2020) suggest analysing data from social media to identify the geographical locations of victims and potential volunteers. However, as regulations regarding access to data from social media platforms potentially change over time, this strategy is not entirely risk-free for emergency managers.

Task Allocation

The vast majority on studies addresses the question of how to allocate volunteers to tasks. One of the objectives in most of these models is either to maximise completed tasks (minimise the uncompleted tasks) or maximise volunteer satisfaction (minimise the dissatisfaction) (Table 1), sometimes in combination with additional objectives. To match the volunteers and the tasks, authors considered different criteria, such as the priorities set by the decision-makers, the volunteers' skills, or their preferences. In the remainder of this subsection, each criterion will be described in more detail.

Collective Level

On a collective level, Sopha and Asih (2018) present a system dynamics model that visualises the impact of allocation policies. In their model, decision-makers must decide on the ratio of volunteers to be assigned to each of the two available tasks, taking into account the dependency between the two tasks. While the model does not support individual decisions, it visualises the overall impact of different assignment policies.

For decision-makers, such a model can be particularly useful when preparing for potential disasters and evaluating different policies. For practical application, future research could therefore focus on linking such a model to databases to retrieve relevant parameters and integrate it into DSS. From an academic perspective, the model could be extended to multiple tasks and their interaction to consider more complex relationships between the tasks.

General Models

Most models aim to support assignments at an individual level. A relatively broad model that addresses this issue is presented by Garcia et al. (2018). The model's objective is to maximise the benefit of allocating resources to tasks (primarily, but not only, volunteers), while also accounting for conflicts and dependencies between different resources. To adapt the model to more specific cases, the authors propose additional constraints, including maximum time limits for volunteers, the allocation of consumable resources, the combination of volunteers with other resources and the inclusion of transport costs.

Rather than maximising the benefit, Falasca, Zobel, and Fetter (2009) present an approach to optimise the allocation of volunteers to tasks by balancing shortage costs due to unfulfilled tasks and deviations from volunteers' preferences and skills with respect to different availability of volunteers and the costs associated with volunteers, e.g. per diem allowances. The model is then extended by Falasca and Zobel (2012) to also account for different group sizes.

Another model that aims to minimise penalty costs caused by a shortage of volunteers as well as deviations from preferences and skills is presented by Aman et al. (2012). Yet, the authors acknowledge that volunteers can be a scarce resource, resulting in an infeasible model. To prevent such a scenario, the authors therefore suggest first solving a model that minimises the volunteers' scarcity before solving the actual model.

These models provide decision-makers with relatively general models for allocating volunteers to tasks, covering the most important aspects. However, even for these models, several parameters need to be known in advance, such as the estimated tasks, the volunteers' preferences, and their skills. In a chaotic disaster situation, it is questionable to what extent these parameters can be estimated or how they could be collected, especially if volunteers arrive continuously. Future research could therefore focus on developing robust practical applications for data collection and optimisation that can be used in disaster situations. To account for the dynamic changes in both tasks and volunteers, another stream of research could focus on developing heuristics and policies that can be applied when tasks and volunteers arrive randomly over time.

Priorities by Decision-Makers

In the aftermath of a disaster, tasks may vary not only in their subjective attractiveness to volunteers, but also in their priority for emergency managers. A model that incorporates these priorities is presented by Rauchecker and Schryen (2018). To ensure that each task is fulfilled at least to a certain extent, the model balances the workload across the tasks by maximising the weighted minimum workload. Moreover, the authors also include constraints to enforce volunteers to work on a single task for a minimum amount of time with respect to their skills and timely availability to avoid chaotic situations and inefficiencies resulting from set-up times.

A strong focus on the different priorities of various tasks is also evident in the model of Sperling and Schryen (2022). Distinguishing between strong and weak priorities, their model aims to assign as many volunteers as necessary to strongly prioritised tasks, while balancing volunteers for weakly prioritised tasks based on quotas. In addition to the time availability and skills, the authors also limit the allocation to non-preemptive schedules.

A model with a special focus on emergency departments is presented by Rabiei et al. (2023). The authors estimate the importance of volunteers' unmet needs and the degree of unsatisfied preferences by proposing a fuzzy interference system. These two metrics are then minimised in a linear mathematical model constrained by the maximum assignment of each volunteer to a single task. To account for the multi-objectivity, the authors present two evolutionary algorithms.

Balancing volunteer allocation between tasks of varying importance can pose a challenge for decision-makers. The models presented above provide different approaches to address this problem. For the practical implementation of these models, several research directions are possible. One potential direction could be the generalisation of these models, as all the authors acknowledge that their model is only tuned for a specific disaster type. Moreover, future research could also put emphasis on the relationship between tasks (e.g. predecessor relationships), or the change in importance over time.

Skills

While most models assume that skills are a fixed parameter, some authors also consider the possibility of training volunteers "on the job". Two models incorporating this option are by Lassiter, Alwahishie, et al. (2014) and Lassiter, Khademi, et al. (2015). As introduced above, both articles present an approach in which volunteers are assigned to tasks according to their skills, but also have the opportunity to acquire new skills through training. While those two models do not really differ in the approach with respect to the training aspect (as discussed above), a significant difference is the mismatch of volunteers' skills and tasks. Lassiter, Alwahishie, et al. (2014) allow for a certain percentage of mismatches, i.e. volunteers are assigned to tasks below their skill level as determined by the emergency manager. On the other hand, Lassiter, Khademi, et al. (2015) do not restrict mismatching by a threshold but assume that the probability of a volunteer leaving depends on the mismatch of skills and thus influences the availability of future volunteers. Moreover, they also associate costs with the mismatch, and include these in the objective function.

To account for the dissatisfaction arising from the mismatch of qualification, Alwahishie and Taaffe (2014) model the problem using agent-based simulation. Their main assumption is that volunteers abandon earlier when dissatisfied, with dissatisfaction arising from both idle time and mismatch of qualification. While the presented agent-based simulation does not suggest an optimal policy, it supports the comparison of different policies with respect to the volunteers' satisfaction and task completion.

By considering the volunteers' skills, decision-makers can increase not only the efficiency, but also the volunteers' satisfaction. While this approach may seem promising in theory, as discussed above, keeping track of the different qualifications and preferences of all volunteers could pose a problem in the aftermath of a disaster. In addition to the research directions already mentioned in the corresponding subsection, future research could also focus on extending the existing models by including bilateral preferences (as introduced in the next paragraphs), e.g. to also consider the preferences of decision-makers for both volunteers performing a task and volunteers being trained.

Bilateral Preferences

Not only volunteers can have preferences regarding tasks, but also decision-makers regarding the volunteers carrying out these tasks. S.-Q. Chen, Wang, et al. (2021) and S.-Q. Chen, Zhang, et al. (2021) address this problem and present a two-sided matching model, in which not only volunteers can place their preferences for different tasks, but also task leaders can indicate their preferences for different volunteer teams. The problem is further extended by considering that volunteers/task leaders may have strong preferences for or aversions to certain tasks/volunteer groups but may not have a preference (positive or negative) for most of the tasks/volunteer groups. To account for the uncertainty that this problem entails, the authors propose an evidential reasoning approach.

The concept of bilateral preferences is also addressed by L.-T. Chen and S.-Q. Chen (2022). In contrast to S.-Q. Chen, Wang, et al. (2021), however, the authors consider individual volunteers (instead of teams) and allow several volunteers to perform several tasks. The optimal allocation is then determined based on a linear optimisation model with the bilateral satisfaction as input.

To collect the preferences of volunteers and their suitability for tasks, emergency managers may use linguistic questionnaires. Xue et al. (2024) therefore propose a method to derive a matrix representing perceived satisfaction. Using this matrix as input, the authors present an algorithm based on foreground theory, differential evolutionary algorithms, and Dempster-Shafer theory to match volunteers to tasks.

The concept of two-sided matching is also included in Schmidt and Albert (2022). However, the suggested approach is unique in that volunteers are offered a list from which they can select a task, rather than assigning them to a task. The authors further extend the model to be also applicable in a multi-epoch setting, and to include individual acceptance probabilities, resulting in customised task recommendations.

For the practical application of the proposed approaches, time might be a relevant factor. Volunteers and decision-makers might be willing to define a few preferences but might be discouraged from filling in long questionnaires. Therefore, future research could focus on predicting preferences based on minimal input from users. Moreover, in addition to preferences for certain tasks, volunteers may also have preferences for collaboration with other volunteers or for certain spatial areas. Including these aspects could increase the volunteers' satisfaction, and thereby, decrease the chance of volunteers abandoning.

Allocation to Queues

Closely related to the allocation of volunteers to tasks is the allocation of volunteers to queues. In these models, queues can either represent counters serving people (disaster-affected people or donors), or assembly lines representing different tasks. The focus of these models is mainly on uncertainty on both sides, on demand, i.e. the arrival of tasks, and on the arrival and abandonment of volunteers. With the exception of the model proposed by Abualkhair et al. (2020), all authors formulate the problem as a continuous time Markov decision process. However, the authors acknowledge the limitations in a chaotic disaster environment, and thus propose practical heuristic policies.

Mayorga et al. (2017) present a problem in which the number of different tasks is fixed and deterministic, while the arrival and abandonment of volunteers and the service rates are stochastic. Each of the different queues is thereby characterised by the number of tasks, the service rate and the maximum number of volunteers that can be allocated to this queue. This problem is then generalised by Paret et al. (2021) to a stochastic arrival of tasks following a Poisson process with rate α_i.

As already introduced above, Zayas-Caba´n et al. (2020) analyse policies for admitting volunteers to a system, and once admitted, assigning, and reassigning them to different queues. These queues differ both in their service time and in their urgency, approximated with holding costs. While several policies are proposed for the decision to admit volunteers, the authors can prove that even for different settings, such as volunteers arriving in batches or working collaboratively on a task, a simply $c\mu$ policy leads to an optimal solution.

The question of how to allocate volunteers to sort donated goods is addressed by Ozen and Krishnamurthy (2020). The authors consider solicited and unsolicited donations, assuming that solicited donations contain only high-priority goods, while unsolicited donation contain a some high-priority goods but also non-priority goods. They aim to support emergency managers in deciding how to allocate a limited number of volunteers to those two queues in order to maximise the throughput of high-priority goods while preventing congestion from unsorted, unsolicited goods.

Another problem related to donations is presented in Abualkhair et al. (2020). The authors model two different queues, one for accepting donations and one for distributing them to beneficiaries. In the scenario where inventories are scarce, the queue of beneficiaries not only depends on the number of volunteers allocated, but also the goods received from donors (and therefore the other queue). The authors then propose a practical solution by suggesting four different heuristic allocation policies.

The models presented can help practitioners to decide on how the allocation of volunteers to queues. In disaster planning, simulating the queues and analysing the consequences of different policies can improve the disaster response. However, this requires a good estimation of parameters such as the arrival or service rates. In the aftermath of a disaster, the practical (heuristic) policies provide a fast decision support. Yet, depending on these policies, different data is required to describe the current state is required. In a chaotic environment, monitoring and tracking systems could support this collection.

FUTURE RESEARCH

As research on the management of volunteers in disaster situations has only been published in recent years, future research can advance all decision problems by extending existing approaches as well as developing new ones.

To the best of our knowledge, there is only one article by S.-Q. Chen and Bai (2023) that addresses the prediction of available volunteers. This leaves room for further research. In addition to extending this model to other disaster types and areas, future research could therefore focus on a more general prediction model that is applicable to multiple disaster types. Another stream of research could shift the focus from the damage to the specific volunteer tasks. S.-Q. Chen and Bai (2023) acknowledged the relationship between the number of volunteers required and the damage caused by the disaster but had to simplify this ratio due to a lack of theoretical background. Future research could therefore focus on the expected number of different tasks depending on the damage and derivation of the number of volunteers required.

There are multiple research directions to further investigate the hiring and admission of volunteers. One potential future direction would be the short-term costs and medium- and long-term effects of rejecting volunteers. While Zayas-Caba´n et al. (2020) consider "rejection costs" in their model to account for the negative consequences of not admitting a volunteer, future research could place more emphasis on the impact of future volunteer availability. In Kebriyaii et al. (2021) and Moug et al. (2023), this effect could be included by also considering the costs if volunteers are not used, while in Urrea et al. (2019) and Zayas-Caba´n et al. (2020), the future arrival rates may depend on the rejection rates. Moreover, future studies could also extend the presented models by including heterogeneous characteristics of volunteers such as experience, skill, or other personal attributes in the decision on how many and which volunteers should be admitted.

A potential future research direction for volunteer training would be the consideration of different, non-hierarchical skills. Volunteers may be highly skilled in one area but lack skills in another. This could result in a volunteer assigned to a task having various levels of satisfaction and efficiency depending on the nature of the task and the skills required. Another future area of research could be the preferences of volunteers in terms of acquiring different skills. In the medium term in particular, the provision of training in the skills favoured by volunteers could have an impact on volunteer satisfaction and therefore on the future availability of these trained volunteers.

Future research on teaming could extend the model by Urrea et al. (2019) to larger team-sizes and more pronounced experience levels. Another potential research direction could also focus on the medium and long-term consequences of pairing. Inexperienced volunteers could benefit from being paired with an experienced volunteer and become an experienced volunteer more quickly than if they were paired with an inexperienced member or vice versa. In the early days, emergency managers may therefore opt for non-optimal pairing strategies in the short-term, allowing them to increase the proportion of experienced volunteers in the medium and long term. For SV, this can be the case a few days or weeks after the disaster.

Several options are available for further research on location planning. First, the model presented by Krstikj et al. (2021) could be extended to more general disaster situations to provide emergency managers with a toolbox for different benchmarks to measure a neighbourhood's marginalisation. Moreover, another research stream could also focus on spatial allocation when tasks differ. Future models could also consider scenarios in which volunteers can easily transfer between locations, but at the costs of time lost for travelling, and scenarios in which this is not possible if the distances between different locations exceeds a certain threshold, thus extending the models presented by Pielorz and Lampert (2016) and Pielorz, Prandtstetter, et al. (2017). To account for the dynamic nature of disasters, future research could apply the approaches by Yang et al. (2020), Zhong et al. (2023) and Arai et al. (2012) to dynamic situations, where the availability of drivers, the need for evacuation and the accessible routes are constantly changing over time. This also raises the question of accurate data collection during a disaster. While some data could be collected in advance, as in Zhong et al. (2023), a relevant part of the data can only be collected once the disaster has hit. To use the proposed approaches efficiently, future research should therefore focus on the collection and integration of this data during a disaster.

With the large variety of models for task allocation, decision-makers have an extensive choice for the combination of different objectives and parameters included. Although most authors approached this question in a relatively similar way using linear programming with the objective of maximising (minimising) the (un)fulfilled tasks or maximising (minimising) the volunteers' (dis)satisfaction (Table 1), the models vary in their focus and emphasis different criteria. While there are still future directions to extend these models from a theoretical perspective, it is questionable whether these extensions would add significant practical value. Therefore, instead of extending existing models, future research could focus on tackling the problems with techniques other than linear programming that account for dynamic environments and also provide solutions for larger instances in a short time.

Some authors have already addressed the managerial implication e.g. by extending their model as in Sperling and Schryen (2022). Answering the question of how to obtain the input data, particularly regarding the volunteers' skills, preferences, and time availability, as presented in Xue et al. (2024), could also simplify the integration of models into real applications. Another approach that could enhance practicality is to give volunteers some degree of choice, as in Schmidt and Albert (2022). To bridge the gap between theory and practice, future research could focus on comparing the usability and practicability of different approaches in disaster situations and proposing "best practises" for future development of DSS.

Regarding the allocation to queues, further research could include different service times based on the volunteers' skills. In particular, if the queues represent specific tasks, as in Mayorga et al. (2017) and Paret et al. (2021), the service time per volunteer may depend on skills and experience (as in Urrea et al. 2019). In addition, the (re)allocation of volunteers to queues may also include set-up times (which can also depend on skills or whether the volunteer is assigned to the queue for the first time). Furthermore, especially when dealing with people as customers as in Zayas-Caba´n et al. (2020), Ozen and Krishnamurthy (2020) or Abualkhair et al. (2020), future research could address the question of fairness between queues with different priorities and thresholds to balance urgency and equity.

CONCLUSION

In this paper we presented a structured literature review of models to support decision-makers in coordinating volunteers in a disaster's aftermath. We identified 31 articles dealing with decisions ranging from predicting the number of volunteers needed to assigning them to tasks and queues. While the literature on task allocation is relatively extensive (Table 1), there is still a lack of research, particularly in the areas of prediction, training, and teams. Moreover, a variety of articles present a deterministic model in which the number, availability, and skills of volunteers and the exact demand is known in advance. This assumption may not hold true in reality, making it difficult for emergency managers to apply these models in the real world. By integrating the two areas of OR/MS and information systems more closely, future research could focus on both the scientific contribution and practical implementation. In particular, the development of versatile models that can be applied to a variety of disaster situations could increase their practical value and facilitate their application.

ABSTRACT

Cooperation between different stakeholders plays an important role in managing crises and disasters. The software tools used must also support cooperation and the mutual exchange of information. The bidirectional exchange of information between the population and official agencies poses a particular challenge. In this paper, we present a software demonstrator for the coordination of spontaneous volunteers and its evaluation as part of an overarching research project to gain design knowledge for the development of interconnected systems in disaster management. We describe how the system demonstrator was instantiated on the basis of our existing design knowledge from technical requirements and reference architecture and show the respective interfaces for the stakeholders involved. As the main contribution of the paper, we describe the implementation of a field test to evaluate the demonstrator and present the results in terms of usability and perceived usefulness, which we obtained using a methodologically sound questionnaire.

Keywords

Volunteer Coordination, Field Test, Interconnected Systems, Population, Bidirectional Communication

INTRODUCTION

Good crisis and disaster management depends on how well different stakeholders cooperate (Grolinger et al., 2013). Due to the possible large number of stakeholders involved, there is also a large number of information and communication systems involved. These are usually specialized in storing and processing the data relevant to their user group. To ensure good cooperation, however, it is necessary for the stakeholders to share their information in order to develop a common picture of the situation and determine the best courses of action (Sakurai & Murayama, 2019). This requires systems that enable a digital exchange between stakeholders that is not based on centralized data but is organized in a decentralized manner.

The civilian population plays a special role as a stakeholder in disaster management (DM). On the one hand, they are directly exposed to the risks and consequences of a crisis or disaster scenario and are therefore dependent on comprehensive and reliable information from authorities in order to protect themselves in the best possible way.

(Nikolai et al., 2015). On the other hand, citizens themselves can also be a very extensive source of information to support official DM (Schimak et al., 2015). Bidirectional communication supports the process, as it increases the validity of the information shared, which is essential for making decisions in DM.(Moshtari & Gonçalves, 2017). Kaufhold (2021) conducted a literature review on communication needs from authorities to citizens (A2C) and citizens to authorities (C2A) in crises. The literature review revealed bidirectional communication requirements in crises, thus motivating the need for bidirectional crisis communication tools. A key benefit seen by authorities resp. emergency services workers is better situational awareness through citizen-generated content, such as situational updates, photos, videos or information on the public mood (Reuter & Spielhofer, 2017). Citizens, on the other hand, benefit from information about threats and possible damages, the duration and the area affected by a crisis as well as recommendations about how to cope with the crisis (Reuter, 2014). In general, authorities help to reduce the information deficit of the citizens in times of crises with bidirectional communication solutions (Reuter, 2014).

Studies show that DM authorities and organizations are open to using data from citizens in operations and also to providing information to citizens via bidirectional communication apps (Holzhüter et al., 2023). In the past, therefore, there have already been some research efforts in this area. One specific branch of research that has already been investigated in the past is the coordination of spontaneous or informal volunteers (Whittaker et al., 2015) using bidirectional information systems (Betke et al., 2023; Poblet, 2013). However, although there are already some approaches that address the design and implementation of such systems, e.g. (Batard et al., 2019; Fuchs-Kittowski et al., 2017; Gerstmann et al., 2019), their evaluation is difficult because the systems do not find their way into application and the exercises or experiments required for evaluation are associated with very high effort. As only a few papers have so far focused on evaluating the practical suitability of the approaches, there is a need for further research in this area. In past crises, it has been shown that the use of ad-hoc applications/platforms, such as social networks, e.g. in (Albris, 2018), has enabled spontaneous volunteers to coordinate themselves with all the associated disadvantages, such as unsolicited voluntary actions, data inaccuracies, data overload and even misleading information (Reuter et al., 2015). For better guidance of spontaneous volunteers by DM authorities and organizations for support in coordinated operations, editorial systems are needed that can address end applications, such as volunteer or warn apps. Instead of relying on centralized systems, the use and networking of ad-hoc applications seems promising to harmonize heterogeneous system landscapes and not end at artificial boundaries (federal states, countries, organizations).

In order to extend the knowledge about the practical applicability of such systems, we present the demonstration and field test-based evaluation of a related software artifact. The results of this paper are part of a larger design science research project in which we want to generate design knowledge about the development of interconnected systems in disaster and crisis management. We want to investigate, if the developed architecture, which allows for the use and networking of other ad-hoc applications, is a valid method for providing technologies for various purposes in crises. In the final step of the current research cycle, we have used the design knowledge gathered so far to develop a software demonstrator using the example of a spontaneous volunteer coordination system (SVCS). We chose the example of coordinating spontaneous volunteers (SVs) because an initial comprehensive acceptance study yielded mixed results: without having used such systems themselves, half of the experts were in favor of using such systems, while the other half were either neutral or had a negative opinion (Holzhüter et al., 2023). Taking into account established methods such as UTAUT (Venkatesh et al., 2003), we want to gain insights into the user experience of SVCS, as well as to gain general insights into the suitability of our current design knowledge, in the form of a requirements catalog and a reference architecture, for the development of practicable software. The collected feedback serves as a foundation for targeted improvements aimed at increasing acceptance in crisis situations. Our current efforts are directed towards ensuring that the systems not only provide utility and user-friendliness but also align with user expectations. With the results presented here, we want to facilitate the future development of interconnected systems and especially SVCS for scientists and practitioners, as well as to show a possibility for the methodical evaluation of corresponding systems with regard to perceived usefulness and usability. For this purpose, we want to examine two research questions in this paper:

(Research question I) *To what extent is our existing design knowledge suitable for the development of application-ready systems?*

(Research question II) *How do the two user groups disaster managers and spontaneous volunteers evaluate a special coordination software in terms of usability and usefulness under practice-oriented conditions*?

This paper is structured as follows: In Section 2, we explain our approach based on a design science research method, and then in Section 3, we describe our instantiated software demonstrator based on our previous gathered design knowledge. In section 4 we describe the experimental setup of our field test to evaluate the software demonstrator In Section 5, we present and discuss our evaluation results. Section 6 contains a brief discussion of related work, particularly in relation to the evaluation of similar software artifacts. Finally, in Section 7 we give an outlook on further research so that our proposal for a reference architecture can be implemented in practice.

RESEARCH METHODOLOGY

It is our superordinate objective to create a theorical IS artifact that helps developers, disaster response experts and researchers to create interconnected systems for DM. Designing such an artifact is a demanding task, requiring innovative approaches, particularly in domains where existing theories fall short (Hevner et al., 2004). To accomplish this goal, we have initiated a design science research (DSR) project, following Hevner et al. (2004). DSR, as defined by Iivari and Venable (2009), involves "[…] a research activity that invents or builds new, innovative artifacts for solving problems or achieving improvements […]" (Iivari & Venable, 2009). By combining scientific principles with practical relevance, we aim to provide valuable design knowledge for the development of ICT in DM (Hevner et al., 2004). Our approach, therefore is based on the design science research methodology by Peffers et al. (2007). In this section we describe how we instantiated the method of Peffers et al. (2007) as our IS research framework to structure the iterative process to design and evaluate a suitable IS addressing our research question (see Figure 1). By employing this framework, we ensure the incorporation of continuous improvement throughout the artifacts development process. As our framework starts with the identification of a problem and motivation, we follow Peffers et al.'s (2007) problem-centered approach to guide our investigation, driven by both practical and scientific demand.

	Identify Problem & Motivate	Define Objectives of a Solution	Design & Development	Demonstration	Evaluation
Instantiation of Research Steps following Peffers et al. 2007	**Method:** Survey on the need for and acceptance of information and communication systems for the exchange between disaster response officers (n = 354) and the public (n = 504). **Result:** Both user groups have a fundamental need and willingness for information exchange in different use cases using an IT system, including a system for coordinating spontaneous voluntary tasks. *(Holzhüter et al., 2023)*	**Method:** Literature analysis and expert survey (n = 49) to derive requirements for a decentralized multi-stakeholder information and communication system in disaster management **Result**: 40 requirements identified (38 functional, 2 non-functional) *(Holzhüter & Meissen, 2021)*	**Method:** Conceptual description of a solution based on the derived requirements **Result**: Service-oriented reference architecture for a decentralized multi-stakeholder information and communication system in disaster management *(Holzhüter & Meissen, 2021)* --- **Method:** Implementation of a software artifact based on the reference architecture using the example of a coordination system for spontaneous volunteers **Result:** Web-based dashboards with widgets for the integration of various situation information and a module for coordinating spontaneous volunteer work. iOS & Android app for registration, alerting and coordination of spontaneous volunteers	**Method:** Application of the software artifact (dashboard & app) in a realistic use case with both user groups **Result**: Planning and execution of a disaster response exercise for the reception of refugees with the participation of disaster management employees (n = 13) and spontaneous volunteers (n =32)	**Method:** Survey among the use case participants to evaluate the usefulness and usability of the software artifact using UTAUT-methodology (Venkatesh et al.(2003)) **Result**: Evaluation results for 22 items per user group plus comments from participants show a consistently positive perception of the software artifact.

Figure 1. Design science research methodology process model by Peffers et al. (2007)

As part of the first step, **problem identification and motivation**, we conducted a broad-based survey among the public (n = 504) and DM professionals (n = 354) to identify specific challenges in the area of information systems for information exchange. In summary, the results showed that participants from both DM and the public were overwhelmingly positive about and in favor of information exchange in various use cases (Holzhüter et al., 2023). The survey showed that there is a need on both sides to provide and receive different types of information. Interconnected systems are a promising approach for bringing together a wealth of information from different sources and processing it in a user-friendly way.

To **define the objectives of a solution**, we drew up a catalog of requirements. This is based on an extensive literature analysis and a survey of experts in the field of interconnected systems development and experience in DM (n=49). As the focus of the survey was on functional requirements, we were able to identify significantly more, resulting in 38 functional and 2 non-functional requirements (Holzhüter & Meissen, 2020). The concrete identification and consideration of the undoubtedly existing non-functional requirements represent a good approach for the processing of a further research cycle.

The **design & development** of a suitable solution consists of a general theoretical part and a use case-related

software development. We have designed and described a reference architecture as a general theoretical basis for the implementation of interconnected systems in DM (Holzhüter & Meissen, 2020). This shows how stakeholders with different applications and technical requirements can exchange information with the help of a decentralized information exchange adapter.

Up to this point the results were generated in previous papers, all following steps are the core contributions of this paper. To further concretize the solution approach, we have developed a software demonstrator considering the requirements and reference architecture. As our acceptance study showed that users are generally positive about a SV coordination system, but that there is also a lot of skepticism, we decided to develop a software demonstrator in this problem area to investigate user acceptance of a specific system. The resulting demonstrator is SVCS, consisting of an iOS & Android app for the registration and alerting of SVs, as well as a web-based dashboard for the creation and monitoring of SV missions. The system is described further in the following chapter.

For the **demonstration**, we carried out a disaster response exercise in a medium-sized German city (approx. 99,500 inhabitants) with the participation of SVs (n = 32) and local DM staff (n = 12). In the exercise context of a mass arrival of refugees, both groups of participants used their respective subsystems of the VCS to manage and process multiple missions. The exercise demonstrated that the processes and tasks in the application area can be supported by an appropriate system.

The **evaluation** was carried out in connection with the demonstration. The exercise participants were asked afterwards to complete a questionnaire on their experience of using and perceived usefulness of the VCS used. The questionnaire was methodologically based on the UTAUT model by Venkatesh et al. (2003). UTAUT, as one of the most common methods for evaluating software artifacts, takes into account other approaches such as the Technology Acceptance Model (TAM), the Theory of Reasoned Action (TRA) and the Theory of Planned Behaviour (TDB). Hence, it offers a comprehensive perspective on the various factors that influence the acceptance and use of technology. The items surveyed by UTAUT are familiar to many scientists and increase the comprehensibility and comparability of the evaluation results in this paper. The results showed a high acceptance of both user groups when using the system. A detailed description of the demonstration and evaluation results can be found in sections 4 & 5.

INSTANTIATION OF THE SOFTWARE DEMONSTRATOR

The objective of the solution is derived from a reference architecture, which was created on the basis of a requirements analysis (Holzhüter & Meissen, 2020). The requirements were derived from a user survey and existing solutions (Holzhüter et al., 2023) in a larger acceptance study. For this purpose, various use cases were created that can better involve the population in disasters. The use cases include the feedback of warning messages (work in progress), the inclusion of data from the population, e.g. private weather stations (Holzhüter et al., 2021) the coordination of SVs (evaluation in this paper) and a feedback function for the population in the warning process (not part of the paper).

The demonstrator focused mainly on interfaces and, for the demonstration in the research project, on visualization using dashboards and widgets for data visualization. In addition, a volunteer component was added to the KatRetter app and a feedback function was added to the KatWarn app as value-added services. The KatRetter app, with the actual aim of coordinating first responders for cardiological emergencies, was extended by an independent KatHelfer component. The KatHelfer component is a value-added service that takes over the coordination of SVs. The following requirements in Table 1 from the reference architecture (Holzhüter & Meissen, 2020) were implemented as described.

Table 1. Mapping of requirements to developed services

ID	Requirement	Description	Realization in the demonstrator
R01	Authentication	Authentication should be state-of-the-art and support multiple authentication methods.	State of the art Authentification-Service implemented.
R02	Multi-client capability	The system must be multi-client capable. It must be possible to configure role-based data display and transfer.	A roles and rights model has been created. This allows different roles to have different views of widgets, for example to create assignments or approve assignments as a decision-maker.

ID	Requirement	Description	Realization in the demonstrator
R03	Filter option	Filter options should be offered; the focus should be on the relevant data.	Data can be freely filtered. When configuring the widgets, filters can be applied to certain regions, certain radiuses, certain deviation criteria or even certain alerts, for example, to create the optimum focus for the user.
R04	Validation of information	A transaction check is to take place. The data must be unchangeable and usable in court.	"Deviation criteria" have been developed for various widgets so that "incorrect" data does not distort calculations. Correct information is to be validated using a blockchain, which is still in the concept phase.
R05	Data exchange	Data should be usable not only in the event of a crisis but also during normal operation to generate synergy effects.	Some data is stored in a local database as an OLAP cube to efficiently access data outside of events, for example for follow-up. To improve data exchange, care was taken to ensure data anonymity when designing the interfaces so that no additional data protection requirements had to be implemented.
R06	Event orientation	It should also be possible to view the data under less-than-optimal conditions, for example when information systems have failed. The system must act event oriented.	The high level of interface orientation means that other connected systems can continue to operate in the event of system failures. In addition, work can continue the existing "old data" until the interface is available again. The user is visually informed when data falls out of the update rhythm.
R07	Data actuality	The system should be able to update information automatically.	The interval at which data should be updated can be set in the dashboard.
R08	System boundary	The system should also be applicable in federal states.	The system design knows no municipal or national borders.
R09	Automation	The system should be fully automated and should not require manual operations.	No further input is required for widgets created by the user.
R10	Prioritization of data transmission	The system must offer the possibility to prioritize certain transactions to certain participants.	Implemented by an ETL service.
R11	Geoinformation system	The system must offer the possibility to transfer data from geographic information systems.	Map service is implemented and can be used as a form of visualization for most widgets.
R12	Interfaces	Standards like OGC (Open Geospatial Consortium), STANAG (NATO contracting parties' Standardization Agreement) should be usable. The exchange format should be easy to design. The interface should be compatible with as many media as possible in terms of hardware and software. The data network should be uniform, and services usable across systems. It should also be possible to establish permanent connections to check availability.	Standardized interfaces were implemented. The requirements have been fully implemented. Interfaces can also be used by other value-added services so that the application can be used not only with the KatRetter or KatWarn apps. However, the app developers are responsible for implementing the interfaces on their side.
R13	Control over connections	The system must be able to give the user full control over the data connections.	Is controlled via the rights and roles system.

ID	Requirement	Description	Realization in the demonstrator
R14	Use of own software, transformation of data	The system must be able to transform data so that users can use their own systems.	Not implemented in the use case. In this case, the company's own dashboard was developed. As part of SPELL, data is also to be made usable in third-party software via interfaces.
R15	Data visualization	The system must be able to prepare data in such a way that it can be displayed within the system if the data is not transferred to another system by the user.	Dashboard with widgets was implemented for this use case.
R16	Central storage of information	The system must also be able to store data centrally so that the user can analyze them even without his own software.	Backend of the dashboard holds the data in OLAP cubes.
R17	Trusted connections	The system must be able to easily establish communication connections to other users.	This use case has been implemented. Additional portals from private weather stations can be easily integrated, as well as additional value-added services such as apps for warning messages or the coordination of SVs.
R18	Digital data transfer	The system must be able to support many different formats and interfaces so that data can be transmitted digitally.	This was the focus of the implementation, so that there were no media disruptions.
R19	Real-time transmission	The system must be able to transmit data in near real-time (e.g. video streams)	This was not necessary for the application.
R20	Filter options	See R03	See R03
R21	Interfaces	The system must be able to create, adapt or delete interfaces	See R12
R22	Decentralized system architecture	The system must be decentralized to increase the availability of information.	The system is designed to be decentralized. The aim is for each user to use their own system, as shown in Figure 2, or to use the dashboard with their own local storage. This means that the architecture is not dependent on any central data or systems.
R23	Open-Source	The system must be open source so that other providers can make extensions (including interfaces, value-added services) quickly available. In addition, a reference architecture should make it possible for different service providers to develop the system.	During system development, care was taken to ensure that free libraries were used.
R24	Validation of information	See R04	See R04

From the continuous evaluation of user feedback and results from previous surveys, on which the requirements analysis is based, and a consideration of the advantages and disadvantages of various architectural models, the following non-functional requirements emerged. When introducing applications, not only the non-functional requirements of end users (such as reliability, user-friendliness, simplicity, intuitive operations, understandability) must be satisfied, but also those of administrators (such as scalability, traceability, interfaces, innovative capability, maintenance) or management (such as it-security, data security and privacy, auditability, costs). These were also evaluated by stakeholders as part of the reference architecture (Holzhüter & Meissen, 2020).

Figure 2 shows the reference architecture from (Holzhüter & Meissen, 2020). The grayed-out areas are the components that were not implemented. For the demonstrator, the part in which the data was processed via the web browser was implemented. In addition, the reference architecture was extended by the stakeholders for value-added services.

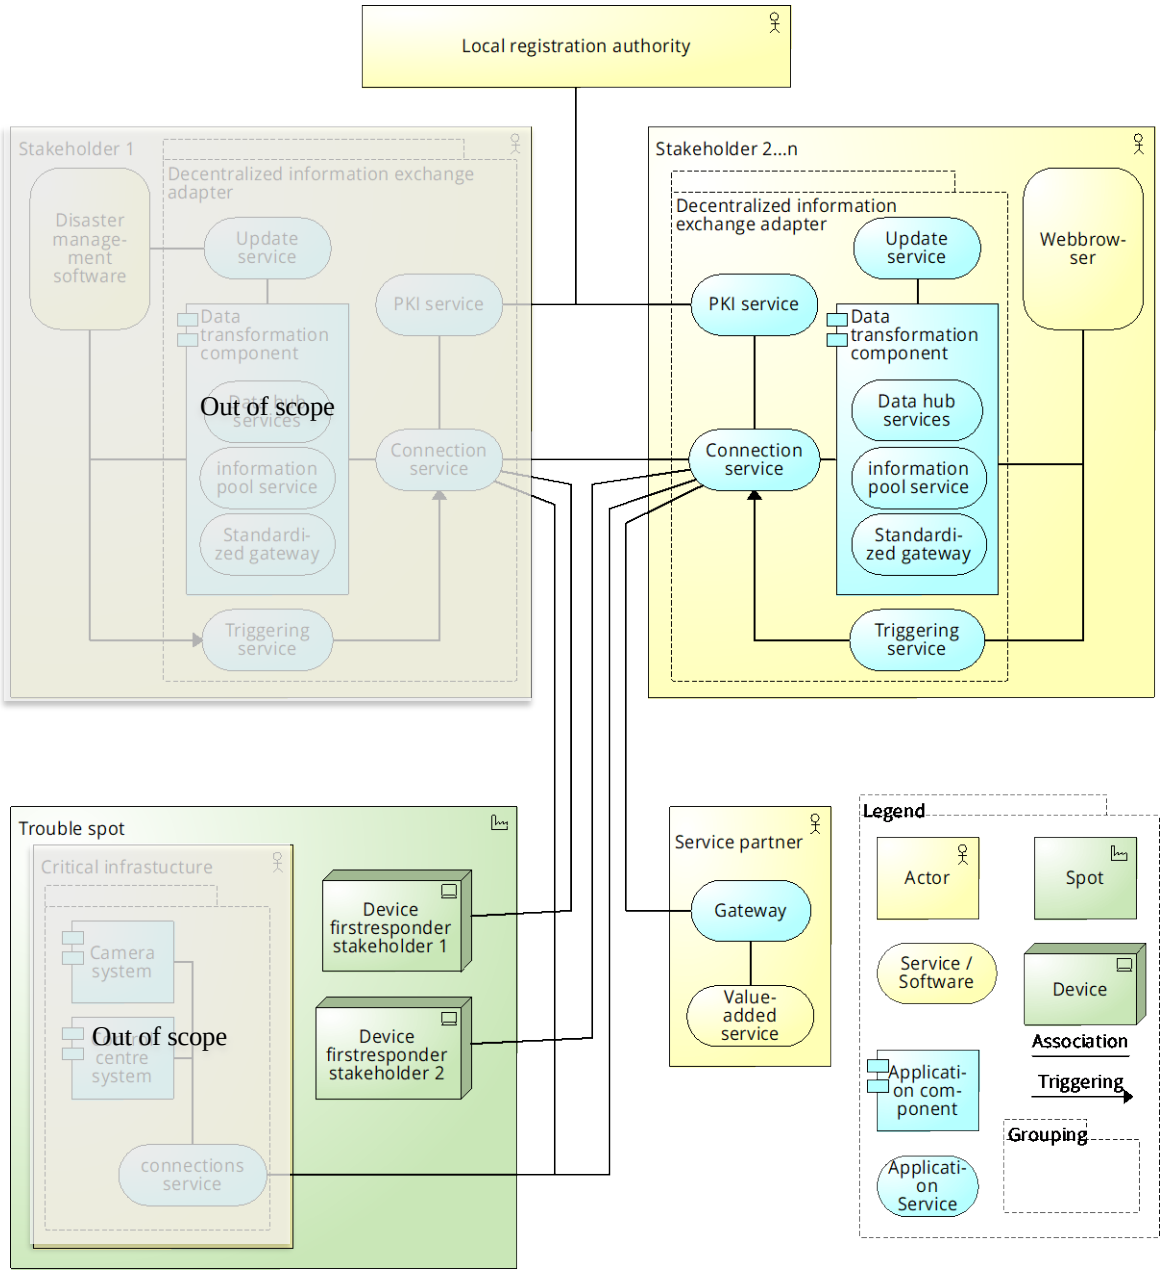

Figure 2. Adapter for decentralized information exchange with value-added services

The components for displaying information were developed in the form of an easy-to-configure dashboard with widgets (see Figure 3). On the left side, new dashboards can be created to have different views for various situations, for example. Each user can create their own dashboards and customize the widgets in the grid differently. This allows most widgets to be displayed as statistics, key figures, maps, or even heatmaps.

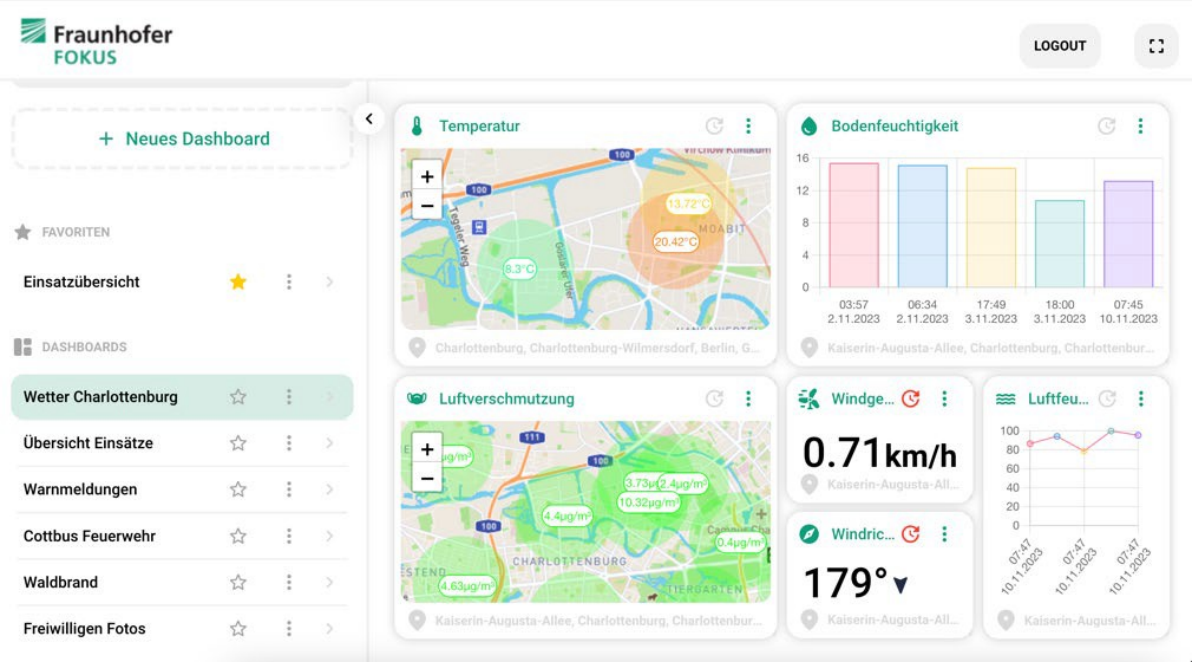

Figure 3. Example of a configured dashboard with widgets for displaying weather data from private weather stations

Figure 4 shows the implementation for displaying the evaluation of warning messages (not the use case of this paper). This shows that the demonstrator also works for other applications of bidirectional communication. In this scenario, the user is presented with information pertaining to an alert notification within a specified area. The user receives an overview, including the number of users who received the alert in the designated area, the quantity of individuals who provided feedback on the alert, and the timeframe during which the feedback was received. This feature will not be discussed further because it was not part of the exercise.

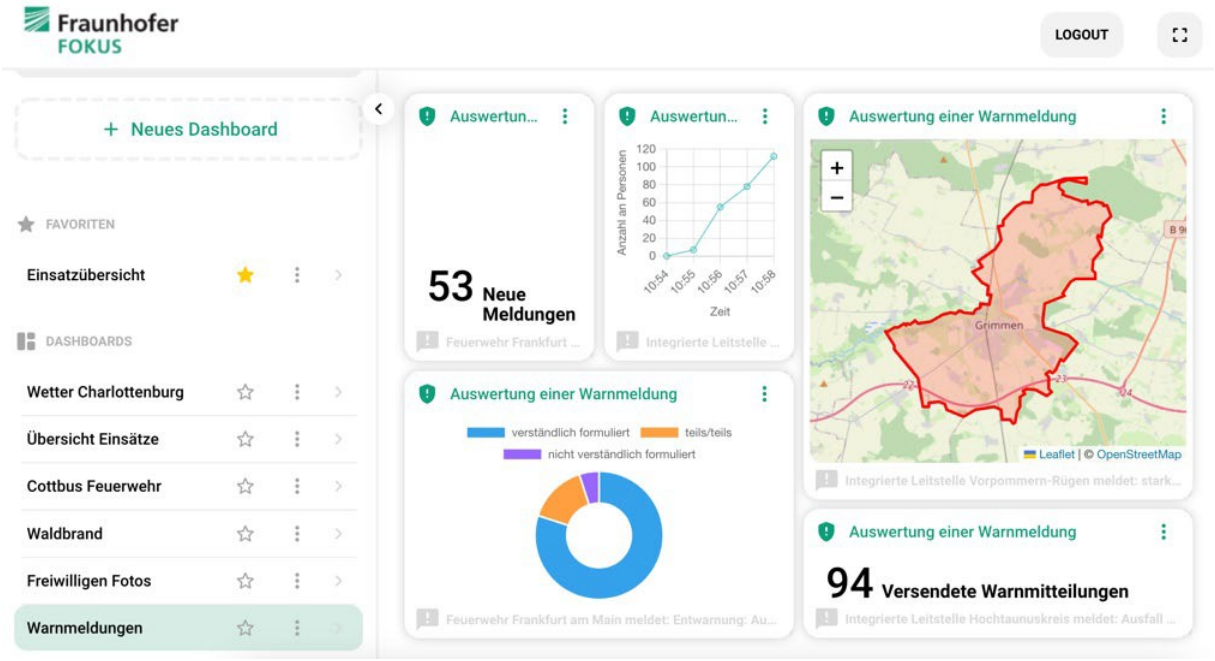

Figure 4. Example of a configured dashboard with widgets for evaluating feedback from alerts

Value-added services, as used in this exercise, represent additional services that cannot be mapped in the adapter. The KatHelfer component designates/ allocates tasks to the right registered volunteers. The component can use the KatRetter app for this, but other services for SVs can also be used. The adapter for decentralized information exchange handles communication with the KatHelfer component. The dashboard is used to create deployments. Figure 5 shows the option of creating assignments for SVs in the dashboard. Specify when the operation starts and ends, what type of operation it is (this becomes crucial for the app settings in Figure 7), what the operation

should be named, provide a description of the operation, indicate the number of SVs needed, specify the meeting point, and identify the geographical area in which the operation is located.

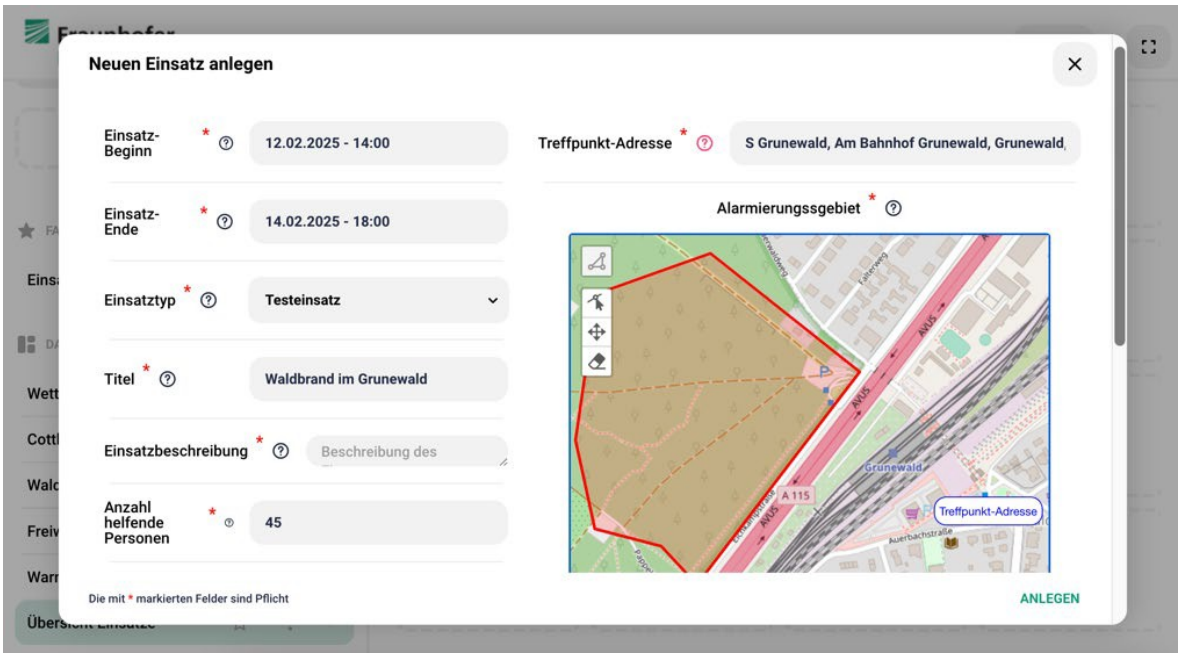

Figure 5. Example of creating an operation in the dashboard

Once the assignment has been created in the dashboard, the assignments are displayed in an overview (see Figure 6). A description, the status and the number of activated volunteers is displayed. The assignment can also be ended via a shortcut.

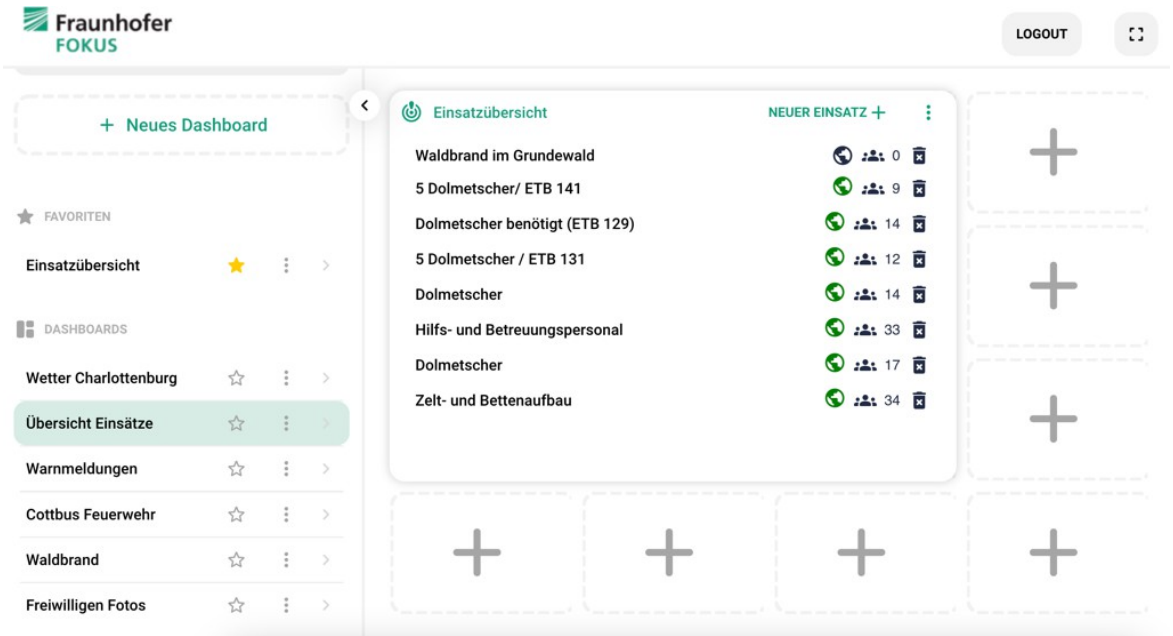

Figure 6. Overview of operations

Value-added services, as used in this exercise, represent additional services that cannot be mapped in the adapter. The adapter for decentralized information exchange handles communication with the KatHelfer component. The dashboard is used to create missions.

To utilize the KatHelfer component within the app, users must configure certain settings, as illustrated in Figure 7. This enables users to specify their availability as a volunteer (named “Mithelfer” in the picture on the left) during disasters. Subsequently, users can select the types of missions for which they wish to receive notifications (in the picture on the right), such as those related to catering support or missions requiring more physical

involvement.

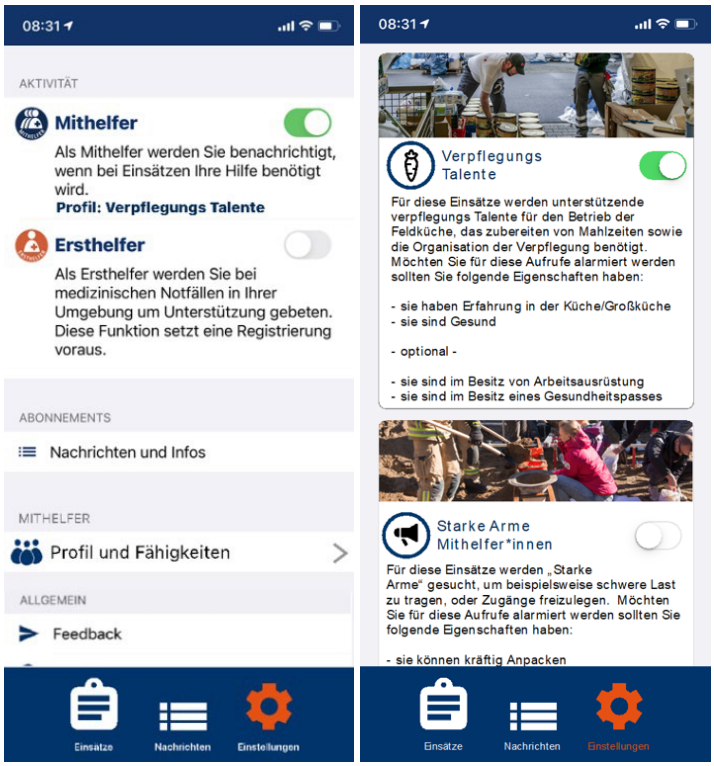

Figure 7. Settings

If volunteer assistance is needed, an operation is created and sent to volunteers, as depicted in the dashboard above. Volunteers can now view the operation details, as shown in Figure 8 (on the left side). Users can review the operation details and decide whether they wish to support the operation (as shown in the middle image). If they opt to do so, they can proceed to the operation site, confirm their on-site presence, or choose to cancel their participation in the operation (as shown in the image on the right).

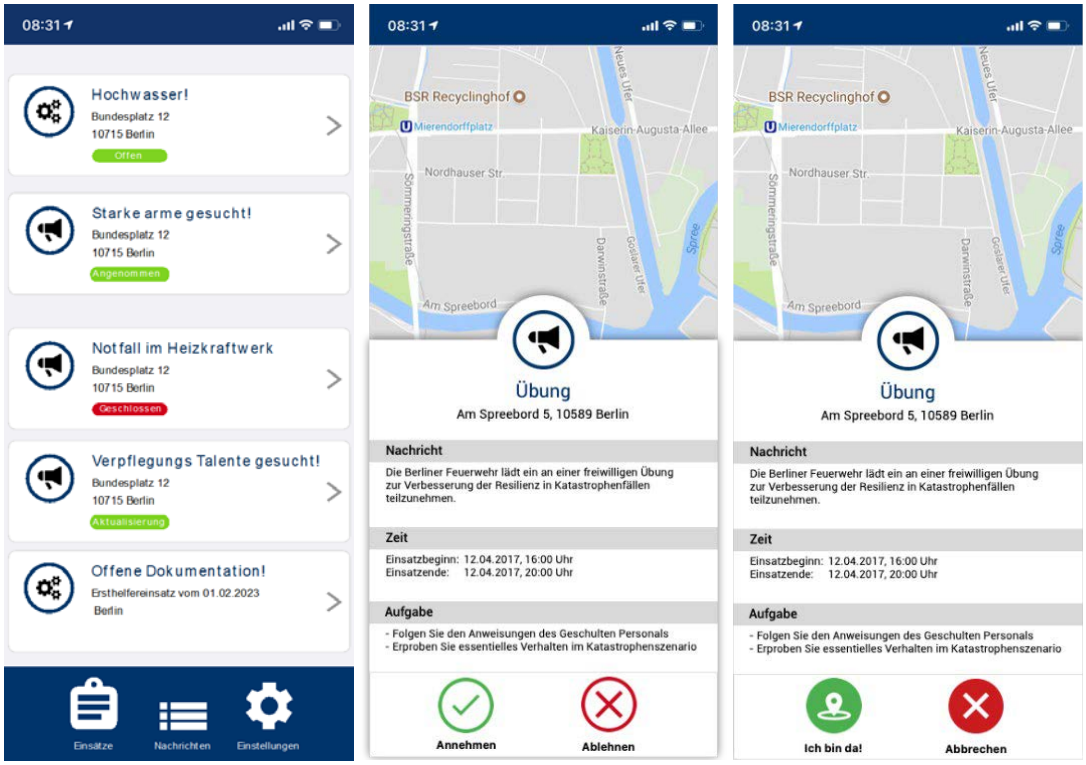

Figure 8. Mission Screens (Mission List, Accept/Decline Mission, Arrived/Mission Aborted).

The acceptance study (Holzhüter et al., 2023) revealed that there is a desire for technological support for spontaneous interventions by voluntary volunteers from both the general population and emergency response forces. However, a crucial aspect is the need for coordination of SVs. To address this, a tool has now been provided to both stakeholders, which needs to be evaluated in use before it can be employed in actual operations.

With the development and presentation of the SVCS in this chapter, we can make initial statements regarding our first research question: We have shown that it is possible to instantiate a software based on our current design knowledge using a concrete application domain. We have shown how the technical requirements can be addressed and how the reference architecture is used, thus providing starting points for the instantiation of further systems. In the following chapter, we show how we demonstrate the suitability of the software for the application and how we have set up the evaluation to answer the research question II.

FIELD TEST & QUESTIONNAIRE DESIGN

For demonstration and evaluation of our solution we conducted a disaster response exercise with both user groups. The exercise was set in Cottbus, a middle-sized city (99.500 residents) in Germany. Aim of the exercise was testing the capabilities of the city's rapid intervention unit and evaluation of the KatHelfer component. A new organizational aspect of this exercise was the involvement of SVs. The exercise was based on a scenario where a large group of refugees arrived from Ukraine. The DM was expected to set up care facilities for the refugees, provide them with medical care and food, register them and look after them until their onward journey, as well as coordinate that journey. Thus, various tasks needed to be completed in order to manage the situation. These tasks included setting up tents and camp beds, providing language mediation for Russian, Ukrainian, Polish and English at various locations, setting up a supportive IT structure and offering nursing and non-acute medical care for the refugees. The tasks were to be accomplished with the help of SVs from the civil population. Throughout the course of the exercise, it was therefore necessary to register, activate and coordinate SVs via the KatHelfer component to manage the situation.

The members of the rapid invention unit served as the coordinating disaster managers (n = 13) while the SVs were people who had already been active as volunteers in previous disaster situations (n = 32). The disaster managers had an average age of 36 years, with a range of 17-61 years. 5 identified as male, 3 as female, 5 did not specify their gender. The majority had a German high school diploma or a comparable qualification. The SVs were on average 44 years old; the youngest participant was 20 years old and the oldest 65 years old. 14 of them were male, 8 female, 10 did not specify. 61% of the volunteers have a German high school diploma or comparable. The exercise began at 9 a.m. with the alert that 600 refugees, in various states of health, would arrive at 10 a.m. in Cottbus and ended at 12 p.m., with the dismantling and the announcement via the KatHelfer component that the exercise was now over. At 12:45 p.m., the units were then moved back to their original locations. Afterwards, the exercise was evaluated with the help of our questionnaire. In addition, short interviews were conducted with some of those involved and observations were made and noted during the exercise, both in DM and on site.

The aim of the evaluation was to gain insights into the perceived usefulness and user-friendliness of the KatHelfer system demonstrator for both user groups (SVs, disaster managers). For this reason, we based the questionnaire on items and constructs from the established UTAUT (Unified Theory of Acceptance and Use of Technology) (Venkatesh et al., 2003). One problem with using the UTAUT, however, is that not all items fit the context of our specific application. For example, the item "If I use the system, I will increase my chances of getting a raise" was not applicable to our scenario since the dashboard and app are not intended to provide an economical benefit for the users. For the same reason of transferability to our specific scenario the item groups that measure the factors "social influence" and "facilitating conditions" were not used, as well as the two items, "It scares me to think that I could lose a lot of information using the system by hitting the wrong key" and "I could complete a job task using the system if I had just the built-in help facility for assistance". In the end, we were left with 14 items of the UTAUT, measuring Performance Expectancy, Attitude towards using technology, effort expectancy, self-efficacy, anxiety, and behavioral intent. To gain further information on how our design is perceived and about user satisfaction, we additionally added 8 items from a questionnaire from (Sindhuja & Dastidar, 2009), which is derived by the Purdue Usability Testing Questionnaire (PUTQ) by (Lin et al., 1997). In conclusion our questionnaire contained 22 items, measuring user acceptance of our dashboard and app with main emphasis on usefulness and ease of use/design. We translated these items to German and developed two versions, one for the members of the rapid intervention unit to rate the dashboard and one for the SVs to rate their experiences with the app. In addition, we added demographical items about age, gender, level of education and profession, taken from the recommendation for demographical standards from the German Federal office of Statistics.

EVALUATION RESULTS

Of the 13 DM experts using the dashboard, 10 completed the questionnaire in full, we consider. Even if this

number of participants is too small for a comprehensive statistical evaluation, this number of experts already provides useful results regarding the usability of software artifacts, as described by (Hwang & Salvendy, 2010) in their 10 +-2 rule. Of the SVs, all 32 participants completed the questionnaire. Of the SVs, all 32 participants completed the questionnaire. This difference in the number of participants should be considered when examining the results presented below as a percentage. The results are presented and briefly summarized in the following based on the dimensions surveyed and the associated items for both user groups responsible frontends (dashboard/ app).

Performance Expectancy: Both user groups rate the usefulness of the system used as predominantly positive (Figure 9). Usefulness in work as SV is rated considerably higher for the app than for the dashboard, going in line with the results of the acceptance study in our earlier research steps.

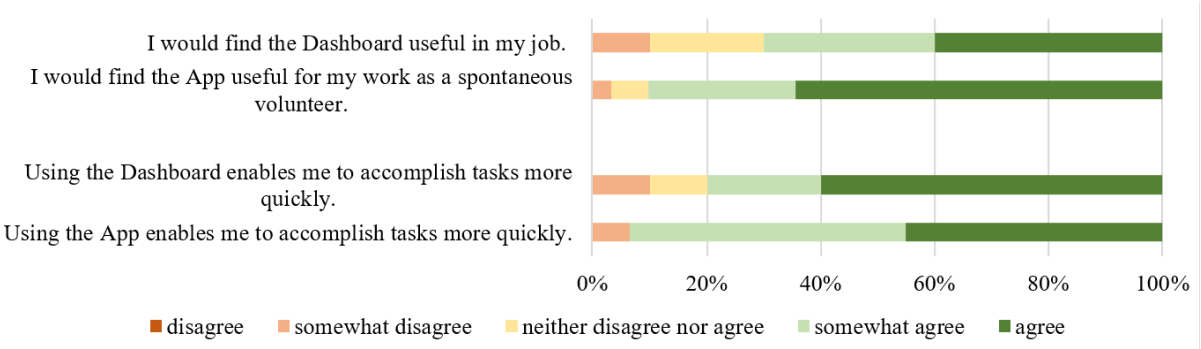

Figure 9. Performance Expectancy

Attitude Towards Technology: The results of this dimension show that both user groups enjoyed interacting with the system by a large majority (Figure 10). The negatively polarized item generates responses with a wider range of agreement to disagreement for the app. However, this pattern is repeated for the other negatively polarized items from other dimensions. Perhaps a percentage of SVs also missed the polarity reversal (however, this does not explain all "Agree" and "Somewhat Agree" responses, because the percentage is lower for the other reversed items). The results of the reversed items show that, overall, the items were read and answered carefully.

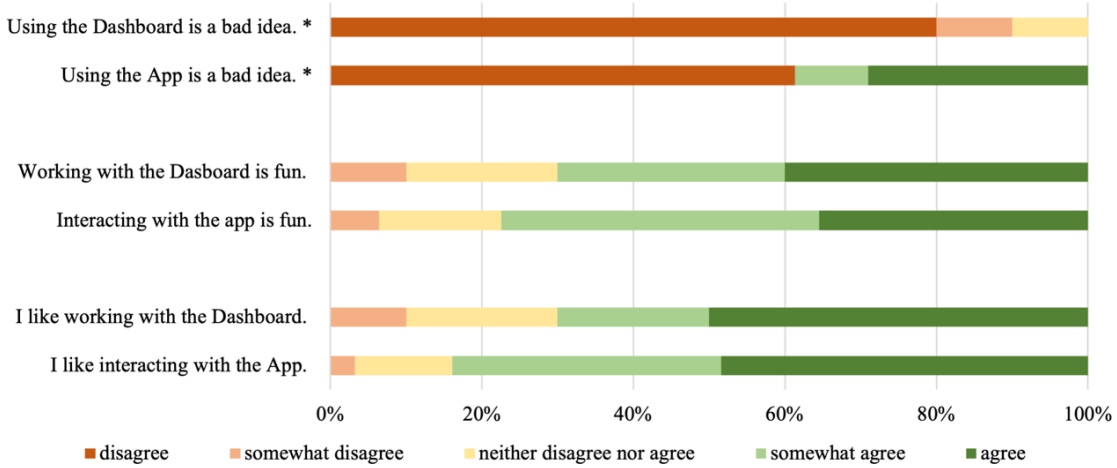

Figure 10. Attitude Towards Using the Technology (* negative polarized items)

Anxiety: The results show that both user groups have few reservations about using the system (Figure 11). However, it is evident that the SVs are more skeptical about using the app. One possible explanation could be that some of the SVs who have so far coordinated via existing communication channels see no need to introduce further systems and are fundamentally skeptical about unknown applications.

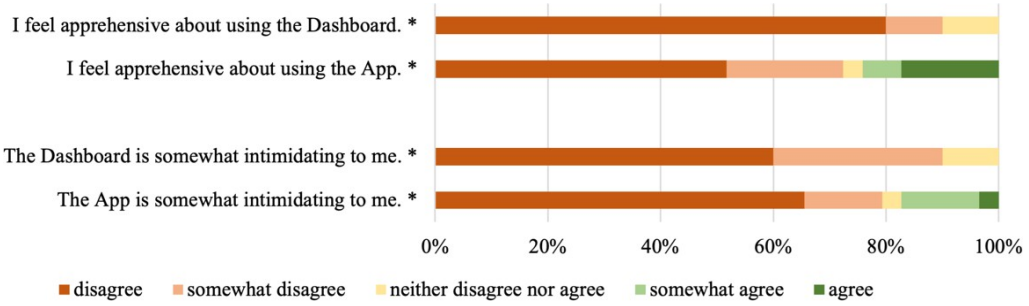

Figure 11. Anxiety (* negative polarized items)

Behavioral Intent: While most respondents in both user groups also had a positive attitude towards the system in the case of behavioral intent, a slightly higher level of rejection was found among SVs (Figure 12). However, the fact that some completely reject the use of the system is consistent with the results of some other dimensions (e.g. satisfaction, anxiety), which show a clearly negative attitude among a small subset of SVs.

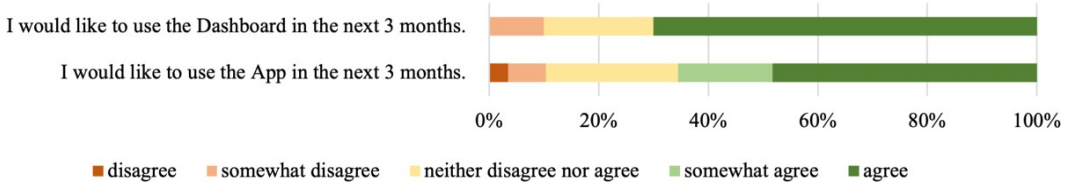

Figure 12. Behavioral Intent

Effort Expectancy: Both user groups rate the simplicity of using the system as overwhelmingly positive (Figure 13). The second item shows that the app appears to be a little easier to use than the dashboard.

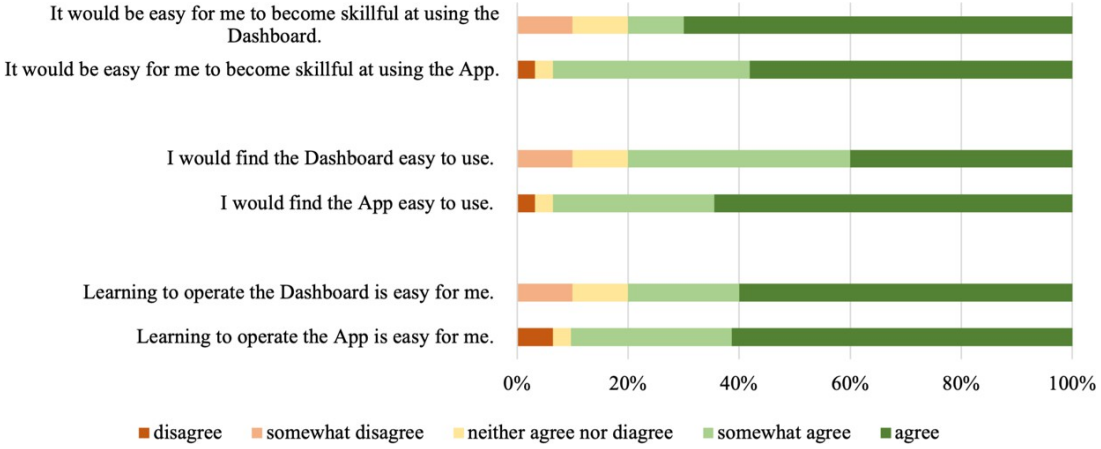

Figure 13. Effort Expectancy

Self-efficacy: Although the results for self-efficacy for both user groups are also largely positive in favor of ease of learning how to use the system, this dimension performs the weakest overall (Figure 14). It is notable that the availability of assistance would not appear to significantly improve the perception of handling the system.

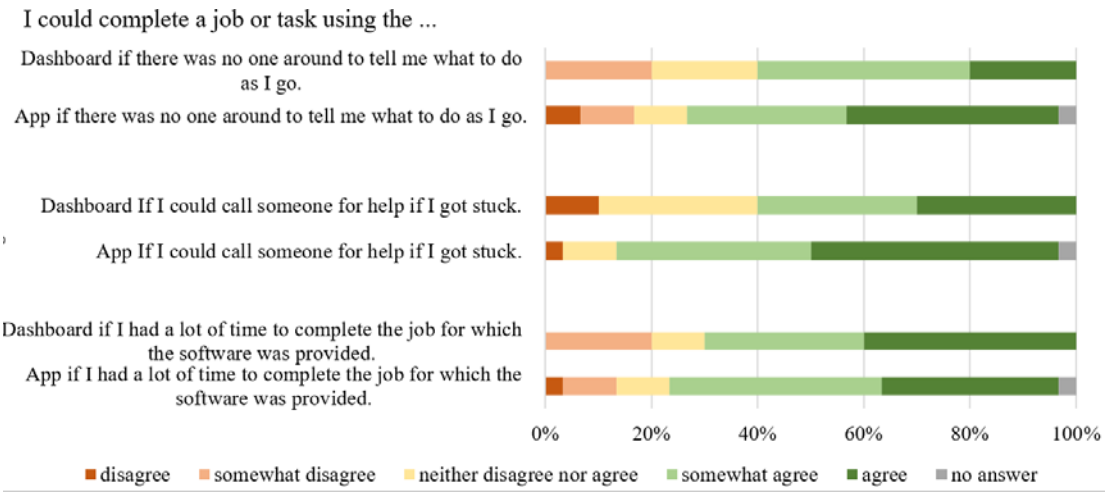

Figure 14. Self-efficacy

Satisfaction: The results indicate that both user groups are highly satisfied with the system overall (Figure 15). With a more hypothetical and less concrete formulation, the difference between app and dashboard is smaller.

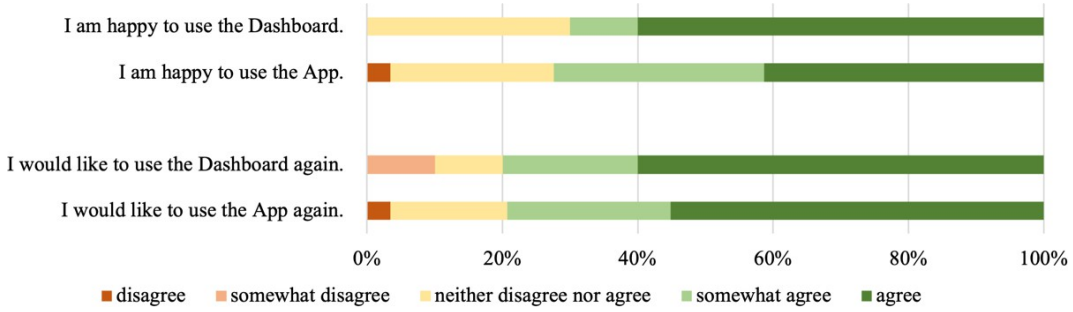

Figure 15. Satisfaction

Design: Both user groups also rated the design of their respective front ends as predominantly positive (Figure 16). The design of the app seems to be more intuitive. Still our software could be improved especially with the color codes used and in clarity and consistency of the wording.

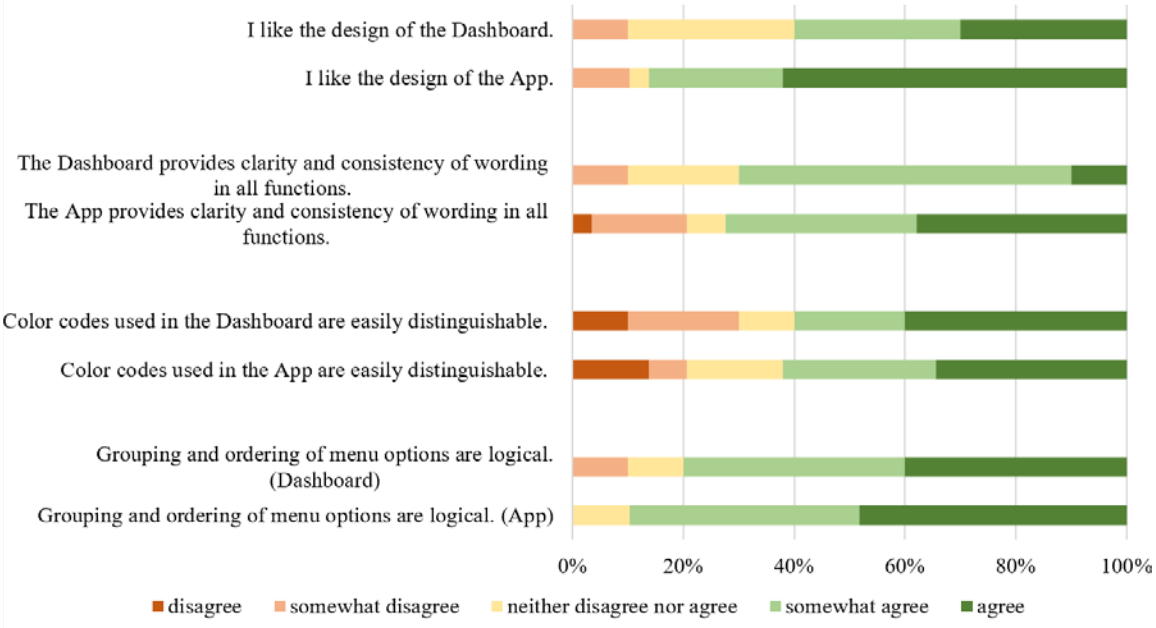

Figure 16. Design

Easiness of Use: While both user groups can easily find the information and functions, they are looking for, SVs believe that the app needs to be used regularly to be fully utilized (Figure 17). Since the answers to other dimensions, in particular effort expectancy, do not indicate that using the app is considered difficult, we assume that the users answered this question more regarding organizational aspects such as community building and gaining experience in disaster response activities and less regarding system design.

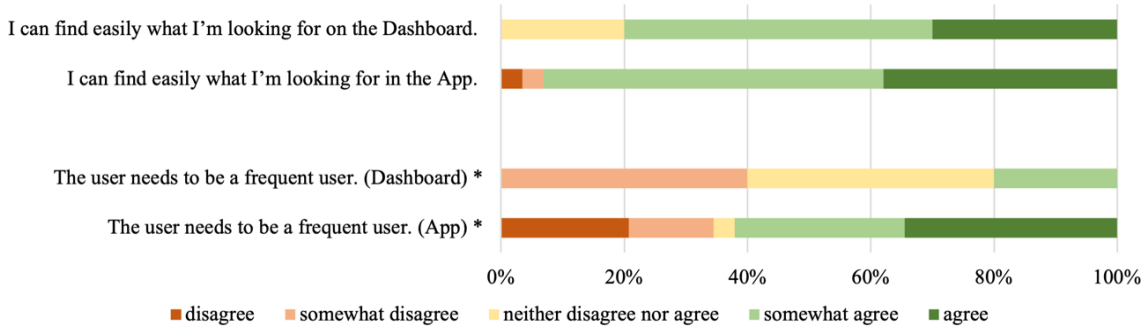

Figure 17. Easiness of Use

In summary, the results presented in relation to our second research question allow the following statements to be made: the results of the questionnaire show that most participants in both user groups have a mostly positive attitude towards the system demonstrator. Compared to the previous acceptance study (Holzhüter et al., 2023), it is clear that users appear to be much more likely to accept a real system. It is notable that the results of the SVs are more polarized and that a small group of participants is very skeptical about the system. Measured in terms of complete agreement (answers with "agree"), there is still room for improvement, particularly in terms of interface design. The good results regarding the perceived usefulness and usability of the system give us an initial indication that the theoretical results we have developed (catalog of requirements, reference architecture) can support the development of suitable systems. Due to the positive perception of the interviewees, we also assume with regard to the first research question that the development of suitable systems is possible on the basis of our design knowledge.

RELATED WORK ON FIELD TESTS OF BIDIRECTIONAL COMMUNICATION TECHNOLOGY FOR CRISES

Since we see the implementation and presentation of the evaluation of the software demonstration as the main contribution of our paper, we would like to briefly discuss the evaluation approaches of related research projects in this chapter. Although some practical studies have already been carried out in the field of volunteer coordination using social media (e.g. Batard et al.,2019; Reuter et al. 2015, Starbird 2013), the related work in relation to specific SVCS is limited. Previous field tests of bidirectional crisis communication apps either focused on an assessment of the overall importance of bidirectional communication between citizens and authorities in crises (Reuter & Kaufhold, 2018) or had a strong focus on the usability aspect of said apps (Jendreck et al., 2016).

Kaufhold et al. 2018 tested the application '112.Social', an application that allows citizens to forward alerts or report an incident to emergency services. '112.Social' then allows authorities to request additional information or disseminate behavioral tips, either via broadcasts or direct reply. Most test users evaluated the citizen to authority component positively (15 out of 21 respondents), and the same applies for the communication from authorities to citizens (14 out of 21). Furthermore, the individual app functions such as sending and receiving messages, assigning categories to messages, adding a description or a multimedia file were positively evaluated by most test persons. The only exception was the GPS tracking functionality, which was negatively evaluated, but this can be explained by the fact that the exercise took place in a building. While Kaufhold et al.'s research shows that the overall assessment of bidirectional communication in crises / disaster exercises is positive, their studies do not provide an in-depth analysis of different aspects of technology acceptance as provided by the UTAUT approach used in this paper.

The research group around the CrowdTasker system has published several papers on their approach (Auferbauer et al., 2016; Havlik et al., 2016; Middlehoff et al., 2016), each of which presents evaluation results from various experiments, although these are not mostly the focus of the paper. A significant evaluation section can be found in Auferbauer & Tellioğlu (2017), in which a field test with 12 participants, which has already been taken up in previous papers (Auferbauer et al., 2016), is discussed to a greater extent. Qualitative observations are discussed here using four categories. In Middelhoff et al. (2016), the results of a larger field test with an unknown number of participants are presented in detail. In addition to qualitative observations, a questionnaire is also used here to have users evaluate two different tools. No reference to the use of established evaluation methodology can be

found in the papers.

Jendreck et al. (2016), on the other hand, conducted a live-drill exercise with potential volunteer responders using a preliminary version of the application described in this paper. Their analysis focused on a usability assessment using the System Usability Scale (SUS). They were able to show that the application tested did have a good overall usability. Furthermore, test users positively evaluated the reliability and availability of the system tested as well as its perceived security and efficiency. The presentation of the evaluation results in (Betke et al., 2024) is similar. In this paper, the field test-based evaluation of the SVCS presented is discussed in detail, whereby the evaluation of the SVs (n = 70) was carried out quantitatively using a questionnaire and that of the disaster managers qualitatively through interviews and observations. While these studies provide important insights in technology acceptance, these studies also did not follow a holistic assessment in line with the UTAUT approach. The additional benefit provided by this paper is that it provides an overall assessment of a bidirectional crisis communication tool in a field test in line with the Unified Theory of Acceptance and Use of Technology.

CONCLUSION

In this paper we have gone through a complete design science process for the development of interconnected systems in DM. Having already conducted a requirements analysis and acceptance study and developed a reference architecture in previous work, in this paper we have focused on the implementation of a concrete software artifact in the context of the coordination of SVs and presented the demonstration and evaluation in the context of a disaster prevention exercise. We were able to show how our software demonstrator addresses the previously collected technical requirements and how its components are designed according to the reference architecture. The demonstrator was used in an exercise involving both user groups (DM, SVs) in the case of providing for large numbers of incoming refugees. The methodical evaluation based on the UTAUT approach showed that both user groups see a great benefit in the demonstrated system and perceive the implementation as very user-friendly. The results provide an initial indication that the requirements and reference architecture also provide suitable design knowledge for developing useful systems in the domain. It also indicated that a system for coordinating SVs that mees the requirements would be accepted by the majority of both user groups.

However, this is also a limitation of the approach, as the assessment based on a single use case with a small user group is only meaningful to a limited extent. However, the results are encouraging for continuing the research in further design sciences cycles. We are currently working on the implementation of an information crowdsourcing system for collecting and analyzing information from the population, which is also based on the design knowledge of our approach. Jurgens & Helsloot (2018) and Starbird (2013) have already outlined this by using social media for collective intelligence. With the evaluation of this system, we want to show that our results can be usefully applied to various interconnected systems in DM. In connection with the design of our demonstrator systems, we also collect further information to enrich our design knowledge and adapt it if necessary. The final goal of the approach is to create an overall design theory with requirements, principles, and features, which is further substantiated by an associated software architecture reference model. A final step in our approach will be to have the design knowledge evaluated by experts in the field of software development and DM to be able to make general statements about its suitability. In addition, further desiderata in the field of SVCS appear promising, so an analysis of existing approaches could synthesize the previous design knowledge into a superordinate design theory for SVCS.

ABSTRACT

When an accident has occurred, first aid before a professional response arrives can improve the outcome for the victims. However, little research has been done on the effect of coordination and leadership on first aid responses. This work-in-progress study reports an experiment using a simulated scenario, i.e. traffic accident, to understand the effect of coordination and leadership on first aid performance in ad-hoc groups of immediate responders. The results showed that coordination and leadership are significantly related to increased self-evaluated team performance while expertise and authority differentiation is not. These results provide a first insight to the coordination and leadership in ad-hoc groups of immediate responders, but more research is needed to validate these results. Structured performance evaluation with subject matter experts is planned as an extension to the present work-in-progress.

Keywords

First aid, immediate responders, emergent groups, leadership, coordination.

INTRODUCTION

Two major health emergencies in the world are out-of-hospital cardiac arrests (OHCA) and traumatic injuries. Over 10 000 people in Europe (Gräsner et al., 2016) and over 30 000 in the US (Virani et al., 2020) suffer from OHCA each month, and traumatic injuries are one of the leading causes of death for young adults globally (Vos et al., 2020). Immediate responders often provide first aid to people who suffer from these medical emergencies, starting cardiopulmonary resuscitation (CPR) in 58% of CPR cases (Gräsner et al., 2016) and providing first aid for traumatic injuries in 59% of traumatic injury cases (Pelinka et al., 2004). An immediate responder is a person that happens to be present where someone needs first aid and provides aid before the professional responders arrive (Harris et al., 2018). Immediate responder intervention increases the chance of survival for the injured person in both OHCA and traumatic injuries such as massive bleeding (Gräsner et al., 2016; Hashmi et al., 2022). Often there are multiple immediate responders providing aid simultaneously (Bakke et al., 2015), which could increase the quality of the aid provided (Takei et al., 2014).

Accidents and OHCA can happen wherever people are, and which individuals will be close and provide aid is therefore random. The immediate responders who decides to provide aid may not know each other beforehand and they would have to quickly establish trust (i.e. swift or immediate trust; Olsen et al., 2020) for an effective response. Furthermore, the first aid knowledge among the immediate responders might also vary. Bakke et al.

(2015) found that many of the immediate responders to first aid traumatic injuries were individuals with jobs such as healthcare professional, police officer and firefighter, but were responding outside of their professional role. While it is likely that they have knowledge about correct first aid measures, if the immediate responders do not know each other beforehand it can be difficult to quickly learn each individual's level of knowledge in first aid. Even in a group with higher levels of knowledge, odds are that they likely have never trained in providing first aid together, which could negatively affect the group's performance (Burke et al., 2004).

Research on ad-hoc groups of immediate responders providing first aid is scarce but has been studied in disasters through case studies (Stallings & Quarantelli, 1985; Twigg & Mosel, 2017; Drabek & McEntire, 2003). Although the scope of the activities of immediate responder in ad-hoc groups in disasters is larger than that of the typical first aid situation, there are similarities between them that make the literature useful for initial expectations of the coordination and leadership. For example, the task of providing first aid by groups of varying and unknown levels of knowledge is present in both disasters and everyday accidents. In disasters, the organization and coordination of ad-hoc groups of immediate responders is described as having a flat hierarchy with loose membership and driven by a mutual feeling of togetherness in the group (Stallings & Quarantelli, 1985; Twigg & Mosel, 2017). The flat hierarchy means that there is no particular individual that is given or takes the leadership role. This flat hierarchy is also known as low authority differentiation (Hollenbeck et al., 2012). However, that does not necessarily mean that the groups have no leadership within them. Leadership could instead be conceptualized as a function (i.e. functional leadership) that is distributed between the individuals in the group rather than a role assigned to a specific individual in the group (Morgeson et al. 2010). The loose membership of an ad-hoc group means that the membership of the group is not predetermined and is subject to change during a response.

Majchrzak et al. (2007) provides a suggestion to extend the theory of transactive memory systems (TMS) so that ad-hoc groups of immediate responders in disasters can be understood as a TMS. A group that works together interdependently toward a common goal is defined as a TMS if the individuals in the group have differentiated knowledge and uses a dynamically coordinated process within the group to encode, store and retrieve knowledge (Lewis & Herndon, 2011). Coordination in the context of TMS can thus be conceptualized as the smooth adaption of actions by individuals to interdependently achieve a common goal (Lewis, 2003). The TMS structure and processes in a group improves team performance (DeChurch & Mesmer-Magnus, 2010) but there are moderating factors, such as leadership, that could influence the effect (Bachrach et al., 2019). Majchrzak et al. (2007) further suggested that expertise in ad-hoc immediate responder groups is coordinated through actions, such that experts communicate their higher levels of knowledge and ability by initiating a response and the non-experts are then to understand the response as a sign of that individual's greater knowledge-level. Additionally, Majchrzak and colleagues suggest that individuals with less knowledge learn through action within the response, i.e. learning by doing.

The lack of experimental research on ad-hoc groups of immediate responders and the implied particularity of such groups made by Majchrzak et al. (2007) suggests a need for further understanding of these groups in more controlled circumstances. Therefore, this work in progress-study aims to use experimental simulation to investigate how aspects of coordination, and leadership affect the performance of ad hoc groups of immediate responders.

METHODS

An experiment with a simulated traffic accident was conducted with a between-group design. Groups of three participants participated, and groups were classified as either low knowledge or high knowledge. The low knowledge groups included three medical laypeople, i.e. individuals with little or no medical knowledge or experience of first aid. In contrast, the high knowledge groups included two medical laypeople and one first responder expert. The experts had previous education and experience in pre-hospital healthcare or as an emergency responder. A total of 28 groups participated in the experiment. However, 9 groups were excluded from the analysis due to participant no-shows resulting in group sizes below three. See Table 1 for demographics of the participants included in the analysis.

To preserve the ad-hoc aspect of the simulation, the participants were not informed that multiple participants would participate in the same scenario. The study was therefore considered a deception study by the Swedish Ethical Review Authority and ethical approval was acquired. Participants received monetary compensation for participation.

Table 1. Demographics of the participants included in the analysis.

		Low knowledge teams			High knowledge teams			Full sample		
		n	%		*n*	%		*n*	%	
Teams (groups of three participants)		12	63		7	37		19	100	
Participants (individuals)		36	63		21	37		57	100	
Gender										
	Female	15	42		6	29		21	37	
	Male	20	55		14	66		34	60	
	Prefer to not answer	1	3		1	5		2	3

Years since first aid education		15	5.1	3.6	15	5.6	9.0	30	5.3	6.7
Age		36	24.7	7.2	21	31.5	13.6	57	27.2	10.5

Note. High knowledge teams included one first responder expert. Level of education is the participants highest achieved level of education at the time of their participation. 4 participants with previous first aid education did not disclose years since they received the education.

Procedure

A convenience sample of medical laypeople was recruited through posters at a university in southern Sweden. The emergency response (prehospital or rescue service) experts were recruited by providing information about the study to relevant employers in the immediate vicinity of the experiment location (see Figure 1 for procedure flowchart). Potential participants that registered for participation were vetted according to medical education and first aid experience. Participants with emergency response expertise were specifically asked to avoid wearing clothes showing text or logos indicating their professional roles to avoid implicitly communicating their expertise to the other participants. Participants who might know each other beforehand (e.g., studied in the same program) were scheduled to different time slots to preserve the ad-hoc aspect of the groups.

At the start of the experiment, the participants were brought one by one to a room where they were separately seated and were asked to read and sign an informed consent form. Sightlines between the seats were blocked, and the participants also wore hearing protection so that they could not hear instructions or questions from other participants. Participants were fitted with a body cam and a lavalier microphone. The participants were individually informed that they could stop the scenario at any point and instructed to act as they thought they would if the scenario was real. To disambiguate their role in the scenario the instructions included contextual information about the scenario. Specifically, that they had heard a car crash and that they had decided to investigate and provide aid in any way they were able to. This was motivated by the aim of the experiment to study first aid response rather than the decision to initiate first aid.

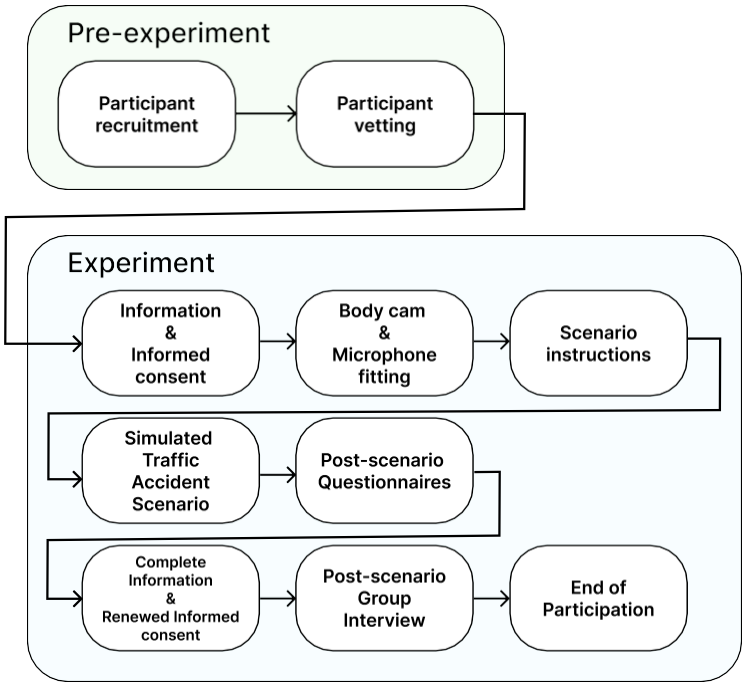

Figure 1. Procedure flowchart

The participants started the scenario simultaneously and the scenario took a maximum of 15min. It included a car with gray smoke from the engine bay and two injured actors sitting in the car. The actor closest to the participants was a human amateur actor with a simulated massive bleeding from the left upper arm. All actors received 2h of training to ensure that they could portray the injury in similar ways with regards to consciousness and responsiveness. The actors were instructed to show drowsiness, to be slow to respond to light stimulation similar to level 2 or 3 on the Reaction Level Scale (Starmark et al., 1988), and to be unable to walk. A protective sleeve with a silicone wound connected to a 1.5L bottle of fake blood was used to simulate the bleeding in the actors' left arm (Tourniquet application trainer, 2023). The flow of the blood was controlled by the actors, who pumped blood until bleeding control via first aid had been achieved. An additional 500ml of fake blood was poured close to the initial position of the actor before the start of the scenario to indicate that the bleeding was severe. The other injured actor consisted of a rescue manikin (Rescue manikin Pro; Svenska Räddningsprodukter AB., n.d) modified to enable CPR compressions (see Figure 2). The rescue manikin had a realistic weight distribution and weighed 80kg, realistic face and arm features in silicone, and no detectable breathing or pulse. Participants that were visibly attempting to detect the manikin's pulse or breathing were prompted by the research leader that they did not detect any pulse or breathing. Groups that decided to simulate a call to the Swedish emergency dispatch center (i.e. SOS Alarm) got a response from the research leader simulating the dispatch center response. After a participant provided the information they deemed important the research leader ended the simulated call by informing the participant that professional help was on its way.

A small red first aid pouch (First Aid pouch, mini, n.d.) was included in the scenario. It included a rescue blanket, non-hemostatic gauze, one pair of plastic gloves, a face shield for rescue breaths and disinfectant wipes. Other minor items such as band aids, scissor and a gel packet for burns were also included in the pouch. A combat application tourniquet model CAT7 was placed in the pouch to enable participants to effectively stop a massive bleed in extremities. In Sweden, there is no legal obligation to keep first aid material in the car and participants may not expect to find such material in a car. Therefore, the first aid pouch was placed in the open glove compartment of the car, visible when the passenger door was opened

After the scenario the participants were seated separately and completed post-scenario questionnaires (see Materials section for a description). After the questionnaires, the participants were seated together and provided complete information about the purpose of the study and informed consent was renewed. Then a group interview focusing on the participants' experience of leadership and coordination during the scenario was conducted. The interview took approximately 30-50min and was audio recorded. The participants had the choice to conduct the interview separately as they had not received information about the interview being conducted in a group beforehand. Lastly, the experiment was concluded by thanking the participants for their participation.

Figure 2. Simulated traffic accident scenario

Materials

Data from the following questionnaires are included in the current work-in-progress analysis. A demographics questionnaire collected data on the age, gender, level of education, first aid education, number of previous first aid experiences, current or previous work as an emergency responder, and previous education and experience of teamwork and leadership. Coordination was measured through a questionnaire on the coordination dimension of TMS (Lewis, 2003). Leadership was measured using an adaption of the questionnaire used in a previous study on teamwork in a simulated pre-hospital scenario (Hughes et al., 2021) and an adaption of the questionnaires on functional leadership in transition processes (Morgeson et al., 2010). Transition processes in a team are the actions that team members do during an entire collaboration to make a plan and mission analysis, specify goals for the team and formulate team strategies (Marks et al., 2001). The participants' experienced authority differentiation was measured by adapting the description of authority differentiation by Hollenbeck et al. (2012) into two questions about leadership experienced as centralized or distributed. Data on participants' self-evaluated performance regarding team performance, leadership performance and individual performance was also collected. Note that only the self-evaluated team performance data was used in the current work-in-progress analysis.

The following questionnaire data was collected but not analyzed further in the current work-in-progress. The participants' experienced team processes were collected using a questionnaire based on the temporal taxonomy of team processes (Mathieu et al., 2020; Marks et al., 2001). A questionnaire on team orientedness was collected as a measure for participants' general tendency to prefer working in groups over working alone (Driskell et al., 2010). Two questions regarding participants' general and immediate trust were adapted from Delhey et al. (2011) and Olsen et al. (2020).

Video was recorded using a camera with 360° field of view and five small cameras: one strapped to each participant, one placed inside of the cabin of the car and one operated by the research leader. The audio of the participants' cameras was recorded using lapel microphones. Audio recordings were made during the group interviews using a field recorder. The group interview was a semi-structured interview with questions based on the questionnaires about functional leadership (Morgeson et al., 2010), team processes (Mathieu et al., 2020) and coordination (Lewis, 2003). During the group interviews the participants were asked to share their experiences related to leadership and coordination during the scenario.

Analysis methods

A two-level hierarchical model was used to assess the effects of expertise, coordination, authority differentiation and functional leadership in transition processes on self-assessed team performance (see Table 2 for a description of the variables). The model was constructed in R Statistical software (v 4.2.1; R Core Team, 2022) using the nlme package (v 3.1.157; Pinheiro et al., 2022). All predictors were on an individual level and thus included in the model as first level units and the team that the participants acted in the scenario with was used as the second-level unit. Only teams with three participants were included in the analysis, resulting in 57 participants in 19 teams. The multilevel model method was used to avoid the assumption of independence in linear regressions.

Distributions for predictors were acceptable and no outliers were found. All predictors were modelled with random intercepts and fixed slopes due to limited amount of data resulting in models with random slopes not converging. The random intercept and fixed slopes in the model mean that the relation between the predictors and the outcome is the same for all teams but the intercept can vary between teams. As the current work is a work-in-progress the analysis did not include any statistical analysis concerning the final model's generalizability.

Table 2. Description of variables included in the analysis.

Concept	Operationalization	Measurement	Reference
Expertise	Current or previous work as an emergency responder	Binary coding of previous/current experience or no previous/current experience as emergency responder	
Coordination	Coordination in TMS	Mean score of 5 questions on a Likert-scale (1-5) with the third question reverse coded	(Lewis, 2003)
Leadership	Functional leadership in transition processes	Mean score of 7 questions on a Likert-scale (1-5)	(Hughes et al., 2021; Morgeson et al., 2010)
	Authority differentiation	Mean score of 2 questions on a Likert-scale (1-5) with the first question reverse coded	(Hollenbeck et al., 2012)
Performance	Team performance	1 question of self-evaluation of the team performance on a Likert-scale (1-5)	

PRELIMINARY RESULTS

The two-level hierarchical model showed coordination and functional leadership in transition processes as significant predictors for self-assessed team performance, while expertise and authority differentiation did not reach significance as predictors (see Table 3). Expertise was found to have a positive effect on self-assessment of team performance. Meaning that an expert participant in this sample tended to rate the team performance higher than a non-expert participant. However, the effect was not statistically significant ($p = 0.053$) with the current sample size ($n = 57$). Therefore, further data collection is needed to determine if the effect is generalizable. Coordination significantly predicted self-assessment of team performance which indicates that participants who experienced more coordination within the group tended to rate the team performance higher. Authority differentiation had a negative effect on self-assessed team performance which means that participants in the current sample that experienced more equal authority distribution in the group tended to rate the team performance higher. However, the effect was not statistically significant ($p = 0.051$) with the current sample size ($n = 57$) and further data collection is needed to determine the generalizability of the authority differentiation effect as well. Functional leadership in transition processes was found to significantly predict self-assessed team performance. Participants that experienced more leadership functions related to team processes that involve planning and understanding the available resources within the group tended to rate team performance higher.

Table 3. The fixed effects of expertise, coordination, authority differentiation and functional leadership in transition processes on self-assessed team performance

	b	SE *b*	DF	t-statistic	*p*	95% CI
Expertise	0.51	0.25	34	2.00	.053	0.02, 1.00
Coordination	0.73	0.20	34	3.59	.001	0.34, 1.13
Authority differentiation	-0.15	0.08	34	-2.02	.051	-0.30, -0.01
Functional leadership in transition processes	0.48	0.13	34	3.66	<.001	0.22, 0.73

DISCUSSION

The result from the current study shows that coordination is positively related to self-evaluated team performance in ad-hoc first aid groups. Coordination has in previous research also been shown to be important for performance in other types of teams (Rico et al., 2019). It would therefore be reasonable to assume that coordination is important for team performance in ad-hoc groups of immediate responders. Additionally, the tasks in the current

scenario were designed to be too difficult to complete successfully for one single person. For example, continuing CPR while also stopping a bleed is impossible for one person as they have a limited number of hands and a limit to their capacity to multitask. However, as the performance measure in the current study consists of self-evaluation rather than a more objective or structured measurement it is also possible to interpret the positive effect of coordination on team performance as coordination being part of the participants mental model of what constitutes more effective team performance. Further analysis is warranted to investigate the effect of coordination on the performance of the first aid interventions attempted by the participants rather than their ability to work together.

Functional leadership in transition processes was also found to positively contribute to the self-assessed team performance in the simulated scenarios. In the current study leadership was defined as a function that one or more people could fill rather than a role that one individual was assigned. This was done due to the emergent and ad-hoc nature of organization of immediate responder groups (Drabek & McEntire, 2003). Dagnell (2020) suggests some characteristics of leadership that have been found to positively influence performance in intra-hospital resuscitation simulations that could also influence the quality of CPR in OHCA. Those overlapping with the operationalization of leadership in the current study are task assignment, planned tasks, and structure initiation. The result from the current study supports part of the suggestion by Dagnell (2020) in the context of CPR by immediate responders in an OHCA simulation. However, (Dagnell, 2020) concerns ad-hoc teams of medical professionals in a pre-hospital context which could have more resources and knowledge available compared to the ad-hoc groups of immediate responders in the current study.

Pelinka et al. (2004) found that immediate responders with more medical education tend to give better aid to victims with traumatic injuries. In the current study, expertise showed a similar effect but the effect did not reach statistical significance. Based on the results reported by Pelinka et al. (2004), expertise would be expected to predict self-evaluated team performance as well. Quarantelli (1988) reports that inability to change strategy and structure in the face of new and unprecedented change negatively affects performance in disaster response. Additionally, difference in team cognition could also be negatively affecting performance (Mohammed et al., 2021). An insufficient overlap in relevant content (knowledge) and procedures (strategy) between experts and medical laypeople could create conflicts that take time and resources from achieving the task at hand. However, the use of self-evaluation of performance as a proxy for a performance measurement could also explain the results as a mismatch between what medical laypeople perceives as good performance and what constitutes actual performance in a first aid setting.

Authority differentiation was not a significant predictor for self-evaluated performance in the current study. In previous research, similarity in goal orientation within a team has been shown to moderate the positive effect of authority differentiation on team performance (Nederveen Pieterse et al., 2019). Specifically, a team where individuals' goal prioritization differs more would increase performance in teams with greater authority differentiation. Interpreting the negative effect that authority differentiation tended toward with regards to team performance in the current study through the interaction described by Nederveeen Pieterse et al. (2019) suggests that there was disagreement within the teams about which goals to pursue. However, the content of the participants goals was not collected in the current study making direct comparison between the results in the current study and the study by Nederveeen Pieterse et al. (2019) difficult.

Limitations

The current study is one of the first to investigate coordination and leadership in ad-hoc immediate responder teams in a simulated scenario. The simulated scenario design allows for more control and reliability compared to the case study methodology used in previous work on ad-hoc immediate responder groups in disasters and crisis management. The experimental simulation methodology also provides more ecological validity than laboratory experiments (McGrath, 1981). However, the study contains some noteworthy limitations. The current study is a work-in-progress and is limited by the use of self-assessment of team performance as outcome variable. Previous research indicates that self-evaluation of performance is only moderately correlated to actual performance (Zell & Krizan, 2014). Therefore, a structured performance evaluation with subject matter experts is being undertaken to gain a more accurate measure of the teams' performance in the simulated scenario (see Future work section).

Although over 70 individuals participated in the study the number of teams included in the analysis was limited. Groups of three participants were planned but due to participant no-shows a third of the scenarios included two participants and were thus excluded from the current analysis. Participant no-shows resulted in fewer datapoints than expected and therefore decreases the chance of statistically determining effects of predictors on the outcome variable. The expertise and authority differentiation variables may suffer from such decreased effects in the current study and further data collection is warranted. However, the results provide a valuable new methodological perspective to a problem previously mainly explored through case studies.

Future work – Performance evaluation procedure

Future work currently under way aims to mitigate the self-evaluated team performance limitation by employing a structured evaluation process using performance indicators and subject matter experts. Performance indicators have been selected in a workshop with two subject matter experts with expertise in pre-hospital healthcare and rescue and response expertise. During the workshop, video and audio from the pilot was used to exemplify which demands the scenario placed on the participants to match the performance indicators with the scenario. Five performance indicators were selected: first aid performance for CPR and hemorrhage control, contacting emergency dispatch, maintaining safety on the scene of the accident and communication with the conscious injured person. The indicators are also designed to measure task performance and not coordination or leadership. Each performance indicator is rated on a scale 1-7 by subject matter experts using the video and audio data collected during the trials. The video and audio data have been edited into a single video to make the rating process easier. After rating each video an interrater measurement will be used to ensure unbiased performance ratings. The swift trust data and the group interview recordings are planned to be included in future work by comparing how participants describe their experience of coordination and leadership with the proposed extension of TMS by Majchrzak et al. (2007).

CONCLUSION

Coordination and functional leadership in transition processes was shown to predict self-evaluated team performance. Expertise and authority differentiation was also found to influence self-evaluated team performance, but the effects did not reach statistical significance. This suggests that more is needed for effective first aid in ad-hoc groups of immediate responders than making sure that there is first responder experience and one individual acting as a leader. Coordination and functional leadership as significant predictors also suggest that they are a vital part of successful first aid. As such, more work is needed to understand how these factors could be included into first aid education to improve immediate responders' ability to provide effective aid in the future. This work-in-progress study also contributes to the understanding of how successful first aid is conducted in a difficult first aid scenario by using a research method with more control and reliability compared to previous research on immediate responders. Future work aims to investigate the effect of coordination and leadership on performance as rated by subject matter experts.

ABSTRACT

Rural areas are typically sparsely populated, and coverage from emergency services is weak. In some such areas in Sweden, professional emergency services train civilian volunteers in providing help for certain types of emergencies. In case of an emergency, they are alerted on their mobile phones and are primarily expected to provide help in the vicinity of their homes. Due to limited resources, it is impossible to include all villages in the volunteer initiative, making the selection of the most beneficial villages for emergency response important. However, this decision is not always trivial to make. Therefore, we propose an optimization model to determine which villages should be included in this initiative to achieve the best possible emergency response coverage. The model is used in a case study for a large Swedish fire and rescue service organization, and based on the results, they have started volunteer centers in two villages.

Keywords

Volunteers, Civilian first responders, Optimization, Coverage, Emergency response.

INTRODUCTION

Emergency services have a pivotal role for managing emergencies ranging from daily emergencies (frequent events that have low consequences such as traffic accidents (Quarantelli, 1995)) to disasters, which happen seldomly but have high level of consequence. To manage any type of emergency, these organizations use different resources, including personnel, physical equipment, and information. However, the availability of these resources plays an important role in their service delivery (Matinrad, 2022). In recent years, emergency services have been facing different challenges, including cost pressures and budget cutbacks as well as long distances to sparsely populated areas (Yousefi Mojir & Pilemalm, 2016). The occurrence of the COVID-19 pandemic also showed how these challenges could be exacerbated under extreme situations. Shortage of resources and longer travel distances translate to longer response times, especially for rural and sparsely populated areas. Longer response times can lead to higher rate of damage to the properties and the environment, harm to human health, and higher mortality rates, for example in cases of cardiac arrest (Waalewijn et al., 2001) and fires (Jaldell, 2004 & 2017). Consequently, emergency services in recent years have tried to use additional resources that will not incur additional cost but can help them improve their response times. One such resource is civilians, who volunteer to help in case of emergencies in their vicinity.

In collaboration with the municipal fire and rescue services (FRS), volunteers in some villages in Sweden, where the emergency coverage is poor, are trained (and potentially equipped) for first response to a selected set of emergency types. The civilians in this initiative receive training in cardiopulmonary resuscitation (CPR), first aid, extinguishing of small fires, and required actions when a person first arrives at some emergencies (e.g., a fire or a traffic accident) (Hallström et al., 2017). These trained civilians are, simultaneous with the dispatch of emergency services, notified of an emergency through a short message service (SMS) or an application on their mobile phones. Training and potentially equipping civilians in rural areas requires monetary and time investment from the emergency services. However, as the FRS have budget (and personnel) restrictions, it is not possible to include a large number of civilians and villages in such a volunteer initiative, especially not in the first round. While a major part of the cost is setup, there are also running costs for maintaining the volunteer centers, including costs for continuous training, and possibly equipment. It is therefore important to initially select a number of

villages that both meet a few minimum requirements for inclusion and gives the best improvement for the emergency response system. However, it is not always trivial to determine which villages will give the most benefit. A possible solution for this problem is to use optimization and develop a model that can take into account the required factors. However, such a model also needs to be comprehensible for the practitioners, which means that a simpler model that can fulfill the purpose might be more suitable than a very complex one.

The aim of the paper is to develop an optimization model to determine which rural villages should be included in a volunteer first response initiative, so that the population in the region receive the best possible emergency coverage from FRS and the volunteer initiative.

The rest of this paper is organized as follows. In the next section, we provide a brief overview of the related literature and positioning of this work with respect to the literature. In the following section, we present the problem description as well as the proposed optimization model. Then, we describe the numerical experiments, detailing the case study, where we help an FRS organization to select rural villages to use as volunteer centers, and the results. Finally, in the last section, we present conclusions and future research directions.

PREVIOUS STUDIES

Emergency response coverage in rural areas in many countries, including Sweden, is weak. As Pilemalm et al. (2013) pointed out, most of Sweden can be considered rural, given that population centers are sparsely located and driving time (by a car) to the nearest town with more than 3000 residents takes more than 45 minutes from many areas. Therefore, strengthening the emergency response for rural areas becomes even more crucial. In the following, we briefly discuss some of the literature that are most relevant to this study.

Volunteer initiatives have emerged and increased in numbers over a relatively short amount of time as a potential solution to enhancing emergency response time and coverage, especially in rural areas. In some initiatives, volunteers respond to only a specific type of emergency (e.g., out-of-hospital cardiac arrest - OHCA). Examples include SMS lifesavers in Sweden (https://heartrunner.com/) and HartslagNu in the Netherlands (https://hartslagnu.nl/), but more examples can be found in several reviews such as Oving et al. (2019), Scquizzato et al. (2020), and Valeriano et al. (2021). In other initiatives, a wider range of emergency types is considered; examples are the enhanced neighbors project (Ramsell et al., 2017) and civilian response persons (Stenberg et al., 2014; Hallström et al., 2017) in Sweden. Here, volunteers respond to selected medical emergencies as well as small fires and traffic accidents. There are also initiatives in Germany for responding to medical emergencies (e.g., Gross et al. (2019)) and in Finland (Tamminen et al., 2019). Several studies, especially within the medical area, have examined the impact of volunteer responses on the outcome of the cases, showing that volunteers can reduce response times (see e.g., Auricchio et al. (2019), Berglund et al. (2018), Ringh et al. (2015), and Stroop et al. (2020)). Svensson et al. (2024) compared emergency service response times between rural and urban areas, showing a notable difference. They also showed that volunteers had the shortest median response times to OHCA compared to emergency medical services (EMS) and FRS. Similarly, Lapidus et al. (2023) showed that volunteers had shorter response times than EMS, especially in sparsely populated areas.

Two crucial aspects for being able to start and maintain volunteer initiatives, are to attract and motivate volunteers. Thus, it is important to understand which factors lead to the involvement of civilians in volunteer initiatives and why they might leave. Cowlishaw et al. (2008) raised family issues as a factor with direct impact on the decrease of the number of volunteers in rural areas. Timmons and Vernon-Evans (2013) as well as Barry et al. (2019) showed that one of the motivating factors for people to volunteer comes from a personal level, their “ideas of altruism and sense of community” and personal experiences of emergencies or illness. Choudhury (2010) stated that local government agencies are important bodies for attracting and managing volunteers.

In many volunteer initiatives, volunteers are alerted through their mobile phones, for example by SMS or specific mobile phone applications (Matinrad & Granberg, 2023). Initiatives such as the enhanced neighbors project relied on SMS for sending notifications to volunteers (Ramsell et al., 2017). SMS lifesavers also started using SMS, but later switched to a mobile phone application (Jonsson et al., 2020), while other initiatives, HartslagNu for example, use both SMS and a mobile phone application (Slaa, 2020). All these initiatives use some type of geographical positioning of the volunteers so that they can send the notification to the volunteers in the vicinity of the incident site. This geographical positioning can be static (i.e., registered addresses) or dynamic using Global Navigation Satellite Systems (GNSS). All these initiatives need some type of decision-making logic, which can be embedded in a decision support system (DSS). The underlying logic in an emergency DSS can be a simple rule such as the one used in SMS lifesavers initiative (Granberg et al., 2022) or it can be more advanced models (see e.g., Matinrad and Granberg (2023) and Frigstad et al. (2023)).

For rural areas, determining which villages that should be included in a volunteer first response initiative relies

on different factors, where one crucial factor is the geographical distribution of the villages. While the literature on volunteer location studies is scarce, there are many studies to be found on the location of emergency service stations (see for example, van den Berg and Aardal (2015), Røislien et al. (2016), van den Berg et al. (2016), Garner and van den Berg (2017), and Jagtenberg and Mason (2020)) or public emergency equipment such as automated external defibrillators (AEDs) (e.g., Chan et al. (2013), Bonnet et al. (2015), and Yang et al. (2021)). The majority of these studies use a type of covering location model, such as the maximal coverage location problem (MCLP) (Church & ReVelle, 1974) or the maximum expected coverage location problem (MEXCLP) (Daskin, 1983). In some studies, such as Bonnet et al. (2015), a MCLP model is extended to incorporate more factors, including temporal aspects (e.g., accessibility of candidate locations across different times for AED locations) and amount of used resources (e.g., number of deployed devices).

In this paper, we address the problem of determining which rural villages that should serve as volunteer centers and present an optimization model that aims to maximize the population coverage, with regards to both volunteer and FRS response. To the best of our knowledge, this is the first optimization model for such a problem. Given the simplicity of the model, it is easily comprehensible for practitioners. Results from the model are currently being utilized in an ongoing volunteer initiative in Sweden for creating volunteer centers across rural areas in order to improve the emergency response system.

PROBLEM DESCRIPTION AND MATHEMATICAL MODEL

In this section, we will first briefly describe the problem statement as well as assumptions that we have made, and then, we will present the optimization model.

Problem Statement and Assumptions

The problem, Selection Of Rural Villages as Volunteer centers for Emergency response (SORVIVE), deals with *determining which rural villages should be included in the volunteer response initiative, aiming to improve the emergency response coverage, considering the current professional emergency service system*.

In this problem, we have made a few assumptions:

- The candidate villages are known and have at least five people that are willing to volunteer and respond to emergencies if they are notified. It is hypothetically possible to consider all villages as candidates, but since one person will not always be able to respond, more than one volunteer is needed to get any effect. Furthermore, in these kinds of initiatives, the volunteers prefer not to be the only one responding to an incident (Ramsell et al., 2017). Thus, it is preferable that the candidate villages have at least five residents willing to volunteer.
- Volunteers in the selected villages are assumed to primarily respond to emergencies within their own villages. However, if their neighboring villages are within a reasonable distance, they can receive help as well.

In Figure 1, we show a schematic representation of the SORVIVE problem, with two FRS stations in the area, and four selected villages that will function as volunteer centers. Note that in this schematic representation, we have considered different coverage radius for different villages, given the size of the villages and their geographical position, and a 20-minute coverage radius for the FRS stations. Each of these volunteer centers will cover a subset of villages and towns (population centers) that can be divided into population squares.

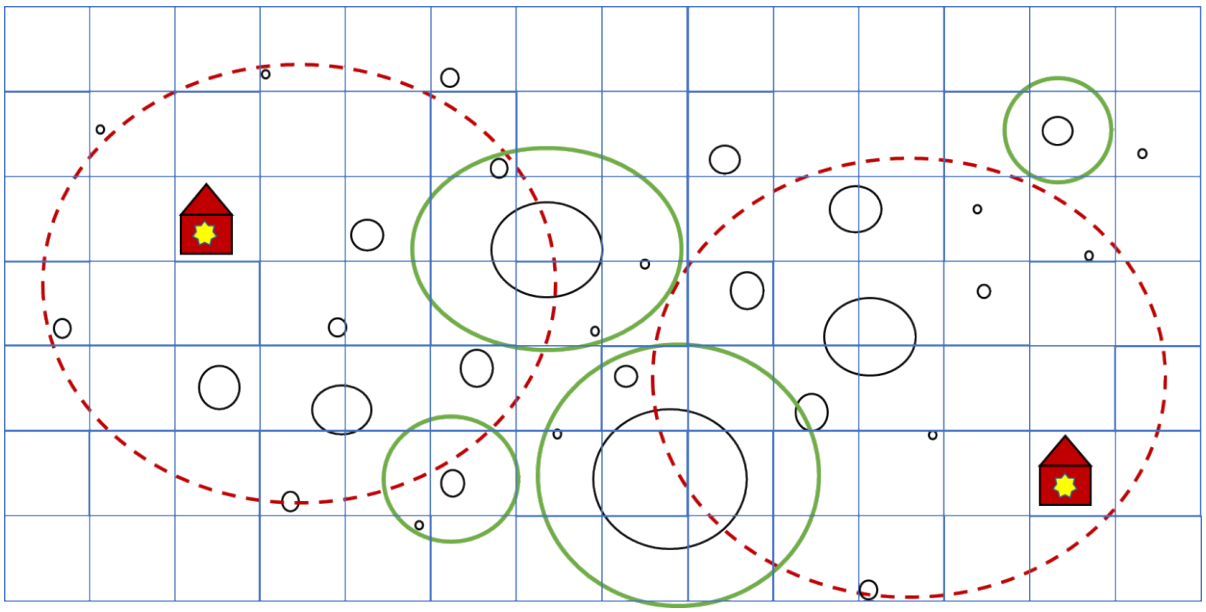

Figure 1. Schematic representation of the problem.
The small black circles represent rural villages, and the blue squares represent population squares; the dashed red circles show the coverage radius of FRS with the red houses representing the FRS stations, and the solid green circles show the coverage area of selected population squares anchored around a village.

Model Formulation

As input to the mathematical formulation of the SORVIVE problem, we know where the FRS stations as well as candidate volunteer centers across a specific region are located. We can also divide the whole region into squares where we know the resident population in each square, and calculate all distances between stations, centers, and squares. We also know the coverage radius for volunteer centers (either individually based on their size and location or a common radius for all of them) and the maximum service time to reach a population center from an FRS station. It is also known how many volunteer centers are planned to be established. The model determines which candidate volunteer centers that are selected, and which population squares they cover.

We have used the following notation in the mathematical formulation of the SORVIVE problem:

Sets and indices

$I = \{1, \dots, m\}$	Set of candidate volunteer centers, indexed by $i \in I$
$K = \{1, \dots, o\}$	Set of population squares, indexed by $k \in K$
$J = \{1, \dots, n\}$	Set of FRS stations, indexed by $j \in J$

Parameters

s_k	Total number of people in population square *k*
z_{jk}	Equals to 1 if FRS station *j* covers population square *k*; otherwise, 0
df_{kj}	(Shortest) response time (i.e., preparation time plus travel time) between FRS station *j* and population square *k*
dp_{ik}	(Shortest) response time between volunteer center *i* and population square *k*
P	Maximum number of volunteer centers
D_i	Coverage radius of volunteer center *i*
L_j	A predefined maximum service time to reach a region from FRS station *j* within a given time

Decision variables

y_i	Equals to 1 if volunteer center is established in *i*; otherwise, 0
x_k	Equals to 1 if population square *k* is covered; otherwise, 0
w_{ik}	Equals to 1 if volunteer center at village *i* covers population square *k*; otherwise, 0

The SORVIVE problem is thus formulated as an integer programing (IP) model:

$$max \sum_{k \in K} s_k x_k \quad (1)$$

$$\sum_{i \in I} y_i \leq P \quad (2)$$

$$D_i y_i \geq dp_{ik} w_{ik} \qquad \forall i \in I, k \in K \quad (3)$$

$$\sum_{i \in I} w_{ik} \leq 1 \qquad \forall k \in K \quad (4)$$

$$x_k \leq \sum_{i \in I} w_{ik} + \sum_{j \in J} z_{jk} \qquad \forall k \in K \quad (5)$$

$$y_i, w_{ik}, x_k \in \{0,1\} \qquad \forall i \in I, j \in J, k \in K \quad (6)$$

The objective function (1) maximizes the weighted coverage of the population squares, where the weight is the population. Constraint (2) is defined to limit the number of the selected volunteer centers to *P*. Constraint set (3) determines which population squares a selected volunteer center covers; coverage is possible if the travel time between a center and a square is shorter than the predefined coverage radius for the volunteer center. Constraints (4) ensure that each square is covered by a maximum of one volunteer center. Constraint set (5) determines whether a square is covered or not, where the coverage can be by FRS stations, by a volunteer center, or by both FRS stations and a volunteer center. Constraints (6) are the binary constraints for the variables.

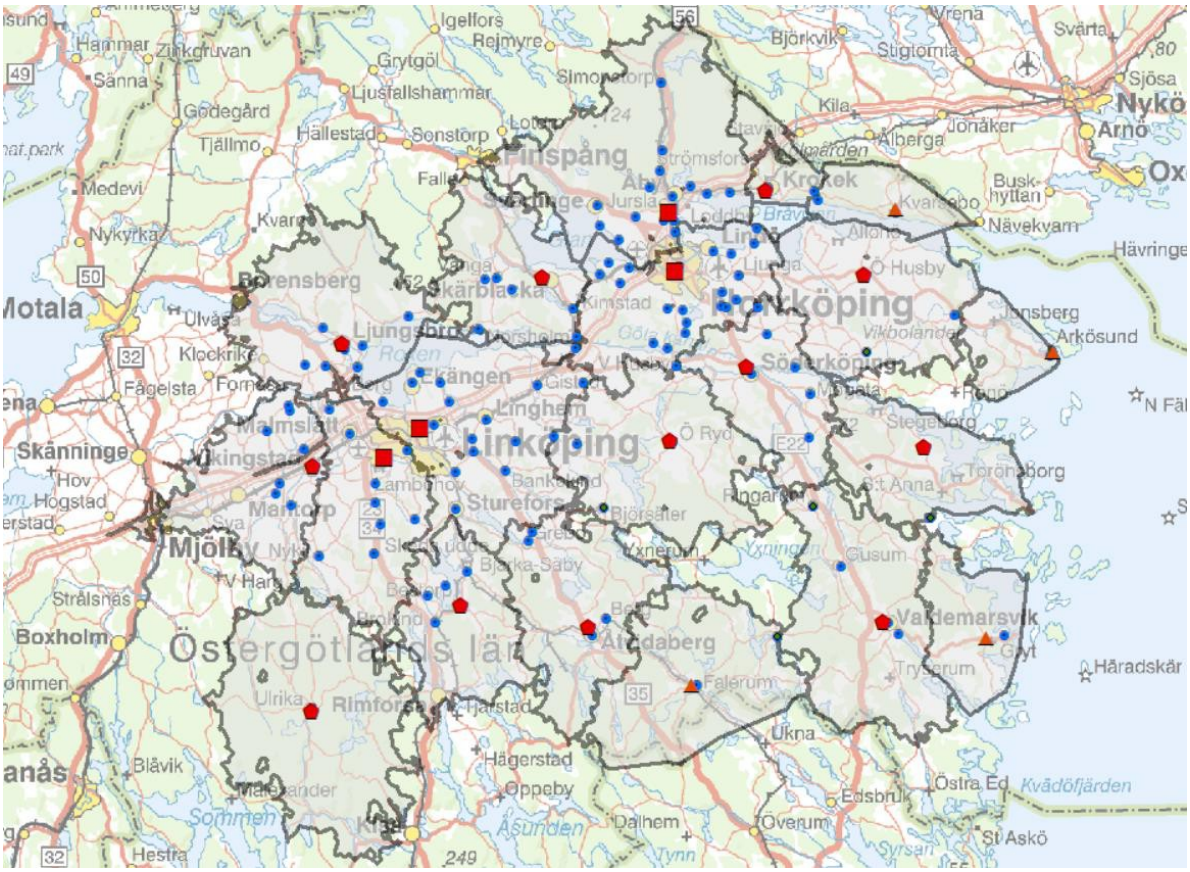
NUMERICAL EXPERIMENTS

In the following, we first present a short description of the case study that we used to test and validate the model and then, we present the numerical results.

Case Description

We used the area of a large FRS organization (Räddningstjänsten Östra Götaland, RTÖG) in Östergötland county in Sweden as our use case. Östergötland is located at the south-east of Sweden with a population of over 470 000 inhabitants and an area of 9 979 square kilometers, leading to a population density of approximately 47.1 inhabitants per square kilometers. Östergötland is divided into 13 municipalities, and RTÖG is responsible to provide FRS in five of these, that together have about 341 140 (72.6% of the county total) inhabitants and spans an area of 5 270 square kilometers (53% of the county). In RTÖG's area of responsibility, there are a total of 120 populations centers, including cities, towns, and villages. A subset of these (the ones where we expect to be able to recruit at least five volunteers) are used as potential volunteer centers. The area is also divided into a set of 6084 population squares, with a known number of permanent residents. This is done to get a detailed view of the expected coverage from fire stations and volunteers centers.

RTÖG currently has 20 fire stations: four fulltime stations, 12 part-time stations, and four volunteer stations. At the fulltime stations, there is always at least one unit (typically consisting of four firefighters and one commander) present. They have a preparation time (i.e., the time from when the alert comes to the station until the resources leave the station) of 90 seconds. At the part-time stations, the firefighters have preparedness at home or at their regular job. When there is an alert, they will go to the station to prepare and leave in an appropriate vehicle. Thus, their preparation time is longer than for the fulltime firefighters, being 300 seconds (five minutes). Volunteer firefighters do not have preparedness and are thus not obligated to respond when there is an alert (although many will do so). Otherwise, a volunteer station is much like a part-time station. There is no set preparation time, since response is voluntary, but for calculation purposes, we use 300 seconds. Volunteer firefighters, and volunteer FRS stations, are different from the civilian volunteer centers that we locate in this case study. While the volunteer firefighters have training, clothes, vehicles and a fire station to which they go before responding, the civilian first response volunteers that are to be trained at the volunteer centers, will have much more limited training and equipment, and will typically respond directly from where they are when they get the alert.



RTÖG plans to start some volunteer centers across the county, and as their starting goal, they plan to begin with initiating two centers. Thus, our initial target for locating volunteer centers is $P = 2$. As previously indicated, the

location of all population centers as well as FRS stations are known, and thus, travel times between each pair of these locations can be easily calculated. We used ArcGIS 10.6.1, utilizing the Network Analyst module to calculate these, based on the Swedish national road database, and using shortest path calculations with the speed limit and link length to estimate the time it takes to travel on a link.

We considered the service radius for all FRS stations (fulltime, part-time, and volunteer) to be 1200 seconds (20 minutes) and for the volunteer centers to be 600 seconds (10 minutes). The preparation time for the fulltime stations was set to 90 seconds, while this time for part-time and volunteer FRS stations was set to 300 seconds.

We considered two scenarios where volunteers had either 90 seconds or 300 seconds preparation time, since real preparation times for volunteers are difficult to estimate. In one additional setting, as a verification, we excluded the volunteer FRS stations from the set of FRS stations, which resulted in a total of 16 stations (rather than the original 20).

In Figure 2, we show the primary coverage areas for the 20 FRS stations, where the border is reached within 20 minutes of driving from a station; the volunteer FRS stations are shown with the red triangles and the remaining are fulltime and part-time FRS stations.

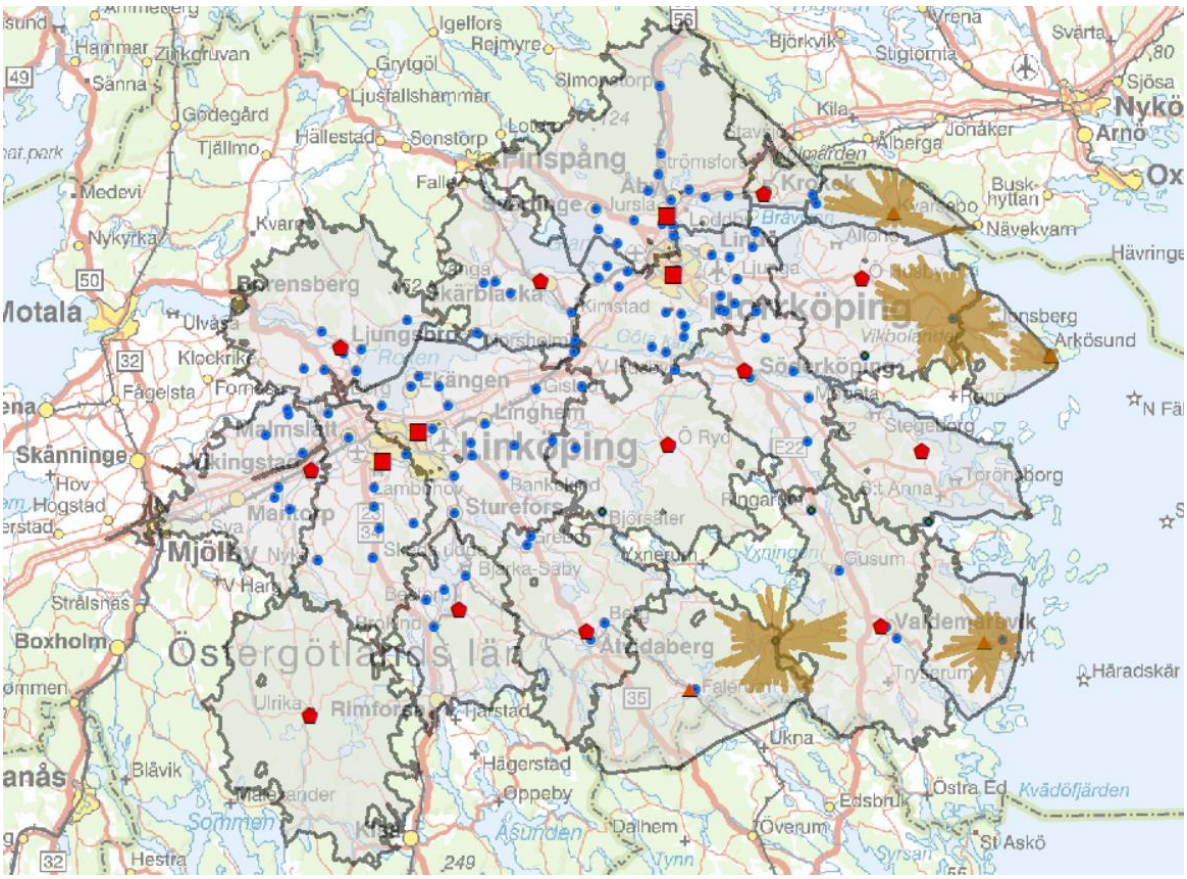

Figure 3. Location of five volunteer centers with 90 seconds preparation time, not considering volunteer FRS stations

Then, we wanted to compare output of the model when including all stations (20 stations) and investigate how different preparation times might affect the coverage. In Table 1, we present results for $P = 2$ but for different setups where volunteers had 90 seconds or 300 seconds as their preparation time. For both setups, the model produces the same optimal locations, indicating stability of the model in producing the results, that is, the variability in preparation time does not affect which centers that are opened, and has only a marginal impact on the coverage. As expected, with the longer volunteer preparation time, a slight decrease in the total coverage rate can be seen as the response time (preparation time plus travel time to the scene) becomes longer. The decrease can, however, be considered fairly small.

Table 1. Comparison of coverage for different data setups, $P = 2$

Row	Data setup	Total number of covered people	Total coverage
1	90 seconds, 20 stations	335 381	98.3%
2	300 seconds, 20 stations	335 293	98.3%

Finally, we ran the model with all 20 FRS stations included, volunteers had 90 seconds preparation time (and 10 minutes coverage radius), and for different values of P. The result of this test for $P = 5$ is visualized in Figure 4. The solid, red circle (Ringarum) shows one of the first selected volunteer centers by the model (i.e., when the model was run for $P = 2$); according to RTÖG, the FRS used to have a part-time fire and rescue service station there, that was closed down in recent years. However, as we can see, parts of the Ringarum area receives a poor coverage from the closest FRS stations, which was also confirmed by RTÖG. Consequently, locating a volunteer center in that region, as shown in Figure 4, was considered reasonable by RTÖG. The dashed, blue circle in Figure 4 is around Ramsdal, the second village which was selected by RTÖG to be a volunteer center, and the second village selected by the model for $P = 2$. Ringarum had a population of 606 residents in 2020 and Ramsdal had 50, but together they cover a total of 3003 inhabitants within 10 minutes. After the selection of these two villages, RTÖG started recruitment and training of volunteers in these two locations.

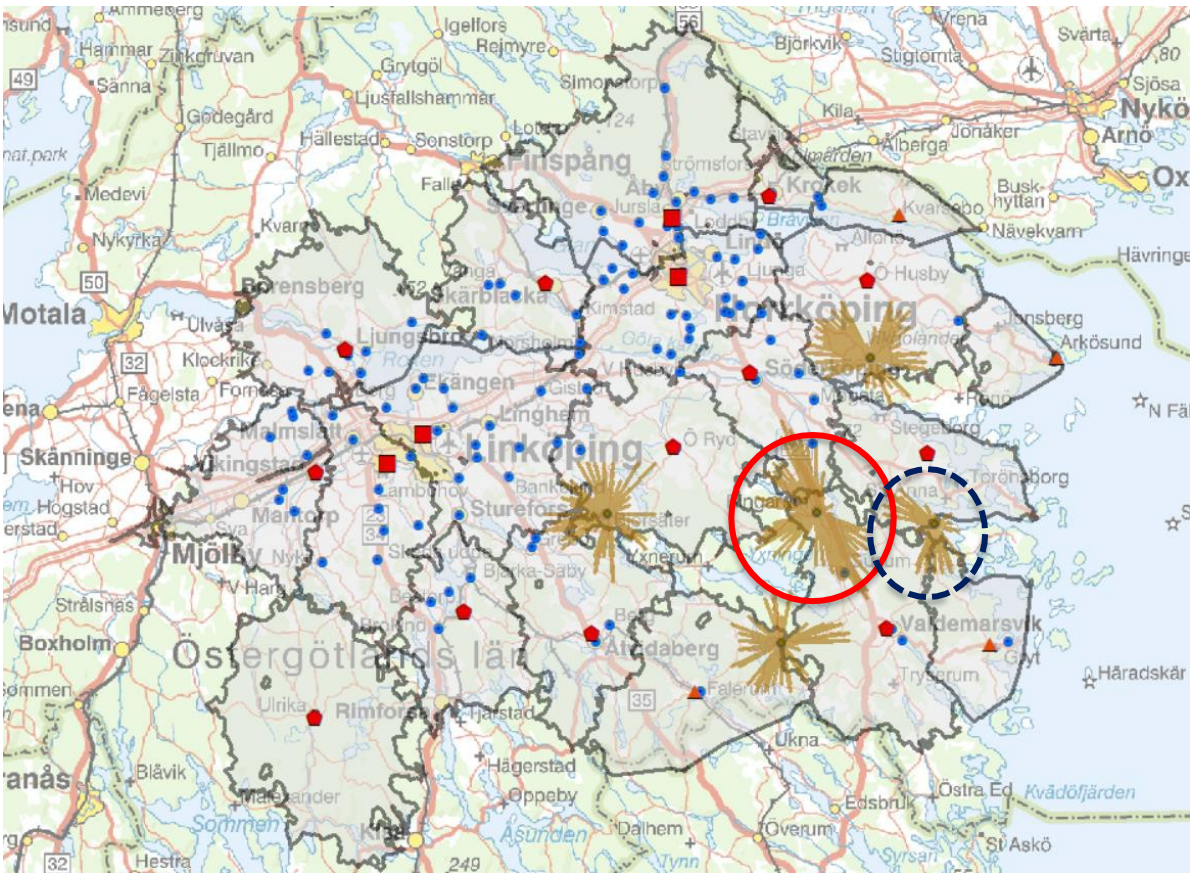

Figure 4. Location of five volunteer centers with 90 seconds preparation time, considering all 20 FRS stations

CONCLUSIONS AND FUTURE STUDIES

In this work, we proposed a simple coverage model for the selection of rural villages as volunteer centers to improve emergency response coverage. The model showed promising results, which were acceptable for practitioners (i.e., the largest FRS organization in Östergötland), and the simplicity of the model makes it easy for them to understand and utilize it. Thus, they picked a solution from the model, and have started volunteer centers in two new villages in Östergötland. This shows that the model is useful as a practical decision support tool. We are now following the implementation process, and when the volunteer initiative has matured, and the volunteers in these two villages have responded to enough events, we will evaluate the practical effects of the initiative. This should give valuable insight into how information system facilitated volunteerism, combined with operations research-based techniques can help improve the emergency response system.

The optimization model can be further extended by considering additional aspects, such as minimizing response times, incorporating uncertain elements, and including budget constraints. However, this must be done carefully, so that the comprehensibility of the model is not lost. Moreover, further research directions related to the volunteer initiative can include studies aimed at assessing the effectiveness of volunteer response and other aspects that should or could be incorporated.

ACKNOWLEDGMENTS

We kindly thank Michael Wahlqvist, Marie Bäck, Joakim Ivarsson, and the rest of the staff involved in the volunteer initiation project at RTÖG for kindly sharing knowledge and data. We are also grateful to the track chair responsible for handling our paper as well as the anonymous reviewers for their valuable comments. This work was funded by the Swedish civil contingencies agency (MSB), through the research program Managing the incident site of the future (MIST), which is managed by the Center for advanced research in emergency response (CARER).

ABSTRACT

This research delves into the intricacies of the Ukrainian military's supply chain during the ongoing Russian-Ukrainian war, with a specific focus on the significant role played by the civilian population in supporting the armed forces. Termed a defense supply chain, our study employs a multilevel model encompassing logistical, informational, and financial dimensions to elucidate the multifaceted levels within the defense supply chain network. Key actors identified include manufacturers, non-governmental organizations (NGOs), donors, and conscripts. The study sheds light on the vulnerabilities in the flow of goods in the defense supply chain. A resilient defense supply chain relies on efficient NGO communication and the crucial alignment of donor income growth with escalating resource prices.

Keywords

Civil-Military Integration, Defense Supply Chain, Russian-Ukrainian War, Supply Chain Network Model.

INTRODUCTION

The year 2022 marked a pivotal moment in global affairs as Russia's full-scale invasion of Ukraine reshaped the geopolitical landscape, prompting a profound reevaluation of military capabilities, strategic responses, and international alliances. Against this backdrop, our research characterizes the intricate web of dynamic civilian-military interactions within the context of the Ukrainian defense supply chain and highlights the role of information in this context.

The Russian-Ukrainian war, characterized by a full-scale invasion, unfolded as an asymmetric warfare scenario where Russia possesses substantial resources over Ukraine (International Institute for Strategic Studies, 2021). This asymmetry catalyzed a distinct military campaign heavily reliant on the self-organization of civilians. Ukrainian self-organization, which, as noted by Channel-Justice (2022), was already evident over a decade ago, as the 2013-2014 Euromaidan protests were unfolding in Ukraine.

Ukraine's two-year defensive challenges initial perceptions regarding the military power balance between Russia and Ukraine (Dalsjö et al, 2023; Ti, 2023). Increasing evidence points to the aggressor's ill-judged and overly optimistic military calculations such as Russia's poor understanding of its own forces, poor Russian training, and low standards of tactical competence. A key, yet understudied, element in Ukraine's surprising success was the role of its citizens. Indeed, Barany (2023), Hackett (2023), Hoffman (2022), and Tierney (2023) underscore the significance of the human factor in warfare, emphasizing the importance of investing in personnel, competent commanders, and comprehensive training.

Armed conflict triggers the application of the Third Geneva Convention of 1949, the First Additional Protocol of 1977, and customary rules of International Humanitarian Law (IHL). Humanitarian organizations, guided by IHL principles, maintain a clear demarcation between military and nonmilitary aid, underscoring the imperative of

Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

principled neutrality to protect civilians and to uphold human rights (Melzer, 2019).
Ley (2022) emphasizes the fundamental role of social networks in mobilizing against insecurity, transforming individual fears into collective anger and providing a sense of security. For Ukrainian civilians, providing aid to the military is viewed as a humanitarian response, as it has helped to stave off the Russian invasion and the resulting horrific damage and suffering to the population (Dunn et al., 2023). Thus, volunteer action was overtly political, a form of resistance to Russian attacks and domination (Konrad et al., 2023; Slim, 2022).

We define the current situation in Ukraine as a full-scale invasion with a defense supply chain. By full-scale invasion we mean that one government's armed forces are defending their sovereign country against an unprovoked invasion by armed forces of another state. The term defense supply chain refers to a logistical system in which civilians are an essential and integral part for a defending nation's military success. Specifically, we study how civilians provide the Ukrainian military with ammunition, food, transport, medical supplies, warehouses, and act as the main channels for information transmission. While civilian surveillance, and participatory gathering and sharing of intelligence have a growing body of evidence, the agentic power of civilians in military logistics has not been documented. Although defense supply chain network economics has been studied (Nagurney, 2023), it has been examined in the context of behavior of defense firms, which are concerned about revenues as well as risk. Moreover, the role of information in defense supply chains has not received much attention and, yet, as we hypothesize, information plays an indispensable role in supply chain effectiveness, by providing the crucial linkages between the logistical and financial domains.

Motivated by our observations in Ukraine, our research question is: to what extent is the defense supply system in Ukraine vulnerable, and how can it be enhanced to bolster resilience?

To answer our question, we set the following three objectives:

1. To describe and visualize the structure of the defense supply chain in the Russian-Ukrainian war.
2. To analyze the roles played by key actors, including manufacturers, NGOs, donors, and conscripts, in sustaining the defense supply chain.
3. To investigate the vulnerabilities of the defense supply chain.

In what follows, we explore civil-military integration across various contexts through a literature review and we review a theoretical framework to describe the levels of the defense supply chain and the roles of key network participants. The method section outlines our approach involving participant interviews and analysis of volunteer funds. In the discussion section vulnerable points in the defense supply chain are identified, and suggestions for strengthening them are offered.

LITERATURE REVIEW

The collaboration between military and civilian entities assumes multifaceted manifestations, each driven by distinct objectives and involving a spectrum of actors, including military personnel, international organizations, local non-governmental organizations (NGOs), and governments (Franke, 2006). We navigate the terminology of Civil-Military Integration (CMI), specifically in the context of the defense supply chain in the Ukrainian case.

NATO's Civil-Military Coordination Doctrine (CIMIC) defines CIMIC as the collaboration between the NATO commander and civil actors in support of missions. Emphasizing cooperation with various organizations, CIMIC's core functions in stability operations encompass liaison, assistance to the civilian environment, and support to the military force (NATO, 2003). Distinguishing itself from Civil Affairs (CA) activities, which doctrinally differ, CIMIC prioritizes humanitarian needs and guides interactions to achieve humanitarian mission objectives, while CA centers on military needs and suggests methods to garner civilian support for military missions (Department of Defense, 2003).

Our study purposefully steers clear of delving into CA in the Russian-Ukrainian war due to the well-established civilian-military relations in Ukraine, which are marked by extensive civilian involvement in supporting and interacting with the Ukrainian military. The Ukrainian military, primarily comprised of civilians mobilized through general conscription, exemplifies CMI in conflict zones. Civilians willingly take on the partial responsibility of supplying resources for the Ukrainian military, thereby enhancing the country's military prowess. This collaborative endeavor is encapsulated by the concept of CMI, aspiring to create a unified and synergistic approach where civilian and military elements work in close tandem, sharing resources, information, and decision-making processes.

CMI emerges as a pivotal facet of collaborative endeavors between civilian and military entities, especially in the realm of global security challenges. Researchers scrutinize CMI from various angles, with one group delving into the theoretical underpinnings and evolutionary dynamics within this context. Brooks (2019) offers an overview

of the theoretical landscape. Su et al. (2020) contributes a quantitative perspective through an evolutionary game framework, and De Coning (2016) delves into the theoretical aspects, shedding light on the complexities and potential constraints in civil-military integration.

A second research perspective regarding CMI revolves around regional insights and case studies, unraveling how this collaboration unfolds in specific contexts. Lafferty et al. (2013) explore China's approach, while Welle (2010) provides an Afghanistan case study, elucidating the challenges and successes in creating a unity of command. Hønneland & Jørgensen (2018) introduce a regional dimension by examining civil-military relations on the Kola Peninsula and the delicate balance between integration and autonomy.

Vuono (2008), Lucius (2016), and Egnell (2009) shift the focus to practical aspects, offering insights into challenges and effective strategies of CMIs. Vuono (2008) addresses practical challenges in stability operations. Lucius & Rietjens (2016) explore practical approaches for cooperation in peace operations, and Egnell (2009) provides insights into navigating diverse operational environments. Berg (2020) investigates the practical implications of civil-military relations in postwar politics, specifically examining their connection to civil war recurrence.

While the existing literature delves into the theoretical underpinnings, challenges, and dynamics of civil-military integration, as well as regional perspectives and case studies, a discernible research gap persists. This gap pertains to understanding the distinct roles, contributions, and challenges of civil initiatives, in contrast to military or government initiatives within the context of CMI. Bridging this gap in the Ukrainian case assumes significance for practitioners seeking effective collaboration strategies, offering a more nuanced understanding of the diverse actors involved and their impact on the success of civil-military integration efforts. Cooperation and possible associated synergies have been modeled with a goal towards quantification in the case of humanitarian organizations by Nagurney and Qiang (2020) using a supply chain network perspective but not yet in a civilian-military defense setting.

THEORETICAL FRAMEWORK

Central to our analysis is the defense supply chain network model that provides a structured framework for understanding the defense supply chain, inspired by Nagurney et al. (2002). The authors introduced a multilevel network perspective for conceptualizing the dynamics underlying supply chains in the presence of competition. This multilevel model comprises the logistical network, the informational network, and the financial network. The authors described the behavior of the decision-makers, including manufacturers, retailers, and consumers.

In contrast, our multi-level structure of the defense supply chain involves four actors: manufacturers, NGOs, and donors. Manufacturers, NGOs, and donors are civilians. NGOs operate voluntarily within this framework. Military conscripts act as the end-users, NGOs serve as intermediaries, manufacturers produce the goods, and donors pay the price of the military product.

We examine the product flow of Unmanned Aerial Vehicles (UAVs) in the defense supply chain – a vital commodity in Ukraine's defensive strategy. The mention of drones serves as an example because even after two years of conflict, drones remain a relevant commodity. Initially, the defense supply chain redistributed goods such as food and clothing, but now there is less demand for such items, whereas drones continue to be in demand. Several studies highlight the significance of UAVs and their applications in military and humanitarian operations. For example, Jasper (2023) discusses the role of UAVs in Ukraine's military response, and Colajanni, Daniele, and Nagurney (2023) construct a three-stage stochastic optimization model focusing on three phases of disaster management integrating 5G technology and UAVs.

Manufacturers

Manufacturers are crucial in determining optimal production quantities and product pricing. Their role is pivotal in shaping supply chain dynamics, as they influence the equilibrium price for UAV products. The manufacturer's supply curve is influenced by the elasticity of production costs. An increase in the supply in UAV production results in higher production costs, affected by factors such as limited inputs (e.g., UAV components and skilled labor).

NGOs

NGOs collect information about the needs of conscripts and inform the civilian community of their needs, purchase goods from manufacturers and deliver them to the military. NGOs determine the volume of shipments based on the conscripts' needs, the manufacturer's price for the product, which they agree upon for the transactions

to take place, and the financial capacity of the community to be donors.

Conscripts

On February 24, 2022, a Presidential Decree declared a general mobilization in Ukraine summoning all military-eligible men, reservists, and conscripts capable of serving based on their health condition to join the armed forces (Presidential Decree, 2022). A part of the Armed Forces of Ukraine consists of men without prior combat experience – conscripts. We examine a scenario in which conscripts were already members of a particular NGO before the onset of Russia's invasion. Positioned as the ultimate consumers in our study, conscripts generate the demand for UAVs based on their military needs. It is important to note that 77% of all NGOs in Ukraine are currently engaged in providing assistance to the Armed Forces (ISAR Ednannia, 2023).

Donors

The process of crowdfunding donations for Ukraine involves leveraging social media platforms such as X (formally Twitter), Facebook, Instagram, and YouTube (Ye et al, 2023). Online channels, facilitated by these platforms, play a crucial role in mobilizing donors for collective action. Donors' financial capacity and relationship proximity with conscripts influence the volume of their contributions, providing an alternative source of income to government funds.

Multi-Level Structure of the Defense Supply Chain Network Model

The defense supply chain model operates on three levels: logistical, informational, and financial (Figure 1).

Logistical Network

- Manufacturers (Top Tier): Producers (m) of UAVs, determining production quantities.
- NGOs (Middle Tier): Intermediaries (n) distributing UAVs to conscripts based on their needs.
- Conscripts (Bottom Tier): End-users (o) with specific affiliations to NGOs, influencing the flow of goods.

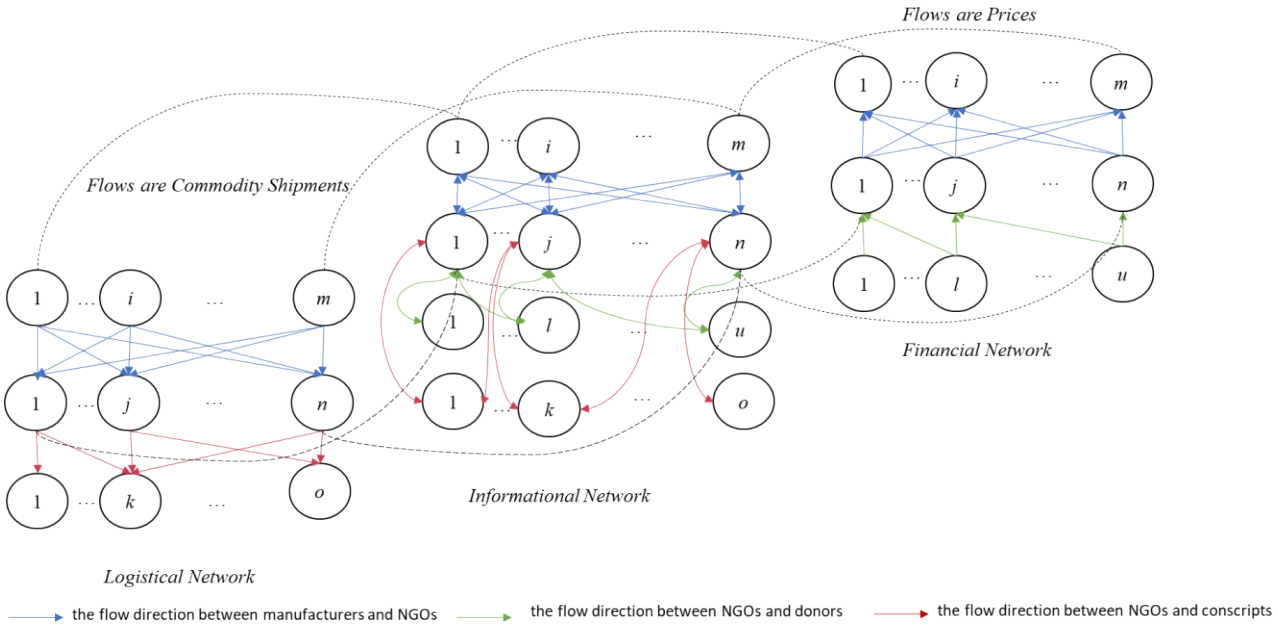

Figure 1. Multi-Level Structure of The Defense Supply Chain Network Model

The logistical network exhibits a downstream flow, starting from manufacturers down to NGOs and ultimately reaching specific conscripts. The flow is contingent on the density of ties between NGOs and conscripts, emphasizing the network's dependence on affiliations.

Informational Network

- Manufacturers (Top Tier): Provide information on prices and quantities of UAVs to NGOs.
- NGOs (Top-Middle Tier): Disseminate conscripts' needs to the civilian community, announce

crowdfunding in local network.
- Donors (Bottom-Middle Tier): Included as an additional level in the information network (u), contribute financial resources based on conscripts' needs announced by NGOs.
- Conscripts (Bottom Tier): Share information about their needs within NGOs' network.

The bidirectional movement of information involves data about commodity shipment quantities and prices, establishing transparency and connectivity within the network.

Financial Network

- Manufacturers (Top Tier): Announce price of UAVs based on costs and availability of goods.
- NGOs (Middle Tier): Facilitate financial transactions by channelling donor contributions to manufacturers.
- Donors (Bottom Tier): Drive purchases by contributing financial resources based on their financial capacity. Donors' income is generated from different sources usually outside the conduct of military operations. The part of income Ukrainian civilians donate regularly for support of an army. A change in income affects the movement of the demand curve.

The upward flow in the financial network reflects a scenario where civilian donors influence purchases through their willingness to contribute, thus driving the financial aspects of the supply chain.

METHOD

To analyze the roles played by key actors and vulnerabilities of the defense supply chain, we use analysed NGO reports and conducted interviews. Quantitative data are obtained from reports issued by the two foremost civilian funds in Ukraine which actively support the Ukrainian military and uphold a commitment to transparent reporting practices – the Serhiy Prytula Foundation, and the "Come Back Alive" Foundation. Concurrently, qualitative insights are garnered through thorough interviews conducted with pivotal stakeholders, encompassing representatives from manufacturing entities, NGOs, and military personnel. These interviews yield nuanced perspectives on decision-making processes, information flow, resource allocation mechanisms, and crucially, the challenges encountered within the defense supply chains.

The methods employed in the research present several limitations that could impact the result. In the context of an ongoing war, the exchange of sensitive information exposes the involved parties to security risks. The interviews were conducted during the summer of 2023. While this timeframe provides valuable insights into the dynamics of the defense supply chain at a specific point in time, it may not reflect changes or developments that occurred before or after the interviews. The ongoing nature of the conflict and the evolving geopolitical situation could influence the effectiveness of the supply chain over time.

The data obtained from reports issued by civilian funds provide valuable information about the flow of goods within the defense supply chain. The "Come Back Alive" Foundation and the Serhiy Prytula Foundation received approximately $286 million USD and $16 million USD respectively in donations between February 2022 and December 2023. However, the scope of these reports may be limited, and they may not capture all relevant aspects of supply chain dynamics.

Despite the limitations outlined in the study, we consider its results valuable. Particularly significant is the portrayal of the ongoing war situation, which can serve as a crucial checkpoint for assessing the broader landscape and dynamics of the conflict. Direct engagement with respondents enabled the establishment of trust and dialogue, enhancing the depth of the findings. Moreover, by using participatory research practices we deem the information valid (Cornwall et al., 1995). One author is in Ukraine, and able to observe the described situation firsthand.

Interviews

To identify connections among actors in the defense supply chain, we conducted interviews. Nine military personnel, three NGO representatives, and one manufacturer were interviewed to gather diverse perspectives on the interactions within the defense network.

The participants included a Ukrainian manufacturer specializing in UAV production. The NGOs selected represented different scales of operation: a nationwide organization, and two local organizations from Lviv and Lutsk (cities in Western Ukraine). These organizations varied in terms of size, annual budget, and the number of members and volunteers in their networks. It is worth noting that all the organizations involved in this study were established prior to 2022, and their primary activities are distinctly different from humanitarian or military operations. Rather, their primary focus is in areas such as education and cultural youth activities (Table 1).

The interviews delved into the methods used by these organizations to disseminate information about the needs of their members, their fundraising strategies, and timelines for collecting and fulfilling those needs.

In addition to inquiring about organizational characteristics and information dissemination strategies, the research methodology encompassed detailed investigations into the types of goods handled by the organizations and the frequency of both receiving and distributing these goods to the military.

Table 1. Characteristics of NGOs Interviewed

	Primary activities	Members	Annual Turnover	Conscripts Supported	Categories of Goods	Source of Funding
Nationwide organization	Education	100-250	Medium (8-40M EUR)	10-50	UAVs, Vehicles, Clothes	International donations, Members' donations
Local NGO (Lviv)	Human Rights	50-100	Small (less 8M EURO)	Less 10	UAVs, Vehicles, Medical supplies	Members' donations
Local NGO (Lutsk)	Youth	less 50	Micro (less 700K EURO)	Less 10	UAVs, Vehicles	Charity Events

Questions addressed organizational membership, categories of goods handled, frequency of transactions, funding sources, storage facilities utilization, duration of processes from need identification to fulfillment, and collaborative partnerships.

The analysis involved synthesizing data from reports with qualitative insights gathered from interviews to understand the interconnectedness and dynamics of the defense supply chain. Findings from both report analyses and interviews were used to draw conclusions and develop recommendations regarding the optimization of the defense supply chain in Ukraine.

FINDINGS

Product Analysis in Defense Supply Chain

In Ukraine, three platforms play a crucial role in supporting the Ukrainian military: the state platform UNITED24, the Serhiy Prytula Foundation, and the "Come Back Alive" Foundation. Notably, UNITED24 serves as a fundraising platform rather than a foundation, channeling contributions directly to relevant ministries, including the Ministry of Defense. The platform has raised $504 million USD in donations from the onset of the conflict until December 2023 (UNITED24, 2023).

The "Come Back Alive" Foundation, operational since 2014, focuses on enhancing the effectiveness of the Ukrainian Defense Forces by procuring equipment such as thermal optics, drones, vehicles, and surveillance systems. The "Come Back Alive" Foundation, received 2,898,936 contributions from February 2022 to December 2023, averaging $100 USD each, with 96% of donations by count and 35% by total amount below $1,000 USD (Come Back Alive, 2023).

The Serhiy Pritula Foundation, established in 2020 in Kyiv, garnered over $16 million USD in donations since the onset of the war, with an average individual contribution of $10 USD. 75% of donations fall within the $1,000 USD range (Serhiy Prytula Foundation, 2023)

Each foundation exhibits unique characteristics in its operations. The "Come Back Alive" Foundation is authorized to allocate funds for weaponry (constituting 20% of its acquisitions) and collaborates with the Ministry of Defense to determine military needs. Additionally, it engages in analytical research that influences nationwide defense decisions and implements projects focused on veteran rehabilitation.

To request assistance for a military unit from the Sergiy Prytula Foundation, an official request must be submitted on the website prytulafoundation.org with the commander's signature and stamp. The foundation then goes through the bureaucratic process, checking for the presence of the stamp and verifying whether individuals are genuinely part of the specified unit. The main challenge arises from the overwhelming number of requests, exceeding the foundation's capacity to fulfill physically (44%). Prioritization becomes necessary based on the unit's location, the tasks it performs, checks on whether aid has been received from other foundations.

Despite variations in reporting practices, our attempt to compare the categories of goods procured by these foundations from January to November 2023 reveals some trends (Figure 2). One notable observation in the foundation reports is the presence of two distinct categories – quadcopters and Unmanned Aerial Vehicles (UAVs), although theoretically, a quadcopter is a type of UAV. Typical quadcopters include the Autel Drone EVO Nano+ and the DJI Mavic 3 Enterprise. UAVs procured by the foundations encompass models such as Leleki, Furii, Valkyrii, among others, each serving diverse military purposes.

Of noteworthy interest, 53% of all acquisitions from the Serhiy Prytula Foundation are comprised of purchases of UAVs and quadcopters (22% and 37% respectively of total acquisitions). In contrast, only 14% of "Come Back Alive" Foundation's acquisitions were UAVs and quadcopters (2% and 12% respectively.

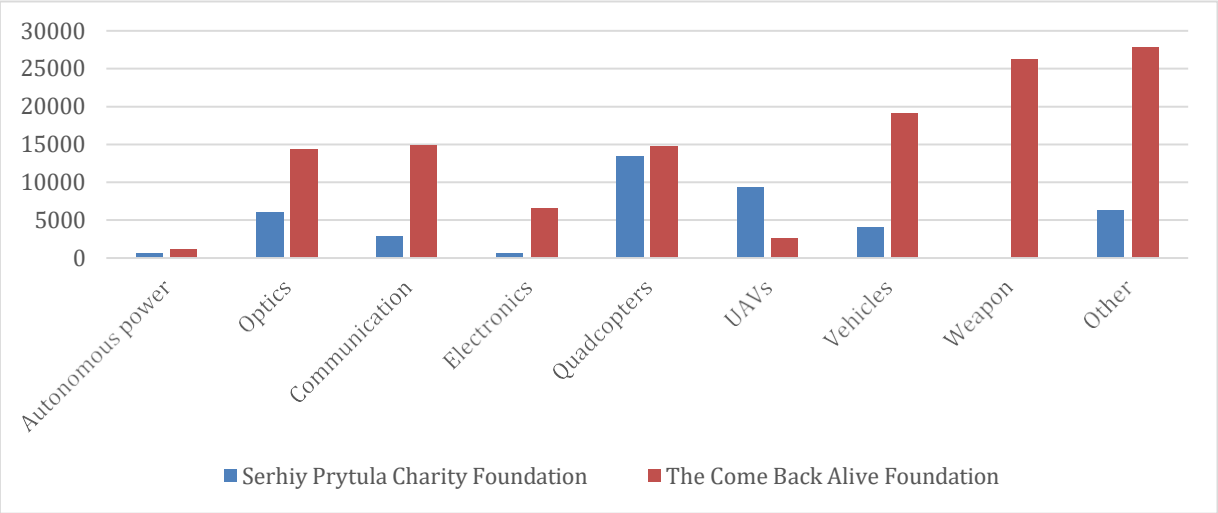

Figure 2. Procurements by Ukrainian foundations during January to November 2023, in thousands of USD

All three organizations interviewed engaged in the collection of funds for UAVs. In addition, one organization also participated in the distribution of medical supplies and another in the distribution of military clothing.

In interviews with military personnel, an additional layer of complexity was uncovered within the defense supply chain. It was revealed that the distribution of needs among military units was not uniform, and this uneven distribution was closely tied to the affiliation of unit members with various civilian networks. The research identified a distinctive pattern wherein the preferences and necessities of military units were intricately linked to their connections within different civilian networks.

An interesting observation emerged: there was a lack of expressed need for food among the military personnel interviewed. Instead, a consistent trend was identified – each individual, regardless of their specific military function, demonstrated a shared experience in expressing the need for fundraising in support of drones and transportation.

Furthermore, military personnel, upon identifying a need, would often use personal savings to fulfill that need before publicly announcing a fundraising campaign within their network of donors. This practice aimed to expedite the satisfaction of requirements by leveraging personal resources before engaging external support networks.

The study also revealed a distinct temporal aspect to the process, with the timeframe for closing requests identified needs ranging from one to three months. This finding shed light on the urgency and efficiency of the defense supply chain in responding to the evolving needs of military units. The dynamic nature of these timelines highlights the adaptability of both the military and the civilian support networks in navigating the challenges posed by the ongoing conflict.

This understanding of the non-uniform distribution of needs, coupled with the intricacies of timing and self-reliance within the military units, contributes valuable insights into the internal dynamics of the defense supply chain and further informs the overarching analysis of the defense supply network. Both report analyses and interviews revealed that UAVs were the most requested item within the defense supply chain; thus, we ground our analyses and discussion around this significant product.

DISCUSSION

Examining the intricacies of the defense supply chain model, we identify key vulnerabilities: network structure vulnerabilities, logistics gap vulnerabilities and financial vulnerability.

Network Structure Vulnerabilities

Non-All-to-All Connections. The defense supply chain operates with a multi-level structure, featuring manufacturers, NGOs, donors, and conscripts. However, the network structure is not an all-to-all connection. This creates challenges in the efficient distribution of information and resources, resulting in a leaky network where gaps in communication and coordination can emerge. Among NGOs, 16,8% continuously involve other NGOs in cooperation after the large-scale invasion and 42,4% in situational project partnerships (ISAR Ednannia, 2023).

Difficulty in Information Flow. The non-all-to-all connection structure makes it challenging to distribute information effectively. This difficulty arises from the fact that a single NGO can assist multiple members, and a recipient can receive aid from various public organizations. The lack of direct connections between all actors hinders seamless information flow, potentially leading to delays and inefficiencies in the supply chain.

Intermediaries as Necessity. To address these challenges, intermediaries become crucial to connect NGOs with one another. Establishing efficient communication and reinforcing networks require that these intermediaries facilitate the exchange of information and resources. Identifying and leveraging influential actors becomes essential for enhancing connectivity within the network.

Logistics Gap Vulnerabilities

Under-Responsiveness. The defense supply chain is vulnerable to under-responsiveness, especially in scenarios where the logistics network fails to provide the right mix of resources at the right place and time. This under-responsiveness results in a gap between the available and required logistic resources, impacting the effectiveness of combat operations.

Cumulative Shortfalls. Shortfalls in resource availability accumulate over time, leading to a widening logistics gap. If under-responsiveness persists, this gap can reach a critical point known as the logistic culmination point. Beyond this point, combat operations cannot be executed as planned, and the effectiveness of military endeavors decreases significantly.

Financial Vulnerability

Funding is essential to NGOs engaged in humanitarian operations and, for many such organizations, securing financial donations is critical to their very sustainability (cf. Toyasaki and Wakolbinger (2014), Nagurney et al. (2018), Nagurney, Salarpour, and Daniele (2019)).

The financial vulnerability of the supply chain is intricately linked to the absolute inelastic demand for military goods, particularly for UAVs. With a price elasticity of zero, changes in the product price do not influence the quantity demanded. The demand function, dependent on conscript needs and donors' income, shapes the dynamics. Conscript needs, influenced by attrition and battlefield consumption, are crucial determinants.

The financial vulnerability arises when the demand surpasses the available supply, triggering an increase in price and production volume. However, internal constraints also exist, demanding a simultaneous growth in donor incomes. If donor incomes stagnate while needs rise, a temporary surge in demand occurs, escalating prices and reducing donor incomes even further. Similarly, if needs outpace declining donor incomes, sustained demand necessitates even higher donor income growth, highlighting the delicate financial equilibrium within the civilian-military supply chain.

Resilience in the Defense Supply Chain

The vulnerabilities in the defense supply chain are rooted in the network structure's complexity, the financial vulnerability, and the potential for under-responsiveness, leading to a logistics gap. Addressing these vulnerabilities requires a focus on strengthening connections, leveraging intermediaries, supporting income growth for donors, and ensuring the adaptability of the logistics system to maintain a responsive and resilient supply chain (Figure 3).

Communication line for NGOs. Efficient communication and network reinforcement require intermediaries to connect NGOs with one another. Identifying influential actors helps to pinpoint organizations that can serve as

effective mediators in the network.

Donor Income Growth. In the realm of financial vulnerability, resilience hinges on the crucial alignment of donor income growth with the escalating prices for resources and demand. The financial network highlights the pivotal connection between donor income and the demand functions, emphasizing the need for a symbiotic relationship where increased demand and prices stimulate growth in donor incomes.

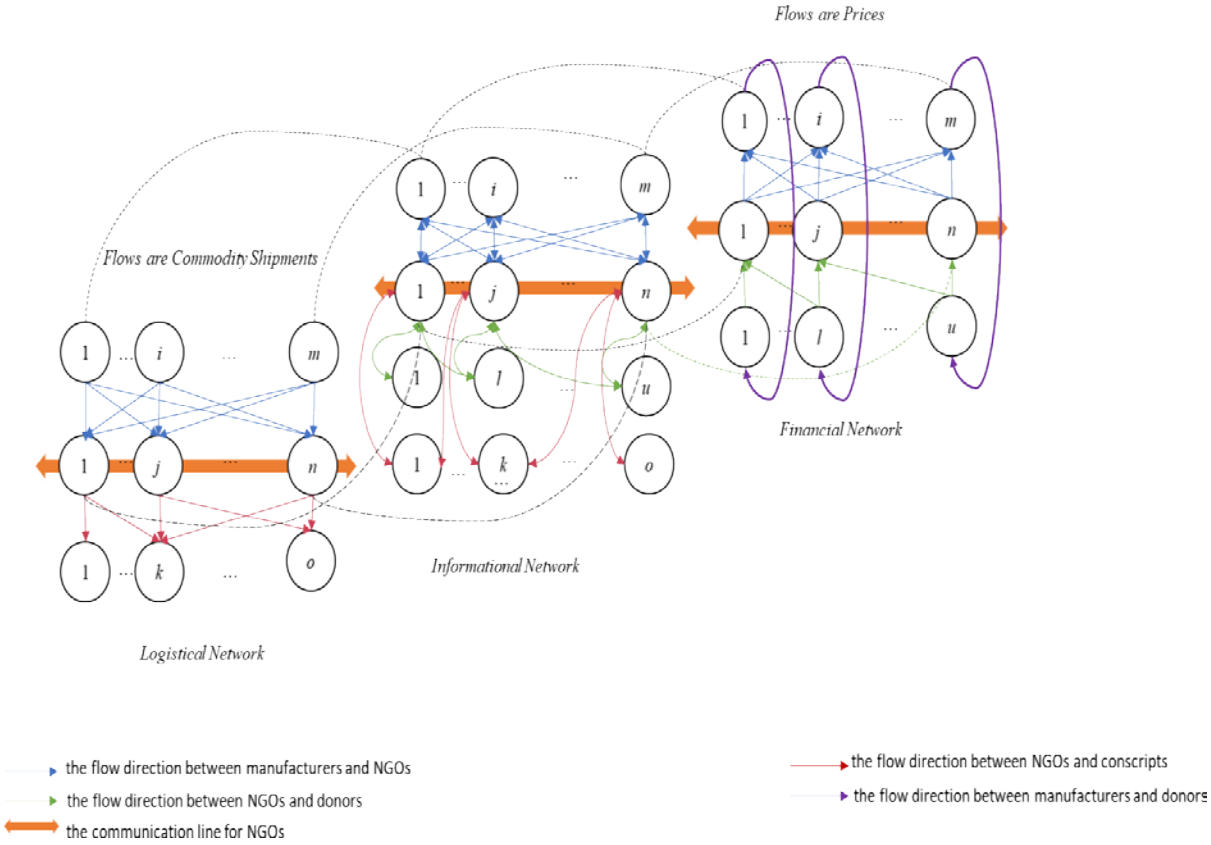

Figure 3. Resilient Defense Supply Chain Model

A noteworthy facet of resiliency involves donors working with the same manufacturers that produce the needed goods, such as UAVs. Procurements by Ukrainian foundations during the war are noteworthy for their sources of origin. For instance, UAVs Leleki, Furii, and Valkyrii are manufactured by Ukrainian companies, while quadcopters Autel and Mavic are of Chinese origin. It is important to mention that in Ukraine, approximately 200 drone manufacturers produce various types of drones, but, these manufacturers often rely on components from Chinese production (Balashova & Melnyk, 2023). In this dynamic, when donors obtain income from external sources, they contribute an amount equivalent to what is accessible as donations. However, as prices rise, their donations decrease, creating a delicate equilibrium between sustaining demand, prices, and donor incomes. The resilient defense supply chain underscores the imperative of directing financial resources towards Ukraine's military-industrial complex. This strategic allocation ensures stability through consistent salaries for the Ukrainian population.

CONCLUSION

We set out to answer the question: To what extent is the defense supply system in Ukraine vulnerable, and how can it be enhanced to bolster resilience? To answer this question, we used three objectives. Beginning with Objective 1 we described and visualized the structure of the defense supply chain in the Russian-Ukrainian war (Figure 3). The multilevel defense supply chain developed provided insight regarding key actors and illuminated their interactions within the supply chain, spanning logistical, informational, and financial dimensions (Objective 2). Our analysis revealed the pivotal roles played by manufacturers, NGOs, donors, and conscripts in sustaining the defense supply chain. By employing both quantitative data from reputable civilian funds and qualitative insights from interviews with key stakeholders, we gained an understanding of the dynamics at play. Finally in our third objective, we sought to investigate the vulnerabilities of a defines supply chain. Our investigation

identified several vulnerabilities including network structure complexities, logistics gaps, and financial fragilities. These vulnerabilities underscore the need for strategic interventions aimed at strengthening connections, leveraging civilian intermediaries, and ensuring the adaptability of the logistics system.

Importantly, our study emphasizes the importance of civilian-military integration in bolstering a nation's military capabilities. By recognizing civilians as active contributors to the defense supply chain, rather than mere recipients of aid, we advocate for a more unified approach that maximizes resources and enhances overall effectiveness.

Moving forward, addressing the identified vulnerabilities will be crucial for enhancing Ukraine's defense resilience. By channeling financial resources into the military-industrial complex and promoting collaboration between civilian and military entities, Ukraine can build a more robust defense supply system capable of effectively responding to evolving challenges and safeguarding its sovereignty.

As further work, we aim to expand our focus to encompass the development of an information network for interaction initiatives within the defense supply chain, represented by NGOs. By examining the interdependence between the flow of goods and the density of connections among NGOs, we seek to identify opportunities for enhancing efficiency, mitigating risks, and improving coordination within the defense supply chain. By undertaking these additional research efforts, we aim to deepen our understanding and identify practical measures to address vulnerabilities and enhance the resilience of the supply chain.

Contextualizing Effective Use of Health Information Systems in Humanitarian Setting: The role of Transparent Interaction

Marta María Vila-Pozo
HISP Centre, University of Oslo
Médecins Sans Frontières Spain
martamv@ifi.uio.no

ABSTRACT

Humanitarian organizations strive for efficient and effective interventions, with information systems playing a crucial role. However, integrating data collection and processes within their operations remains a challenge. This paper examines the effective use of a Health Management Information System in a humanitarian context. Effective use aims at helping information systems contribute to the organisational objectives and holds promises to help improving information systems in this domain. The analysis uncovers obstacles related to system access and learning processes, suggesting that transparent interaction is vital for success. Transparent interaction is the first dimension in the Theory of Effective Use. Through contextualization, this paper defines effective use in humanitarian settings and evaluates the theoretical model's validity in this unique context. Drawing from concepts from the information systems body of theory, it contributes to the understanding of effective use by offering a contextualized model and a clear definition of transparent interaction, emphasizing its significance.

Keywords

Effective Use, Humanitarian Health Information Systems, Transparent Interaction, Affordance Network.

INTRODUCTION

The past year has been marked by ongoing conflicts, severe climate issues, and health crises like cholera and COVID-19. These factors have led to an alarming rise in hunger, displacement, and poverty. As a result, it is estimated that 339 million people will require humanitarian assistance and protection. This is a significant increase from the 274 million people estimated at the start of 2022. In short, one out of every 23 people will be in need of humanitarian aid (OCHA, 2022). In response to such existing and increasing demand humanitarian organizations assist people and communities who are in need and face significant challenges. This includes refugees, asylum - seekers, internally displaced populations, and others who have been affected by diseases, conflicts, and both human-made and natural disasters. Humanitarian organizations need to ensure efficiency and efficacy in their interventions and are expected to share data effectively to provide more coordinated interventions, imp rove accountability and provide efficient response (Checchi et al., 2017). The use of digital technologies and information systems are an integral part of the deployment of the response provided (Hunt et al., 2016). They facilitate communication, coordination, and the collection and analysis of large amounts of data, enabling timely responses in humanitarian contexts (Mesmar et al., 2016).

Information systems are contributing to providing the required information, and operational improvements involve the use of project management information systems and digital technologies for data collection and analysis. This shift has been observed in many humanitarian organizations over the past decade (ALNAP, 2015), replacing outdated spreadsheets and paper-based systems. These changes are expected to increased efficiency and effectiveness in their interventions; however, organizations have not yet fully succeeded in integrating data

collection and integration processes within their operations (ALNAP, 2022). Field interventions are not heavily scrutinized form a public health perspective among humanitarian actors, however, public health data is fundamental for documenting processes and interventions and to reinforce accountability and advocacy, really important in the context (Jarrett et al., 2021). A recent study of the status of the humanitarian system on the evidence of monitoring and evaluation data from eight big humanitarian funders showed evidence of impact was only available for 16% of the projects (ALNAP, 2022), in most cases it was not possible to collect data on the outcomes after the funding ended. This reveals a significant data gap on what impact innovations are collectively having on humanitarian effectiveness and efficiency (ALNAP, 2022).

The role of Humanitarian Health Management Information Systems (H-HMIS) is to collect routine data from the field interventions and generate the indicators and data aggregations necessary to follow up the status of the intervention and population needs (Magnuson & Dixon, 2020). Routine health data provides crucial public health information, enabling real-time surveillance, monitoring systems, and guiding timely interventions. Additionally, it facilitates the evaluation of intervention and accountability towards the organization's mission and objectives (Checchi et al., 2017). Measuring impact in the wellbeing of the population might exceed the domain of information systems theories, however, having robust information systems is a key component for it. The theory for Effective Use holds promises to contribute to improving information systems in this domain by helping assess to what extent information systems are effectively contributing to the organisational objectives and provide instrumental guidance to organizations to strengthen their internal information systems and report ing mechanisms. With the aim of analysing the adequacy of the theory for the context of humanitarian organizations, this paper aims to answer the following research question:

What are the challenges for attaining effective use of a humanitarian health management information system?

In the empirical setting of a field intervention of Médecins Sans Frontières Spain (MSF Spain), this analysis builds upon previous research which has studied the implementation and adoption of a H -HMIS from the headquarters offices in the global context of the organization (Vila-Pozo & Sahay, 2018), to the project coordination office (Vila-Pozo & Sahay, 2019) and the inpatient wards in the field hospitals (Vila-Pozo et al., 2022) of one of its field interventions.

The core analysis is based on a contextualization of the theory for effective use. In the next section, the theoretical component of this analysis is introduced. The third section introduces the case study, followed by an analysis and findings. The paper concludes with the discussion of findings and theoretical contributions.

RELEVANT LITERATURE

Theory of Effective Use

The theory of effective use (TEU) draws from Representation Theory (RT) and the conception of information systems as semantic systems (Wand & Weber, 1995). Representation Theory conceptualizes systems as capable of representing phenomena from which individuals retrieve digital representations of the real world. Therefore, an information system conveys meaning through a structure of signs. Representation Theory posits that information systems are comprised of three interrelated structures:

- Deep structure: This refers to the definition of data structures and their specifications to represent the domain. In the case of the H-HMIS it refers to the database and data model definition.
- Surface structure: This is the structure that enables the user to access the deep structure. It would mainly be the user interface of the H-HMIS.
- Physical structure: This component connects the deep and surface structures. This is the hardware supporting the implementation, from the computers or mobile devices to the broader infrastructure.

Individuals use digital representations to gain knowledge about a particular situation from the real world that informs their actions (Burton-Jones et al., 2017). The transition from use to effective use can be seen as the evolution from looking at the mere use of the system to perform a specific task (system use) to its use in a manner that contributes to the attainment of the organizational desired goals (effective use). The use of the information system is not seen as a goal itself, but as a mean to an end, i.e., the organization's objectives. Effective use is defined as "using a system in a way that helps attain the goals for using the system " (Burton-Jones & Grange, 2013). The nature of effective use is modelled across the following three dimensions, as described by Burton - Jones and Granje (2013):

- Transparent interaction: refers to "the extent to which a user is accessing the system's representations unimpeded by its surface and physical structures".

- Representational fidelity: relates to "the extent to which a user is obtaining representations from the system that faithfully reflect the domain being represented".
- Informed action: refers to "the extent to which a user acts upon the faithful representations he or she obtains from the system to improve his or her state in the domain of work".

The relationship between these dimensions is hierarchical. As a hierarchical network, transparent interaction activates information potential, which enables representational fidelity. Representational fidelity can then be leveraged by informed action (Burton-Jones & Grange, 2013). Actualizing these three dimensions is crucial to achieve effective use, where each of them is necessary but not sufficient for the next. This relationship is visually represented in Figure 1 below.

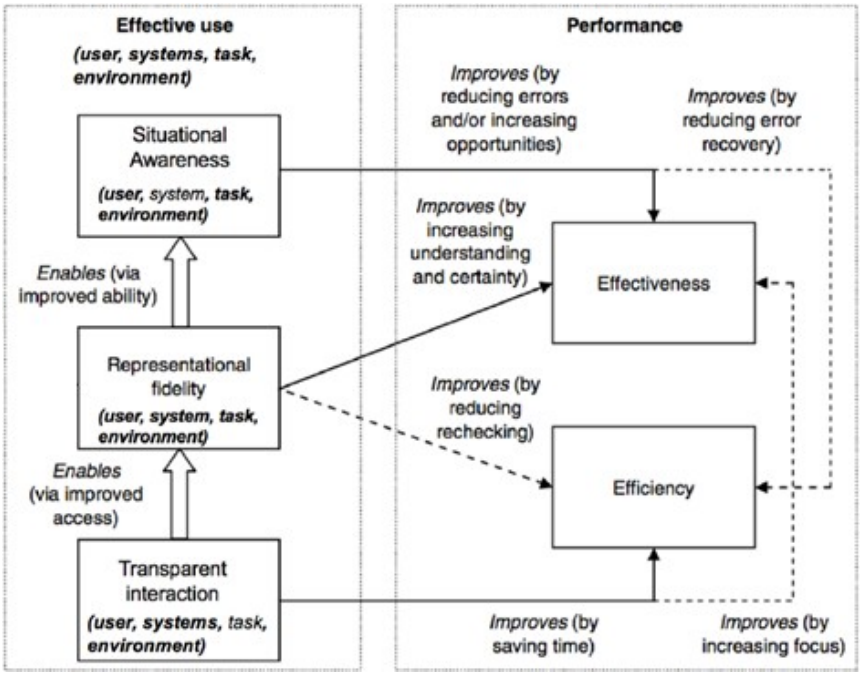

Figure 1. Effective Use model adapted for emergency management contexts (Bonaretti & Piccoli, 2018).

The theory of effective use has been used to guide research on IS implementations in a variety of domains, such as hospitals (Eden et al., 2018; Eden et al., 2019), educational providers (Eden et al., 2020), enterprises (Trieu, 2013), banking (Haake et al., 2018), and more recently in Emergency Management (Bonaretti & Piccoli, 2018) which proposed modifications to the TEU model. The main modification involved replacing the Informed Action dimension with Situational Awareness as the third dimension of effective use. Situational awareness assumes that all the necessary information may not be present in the information system (Endsley, 1995), and the focus instead is on sufficiency of the information as a foundation of effective use. The resulting TEU model adapted for emergency management contexts can be also found in Figure 1. When analysing the dimensions for effective use in this paper, I will use this model with situational awareness as the third dimension and the environment included as a function for effective use in addition to the user, the system, and the task, that are introduced in the original model. My application of the theory of effective use is based on its operationalization for the humanitarian field .

CASE ANALYSIS AND FINDINGS

Research Context

This work builds upon a longitudinal case study (2015-2021) examining the implementation and adoption of the H-HMIS across the whole organization. From the headquarters offices in the global context of the organization (Vila-Pozo & Sahay, 2018), to the project coordination offices (Vila-Pozo & Sahay, 2019) and further to inpatient wards in two field hospitals (Vila-Pozo et al., 2022) within one of its field projects deployed to providing health care in a camp for internal displaced populations.

The empirical setting of this analysis was the field mission of MSF Spain in South Sudan. South Sudan has been a consistent focus for MSF Spain since 2013, following the eruption of civil war shortly after the nation's 2011

independence. In the ensuing chaos, an estimated 400,000 lives were lost, 2.28 million individuals sought refuge in neighbouring countries, and another 1.87 million were displaced within South Sudan's borders (MSF Spain, 2021).

Analysis and Findings

This section presents a contextual analysis based on the conceptualization of the theory for effective use in a humanitarian setting. The approach follows a step-by-step recommendation from Burton-Jones and Volkoff (Burton-Jones & Volkoff, 2017) for developing contextualized theories of effective use which consists on:

1. Understanding how a network of affordances supports the achievement of organizational goals.
2. Understanding how the affordances are actualized.
3. Using inductive theorizing to elaborate those principles in a given context.

The theory of effective use, and this process for its contextualisation, govern the analytical framework guiding this research. This approach however, introduces and builds upon the concept of affordances (Strong et al., 2014) and network of affordances (Burton-Jones & Volkoff, 2017). Affordances are theoretically defined as "the potential for behaviours associated with achieving an immediate concrete outcome" (Strong et al., 2014, p. 69), and their actualization is the enactment of such potential in context. Affordances, hence, refer to the relation between the users and the system and their capacity to use it to support their everyday actions, in our case related to the use of the information system during a humanitarian intervention. In the interest of clarity and to align with the theoretical emphasis of this article on the theory of effective use, the term affordances will, in the context of this study, be substituted with *functionalities* and their related process of actualization or realization. Consequently, the network of affordances, will be designated as the network of functionalities facilitating the attainment of the organizational objectives. The following sections develop each of the three different phases enumerated above, using the proposed terminology.

Understanding how a Network of Functionalities Supports the Achievement of Organizational Goals.

The network of functionalities is built upon outcome-units, which represent the relationship between each functionality and its potential outcome (Burton-Jones & Volkoff, 2017). These outcome-units collectively contribute to the overall organizational objectives. By analysing the interconnections between functionalities, the network allows us to understand the interdependence, chronological sequence, and presence of functionalities and outcomes across different organizational levels. Taking together the functionalities and organizational objectives, the analysis helps to understand how the technology helps to meet the objectives of the organization, concerning the effective use of the system in the field project. As introduced above, prior research has identified the operating functionalities of an H-HMIS at the two field levels under study *i)* the project coordination office (Vila-Pozo & Sahay, 2019), and *ii)* the inpatient ward in the health facilities (Vila-Pozo et al., 2022).

Table 1 Operating Functionalities of H-HMIS in the field setting

Level	Functionality	Description
Project Coordination	Operationability	The possibility to use data to follow up trends and identify alerts for constant response and adaptation of activities.
	Contextuability	the possibility to know and analyse context when you are new to the intervention.
	Accountability	the possibility of data to be accountable for day-to-day activities and operational decisions.
Health Facility [1]	Collectability	The possibility to collect patient data along with the medical interventions.
	Aggregability	The possibility to aggregate data at the end of each reporting period.
	Manageability	The possibility to manage the hospital ward with the data collected.
	Recordability	The possibility to access patient historical records when they are readmitted.

[1] The functionalities at facility level were published with a different naming convention. Names have been adjusted to match the style of those identified at the project coordination level.

The organizational objectives to which the functionalities contribute to are those of:

Monitoring the quality of health services: this objective refers to the continued follow-up, assessment, and evaluation of the different aspects of the intervention related to the health services provided. The functionalities contributing to this objective are mainly those operating at the project coordination office. Operationability allows the tailoring of the services provided to the actual and changing needs. Accountability ensures following the organizational paths for mobilizing or relocating resources, and contextuability helps newcomers gain understanding of the situation when initiating their professional activity in context.

Minimizing data management workload of field workers: this objective aims at reducing the effort and time dedicated by field health staff to collect and process data. The functionality contributing principally and directly to this objective is that of Aggregability, since it eliminates the manual processes of aggregation and subsequent data entry, considered the most time consuming and prone to errors by field staff (Vila-Pozo & Sahay, 2019).

Reducing reporting and data integration delays: this objective aims at reducing the time span between data collection and its availability for integrated analysis at the higher levels in the organization. The functionality described as aggregability is again the main one contributing to this objective as it eliminates both, the manual process of aggregation and the data entry of the routine information into the H -HMIS. Once the data reaches the system, its integrated architecture guarantees data available at all levels at close to real-time without manual steps at the higher levels. Being data aggregation, data entry and data integration the main cause of delays in having managerial information, aggregability becomes the key functionality contributing to this objective.

Improving data use and informed decision-making: this objective aims at providing access to data and information and the right time to support operational decisions. From a coordination level, all three functionalities build the basis for informed decision-making for managing the intervention. At a lower level, manageability contributes to decision making at a lower level for the day-to-day logistics of the ward.

The network of functionalities

The representation of the network of functionalities presented below helps to illustrate the dependencies between functionalities and their contribution to achieving organizational goals. The diagram uses different colours to distinguish between facility-level (green) and project coordination-level (blue). The arrows between levels indicate the dependencies and follow the colour of the source level.

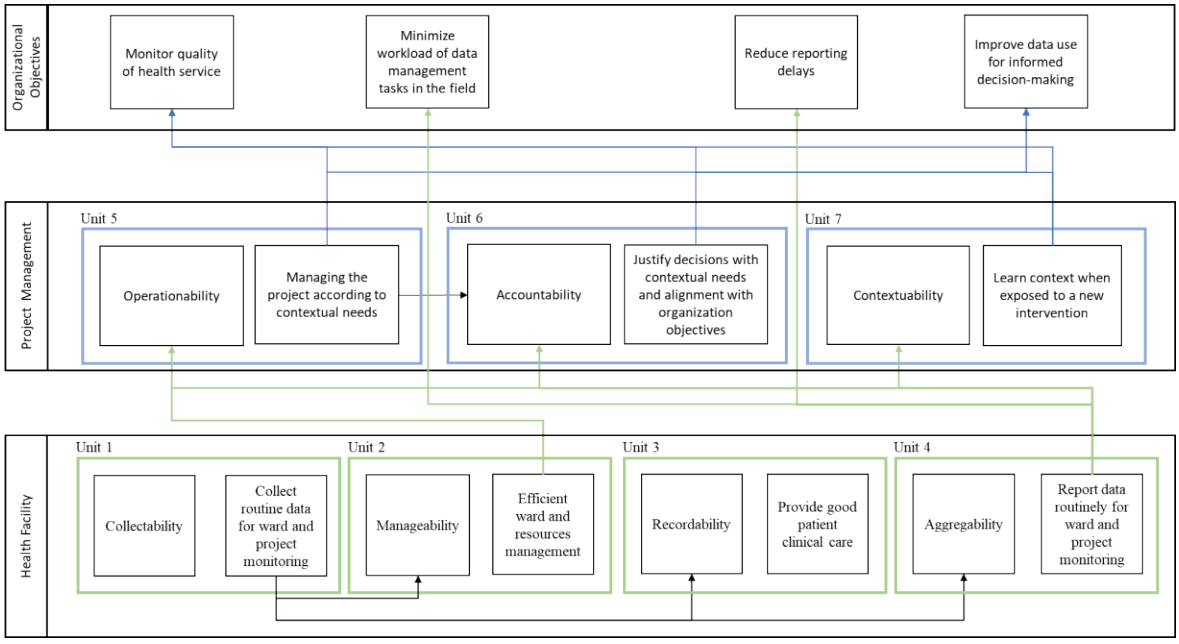

Figure 2. The network of functionalities.

This analysis focuses on the data collection process in a H-HMIS, from four different in-patient wards: adults, paediatrics, neonatology, and therapeutic feeding program, to the coordination office. In all these wards, patient data is collected daily through registration in a register book, where each patient is registered in one line with the basic information (Unit 1). This data serves as a basis for managing the ward (Unit 2), including the provision of food supplies, pharmacy stocks, bed linen, and bed nets, as well as accessing patient information for future readmissions (Unit 3). Additionally, at the end of each reporting period, data is aggregated on a weekly basis to

generate project monitoring reports (Unit 4). These outcome-units operate at the health facility level, they enable the functionalities at the next level and, in some cases (Unit 2 and 4), contribute directly to the organisational objectives of minimizing workload of data management in the field and reduce reporting times.

At the project coordination level, operationability is crucial to manage the evolution of the project according to contextual needs (Unit 5) and enables the functionality described as accountability (Unit 6). Contextuability allows new staff members to familiarize themselves with the specific work environment (Unit 7). The three functionalities contribute to the continued monitoring of quality of the health service and the improvement of data use for enabling informed decision-making.

Understanding how the Functionalities are Actualized

Building upon the network of functionalities as the path for effective use, the next analytical step is the study of the process of actualization for this setting and its work conditions.

To determine the potential impact of the context on achieving effective use, the next step involves analysing the operating conditions. The contextual characteristics operating in the deployment of an H-HMIS in a humanitarian setting respond to those of *dynamicity*, *restrictive infrastructure* that requires *independency*, and *heterogeneity* (Vila-Pozo & Sahay, 2018). Those contradict with the fundamental principles governing routine health information system: stability, infrastructural dependency, and homogeneity (Vila-Pozo & Sahay, 2018).

To better understand the impact of such contradictory principles on achieving effective use, it is necessary to analyse the operating contradictions at a lower level, specifically with respect to the core components of the information system: the deep, surface, and physical structure (Wand & Weber, 1995).

Deep structure: The H-HMIS evolves in a context where work routines tend to not facilitate the requirements gathering process, which potentially results in inadequate database and design configurations. In addition, the varied modes of operation through which humanitarian organizations must respond to different emergencies, such as armed conflicts, natural and man-made disasters, and epidemics raise different information needs. This requires a flexible data model which directly shapes the deep structure of the information system.

Surface structure: The context in which the system is implemented is also dynamic and the needs of the population evolve as the emergency unfolds. This creates a need for different data to be collected, and possibly from different new locations. The surface structure, consisting of the user interface, must be adaptable and able to absorb these changes to provide a meaningful user experience that facilitates data collection in multiple settings. In addition, there are severe infrastructure limitations that raise the need to support offline mode, data synchronization, and distributed systems, to manage the distributed data flows. The need to operate in independent and restricted settings can potentially affect the surface structures of the information system that needs to offer a flexible yet simple user experience.

Physical structure: The dynamic context explained above creates a need for different data to be collected from new locations. The physical structure may be affected due to the opening (and closing) of health units, with varying levels of access to Internet or electricity networks. This combined with environments with severe infrastructure restrictions where internet access, regular electricity supply, and where adequate workstations may not be readily available poses challenges on hardware and infrastructu re. Deploying an information system that can function under such conditions directly affects the physical structure. The interplay between the system principles, the operating conditions and their impact on the system structures is represented in the figure below.

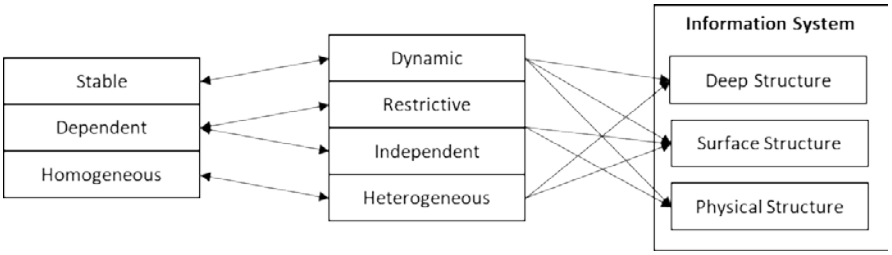

Figure 3. Conflicting logics and influence on system structures.

The environment, hence, affects all structures of the health information system, which in turn influence its implementation adoption and use. The operating conditions shape both, the features of the system as well as the interaction system-user. These characteristics of the humanitarian environment generate what I conceptualised as operating conditions. The operating conditions shape the actualization of the functionalities at their different levels of operation, sometimes as enablers sometimes as blockers for system use.

They have been identified as (Vila-Pozo & Sahay, 2019):

Mature use of information and positive perception of data was shown on day-to-day work practices. The field team relied on data to inform their meetings and decisions. Team leads encouraged collaborative analysis and events were discussed basing their arguments in the data available, when possible.

Limited available information refers to the cases where the configuration of the H-HMIS in terms of the health content available to collect and analyse was not flexible enough to cover needs of the field teams leaving out sometimes critical information, while including other aspects less relevant for the intervention.

Characteristics of the humanitarian work environment represented the biggest challenges. The work environment is intense, and the team works long hours- Staff is limited, and personal and professional spaces and times are often mixed. Turnover rates among field staff are high which adds complexity to the already challenging work atmosphere.

Technical features of the system at the infrastructure level, require having an offline server which operates as independently as possible from the internet connection and power supplies, which influences both the infrastructure and hardware as well as the user interface. At a functional level, the automatic integration of data in one central database was seen as useful for integrated analysis. The system, however, was perceived as adequate for data entry tasks, but having all data in one system was perceived as complicated by users accustomed to work on excel files for data analysis.

The impact of such operating conditions shapes the actualization of functionalities when the user interacts with the technology. At the project coordination office, the actualization process suffered interaction effects – enabling or constraining, which shaped the overall actualization of the functionalities (Vila-Pozo & Sahay, 2019). The limitations in information and the work environment where always constraining and negatively affecting the actualization of functionalities, as they imposed challenges at different levels, from data related limitations to human resources difficulties caused by a high turnover of staff, very common in these types of organizations.

Other operationalconditions had dual effects. The mature use of data was perceived as fuel for system use is most cases, however, when combined with limitations in the information available, resulted in a motivation for using parallel tools and ad-hoc solutions, including does based on paper reporting. The technical features had similarly dual effects, a centralized integrated model introduced benefits like an increase in data quality, more comprehensive data analysis and an enhanced ownership of data at the lower levels in the field. It did require however a data model which was perceived as rigid to respond to dynamic needs and complex for data analysis in the field.

At the health facility level the actualization of functionalities was tightly coupled with an intuitive user experience that did not require training, and user motivation towards introducing the digital system in their day -to-day medical work was mainly based on the system providing such intuitive user experience and/or being explicitly useful for their daily responsibilities (Vila-Pozo et al., 2022). Under the operating conditions identified at the work-place in the humanitarian intervention, the way technology is perceived and more importantly, its perceived usefulness, influence how technology functionalities are realized. The analysis conducted in the study (Vila-Pozo et al., 2022) revealed that users consistently favoured technology solutions that were perceived as easy to use, requiring minimal training efforts and without any friction. However, this preference shifted when the technology demonstrated an immediate perception of usefulness, particularly through significant time savings in data management compared to traditional paper-based methods (Vila-Pozo et al., 2022).

Using Inductive Theorizing to Elaborate the Principles for Effective Use in the Context of Study

The main goal of the final step of this contextualization is to perform an analysis of the suitability of the theoretical model for effective use and its application in a humanitarian setting. To guide this analysis, I summarize the findings from the previous steps in three principles for effective use of information systems in humanitarian settings.

1. Humanitarian projects experience high turnover, and users work in hectic and autonomous environments. The completion of training tasks is challenging, and user adaptations may lead to system abandonment.
2. Humanitarian work develops in non-structured and fast-paced environments, an intuitive user experience is considered imperative to ensure use of the system.
3. Humanitarian workers have to juggle multiple priorities constantly, optimizing time and perceived usefulness are critical factors for effective system use within this context.

The theoretical model for effective use in a n emergency environment is depicted in Figure 4 below.

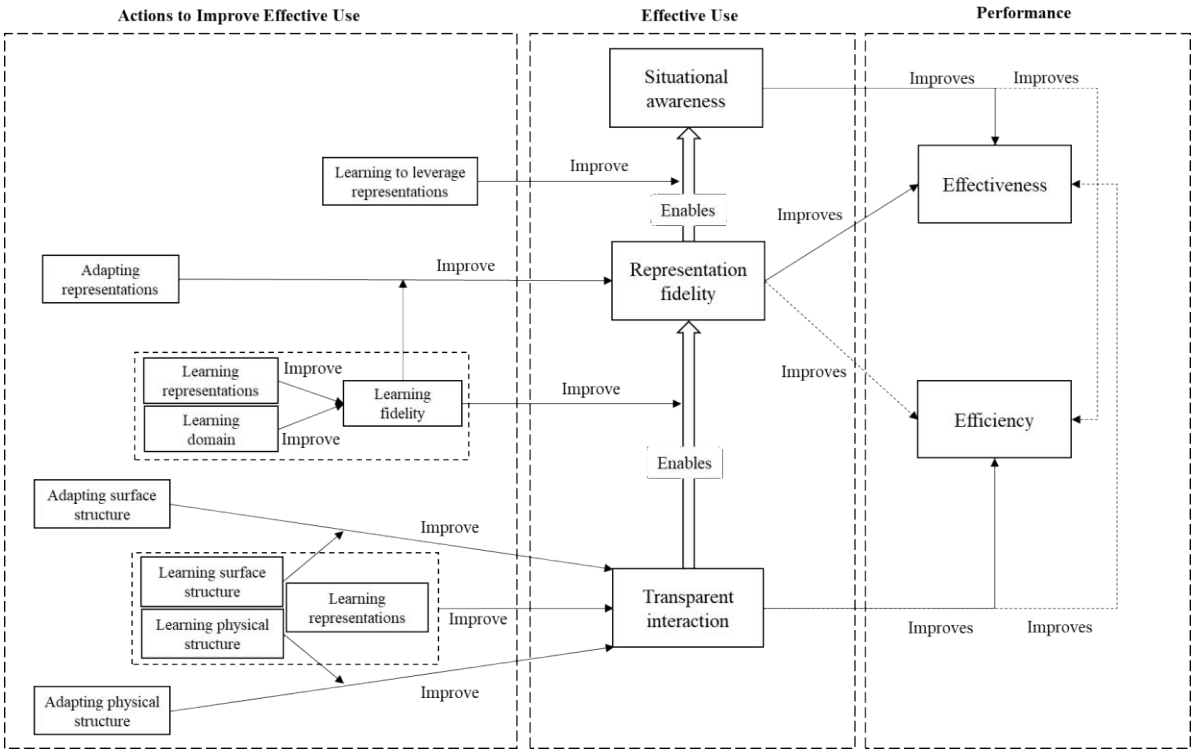

Figure 4. Representation of the TEU model (Burton-Jones & Grange, 2013) extended for emergency management (Bonaretti & Piccoli, 2018)

The image guides a discussion in which the fundamental principles of both the theory and the setting are assessed in combination. The analysis focuses on examining the dimensions for effective use, as defined in the original theory (Burton-Jones & Grange, 2013), which include transparent interaction, representational fidelity, and situational awareness (Bonaretti & Piccoli, 2018). The aim is to assess their suitability for the users and context of the H-HMIS, rather than customizing the dimensions specifically for this context, as suggested by the authors in their approach to contextualizing effective use (Burton-Jones & Volkoff, 2017) . The contextualisation approach taken in this study, hence, is based on the assessment of the nomological principles of the theory for effective use in contrast with the three principles for effective use in humanitarian settings derived from the previously presented findings.

The discussion will commence by understanding the relationship between the identified functionalities and the dimensions for effective use, followed by an assessment of the overall theoretical model in contrast with the three principles for effective use in humanitarian settings.

Effective Use through Effective Actualization

Situational awareness, as referenced in the literature (Endsley, 1995), is a precedent for informed action and is associated with understanding and comprehending the domain of work in context. This dimension plays a crucial role in enabling functionalities that involve decision-making at higher levels, including operationability, accountability, and contextuability in project coordination. Situational awareness is also relevant in tasks such as ward management and accessing patient data at the healthcare facilities. By enhancing the understanding of the situation, this dimension has the potential to enhance effectiveness and improve efficiency by helping guide the intervention providing information for informed decision-making, and minimizing the time required to rectify errors resulting from ill-informed decisions.

Representational fidelity refers to "the extent to which a user is obtaining representations from the system that faithfully reflect the domain being represented" (Burton-Jones & Grange, 2013). This dimension enhances effectiveness by facilitating users' comprehension of their domain and reducing uncertainty. And improves efficiency by reducing the time required to verify information that is mistrusted by the user. Representational fidelity enables situational awareness, thereby contributing to the functionalities associated with decision-making. In the context of this case study, it will also impact the functionality of collectability, as the limitations on available health related information in the system configuration can pose challenges to data collection when does not reflect properly the contextual needs. It will also influence the functionality of aggregability, as the subsequent

representations generated for data analysis are based on the periodically aggregated information.

Transparent interaction refers to "the extent to which a user is accessing the system's representations unimpeded by its surface and physical structures" (Burton-Jones & Grange, 2013). This dimension contributes to efficiency primarily by reducing the time users allocate to interacting with the system. Also, the system's capacity to provision useful representations can facilitate more seamless interactions, which, in turn, can enhance us er focus—a crucial factor for efficacy. This dimension is about system access. As such, it holds the initial position within the hierarchical construct of effective use, being placed at the point direct interaction occurs between the user and the technology. When analyzing technology use in the setting under study, the key conditions for the actualization of the functionalities required a seamless experience of system use and a direct perception of usefulness of the system as pivotal conditions for realizing the functionalities that support users' operational tasks.

The Model of Effective Use in the Humanitarian Environment

Actions to Improve Effective Use

The theoretical model suggests that users can do certain actions to improve how effectively they use the system. There are two types of actions: adaptation and learning. Learning actions are those taken to learn the system, the domain it represents or its representations. Adaptation actions are those made to improve the system representations or the access to them. According to the model (shown in Figure 4. Representation of the TEU model (Burton-Jones & Grange, 2013) extended for emergency management (Bonaretti & Piccoli, 2018)), these actions aim to improve the different dimensions of effective use, transparent interaction, representational fidelity, and situational awareness. They aim however more prominently at improving transparent interaction, which has a primary role on the dimension ladder (Burton-Jones & Grange, 2013).

When analysing the drivers for effective use, the first of the three principles for effective us in humanitarian contexts contrasts with the theory of effective use in the perception of the role of learning and adaptations. The theory of effective use positions learnings and adaptations as the mechanisms for improving the dimensions for effective use, while the first principle for effective use of information systems in humanitarian settings position these actions as a challenge and barrier to system action based on work environment and high turnover rates: "1. Humanitarian projects experience high turnover and users work in hectic and autonomous environments. The completion of training tasks is challenging, and user adaptations may lead to the abandonment of the system ".

This arguably constitutes a limitation in the applicability of EUT for humanitarian settings.

The Dimensions of Effective Use

Situational awareness is the dimensions which operates farther from the system -user interaction, as it is enacted through the processing of the information retrieved from the system to gain knowledge about a particular situation or aspect of a domain. In this sense, the principles for effective use in humanitarian settings do not question this construct, the opposite, they define the conditions the system should offer at the precedent dimensions to guarantee that users can attain situational awareness.

Representational fidelity. As stated in the third principle for effective use of information systems in humanitarian settings: "3. Humanitarian workers have to juggle multiple priorities constantly, optimizing time and perceived usefulness are critical factors for effective system use within this context". Meaning that users need to perceive that the system is useful. The representations provided play a key role in providing such experience as they need to inform about the situation the user is traying to understand and analyse is a simple way. Users need to read and process information in an agile and intuitive manner. If having good understanding of the representation requires training or adaptations, the system would be challenging the first principle, which state that "3. … the completion of training tasks is challenging, and user adaptations may lead to system abandonment and an intuitive user experience is considered imperative to ensure use of the system ".

Transparent interaction addresses system access as it is the "port of entry" for the interaction user-technology. The three principles for effective use pose challenges to this dimension, as it is a that level where the humanitarian setting imposes more restrictions. The more explicit mention to system action and user interaction is on the second principle which states that "2. …an intuitive user experience is considered imperative to ensure use of the system ". This couples with a need to minimize training, ideally system use would not require a cognitive process or explicit training because, according to principle "… the completion of training tasks is challenging" and would not require user adaptations as humanitarian workers operate in a very decentralized and autonomous way and "…user adaptations may lead to system abandonment". The last principle puts even more conditions to the user experience

as it adds a requirement of perceived usefulness. In an environment where "… workers have to juggle multiple priorities constantly", and the system must compete with other duties the perception of usefulness is a critical factor for effective system use.

Performance

The dimensions of effective use are necessary for improving performance through both effectiveness, which refers to "the extent to which a user has attained the goals of the task for which the system was used ", and efficiency, which relates to "the extent of goal attainment for a given input" (Burton-Jones & Grange, 2013). Performance is addressed from all the three principles for effective use in a humanitarian context but is the key focus of the third one stating that "3. Humanitarian workers need to constantly juggle priorities, optimizing time (efficiency) and ensuring perceived usefulness (efficacy) are critical factors for effective system use within this context."

In summary, the conceptualization of the dimensions for effective use as a hierarchical mechanism towards improving performance, aligns well with the contextual analysis of the H -HMIS and the individual functionalities identified in this contextualization. The analysis highlights, however, two main aspects where the theoretical model and principles might arguably not be directly applicable. Firstly, relying on user's actions, such as training and adaptation, to improve effective use is arguably not appropriate for the humanitarian context, and secondly, transparent interaction holds the majority of the challenges imposed by the context while being a determinant in system use and adoption of the H-HMIS under the conditions of the humanitarian environment.

These results raise an evident concern, humanitarian organisations need to improve transparent interaction while reducing the need for training and drastic adaptations. This builds the foundation to answer the research question which is addressed and discussed in the next section.

DISCUSSION

The contextualization of effective use in the case of a H-HMIS in a field intervention has provided the basis to answer the research question posed in this research *What are the challenges for attaining effective use of a humanitarian health management information system?*

In conclusion, the analysis and findings can be presented around two main aspects of effective use:

i) Transparent interaction is an essential dimension for effective use in humanitarian settings, being a major determinant in system use and adoption.
ii) Relying on user's actions (such as training and adaptation) to improve effective use through its dimensions, is arguably not appropriate for the humanitarian context.

These results position the challenges for attaining effective use of a humanitarian health management information system at the level of system access, with special emphasis in user experience and training actions as the ma in challenges for effective use is such work conditions. The role of transparent interaction is fundamental to address these concerns, hence this discussion will focus on understanding the construct and its application in the setting of study.

The Role of Transparent Interaction in Humanitarian Settings

The user experience of an H-HMIS needs to be extremely intuitive and provide a feeling of usefulness. In addition, due to contextual conditions, to complement an adequate level of transparent interaction, organizations need to minimize the need of training and adaptations. The main challenge to effective use is providing a maximized transparent interaction. This strong dependency leads to the refinement of the original definition in order to develop one that accounts for the particularities of the humanitarian setting.

Transparent is the adjective that describes the qualities of the user system interactio n. To refine the concept of transparent interaction, I will start by focusing on its etymological meaning, *Transparent*[2] means "*Having the property of transmitting light, so as to render bodies lying beyond completely visible; that can be seen through; diaphanous*". In figurative terms "*Easily seen through, recognized, understood, or detected; manifest, evident, obvious, clear*".

When applied to information system, this can be interpreted as the ability of the system to let the usefulness (as the light does in surfaces) pass through its structures. When this happens, the potential actions offered to the user

[2] Oxford English Dictionary

are perceivable in an intuitive manner. Users would see that they can perform certain tasks, for example, registering a patient, by looking at the user interface and interpreting its labels and menus. And that action will be important for them and contribute to their day-to-day tasks to a level that dedicating time to it compensates the required dedication of time and effort. This understanding of the interaction aligns the original definition of affordances as "the affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill" (Gibson, 1979). The conceptualization of affordances assumes no need of an explicit cognitive process for the animal to actualize the affordance, affordances are perceived. While the concept of affordances remains at the theoretical underpinning of th is research, the interaction of the user and the technology has been referred to as functionalities in this work. Hence, in the context of this article, this would be described as the intuitive perception and use of a functionality of the technology.

Winograd and Flores (Winograd & Flores, 1986) described readiness-to-hand as a very similar experience. They introduced it when describing transparent interaction in the domain of user experience and inspired the authors of the theory of effective use to propose the term *transparent interaction* as the first dimension (Burton-Jones & Grange, 2013). Readiness-to-hand emphasizes that users know the ultimate goal they want to achieve, such as driving a car, rather than the specific details of how to accomplish it, like determining the precise angle to turn the steering wheel. It highlights the user's perception of the possible actions involved (Winograd & Flores, 1986). This user experience relies on providing "the right coupling between the user and the action s/he wants to perform in the relevant domain" (Winograd & Flores, 1986). The domain refers to the reality in which the user develops its professional activities, and the key mechanism to coupling the system and the domain relies on the system´s ontology (Winograd & Flores, 1986). This emphasizes the importance of designing a system that uses a langua ge which aligns with the environment where it is used. This is particularly relevant for humanitarian interventions which develop a specific vocabulary sometimes based on operational terms or specific acronyms.

The original term "Transparent Interaction" is described in the EUT model as: the extent to which a user is accessing the system's representations not impeded by its surface and physical structures (Burton-Jones & Grange, 2013). Based on this analysis, this paper proposes to expand the definition of transparent interaction in two aspects: the system structures influencing transparent interaction and the understanding of what does it entail to impede system access.

In relation to the system structures, the definition of transparent interaction explicitly mentions the access through the surface and physical structures, not including the deep structure. The analysis of the operating conditions, however, revealed the deep structure as a fundamental influence in the final user experience. In some systems the deep structure defines the ontology of the system which shapes the surface structure. The available data points or variables shaping the analysis are defined at the deep structure and can impose limitations which come from the inner data model which and cannot be overcome by a user interface. The adequacy of the system definition with the domain of work is of utmost importance and an inadequate configuration can lead to low understanding of the system and a weakened sense of usefulness. The importance of the deep structure in creating the basis for an appropriate domain for the user is key for providing an intuitive and "transparent" interaction. The first modification proposed to the definition of Transparent interaction is to make it inclusive to the three levels of the information system structures.

In relation to system access, the proposed definition mentions "impeded access" but is not explicit about how access can be impeded, or what constitutes unimpeded access. Findings from previous research showed that functionalities offering natural interaction with the system and perceived intuitively were more likely to be actualized over other ones which required learning or bigger efforts (Vila-Pozo et al., 2022; Vila-Pozo & Sahay, 2019). If we combine that user experience with the fact that learning actions are not anadequate driver for effective use, then the need of learning itself becomes an impediment to both the intuitiveness and the perception of usefulness for specific goals.

Both, Gibson in its original definition of affordances, and Winograd and Flores in their understanding of readiness-to-use, point to the same type of friction-free experience required for actualizing functionalities in humanitarian settings. And bringing back the etymological meaning of transparency as the transparent material "allowing light to pass through so that objects behind can be distinctly seen", this work proposes that transparent interaction is attained when the structures provide a n extremely natural level of access in which the user can "see through" the system structures and perceive the required actions to attain a goal and its potential usefulness.

With these two considerations in mind, the proposed definition for transparent interaction is:

> *Transparent interaction*: the extent to which a user is accessing the system's representations in a way that its potential use is perceived through a surface, physical and deep structures.

This definition builds upon three qualitative field studies which scrutinized the organizational environment, the

functionalities, and their process of actualization of the H-HMIS in a humanitarian setting.

The definition and analysis of the concept of transparent interaction encapsulates two key aspects of the dimension: *(i)* the level of training required to use the system and *(ii)* the alignment between the system's ontology and the domain in which the user operates. Both aspects could be relevant in building measurement instruments for evaluating transparent interaction.

CONTRIBUTIONS AND FUTURE WORK

The contextualization of the theory of effective use in the humanitarian setting is accomplished through three means. Firstly, it involves studying the micro network of functionalities enabling effective use in the field settings. Secondly, it entails studying the micro-level process of actualization when situated in context. Lastly, it concludes by revisiting the dimension of transparent interaction and proposing two specific aspects for improving its measurement.

From a theoretical perspective, the analytical work contributes the theory of effective use by contextualizing and testing the theoretical model in the novel domain of humanitarian interventions, leading to the development of an empirically based definition of transparent interaction. Findings of this research identify learning and adaptations as a barrier for system use, and the development of the new definition for transparent interaction points out that coupling the system with the domain through an adequate and specific ontology is an integral mechanism for enhancingthe transparency of surface, physical, and deep structures to the user and reducing the need of training. Practically, this work aims at providing practitioners and researcher new paths for studying and strengthening health information systems in humanitarian field settings. The proposed definition can be instrumental for helping practitioners assess the level of transparent interaction of their systems identified as they key challenge for attaining effective use.

ACKNOWLEDGMENTS

I would like to explicitly express my recognition and gratitude to the organization, MSF Spain. Headquarters office, field mission and field project staff who made this research possible. I am deeply grateful and appreciate the efforts made and the time dedicated to contributing to this project amidst their already hectic schedules.

frode.guribye@uib.no

ABSTRACT

The work of melting furnace operators is potentially hazardous and serious accidents do occur. Training on the monitoring and safe operation of furnaces is key to the safety of the operators and their surroundings. Virtual Reality (VR) environments can simulate safety critical work environments and provide realistic, safe and engaging ways to train on situations otherwise unavailable. To address the potential of using VR in safety training, the VR environment called VR Safe was developed. This paper presents a study of the user experience of training safety critical procedures in VR. VR Safe simulates malfunction in one of the most important systems regarding safe operation of furnaces: furnace cooling system monitoring and how to respond to cooling system failure. The evaluation included professional furnace operators, and was focused on usability of the system, user engagement and the training value as it relates to the operators' work.

Keywords

Safety critical training, virtual reality, usability, melting furnace operation.

INTRODUCTION, BACKGROUND AND RELATED WORK

Training is a common strategy to reduce the risk of accidents in hazardous work environments and is centered around increasing the skills of humans to identify, analyse and assess the risks involved in a particular environment or situation (Scorgie et al., 2024). Traditionally, training is facilitated by making use of different types of learning aids such as manuals, lectures, videos and drills (Feng et al., 2018). Managing high-risk environments requires a tight coupling between understanding unwanted situations as they unfold, being able to manually carry out the necessary operations, whilst simultaneously experiencing stress. Ultimately it is about developing competences in both knowing and doing. Virtual Reality (VR) environments is an emerging and promising platform for training in contexts such as these as it offers an engaging mode of interaction by immersing the user in a representation of a real environment that offers rich interaction modes (Grassini & Laumann, 2020), feedback in the form of observing the result of actions, the development of hands-on skills and learning-by-doing, and opportunities for repetition (Deb et al., 2017). Particularly relevant to training for high-risk situations, VR can also provide first-person access to environments that are potentially dangerous, unethical, costly, temporally unavailable or unpractical to access in the real world (Freina & Ott, 2015).

VR systems are being used in education and training for their potential for creating immersive experiences, in which the users can experience a sense of presence (Jensen & Konradsen, 2018). Examples of VR-training in safety critical environments are available for firefighting (Wijkmark & Heldal, 2020; Wijkmark et al., 2021); first responders (Binsch et al., 2021; Mossel et al., 2021) and several other areas. VR in safety critical training has also been studied in industrial work settings, for example working from heights (Cyma-Wejchenig et al., 2020; Loreto et al., 2018), working in confined spaces (Lu et al., 2020), overhead load movement and operation of cranes (Zhang et al., 2023) and electrical/high-voltage safety training (Ayala García et al., 2016; Wang & Messner, 2020). While VR environments for various purposes connected to metallurgical production and melting furnace operation exist, for example visualising and simulating processes (e.g. (Freitag & Urness, 2002; Fu et al., 2009; Ratts et al., 2000)),

*corresponding author

little work is done on VR-based safety critical training in this domain. Li and colleagues (Li et al., 2019) describe a system developed for safety training in metallurgical production, but their approach is more oriented towards technical systems description, and not on the experience of the operator.

This paper presents a user experience evaluation of a VR environment designed for safety critical training for operators of the hazardous work environment of melting furnaces in metallurgical production. The case illustrates the potential of using VR-training for safety critical and hazardous environments. In the study we recruited professional metal furnace operators to participate in the VR-training and focus on how they experience the training. The empirical data consists of physiological sensor data, answers to standardized questionnaires on usability, user experience and VR experience, and in-depth interviews with the operators. The data is used to explore the perceived usability of the environment, the way in which it engages the operators, and what kind of training experience the environment facilitates.

The study provides a rich account of how VR-training can be used in safety critical industrial work settings with a focus on how VR environments can provide realistic training situations. Further, we discuss how VR-training experiences can be evaluated by including different kinds of empirical data to address different aspects of the VR experience including engagement, usability and user experience, and the training value.

TECHNOLOGY AND CONTEXT: MELTING FURNACE OPERATION AND TRAINING

Melting Furnace Operation and Training

The educational requirement for the staff who operate the melting furnaces is a certificate of apprenticeship as industry process operator or chemical process operator. There are several safety risks connected to operating the furnaces, and the most commonly referred to hazard is called "metal astray". "Metal astray" means metal in liquid form anywhere else than where it is designed to be handled. "Metal astray" covers both minor or major spilling from containers, but also ejections from the furnace as a result from explosions. To avoid metal astray, the furnaces need to operate at the correct temperature. To ensure correct temperature, the furnaces rely on a cooling system consisting of a set of pipes streaming pressurised water surrounding the furnace exterior. Cooling water leakage occurs infrequently and episodically, but causes a situation that can be very dangerous because of the high energy matters and volumes involved. These situations require intervention by the operators, and how to intervene depends on the nature of the leakage, and the understanding of which depends on the perception, experience and discretion of the operator. The water pressure in the cooling pipes is monitored in a control room. Falling pressure, readable on manometer displays, is an indicator of leakage in a pipe, which reduces cooling. The leakage is not visible to the naked eye because of the temperature of the water and visual hindrances caused by the furnace (fire, smoke), but a mild reduction of the furnace temperature can make the leakage visible. These situations occur very rarely, but when they do the operator is usually alone. The risks are both economical and physical. Shutting down the furnace if not necessary is very expensive, whilst not shutting down if required is potentially catastrophic.

The current practice for safety training at the plant involved in this study consists of lectures and bi-annual certification tests presented as imaginary scenarios with challenges responded to in writing. They also use a digital reference manual, where all the relevant procedures are described. Additionally there is on-the-job training and knowledge exchange between novice and experienced operators. The opportunities for practical and physical experimentation are limited, due to the costs of taking the furnace out of production. Needless to say, there are also limits on the experimentation with the furnace because of the dangers involved with mixing high temperatures (ca 1600 degrees Celsius) and large quantities of melted metal, electricity and pressurised water. With VR it is possible to overcome some of these limitations. With VR, the physical environment can be realistically recreated, including the visual, three-dimensional appearance of the plant, the sound, and how the environment is manipulated in a dynamic way. VR can also provide opportunities to train on safety procedures without stopping the furnace.

VR Safe

VR Safe is a prototype of a training environment for melting furnace operators, currently containing one training scenario. It is developed by a consortium of VR software companies, in collaboration a Norwegian metallurgical production company. VR Safe allows operators to handle loss of cooling of a furnace. The cooling system consists of several water pipes, and currently VR Safe can simulate malfunction in one of those pipes. Additional common safety hazards for operating furnaces have been been placed in the environment, for example misplaced objects and hindrances that can cause safety issues. VR Safe is being created using the Unity engine to recreate the environment of an existing furnace, with adhering cooling system, building and control room. VR Safe is interacted with using a Head Mounted Display (HMD). Figure 1 illustrates clockwise from top left: a. The furnace, b. The control room, c. Break area and d. Water pipe panel with valves.

Figure 1. VR Safe environment

When opening VR Safe, the operator is placed in the melting plant control room. When the operator looks around, he/she can see the computer displays with readings of the pressure in the water pipes (b.), the inspection window to the furnace opening (a.). When turning around, the operators can see the rest of the control room with the kitchen area and electrical boxes (c.). There is a lever for reducing the energy in the furnace. The operator can also navigate to the valve panel area and close the correct valve (d.). Additionally, the operator can navigate to the furnace itself. The currently available scenarios are 1. falling pressure in one of the pipes, and 2. cluttered work spaces around the furnace area.

EVALUATION APPROACH AND METHODS

Evaluation Approach

This study examines the experience of interacting with VR Safe. Three aspects of the interaction is in focus, all considered central to the overall goal of facilitating critical safety training for furnace operators: 1. engagement, 2. usability and 3. training value. Each of the aspects were examined in its own way. The overall approach is illustrated in Figure 2

How users engage with training exercises can have an impact on the outcome (Xin, 2022). While different ways to measure and understand engagement have been suggested (Doherty & Doherty, 2019; Flobak, 2023), we focus on how we can use physiological data as an indicator of engagement. As Electrodermal activity (EDA) has been used as an indicator of mental effort (Agarwal et al., 2021; Pijeira-Díaz et al., 2018), we explore how such data, obtained with the biosensor Empatica E4, can be used to inform our study of the experience of VR-safety training for furnace operators. We assume a correlation between EDA values and an affective response - here understood as levels of

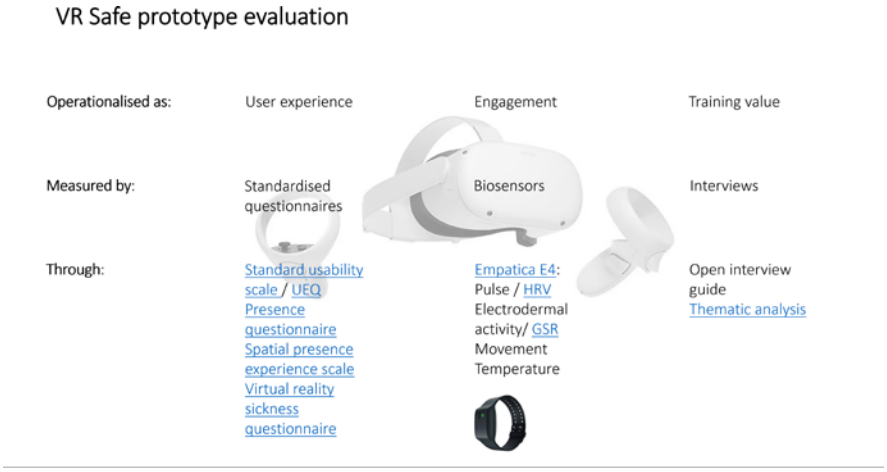

Figure 2. Overview of the evaluation

arousal, which again can be used as an indicator of the level of engagement with the environment and the training content.

The evaluation also focused on the user experience of the VR-training. In Human-Computer Interaction user experience is a term that can encompass both the usability of a system and the experience that the user has when using the system (Turner, 2023). We have approached the evaluation of the total VR-training experience as including both usability, user experience in general, but also including more specific elements that pertains to interaction in virtual environments.

The training value is seen in relation to the existing work and training practice for melting furnace operators. The training is studied in terms of how it relates to the operators established, professional understanding of work, with emphasis on critical safety procedures. These procedures consist of monitoring output from the furnace and the cooling system, and investigating and solving potential problems.

Methods

We collected physiological data for each participant to compare three different conditions: baseline, VR Safe use and VR gaming. Baseline was defined as taking part in a lecture for 15-20 minutes. Baseline should represent the "normal" training situation for the operators, but training takes place across a range of modalities as described above. We are interested in seeing how using VR Safe compares with taking part in lectures. Additionally, we included a VR game (Richies Plank Experience), to see how VR Safe compares with games that are designed for fun. Our expectation is that EDA will increase with VR Safe, as it involves the user in carrying out safety critical professional tasks, and expect it to increase even more when playing VR games. Physiological processes are individual, thus we are not interested in comparing persons, but rather how the different activities affect the physiological processes for an individual.

For this pilot study we decided to provide standardised questionnaires to expert/professional users. We chose to use questionnaires as we see it as an efficient way of getting user experience data with few participants accessible for a short time. The questionnaires are therefore analysed descriptively, and the results are seen as valuable when combined with the other data. We used two questionnaires for general usability assessment; System Usability Scale (SUS) (Brooke, 1996; Lewis, 2018), and User Experience Questionnaire (UEQ) (Schrepp et al., 2014). Two questionnaires were more specific to user experience with VR systems: Presence Questionnaire (PQ) (Witmer & Singer, 1998) and Spatial Presence Experience Scale (SPES) (Hartmann et al., 2015). Finally, two questionnaires for assessing any discomfort or unwanted bodily effects with use of VR Safe were used: Virtual Reality Sickness Questionnaire (VRSQ) (Kim et al., 2018) and Cyber Sickness Questionnaire – VR (CSQ-VR) (Kourtesis et al., 2023).

The part of the evaluation considering training value is about how the operators work in a wider context of colleagues, information systems, tasks, goals, tools and work culture. To access this information, an open qualitative interview guide was constructed. The themes included are how the operators understand learning goals for VR Safe,

Figure 3. Evaluation timeline

engagement, their perception of interacting with VR Safe, realism and fidelity, the relevance of the content and tasks, immersion, comfort and ergonomics in addition to how they would like to see VR Safe further developed.

The timeline for the evaluation activities is illustrated in Figure 3.

EVALUATION WITH MELTING FURNACE OPERATORS

The evaluation with melting furnace operators was carried out over two days at a smelting plant. The first day involved observation and getting an overview of the basics of melting furnace operation. The second day was used for evaluation with operators. Five melting furnace operators took part. Two worked at the furnace that VR Safe is a replica of, whilst three worked on a different furnace. Four were young, yet experienced operators (age < 30), and one was more senior (age > 50). One participant had used VR Safe previously. The evaluation was carried out in groups, following the structure 2+2+1. Two were first introduced to VR Safe through listening to a presentation of VR Safe for 15-20 minutes. This was used as baseline for the physiological data capture, with one of the participants. Then they tried out VR Safe using one HMD each for around 20 minutes, whilst the physiological response was recorded for the same participant. Afterwards, they played RPE, for up to five minutes. Finally, they completed the questionnaires and took part in an interview. We recorded the physiological response for three of the participants, as we only had one Empatica available.

Results

EDA: The physiological responses are presented in Table 1, for participant 1, 3 and 5, clockwise from top left. The EDA levels for VR Safe are higher than for baseline for the three participants. Although EDA levels are individual (Baker et al., 2010), the tendencies between activities are similar, and seem to support our expectation that EDA levels would increase with engaging with VR Safe compared to baseline. For the two participants who played RPE, they show a (relatively) flat line before peaking rapidly.

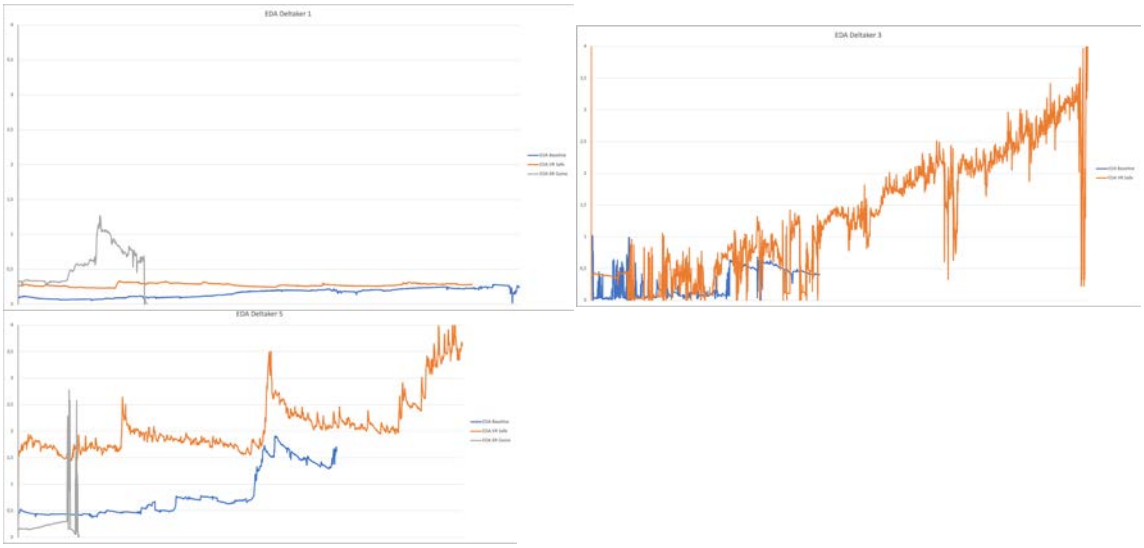

Table 1. EDA results, evaluation with operators

Participant 1 has marginally higher EDA levels with VR Safe compared to baseline, whilst both levels are low. RPE is higher, which increases trust in the data. The EDA levels for Participant 3 is higher than for baseline, and also increases noticeably throughout the activity. Participant 3 declined the RPE activity. The EDA levels for Participant 5 are higher with VR Safe than for baseline. The EDA levels for RPE seem to follow the same structure as for Participant 1. Overall, the EDA results can be an indication that the mental effort exerted with VR Safe is higher

than listening to a presentation and taking part in a discussion, and that training with VR Safe is a more active way of training.

Questionnaires: The results from the questionnaires have been visualised and analysed descriptively. In the visualisations, the positive/negative phrasing of questions have been rearranged to show the most positive responses to the right, to increase readability. For the two questionnaires measuring unwanted effects or discomfort following use of VR (the last two), the most positive responses are to the left.

The SUS questionnaire contains 10 statements about the perceived usability of a system. In the visualisation in Table 2, the SUS results appear mostly positive, with the most or second most affirmative responses being most frequent. The average SUS score is 77,5. For SUS scores, results over 70 are considered good. UEQ measures the qualities attractiveness, perspicuity, efficiency, dependability, stimulation and novelty. The major tendency in the replies are positive.

The results from the questionnaires that measure the VR experience are visualised in Table 3. The results are mainly positive, with the most or second most affirmative answer option being used for most of the items. The PQ contains how control and realism factors contribute to the experience of presence in a VR system (Witmer & Singer, 1998). The SPES questionnaire contains 20 items that measure the subjective feeling of being present in a virtual environment (Hartmann et al., 2015), and is based on the theory that to experience spatial presence, users first develop a mental model of the VR environment, and secondly accepts it as their egocentric viewpoint (ibid.). The users ability to visually create a mental model of the VR space affects the experience of spatial presence positively. This experience is relevant for the participants in our study, as the virtual environment is based on an environment that the participants know well.

The results from the two questionnaires measuring discomfort resulting from using VR are available in Table 4, where the lowest symptom reports are presented to the left in both tables. We consider these to indicate no serious discomfort from using VR Safe.

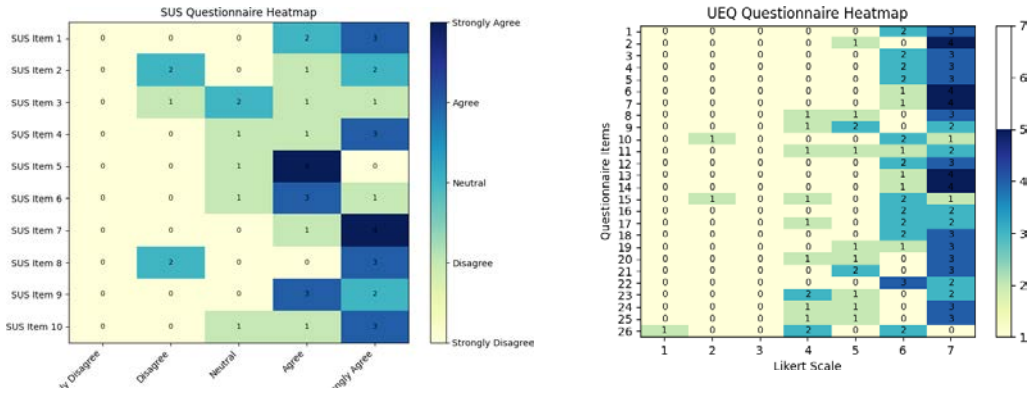

Table 2. Usability questionnaires

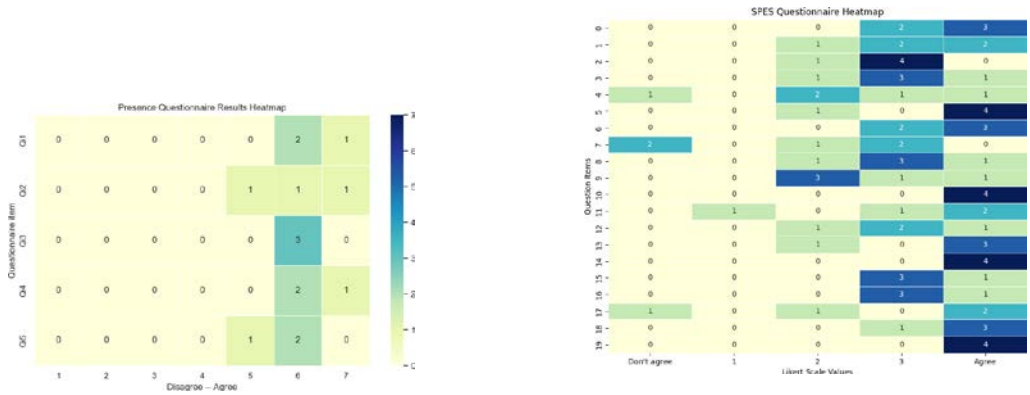

Table 3. VR experience questionnaires

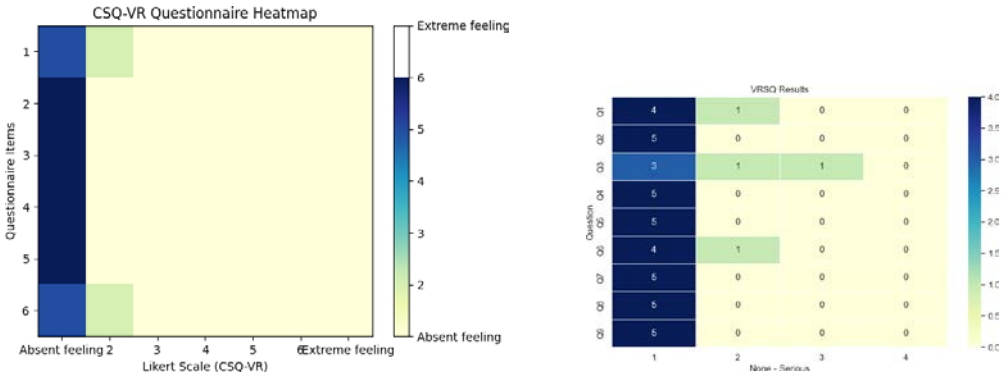

Table 4. Unwanted effects of VR use

Interviews: The interviews were recorded and transcribed in full before being analysed using Thematic analysis (Braun & Clarke, 2006). One theme is how the VR training is relevant to the existing training practices and needs at the smelting plant. This means in how it fits in with current practices, and whether and in which way it creates new training opportunities. The following two quotes illustrates how the operators considered the training relevant; it makes available situations that are unpractical, uneconomical or unsafe with their training practices today. There is also a need to train on practical intervention and solving problems in a manual way.

Participant 5: "I have trained a lot of new people (*operators*). And what is difficult with training new employees is, what do you do with a water leak? We can´t just go up and close a valve... "

Participant 5: "There is a lot of theory. But if you are unlucky and actually get a water leak, then you have to go up and close a valve. But here (*in VR Safe*) you actually get to do it. We are actually trying to do those things."

The operator is speaking about the notion of opening and closing furnace cooling valves on a furnace in production. The environment in which the operators work can be considered "low risk / high consequences". The low risk is contingent on following the designed procedures for handling high energy matter, and also being competent to perceive and intervene in randomly occurring unwanted situations. Tied to the theme of relevance is also managing the potential magnitude of the consequences, whilst experiencing stress. The following dialogue captures how they consider the consequences if things should go wrong:

Participant 1: "Yes, the potential that it can go wrong is very large, in case there should be an accident. I think that would be the very worst that could happen."
Participant 2: "Yes. That would be a crisis."
Participant 1: "Yes, you don´t want that to happen on your watch, to put it like that."

When considered as to how VR Safe is relevant to the safety training of the operators, the dialogue further highlights how being able to train repeatedly on detecting unfolding, unwanted situations and practical intervention becomes available in VR. VR also supports the formation of automated actions through repetition, as automated actions are much easier and probable to be undertaken when a person is experiencing a high state of stress.

Regarding the design of VR Safe, and whether it is developed in a way that the operators can recognise and find meaningful, the operator reported that they found it to be a useful way to carry out training. In the first quote, Participant 1 explains this by making a reference to the real world functioning of the furnace, and that VR Safe matches this. His conception of VR Safe is similar to that of the real life furnace. This is an indication of the importance of creating simulations that align well with real-world processes, when creating VR-based safety critical training environments. The operators who did not work at "Furnace 5" responded similarly to the operators that did, indicating that the formation of mental models corresponds to more than visual similarity of real and virtual environments, and also include dynamic relations in processes. This relates to the underlying theoretical foundations of spatial presence. Participant 3 highlights how VR-based training is more interesting than some other alternatives, such as the digital reference manual where every relevant procedure is described in detail in text.

Interviewer: "Was it an adequate way to learn to handle leakages in the cooling system?"
Participant 2: "Yes it is."
Participant 1: "It is sort of made the way that it actually works. It is quite easy to discover what you should do."

Participant 3: "Yes, it is, absolutely. I would rather use this than "Rosa". "Rosa" is where we keep all in-depth content. It is a system where we read and sign that we have understood (the procedures). It describes how to do everything in detail."

Regarding the visual representation of the furnace in VR Safe, it is considered to be adequate by the operators. One operator described the audiovisual appearance as meeting his expectations. "Participant 2: It appeared the way I imagined it would. The representation of objects..."

Participant 1: "The recognition effect. It is the way it looks."

Four of the participants had never used VR Safe previously. When asked about how it was to learn to interact with VR Safe, all participants reported that it was easy to use, although it took a little while to learn how to move for some (VR Safe uses the "teleport" mode for moving in the environment, where the user points the controller to a spot on the floor and click the joystick to move, or press the joystick forward to move in steps.). Once they had learned it, all participants found it easy to interact with VR Safe. One exception was operating the valves. The design for user input on objects is done by highlighting the objects when moving the hand/controller near the object. When highlighted, the valves can be opened/closed by making a twisting motion with the hand. This operation was experienced as difficult to perform by most operators. It is a central operation in connection with the safety procedures.

Participant 3: "(VR Safe) was easy to learn. That went smoothly. The only thing that did not work properly, was opening the valves."
Participant 4: "It worked okay to close them, but not opening them again."

DISCUSSION

In this study, we have engaged professional experts in testing a virtual environment for critical safety training. VR Safe simulates certain safety operations in the handling of a real furnace, and is, as such, a representation of key aspects of a real system for metallurgical production. To be useful for the operators in training, the virtual environment needs to simulate the real environment in a realistic way. To further understand the realism and perceived authenticity of the VR system, the study highlights how the fidelity of the representation affects the user experience. We describe these as **audiovisual, task** and **operational** fidelity. The audiovisual fidelity of representation concerns how the virtual environment matches the environment known to the operators. The task fidelity describes how the tasks in the virtual environment matches the tasks carried out by the operators while they work. The operational fidelity describes how the manual operations that the operators carry out in their work matches those in real life. In our study, the operators described the virtual environment as familiar to them in a visual sense, and that there was a recognition effect. The interviews also highlight that task representation is likely to affect their overall experience, including the audiovisual experience. The audiovisual representation in VR Safe contains a limited selection of the smelting plant, and even includes some minor mismatches with the real environment, such as it being possible to walk near the furnace (something that they would not to in the real environment, but instead use a forklift for protection). The fact that they understand the task (possible cooling malfunction), prompts them to carry out operations that they can understand based on their professional experience. The task fidelity, which speaks to the relevance of a task in the virtual environment, is likely to support the operators in forming a mental model of the virtual environment, and experience spatial presence. The interviews also revealed that there was an interactional problem with carrying out an operation important to the task, which was opening/closing the valves. This is a critical safety operation, needed for the safe operation of the furnace, and was not represented very well in VR Safe as it is a simple operation to complete on an actual furnace. Further refinement of VR Safe should look into different solutions for this operation. This identified shortcoming, points another kind of fidelity, namely haptic or tangible fidelity. To train on the physical and motor skills required for operating the system, can be hard to replicate in a virtual environment. Still, advances in haptic interaction in VR systems can possibly help to increase also the haptic fidelity and increase the realism of performing such tasks virtually.

The measurement of physiological responses of the participants revealed an increase in EDA levels whilst using VR Safe, indicating an increase in mental effort or activeness whilst using the VR environment. Activeness, and cognitive and emotional arousal has previously been found to be conducive to learning (see e.g. (Baker et al., 2010; Bjork et al., 2013; Pijeira-Díaz et al., 2018). Whilst the interview and questionnaire data are based on self reporting, the affective sensing represent more direct measurement of the process of engaging with VR Safe as it unfolds. Yet, we don't know exactly what in the VR experience that caused changes EDA levels. A further refinement of the method would be to connect physiological responses with what the participant is doing in VR at each moment, for example by streaming the view of the user. This approach could provide useful design information, for example by identifying particular tasks or other design elements that correlate with particular responses. The EDA data, and

particularly the VR Gaming data indicate that these kind of responses exist. Noori and colleagues (Noori et al., 2019), have demonstrated that continuous capture of physiological responses can be used to create VR systems that adapt to the users physiological responses for VR-based exposure therapy. In the context of safety critical training the responses could be used to increase or decrease difficulty or complexity of the task.

Considering VR Safe as a Proof-of-concept, the questionnaire data from expert participants seem to indicate that there are no major usability issues with VR Safe, and that the usability does not provide major hindrances to engaging in training based on VR.

Limitations: A major limitation in our study is that the data are based on a limited number of participants for the findings to be generalised to a larger population. Still we have recruited expert professional operators and there is a limited number of such professionals available. This limitation could be met by doing a less episodic study over time with several iterations of design and evaluation with professionals.

CONCLUSION AND NEXT STEPS

The paper has reported on a user experience study of professional operators engaged in VR-based safety critical training on handling malfunction of a melting furnace. A method for evaluating the experience focused on engagement, usability and training value was designed, and carried out in practice. We found the prototype VR Safe to be a method for safety critical training that has a promising potential as a way to overcome the limitations associated with other ways of training, such as the need for tying theoretical knowledge with operational practice and engaging the user.

Acknowledgements: Thanks to Gunnar Maltsev Hansen and Isabella Mikkelsen and the furnace operators at Elkem Bremanger for generously facilitating and participating in the evaluation. Also, thanks to Broomstick AS and Agder XR Productions for enabling the screenshots from VR Safe in Figure 1.

ABSTRACT

One way to reduce the communication challenges associated with Chemical, Biological, Radiological, Nuclear and explosive (CBRNe) incidents management could be a public facing disaster smartphone app, of which none are currently available. The EU funded project PROACTIVE used an iterative, co-creation methodology to develop such an app. This work-in-progress paper examines the preliminary results of a questionnaire given to observers who were tasked with using the beta app during a first field training exercise. The results show that the app was found to be usable and useful. Based on the results of the current evaluation exercise, the app will be updated, taking into account the end-user inputs. Following which, the app will undergo testing in two additional field training exercises, in an iterative manner, before reaching the final, end-of-project version.

Keywords

CBRNe, Universal Design, disaster apps, co-creation, user interface.

INTRODUCTION

Chemical, Biological, Radiological, Nuclear and explosive (CBRNe) incidents present unique challenges for disaster management and crisis communication. For example, first responders may need to wear Personal Protective Equipment (PPE), which includes face masks, when interacting with victims and victims will most likely undergo unique protocols such as decontamination. Furthermore, while all disasters can lead to anxiety, seeing practitioners arrive in PPE on the scene while waiting to begin decontamination has been found to induce fear (Carbon et al., 2021).

These challenges are only compounded by the fact that public awareness of CBRNe incidents is low, which means that the public at large is likely to depend even more than in other types of disasters on the communication and technology employed by practitioners (Hall et al., 2020). One way to overcome or at least reduce these communication challenges as well as the public's anxiety about such events could be a dedicated CBRNe disaster app. Disaster apps are a widely recognized, useful tool for disaster management, contributing to the reduction of anxiety (Bossu et al., 2018), yet few available apps address the CBRNe topic (Petersen et al., 2021).

That said, it is important to keep in mind that the public is not a homogenous mass and a switch must be made from interacting with the public on a 'one-size-fits-all' basis towards more nuanced planning and preparing to deal with the range of individuals that together constitute a diverse 'public', e.g., disabled persons, older persons (Petersen et al., 2019). Unfortunately, rarely are digital tools for emergency management, including public facing disaster apps, designed with accessibility in mind (Gjøsæter et al., 2021).

Accessibility is a key component of social sustainability and inclusiveness, contributing to usability and durability – as stated in the European Accessibility Act (European Commission, 2019). It may be argued that accessibility

should have a key place in disaster apps, as when a disaster occurs, anxiety is likely to be high and therefore comprehension levels reduced. This is an effect known as situational disability , as indeed circumstances surrounding a disaster may lead to temporary impairments (Gjøsæter et al., 2019). One way to help make disaster apps accessible is to include universal design principles from the beginning of ICT (Information and Communication Technology) tool development (Radianti et al., 2017). Universal design is defined as the design of products and environments to be usable to the greatest extent possible by people of all ages and abilities. It is based on the following seven principles as elaborated by Connell et al. (1997): equitable use; flexibility in use; simple and intuitive use; perceptible information; tolerance for error; low physical effort; and size and space for approach and use.

The EU H2020 project PROACTIVE (PReparedness against CBRNE threats through cOmmon Approaches between security pra CTItioners and the VulnerablE civil society) presents a novel solution in the form of a mobile app to i) provide a public-facing CBRNe disaster app while ii) minimising the accessibility gap in such kinds of apps.

THE PROACTIVE MOBILE APP

The PROACTIVE mobile app was developed following the above-mentioned principles of universal design, based on input from the project's desk research phase, the experience of the app developers and a co-creation methodology, whereby both CBRNe practitioners and the civil society beta-tested a web-version of the app, as described in Petersen et al. (2021, 2022, 2023).

The app aims to improve the efficiency of communication between Law Enforcement Agencies (LEAs) and citizens around CBRNe incident preparedness and response by allowing LEAs to inform the public about ongoing incidents, to allow the public who have registered as app users to report to LEAs, and by providing CBRNe preparedness information materials to anyone who has the app.

Therefore, the app administrator is intended to be the LEA who would be responsible for CBRNe incident response and the main user of the app is intended to be the public at large. The app administrator/LEA would send the in-app notifications, create the incidents viewable on the app, receive the reported incidents from the registered public users and choose which information materials to include in the app repository.

The beta version of the mobile app (Figure 1) has the following four main features:

(i) In-app notifications: allow the administrator to push information about an ongoing incident. They are accessed by clicking on the "news" button at the bottom of the screen (Figure 1B).

(ii) Incident List: this section of the app shows the geographical location of all the incidents added to the app by the app administrator. The app administrator may include the following information about an incident: time, date, location (via GPS or manually inserted), classification (emergency, non-emergency), status (ongoing, awaiting information, resolved), headline, description and choose whether or not to send out an in-app notification.

The incident list is accessed by clicking on the "map" button at the button of the screen and a given incident can be seen in Figure 1D. Incidents are presented on a scrollable map and, below, a short description can be seen. More information can be found for each incident by clicking on either the dot on the map or the incident on the list.

(iii) Report an Incident: allows registered public users to provide information (e.g., time, location (via GPS or manually inserted), photos, description) about a suspected CBRNe incident. This feature is intended to aid CBRNe practitioners in evidence and information gathering (Gavel et al. 2021). It is accessed by clicking on the red button seen on the home screen (Figure 1A), and the screen to actually report the incident can be seen in Figure 1 C.

(iv) CBRNe Information: is a repository of public pre-incident information materials which are downloadable as PDFs. It can be accessed by clicking on the blue button on the home screen (Figure 1 A) and looks like Figure1E.

METHOD

This paper examines the preliminary results of a questionnaire on the usability and usefulness of the beta version of the PROACTIVE mobile app which was first tested during a field training exercise by observers.

Observers

The ISO 22398:2013 Societal security — Guidelines for exercises (ISO, 2013) defines an observer as an "exercise

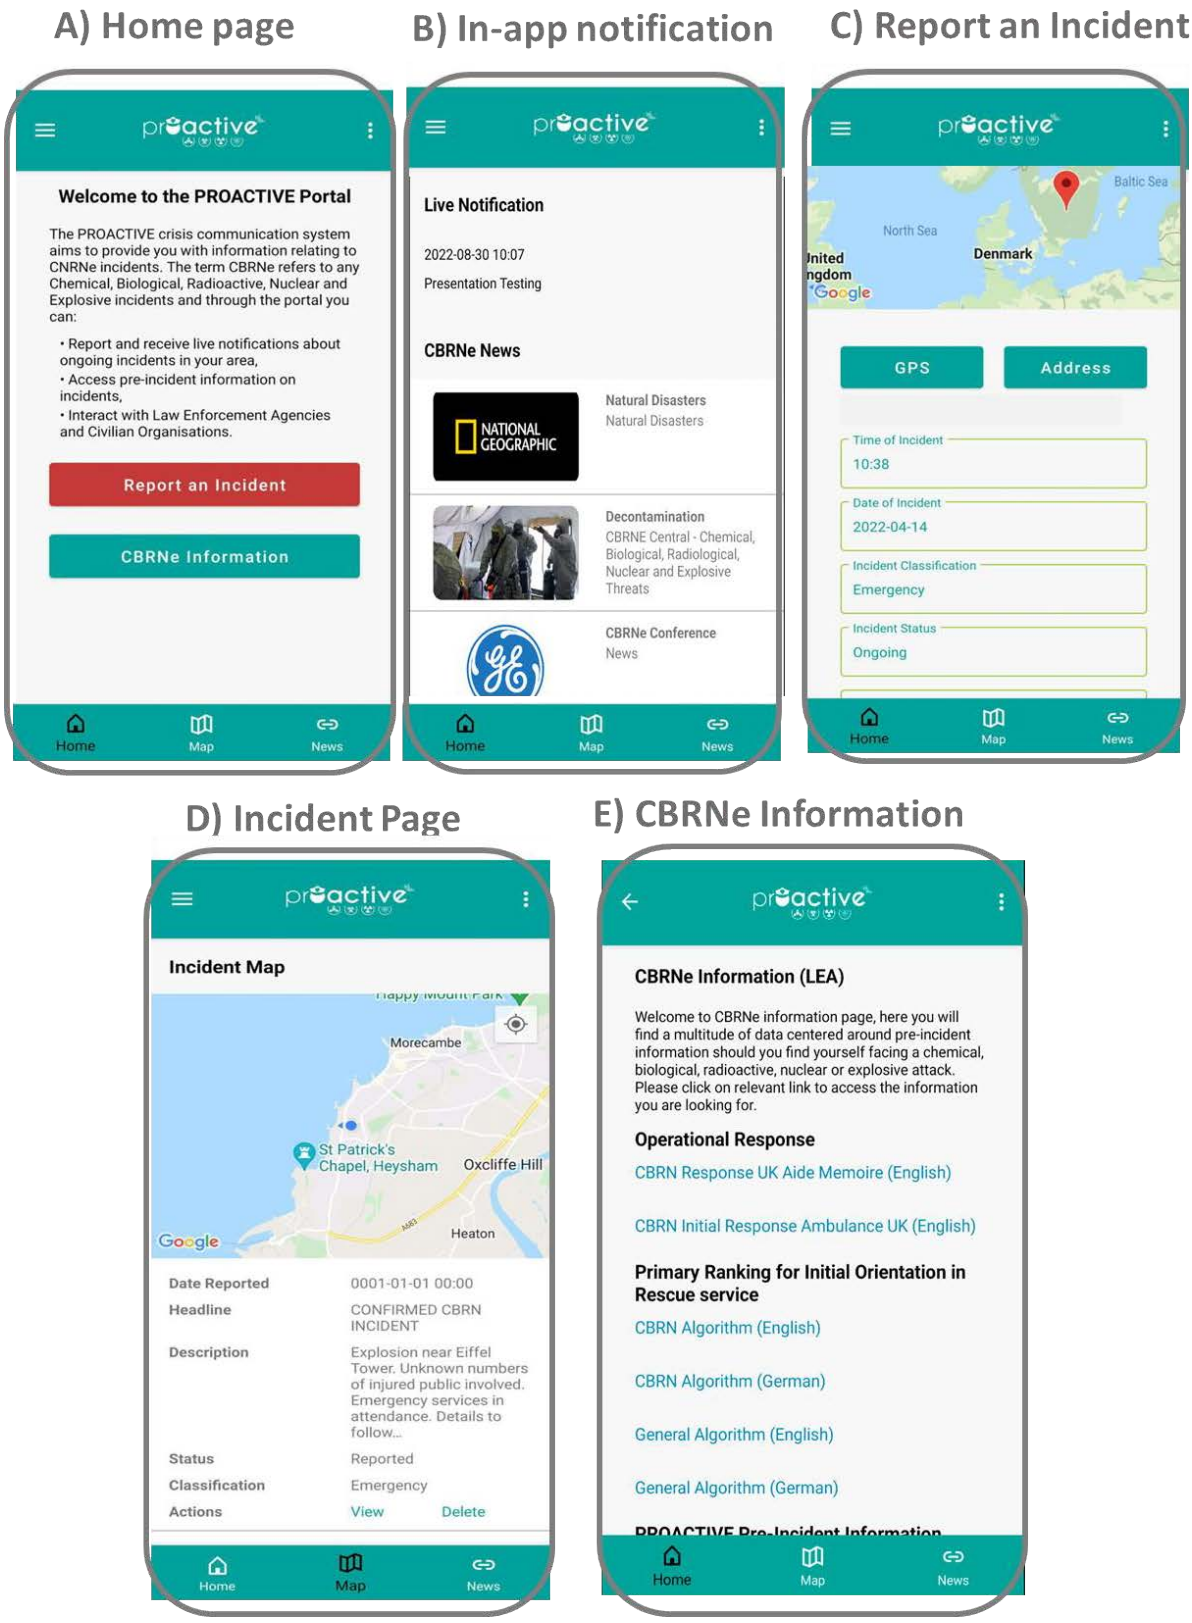

Figure 1. Graphic user interface (GUI) overview of the PROACTIVE app

participant who witnesses the exercise while remaining separate from exercise activities." Traditionally, the people invited to act as observers of a given field training exercise are security practitioners (e.g., firefighters, law enforcement, civil protection) with good knowledge of expected response protocols and standard operating procedures. A unique aspect of the PROACTIVE project was to also invite representatives of civil society organisations to attend the exercise as observers, to better understand the needs and expectations of the public during such incidents. As such, observers for the PROACTIVE field training exercise were dra wn from the two advisory boards of the PROACTIVE project: the Practitioner Stakeholder Advisory Board, made up of CBRNe practitioners, and the Civil Society Advisory Board, made up of civil society organisations.

During the field exercise one of the roles assigned to observers was to role play a witness to the incident who would use the PROACTIVE app as a registered, public user to a) look for information about the ongoing incident and b) use the 'report an incident' feature. In total, 33 observers were present for the field training exercise, of which 19 filled-in the questionnaire.

Field Training Exercise Scenario

The field training exercise took place on 7 May 2022 in Dortmund, Germany and was hosted by the Fire Department in Dortmund (FDDO) at their Civil Training Centre. The exercise was based on a scenario of a chemical substance from a freight train being released near a train station, leading to a specialised operational response. The chemical leak was simulated using disco fog in order to increase realism. The exercise was run in German and focused on the decontamination phase of emergency response. FDDO involved 130 firefighters who trained their decontamination skills. The role of victim was played by members of the local community, as opposed to the usual practice of off-duty first responders. The volunteers underwent disrobing, showering and rerobing.

During the field training exercise, seven pre-defined in-app notifications were sent out by the PROACTIVE app administrator, simulating notifications that would be sent by a LEA in the case of a real incident (Table 1). Each notification was sent in both English and German. Furthermore, the app was translated into German and available in both languages during the exercise.

Time	Notification
Exercise start	It is confirmed that an incident occurred around 07.00 this morning on the 7 th May at the local railway station. Reports have been received of smoke near a train. Please avoid the area as much as possible. Further information is being collected, please check this App for further updates.
+45 minutes	Confirmation received of a chemical substance leak requiring full decontamination. All people involved in the incident are being asked to remain calm, stay in the designated area indicated by the Fire Brigade and wait for instructions.
+1 hour	People requiring First Aid are asked to make the authorities on site aware of their needs
+1 hour 15 minutes	First responders have arrived on scene. A decontamination procedure is underway. Please keep calm and follow the instructions provided by the Fire Brigade on site.
+1 hour 30 minutes	The situation is now under control, the people affected are in the process of decontamination and no further risk to the public is perceived at this point. We continue to ask the public to stay away from the area until further notice.
+2 hours 45 minutes	People effected have been decontaminated and are being supported by the team on site. If you are looking for a loved one please contact your local authority through existing channels.
End exercise	The exercise is now over!

Table 1 In-app notifications

Questionnaire

As part of a larger questionnaire of 43 questions entitled the Observer Guide (Carbon et al., 2022), this paper focuses on the questions related to the PROACTIVE mobile app only. The entire Observer Guide was given ethics approval by the PROACTIVE Project Ethics Officer under approval reference: no15/ 26.04.22. Observers were asked to sign an informed consent sheet which explained that their participation in the research was completely voluntary, could be stopped at any time, and that filling in the questionnaire was not mandatory. The questionna ire was distributed in paper format.

The questions on usability and usefulness of the app were developed based on relevant disaster app literature (e.g., Tan et al., 2020) and the available features of the existing app. The questionnaire was composed of 16 questions, with answers on a Likert-type scale ranging from strongly disagree (1) to strongly agree (6) for questions 1 to 12, from not at all useful (1) to very useful (6) for question 13 to 16 on the app features. Respondents also were asked to explain their answer in an open-answer format for all questions.

The first questions focused on aspects of usability:

1. I felt confident using the app
2. The app design is easy-to-use
3. Most people would learn to use the PROACTIVE app quickly
4. The app has effective accessibility features
5. The amount of text displayed was appropriate
6. The visualisations were appropriate
7. It was easy to find critical information about the incident (e.g., time, location, severity)
8. I was able to find information resources/ materials on the topic of CBRNe

The next set of questions focused on usefulness:

9. I would use the PROACTIVE app in the case of a real CBRNe incident
10. I was confident that the incident information I saw on the app was the most recent update
11. The PROACTIVE app enhances the situation awareness of the population on CBRNe events
12. The app respects my privacy (e.g., the privacy statement, GDPR obligations)
13. In-app notifications
14. Incident list
15. Maps showing incidents
16. CBRNe Information Library

The questionnaire responses have undergone a preliminary analysis, both quantitatively and qualitatively. For the Likert scale answers, the average rating is reported, and a higher average score represents a better performance. The content of the open answers provided by the observers were analysed and reported in a qualitative way. The focus was to understand why certain observers provided a lower rating and what were their suggestions for improvement.

Sample Description

The majority of respondents represent CBRNe practitioners (61%) (Figure 2). The majority of the respondents (71%) were also unfamiliar with the PROACTIVE app before the exercise (Figure 3).

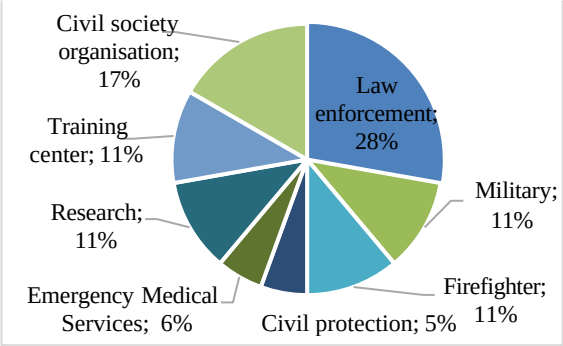

Figure 2. Category of the respondents

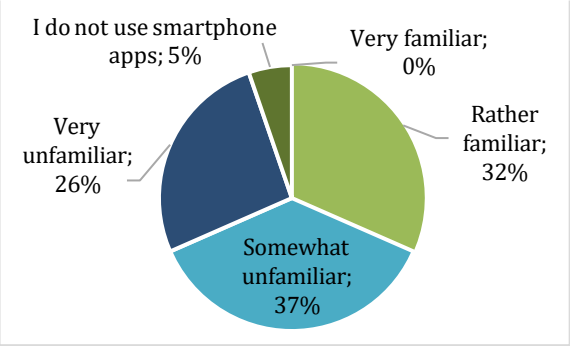

Figure 3. Familiarity with the PROACTIVE app before the field training exercise

RESULTS

Overall, the PROACTIVE app averaged the score of 4.0 on usability (see Table 2 for detailed answers) and 3.9 (see Table 3 for detailed answers) on usefulness.

Question	Number of responses	Average Score	Qualitative Feedback
1	16	3.2	Registration issues, no time to understand the app
2	14	3.9	Simple to use, some technical issues (crashes)
3	14	4.2	Simple to use, concern for the elderly, technical issues (crashes)
4	11	4.0	Suggestions to include language flags and more symbols
5	12	4.3	Well balanced, some translation issues
6	11	4.2	Use of pdf files not appropriate, map to include additional layers
7	13	3.4	Language options to be clearer, use images for incident updates
8	12	4.5	Easy to find, clear and useful information. Use of pdfs advised.

Table 2 PROACTIVE app usability

Question	Number of responses	Average Score	Qualitative Feedback
9	14	3.0	Yes, if linked to national processes and available in local languages
10	13	3.3	Technical Issues prevented this feature being tested
11	13	3.9	Suggestion to be part of existing national processes and apps.
12	12	4.6	Suggestion to include privacy audit and compliance with standards
13	12	3.9	Notifications are useful to verify incidents, but must work flawlessly
14	11	3.7	Useful for multiple stakeholders, suggestion to focus on only live incident and possibility to categorise and/or filter incidents
15	12	4.5	Maps negate language barriers
16	12	4.3	Good feature, only for use outside incident

Table 3 PROACTIVE app usefulness

DISCUSSION

Technical Issues on the Day Appear to Have Impacted Both Usability and Usefulness Scores

On the day of the field training exercise, the PROACTIVE app experienced some (serious) technical difficulties, i.e. the app crashed or froze, clicking on notifications led to an error message, the scroll option was disabled for some users, users who had not yet registered or had forgotten their passwords found it difficult to access the app. However, with support from the on-site technical team, 90% managed to successfully gain access. While not an unusual occurrence for the first time an app or other new technology is tested in a real-life setting, this understandably would influence the questionnaire responses received.

Indeed, the qualitative analysis demonstrates that this is what influenced many of the lower scores, with open-ended answers of "it did not work" or "it kept crashing/freezing" given throughout the questions on usability. Other respondents were able to look past the technical difficulties, for example one observer gave a score of 5 and left an open-ended response of "if it worked" to Q3. These respondents tended to provide rather positive qualitative feedback, such as "the app is self-explanatory," "it is intuitive" or "it is easy to find things." Hence, with an average usability score of 4, it would seem that the observers felt that the PROACTIVE app was usable despite the technical issues, or would be usable if it had worked properly.

These technical issues seem to also have impacted the reported usefulness of the PROACTIVE app. Indeed, if the notifications were not working, and the app kept crashing, it is understandable that observers might not have been sure if the information they saw was from the most recent update (Q10) and were critical of the in-app notification feature (Q13), commenting that it would need to "work flawlessly" to be useful. That said, the average usefulness score of 3.9 seems to indicate that observers felt the app would be, once again, useful despite the technical issues experienced during the field training exercise.

PROACTIVE App Features Could Be Improved

The features were overall deemed useful by participants and it also averaged highly on privacy concerns. With an average of 4.2 for effective accessibility features, it is clear that improvements should be made. Furthermore, qualitative feedback on other questions, not directly related to accessibility, also pinpointed ways forward to ensure the app is developed in line with the principles of universal design, such as using symbols and images to replace the heavy reliance on the written word, avoiding language barriers and making it available in multiple languages. The suggestion to use a country flag to depict which language the app is currently being shown in will be taken forward in the app redesign process.

Usefulness of Yet Another Disaster App Questioned

With a score of 3, it can be said that respondents do not believe they would use the app in the case of a real CBRNe incident. The main qualitative feedback to explain this score was linked to the fact that the app is, as one observer put it, "not connected to national system," and others weren't sure of its added value when compared to other, already existing disaster apps or social media platforms.

This is in line with previous research findings on crisis communication, social media and disaster apps. During a crisis, people tend to turn to the communication channels they use in their everyday life to find information about the crisis (e.g. Steelman et al., 2014), and since disasters are hopefully rare, it can be assumed that few people will have downloaded such an app prior to the given crisis (Petersen et al., 2018). Indeed, a recent representative study of German citizens found that only 16% have downloaded a disaster app (Kaufhold et al., 2020). Furthermore, many studies demonstrate that users prefer to have a single app which would cover all hazards and threats, rather than a single app for each different one (e.g., one app for earthquakes, one app for terrorist attacks) (e.g., Dallo & Marti, 2021; Kaufhold et al, 2020; Haunschild et al. 2022).

As far as being integrated into a national system, the PROACTIVE app is intended to be administered by the local LEA and is being designed so as to easily integrate with legacy systems, thus hopefully meeting this end-user requirement.

FURTHER WORK

In terms of research, it is foreseen to delve deeper into the data presented in this work-in-progress paper, for instance by comparing the responses from CBRNe practitioners to those of civil society organisations.

Furthermore, as part of the iterative, co-creation cycle, the avenues for improvement identified by the questionnaire respondents are planned to be implemented in a new version of the PROACTIVE app. This newer version of the app will then be tested in the second PROACTIVE field training exercise, whereby once aga in feedback will be collected from observers. The third and final PROACTIVE field training exercise will be run using the same methodology. After the last round of improvements, the PROACTIVE app will be considered as the finalised version, concluding the research and development in the context of the PROACTIVE project.

CONCLUSION

This work-in-progress paper presents the preliminary results from a questionnaire on the usability and usefulness of the PROACTIVE CBRNe disaster app, filled in by observers who tested the app during a field training exercise. Overall, observers felt that the app is slightly usable and slightly useful. Their constructive qualitative feedback will be used to improve the app, which will then be tested in an iterative manner in two more field training exercises.

When the project is completed, the PROACTIVE CBRNe app is expected to fill the gap in a lack of citizen oriented CBRNe disaster apps available on the market today. It will be in line with both civil society and CBRNe practitioner's expectations thanks to the co-creation process and should provide the opportunity to minimise the wider "accessibility gap" in emergency management.

ACKNOWLEDGMENTS

We thank all PROACTIVE Dortmund field training exercise observers for their inputs.

Project PROACTIVE has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement no. 832981.

ABSTRACT

In forest fire management, uncertainties are inherent. One major challenge for forest fire managers is the uncertainty of whether a fire will start at all, where, when and with what effect. In particular, human negligence and arson are unforeseeable. This research focuses on these uncertainties affecting the preparatory practices of forest fire managers in Brandenburg, Germany, and how they are anticipated and dealt with. Qualitative content analysis of expert interviews and focus group discussions generate in-depth insights into the role of uncertainties in the prevention phase and during the control of the event. Findings shows that uncertainties pose barriers to preparatory action. Coping mechanisms rely on individual sensemaking that are in turn influenced by one's role, knowledge and experience as well as organizational habits and values. Analysis of German firefighters' perceptions of and coping with uncertainty shows that practices of imagination help to anticipate uncertain futures and to cope with dynamic, complex disasters.

Keywords

embodied uncertainty, forest fire, emergency management

INTRODUCTION

In the management of forest fires, uncertainties are inherent. One major challenge for emergency managers is the uncertainty of whether a fire will start at all, where, when and with what effect (McCaffrey et al., 2020). Forest fire events cannot be predicted with absolute precision, since they arise from a complex of causes consisting of physical and human factors, the actual cause of ignition and the predisposition of the affected areas (Su¨ssner, 2020). Only the potential of the environment to spread the fire, e.g., soil condition, fuel potential and weather facilitating the burning, is used to calculate fire risk such as fire weather forecasts. Thus, uncertainties in fire management previously have mainly been examined in quantitative calculations and models (e.g. Barros-Daza et al., 2022; Diao et al., 2020; Doyle et al., 2019; Wibbenmeyer et al., 2013). These predictions have their limits, as they are subject to forecast uncertainty (Neisser & Kox, 2021; Owen et al., 2012). According to the German forest fire statistics, human action (negligent or intentional arson) is the main cause for forest fires (Bundesanstalt für Landwirtschaft und Erna¨hrung, 2020). This makes the anticipation of such events very challenging. It is therefore important to consider how uncertainties affect the decision-making of forest fire managers and how they cope with these uncertainties (Taylor et al., 2013, p. 7).

Uncertainty is typically split into epistemic uncertainty, which arises from a lack of knowledge, and aleatory or variability uncertainty, which describes unpredictable variables (e.g. Aven, 2011; Kox et al., 2015; Sword-Daniels et al., 2018). Although many models assume that decision-making is predominantly analytic based on calculations and logic, the affective decision-making oftentimes overrules logic if both processes disagree. To enable a more representative concept of decision-making processes, the concept of embodied uncertainty considers the perception

*corresponding author

and handling of uncertainty form a multi-faceted perspective, including emotions and experience (Sword-Daniels et al., 2018). Embodied uncertainty aims to incorporate all aspects of uncertainty in the context of disaster management decision-making and calls for accepting uncertainty as an inherent part of the disaster management task (Sword-Daniels et al., 2018).

Using a qualitative approach, this paper dives deeper into constructions of social reality and thereby reveal underlying belief sets and processes of sensemaking that become relevant when dealing with uncertainty in forest fire management. By doing that, we investigate how uncertainty is embodied. The integration of socio-cultural factors into forest fire management models is still rare. It has previously been attempted by Patra˜o (2020), who calls for a more comprehensive conceptualization of forest fire management that includes socio-cultural realities and a multitude of stakeholders in all phases (e.g. not only firefighters but also the public, the government and agricultural professionals) and emphasizes the role of humans in forest fire management. Through a qualitative perspective this paper aims to explore uncertainties that forest fire managers perceive prior to and during the handling of a forest fire. Furthermore, it reveals how these practitioners contextualize and deal with these uncertainties and which strategies they use (or do not use) to handle the disaster.

Operational decisions are never based on a single piece of information, especially when decision-making is done in the context of multiple factors of uncertainty (Roncoli et al., 2012). Anderson (2010) identifies three practices of anticipation: imagination, performance and calculation. Practices of calculation are limited in forest fire management. Important tools for calculating the hazard risk of forest fires are fire danger rating systems, which are numerical or qualitative indicators that reflect the fire potential (Goldammer, 1998; Neisser & Kox, 2021). These include, in particular, meteorological indices, which combine several influencing factors in one index. In Germany, the forest fire hazard index (WBI) is provided by the agro-meteorological department of the German Weather Service (DWD) indicating daily and weekly forest fire danger levels from 1 (very low danger) to 5 (very high danger) for each county based on air temperature, relative humidity, wind speed and precipitation. Performative practices of anticipation in disaster management are for example training exercises, imitating and therefore embodying possible futures. Regular firefighting drills are part of the training of firefighters, but the focus on specifics of forest firefighting is still rare. Imagination as anticipatory practice refers to envisioning certain futures through scenario planning, and exchanging visions and stories of past events (Anderson, 2010; Neisser & Kox, 2021).

Another concept investigating the perception and management of the unexpected is sensemaking (Weick & Sutcliffe, 2015). In general, sensemaking can be seen as a process of social construction that occurs when discrepant cues interrupt individuals' ongoing activities and involves the retrospective development of plausible meanings that rationalize people's actions (Weick, 1995, 2005). In particular in ambiguous and uncertain moments, sensemaking happens on the account of cues from the environment (Maitlis & Christianson, 2014). Sensemaking processes hence happen in the context of individual and organizational values, experience and knowledge (Barton et al., 2015, p. 81). Whiteman and Cooper (2011) further differentiate that sense-giving while in action plays an important role in managing sudden disasters, such as forest fires. However, unexpected events do not trigger sensemaking per se, but sensemaking occurs when the discrepancy between what is expected and what is experienced is large and important enough to cause individuals or groups to ask "what's going on" and what they should do next. Under growing pressure and prolonged operations sensemaking is deemed to become more challenging and hence, it has been found that under those conditions people rely on their previous understanding of their role and fall back into old habits (Weick & Sutcliffe, 2008).

The purpose of this study is to gain insight into perceptions of uncertainties and barriers to preparedness activities: What uncertainties do forest fire managers perceive in their work? What is their role in forest fire prevention?

MATERIALS AND METHODS

To gain insight into the perceptions of uncertainties and barriers to preparatory measures of forest fire management in Germany, a qualitative research approach was selected. This approach allows to not only shed light on underlying decision-making but also emotions and habits guiding sensemaking and more affective decision-making and reveals in how far uncertainties are embodied. After a systematic literature research, two focus group discussions with overall twelve participants and six in-depth, problem-centered expert interviews were conducted with forest fire protection and management practitioners in Brandenburg, Germany. Brandenburg is the federal state in Germany that is most vulnerable to forest fires, because of its dry soils, same-aged needle woods plantation and continental climate (Gnilke & Sanders, 2021; Thonicke & Cramer, 2006), making it a suitable case study area for assessing forest fire management strategies in Germany. The interviewees included representatives of the Brandenburg Forestry Administration's Forest Fire Monitoring Center and of the Brandenburg State Firefighters Association, employees of regional disaster control administration, as well as local fire chiefs and staff of the control and dispatch centers. The anonymized transcriptions of the interviews were analyzed using qualitative content analysis with

support of MaxQDA software. Qualitative content analysis is particularly useful for gaining detailed insight into the thought processes, meaning-making, and overarching narratives of individuals and groups, and is therefore an appropriate method for uncovering the uncertainties perceived by forest fire managers. Coding was done using a combination of inductive and deductive categories, guided by the relevant literature and taking into account, among other things, the theoretical foundations of organizational sensemaking, organizational culture and management under uncertainty.

RESULTS

The results show that dealing with uncertainty is an important part of the work of forest fire managers. Uncertainty is generally seen as a normal influencing factor of work, which one simply has to accept, since forest fire managers see little possibility to influence it. One can classify the mentioning of uncertainties into uncertainties prior to and during a forest fire event. After examining the general uncertainties that came up during the interviews, we describe coping strategies that have been mentioned or became clear indirectly. The focus lies on the use of forecasting and the role of organizational knowledge. As a final step, we put the results together in a visual overview, attempting to systematize the findings and relate them to the theory discussed above.

Uncertainties Identified Prior to and During the Forest Fire Event

Generally, forest fire managers acknowledge that uncertainties are inherent to forest fire events and mention several uncertainties affecting their work. Overall, they accept that in uncertainty is an invariable inherent component of their work. The uncertainties mentioned by the forest fire managers can be categorized into uncertainty perceived in the phases prior to and during the event (see Tab. 1). Prior to the event uncertainties revolve mainly around the occurrence of a fire and during the event they mostly concern fire behavior (see Fig. 1).

Table 1. Uncertainties prior to and during a forest fire event

Prior to the event	During the event
Weather condition & fuel potential	Availability of volunteer fire fighters
Cause (human ignition)	Development of weather conditions (& fire)
Time and place of the event	Duration of the event

In the anticipation of a possible forest fire, practitioners describe uncertainty mainly as the unpredictability of the time and place of forest fire events, especially since most forest fires in Brandenburg are started by people due to negligent or intentional arson.

Although there is generally an understanding that even weather forecasts cannot predict the upcoming weather conditions in their region with 100% accuracy, forest fire managers still wish for them to be as precise as possibility. Especially the spatial accuracy considering regional conditions and the visualization of meteorological values and their probability are important for practitioners. They state wind direction and speed, wind gusts potential, precipitation, heat, UV radiation and soil moisture as most important variables for them. The ambiguity of trust in weather forecasts becomes clear. On the one hand, the tendency to distrust weather forecasts is due to past deceptions and perceived errors in forecasting; on the other hand, forecasts represent at least one means of computational practice to predict an unexpected event. The actual forecasting of a forest fire event is perceived as highly uncertain and forest fire managers tend to check forecasts through their own observations or through information from people on site.

After the alarm to a forest fire, the biggest uncertainty lies in the structure inherent to the fire management system, namely its dependency on volunteer firefighters. Because of the sudden alarm, it is difficult to know exactly how many of the firefighters can arrive in time at the forest fire event. A major problem with this is that many volunteer firefighters today work in larger cities that are far from their home. This limits their ability to arrive at their assigned fire station or on site in the shortest time possible. Another unknown variable is the duration of the forest fire, as it depends heavily on the time of arrival of the first firefighters, weather conditions such as wind speed and direction, soil moisture and precipitation, and the local conditions of the affected area. In the region, there is also the problem that some forests are former military sites and therefore there are restrictions on entering the area to ensure the safety of firefighters.

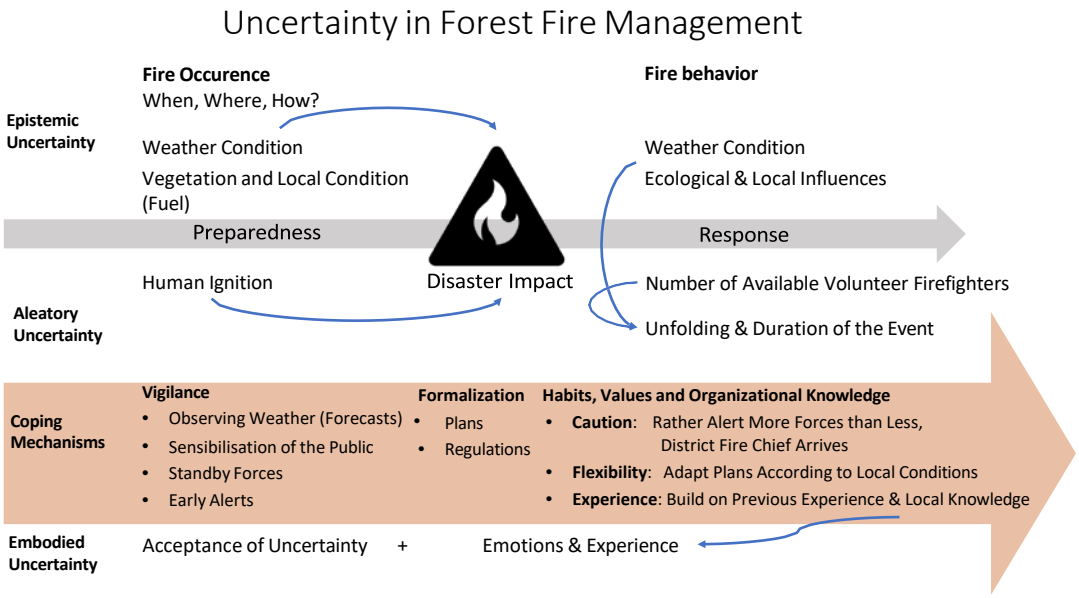

Figure 1. Uncertainty in forest fire management and coping mechanisms to deal with these uncertainties

Coping Mechanisms for Dealing with Uncertainties

The interviews revealed different strategies for coping with uncertainty. While tools and probabilistic calculations such as weather forecasts and formalized structures such as plans and established procedures minimize epistemic uncertainty, values and experiences as part of organizational culture seem to play an important role in managing aleatory uncertainty.

Vigilance

To minimize the impact of uncertainties on forest fire management, most forest fire managers seem to be increasingly vigilant towards cues for forest fire risks. Most importantly, weather forecasts and forest fire risk indices are a relevant tool to envision possible origins of forest fires and even more so the potential development of the forest fire behavior. Forest fire managers rely mostly on calculations such as meteorological weather information because regulations and legal liability hold them responsible for actions taken or not taken based on different forecasts or fire warning levels of the German forest fire risk index. Probabilistic forecasts are sometimes mentioned to help consider those uncertainties in an even more detailed way. Nevertheless, the aim to counter the uncertainties of weather forecasts by predicting possible impacts through impact-based forecasting is oftentimes considered irrelevant by the interviewees, who emphasize that experience and local knowledge are their most important guidance. However, forest fire managers see potential in providing such additional guidance to the public, who they believe are not as well informed. The interviewees deem that the public could be more inclined to seek protection and change their behavior when receiving additional information on possible weather impacts. This in turn would ease their job, as fewer operations would become necessary if people were more sensitized to the risk of fire weather and acted in accordance with the warnings. Another aspect of vigilance and increased alertness is to call standby forces to the fire station, if the fire risk is assessed to be high according to the weather forecast, the forest fire warning index, or personal feeling. However, as there are no formal regulations to allow this standby procedure and most German firefighters are volunteers, this is only possible on weekends or evenings, when the firefighters do not have to attend their regular job. Otherwise, firefighters rely on early alerts to get to the scene as quickly as possible.

Formalization

Another way to cope with uncertainties is to prepare for events through plans based on previous experiences and risk calculations. In Brandenburg, Germany, there is a defined organizational structure specifying who is in charge of making plans, revising and enacting these plans. These regulations and guidelines are distributed in the emergency vehicles, the command and dispatch center and at the fire stations. Commonly, plans are to be updated every three years or after extreme forest fires. There are also forestry regulations that allow forest managers to restrict public access to the forest when there is a high forest fire warning level of 4 or 5 out of 5. However, this is not commonly used by the practitioners, because the forest managers feel that these regulations cannot be enforced.

Habits, Values and Organizational Knowledge

To balance uncertainties, some general organizational and individual habits come into play. One of them is increased caution. According to the interviewed fire managers, the district (or county) fire chief (*Kreisbrandmeister*) always takes part in the first forest fire assessment onsite if the notifying command and dispatch center alerts a bigger forest fire with the code for larger forest fires (*Brand: Wald/groß*). The motto is to rather request more emergency personnel than necessary than have too few available. Since one of the greatest uncertainties is that the volunteer firefighters will actually show up in time. Because of that, some fire brigades even choose to call a stationary attendance if they suspect an event happening in the close future, although no formal plans to call such stand-by attendance exist. Another aspect of taking caution is to forward every warning received, even if it is a false alarm. Caution during the incident particularly involves keeping the firefighters safe, e.g. from threats arising from old munition, thunderstorm, heat and high UV or landslide risk. Especially during a bigger event some interviewees deem it relevant to stay calm. For example, one interviewee emphasizes that he learned from older colleagues to keep calm and wait, and manage a the event with composure. Other practitioners emphasize that there is "no universal dogma" applicable to any situation and all fire stations as "no operation is the same as another". This demonstrates that adaptivity and flexibility are relevant to coping with forest fires, their unexpected cause and their uncertain development. A positive attitude and motivation for their job support these habits and values. All practitioners agree that experience is more important than any predictive calculation, weather forecast, or forest fire risk index. As one fire brigade leader puts it, firefighting is always a "step by step" learning process, in which all firefighters evolve and enhance their skills. This implies that knowledge transfer within the organization is of high relevancy. However, knowledge transfer is rarely systematic. In some organizations, certain stories are told by senior colleagues, while in others it is emphasized that experience is best gained by being exposed to real firefighting operations, not just practical exercises or theoretical lessons. Talking to other members of the organization and learning from their experience is thought to be more helpful than learning by book. Some use a mentoring program that gradually gives younger, newer firefighters more responsibility in the field, but always offers the chance to draw on the experience of the mentor in case of difficulties. At the governance level, knowledge exchange also extends to international and scientific exchange. Successful firefighting is also based on mutual trust. Local fire brigade leaders create this trust by repeatedly making it clear that the safety of the firefighters is paramount, by promoting an open culture of error and being proud of their comrades.

Integrative Framework of Uncertainty Perceptions and Coping Mechanisms

Fig. 1 visualizes which types of uncertainties forest fire managers perceive, how they can be theoretically categorized and which organizational coping strategies are employed to encounter them. The uncertainties and their coping strategies are organized along their stage of appearance in the disaster cycle. Interactions and dependencies are presented as blue arrows. For example, the uncertainties of the fire occurrence also affect the disaster impact. Furthermore, uncertainties about the fire behavior that we categorized as epistemic such as the weather condition predicted by forecasts, but also aleatory uncertainties such as the number of volunteer firefighters actually showing up, influence another factor of uncertainty: the unfolding and duration of the event. The coping mechanisms primarily applied in the different phases can be categorized into the anticipatory practices, which help deal with the different types of uncertainties and at different disaster stages (see 1). At different stages of the disaster cycle different practices of anticipations have varying relevancy to anticipate uncertainties and cope with the uncertainties. Furthermore, the type of uncertainty seems to influence the type of anticipation and coping strategy .

DISCUSSION

In the literature on forest fire management, it has been widely acknowledged that weather is an important factor in the development and modification of forest fire events (Boychuk et al., 2020). This study goes further and assesses the perception of weather forecast uncertainty in context with further uncertainties affecting forest fire management decision-making. Weather forecasts and warnings are important for practitioners, especially because of the related legal regulations. For the actual firefighting, however, they are combined with personal experience, own observations and local knowledge in order to make optimal adapted decisions. Hence, when distinguishing between intrinsic and contextual factors of operational decision-making (Roncoli et al., 2012), particularly the contextual factors of decision-making seem to be of relevance in forest fire management, as the situation is very dynamic and decisions have to be assessed and adapted accordingly.

When uncertainties prevail, the decision environment in which predictions are used matters. The results of our research show that apart from formalized structures in forest fire management, such as the organizational structure, information flows, or human factors especially values, previous experiences and local and organizational knowledge affect decision-making processes under uncertainty in forest fire management. To respond to the uncertainty

inherent to their job, organizations tend to follow habits, plans, goals or rituals that are intended to create more certainty and control over the situation, well-knowing that they can never be sure of the success of these aims (Turner, 1976, p. 378). The relevancy of values, experience and knowledge in sensemaking processes has also been demonstrated to be crucial by former studies (Barton et al., 2015, p. 81). In our case study, especially experience and local knowledge were significant factors to cope with uncertainties in forest fire management. This finding agrees with Weick and Sutcliffe's 2008 analysis of forest fire managers' sensemaking practices, who state that under growing pressure sensemaking becomes more challenging and hence people rely on their previous experiences and understanding of their role.

The analysis shows that values such as flexibility and adaptivity and a calm mindset are deemed crucial to cope with uncertainties in forest fire management. This finding can be used to develop these skills in forest fire exercises. Especially the aspect of flexibility and openness to adapt the current organizational structures and decision-making to the dynamic situation has been considered beneficial for emergency management by previous scholars and has been highlighted especially for firefighting (Weick & Sutcliffe, 2008).

Another mechanism that German forest fire practitioners emphasized for coping with uncertainty is increased vigilance and caution. Practitioners remain attentive to indications that the situation may change and not unnecessarily jeopardizing the safety of responders. Firefighters in Germany deem it impossible to completely hinder the occurrence of an event, but they always aim to get ahead of the threat and change the situation (Kox & Lüder, 2021). The forest fire managers tendency to rather warn and alert too often than too little has for instance also been observed in a study on hurricane prevention management, calling this practice the "worst-cased approach" (Bostrom, A., 2016), or in firefighters' response to weather warnings, calling it a "zero-risk strategy, in which even the lowest probability of occurrence is too much of a risk and thus has to be avoided" (Kox et al., 2018, p. 126). The safety of responders is a key priority in managing the event and previous studies have recognized the influence of self-protection decisions on fire suppression strategies (e.g. Patra˜o, 2020). The interviewees in this study also mentioned the aim to reach out to the public as part of their preparatory measures trying to prevent forest fires from happening. It seems that practitioners in fact already include socio-cultural factors in their management strategies and acknowledge the value of incorporating local communities into forest fire management (Patra˜o, 2020; Paveglio et al., 2019).

Barton et al. (2015, p. 81 find as an additional factor to manage uncertainty that leadership behavior influences effective disaster response. This aspect has not come up much with the interviewees in this context. One reason why this was only rarely mentioned could be that all interviewed persons were in a leadership position, and hence did not reflect the importance of their position and influence. Another reason could be that organizational structures and culture, and experience just matter more for forest fire managers than leadership behavior. However, the research shows that knowledge transfer is another important factor for managing uncertain complex fire events and the effectiveness of organizational knowledge transfer probably relies on leadership. The unclarity of the role of leadership in this research opens room for further research that should investigate on the links of knowledge transfer as part of leadership behavior, and leadership's potential to minimize uncertainties. Previous research has already discussed the impact of leadership on firefighters well-being but not focused on perceptions of uncertainty (Marques-Quinteiro et al., 2022).

Overall, our research has shown that to cope with uncertainties, practices of imagination, such as knowledge transfer, experience of senior colleagues told through stories or organizational values shaping individual sensemaking are highly relevant. These habits and values are shaped by a general acceptance of uncertainty. This finding agrees with previous research that asserts professional weather forecast users relatively good knowledge of forecast uncertainty (Kox et al., 2015). This embodied uncertainty helps to face the emerging threats with composure and to remain calm and flexible even in extreme situations. Accordingly, the interviewees stressed the relevancy of personal experiences, mindsets and emotions. As this is an exploratory case study, the research is limited to providing deep insights into the expert group in question; it cannot be expected that practitioners in other fields or other cultural contexts will necessarily hold the same views. Moreover, qualitative research is never completely free of subjectivity. Employing Lincoln and Guba's Standards for qualitative research in respect to transparency, credibility, dependability and confirmability was a measure to overcome this challenge (Shenton, 2004). Our results represent the viewpoints of the interviewees, which may be affected by social desirability and the general interview setting but are contextualized in the discussion and interpreted in the light of previous studies and findings of scholars exploring the management of the unexpected.

In contrast to previous quantitative studies, our research sheds deep insights into perceptions of uncertainties in forest fire management from the perspective of practitioners and analyses these in the context of the current state of organizational and disaster management research approaches. The findings serve to reveal underlying reasonings that influence decision-making under uncertainty in forest fire management as well as coping strategies. The

study thereby confirms findings of previous studies by analyzing first-hand experiences and conceptualizations of emergency service personnel in the forest fire sector. Moreover, we showed performance practices such as exercises to be less relevant to the group and highlighted aspects such as the role of local knowledge and knowledge transfer, that so far have received less attention by disaster scientists in Western countries. Presenting these findings will not only help advance research on management strategies in disaster management but also aid practitioners to contextualize and adapt their strategies. Our work adds to the growing literature on anticipatory wildfire governance a qualitative perspectives on use and perception of uncertainties (Miller et al., 2022). Future studies should take these findings and compare them in a wider, more international scope to find differences and similarities. This will enrich future strategies for managing and accepting the unexpected and integrating embodied uncertainty into forest fire management approaches.

CONCLUSIONS

Our study demonstrated perceptions of uncertainty in forest fire management prior to and during the event. The sensemaking approach was a valuable approach to classify these perceptions and how to deal with them. We show how German firefighters consciously and unconsciously employ certain strategies to deal with uncertainty, e.g., adaptive informal awareness mechanisms or formalization such as making plans based on past events. In general, a wait-and-see caution and constant vigilance are evident. In particularly extreme events, where aleatory uncertainties dominate, computational and performance practices are less relevant to anticipating the future development of a fire, while practices of imagination are essential. Experience, caution, composure, and flexibility are values that have been shown to be relevant to forest fire management in the face of uncertainty. In addition, the role of local knowledge and knowledge transfer in managing unexpected extreme fire events was emphasized and should be further explored in future studies.

ABSTRACT

Wildfires, exacerbated by climate extremes, pose escalating global threats. Despite advancements in technology, current wildfire management policies lack specific details about integrated management and stakeholder engagement. This study provides empirical evidence on how five European wildfire management locations align with networked governance models by analyzing how their stakeholder networks are configured through social network analysis (SNA). This is measured by assessing network configuration and stakeholder group profiles. Measurements at the network level assess the size, density, diversity of sectors, scalar levels of operation, and phases. At stakeholder level, relevance is assessed by measuringin degree, eccentricity, closeness centrality, and betweenness centrality. Analysis qualitatively assesses the network profile, leading to the discussion on the primary factors influencing network configurations and the potential outcomes of these attributes.

KEYWORDS

Integrated Wildfire Management, Social Network Analysis, Stakeholders Analysis

FUNDING DECLARATION

This research has received funding from the European Union's Horizon 2020 programme under grant agreement No 101036926 (A Holistic Fire Management Ecosystem for Prevention, Detection and Restoration of Environmental Disasters [TREEADS]). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

INTRODUCTION

The frequency of wildfires and the risk they pose is increasing, exacerbated by extreme climate events such as heatwaves and droughts. In the past five years, Portugal (2017), Greece, (2023), and other locations experienced devastating fires, highlighting the severity of the issue. Inadequate disaster and forest management increase the short-term impact and long-term repercussions of wildfires (Marie & Labossière, 2015; Pearce, 2003; Pereira et al., 2016). These events prompted extensive discussion on the necessity of improving existing mechanisms, collaborations, and management approaches. Beyond advancements in technology, stakeholders emphasize the importance of integrated strategies spanning wildfire management phases, focusing on actors, governance, technology, and socio-economic factors. Within the European Union, the integrated approach is promoted through projects funded by Horizon 2020 Innovation Action grants and Union Civil Protection Calls.

Wildfire management is as a collective action problem requiring strong coordination among stakeholders (Charnley et al., 2020). Engaging diverse stakeholders in collaborative processes that integrate environmental information into decision-making is crucial, but also challenging. It is necessary to work at and across the boundaries of knowledge types, which involves navigating complex environments and multiple stakeholder-engagement processes that can promote knowledge exchange and co -creation (Sitas et al., 2016). Despite developments in comprehensive wildfire management, prevailing strategies lack detail about how to identify relevant stakeholders and the purpose of stakeholder engagement. Crucially, there is also little research evaluating existing levels of stakeholder engagement in the contexts where these processes are situated. A changing environment, the need to disseminate information, complex decision-making processes, and insufficient understanding of all actors increase the risk of managerial mistakes (Battistoni et al, 2020).

A central tenant in comprehensive wildfire management involves transitioning from a paradigm focused solely on enhancing the efficiency of civil protection services in response to wildfires to a model that prioritizes risk identification and assessment, coupled with proactive prevention measures. The use of SNA methods in wildfire management research is justified by recent calls from academics, land managers, and policymakers for an approach to wildfire risk management that works across sectors to consider the needs of different stakeholders in risk assessment and communication efforts (AGIF, 2023; Casartelli, & Mysiak, 2023; Chuvieco et al., 2023; United Nations, 2015). These calls to bridge gaps across sectors and scalar levels of operations fits into the debate on integrated wildfire management that began in the1980s. The issue has become more pressing in recent years as the frequency of catastrophic fires increases along with demand that land management processes align with economic, public, and environmental pressures (Ferrara et al., 2019; Moore, 2019).

Successfully implementing this new approach to wildfire risk management is contingent on stakeholder engagement. For example, the significance and effectiveness of governing institutions may not align with their formal roles, or specific information on practices may be held by stakeholders not formally participating in governance. Social network analysis (SNA) is a valuable tool for examining the dynamics of social interactions, which cannot be fully grasped by only examining formal institutions in a natural resource governance system. It provides insights on the most relevant actors within a given a network, how these actors collaborate, and how information flows in systems across different scalar levels in wildfire management contexts within the European Union.

LITERATURE REVIEW

Changes in wildland-urban interfaces, climate change, and inadequate forest and disaster management increase the severity of wildfires and the complexity of wildfire management (Marie & Labossière, 2015; Pearce, 2003; Pereira et al., 2016). A new wildfire management approach is needed to effectively adapt to these changes.

Governments, policy experts, and researchers have extensively discussed the necessity of improving existing governance mechanisms, collaborations, and management approaches to wildfires. Beyond the adoption of new technologies, they emphasize the importance of integrated strategies encompassing all wildfire management phases by focusing on stakeholders, governance, technologies, and socio-economic factors. Understanding wildfire management as a collective action problem that requires strong coordination amo ng stakeholders is key to successfully shifting approaches (Charnley et al., 2020). Engaging diverse stakeholders in collaborative processes involves navigating complex environments (value systems, social conventions, and mental models) through multiple stakeholder-engagement processes that can promote knowledge exchange and co -creation (Sitas et al., 2016). The long-term complexity of these issues is evidenced by what researchers refer to as the "wildfire paradox" created by fire suppression strategies, including public awareness campaigns aimed at preventing wildfires. Fewer fires in the short term raises the fire risk from stored fuel (Calkin et al., 2015).

Limiting management fires also contributes to excess fuel storage. Scholars and policy makers in wildfire-prone regions argued that past approaches to fire suppression and climate change necessitate society creating "a new relationship with fire" (Thompson et al., 2018, p. 382).

Efforts to formulate pathways to change entail realigning priorities and risk sharing among multiple public and private stakeholders and viewing wildfire governance as a "social-ecological problem" (Steelman, 2016). Making these shifts, however, opens complexity that needs to be managed by policy makers, practitioners, and researchers. Relationships between stakeholders and distinct stakeholder understandings of the risks posed by wildfires need to be factored into effective wildfire governance strategies. However, Kirschner et al. (2023) noted imprecise definitions and the lack of a consistent approach to studying wildfire governance. The authors proposed a four-part analytic framework of participation, collaboration and co-production, path-dependencies and place-based dynamics, and adaptation and anticipation.

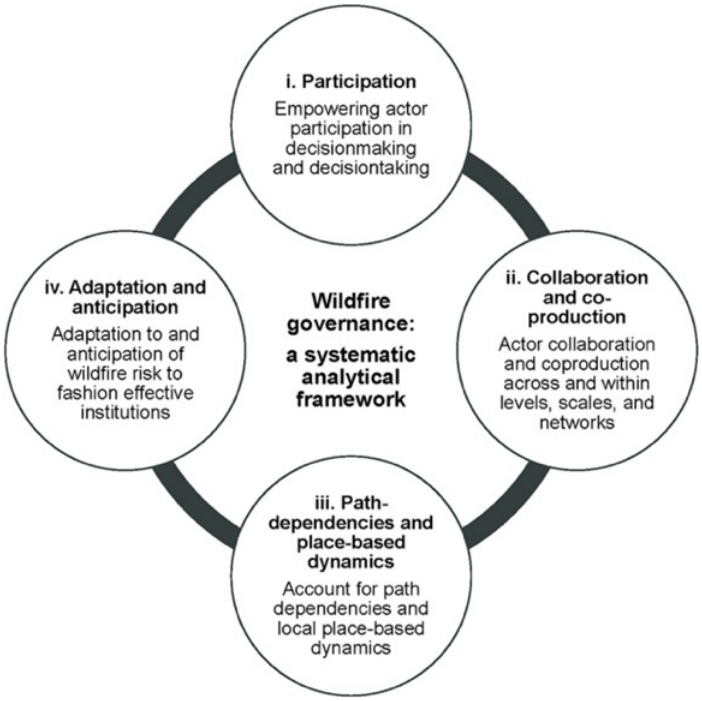

Figure 1: Wildfire Governance Framework (Source: Kirschner et al., 2023)

Kirschner et al. (2023) is an important reframing that provides analytical categories for understanding relationships among stakeholders and governance processes. Research by networked governance scholars resonate with these categories. Provan and Kenis (2007) documented three types of network governance—participant-governed networks, lead organization-governed networks, and network administrative organization—and developed criteria for evaluating the effectiveness of network governance. Addressing complex issues demanding multilateral coordination in areas such as disaster management, economic development, or social services requires achieving the goals of multiple organizations (Provan and Kenis, 2007; O'Toole, 1997).

Bodin & Nohrstedt (2016) built on this knowledge to develop a model to "empirically investigate relationships between task interdependency and collaborative (social) network structures" (p. 184). The authors argued for "the importance of moving beyond simplified assertions of the utility of collaborative governance in addressing disasters by enabling more precise and theoretically informed empirical inquiries regarding the mechanisms that shape the structure and performance of collaborative networks" (p. 192). Carboni et al.'s (2019) examination of purpose-oriented networks draws our attention back to the goal of the project pilots, namely, improving wildfire response, which their work provides theoretical insight to evaluate.

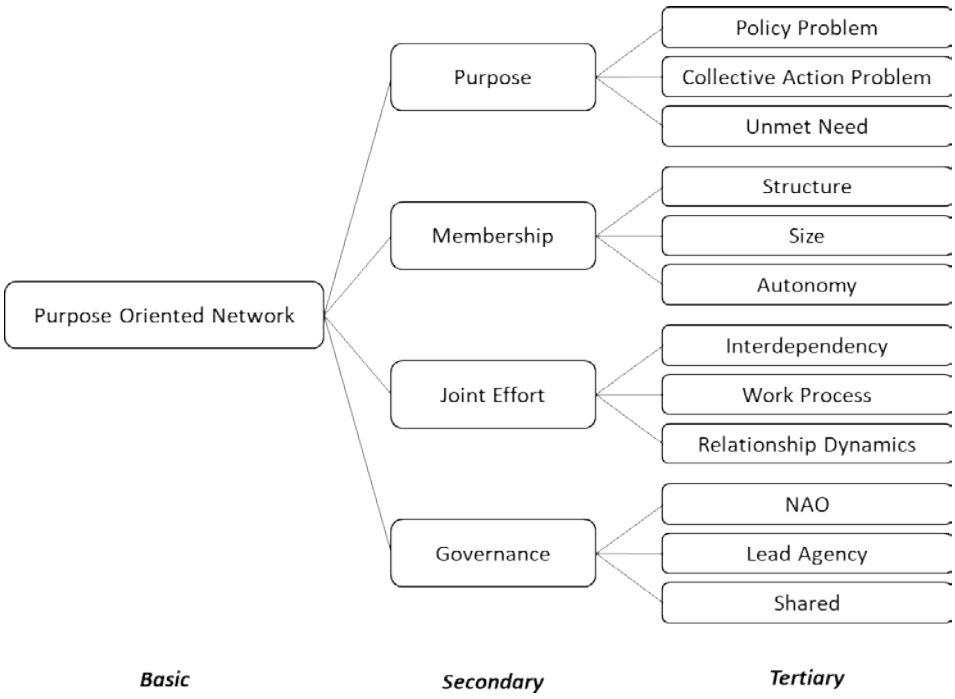

Figure 2: Purpose-Oriented Network Conceptual Framework (Source: Carboni et al., 2019, p. 212)

Charnley et al. (2020) framed wildfires as a "collective action problem in multi-ownership landscapes" (p. 2). Steelman et al. (2021) begin their article by centering the networked aspects of disasters before introducing structuring factors of networked governance during wildfires. De Hoop et al. (2022) contributed to understandings of the multi-stakeholder aspects of wildfire management. Bradshaw (2019) provided guidance through their evaluation of stakeholder-agency interactions in wildfire management (see also Burns et al., 2003). Essen et al. (2023) specifically examine risk sharing in this domain (see also Fischer & Jasny, 2017). Hamilton et al. (2023) contributed findings about risk, wildfires, and multilevel governance.

There are significant policy efforts to implement these networked approaches to wildfire management. The EU's Wildfire Peer Review Assessment Framework (WPRAF) (Casartelli & Mysiak, 2023) and the 8th International Fire Land Conference's Landscape Fire Governance Framework (LFGF) (AGIF, 2023) are two recently formulated governance frameworks created to account for the shifts discussed above. These two holistic frameworks structure governance approaches across wildfire phases, eco -socio-economic factors, and stakeholders. They promote novel approaches to risk governance that changes how information about risk is collected, analyzed, and communicated with the goal of improving risk management decision making. These frameworks position decision making as a negotiated process rather than determined by governmental authorities and break silos, increase collaboration, and prioritize training and preparation. Our study draws from the research discussed above and these two governance frameworks to stress the importance of understanding diverse stakeholders and their relationships in holistic wildfire management.

METHODS

The project partners conducted in-depth stakeholder analysis in support of the project's proposed outcomes of improving wildfire management through the project pilots. Stakeholder mapping and analysis is an effective starting point for identifying stakeholders, understanding their rela tionships, and their positions in holistic wildfire governance approaches. It also supports continuous stakeholder engagement through the project pilots. We approached stakeholder analysis through Reed et al.'s (2009) survey of stakeholder literature in business management and natural resource management cataloging stakeholder analysis methods. Our methodological approach to understanding the multi-actor complexities of wildfire governance treated the pilots as focus groups to work with in order to map stakeholders within and outside of the project pilots. After completing the stakeholder map for each pilot area, we analyzed stakeholder relationships through social network analysis. Reed et al. (2009) characterized the strength of SNA as helping "Gain insight into the boundary of stakeholder network; the structure of the network; identifies influential stakeholders and peripheral stakeholders" (p. 1937).

The stakeholder analysis method employed in this study aims to identify groups and organizations that impact

or are impacted by wildfire regimes in the target regions, develop knowledge about their relationships, and determine their relevance in the wildfire management process. The approach follows Wasserman and Faust (1994) and Carrington et al. (2009) that advocate for the importance of networks as the primary units of analysis. The relationships between stakeholders are of primary interest and the attributes of stakeholders arise from the relational processes in which they are integrated.

Our approach follows Reed et al. (2009) and Ahmadi (2019) work on stakeholder analysis in natural resource governance. Stakeholder analysis is a process that starts with identif ying stakeholders (I), before categorizing (II) and mapping (III) their relationships through social network analysis (SNA).

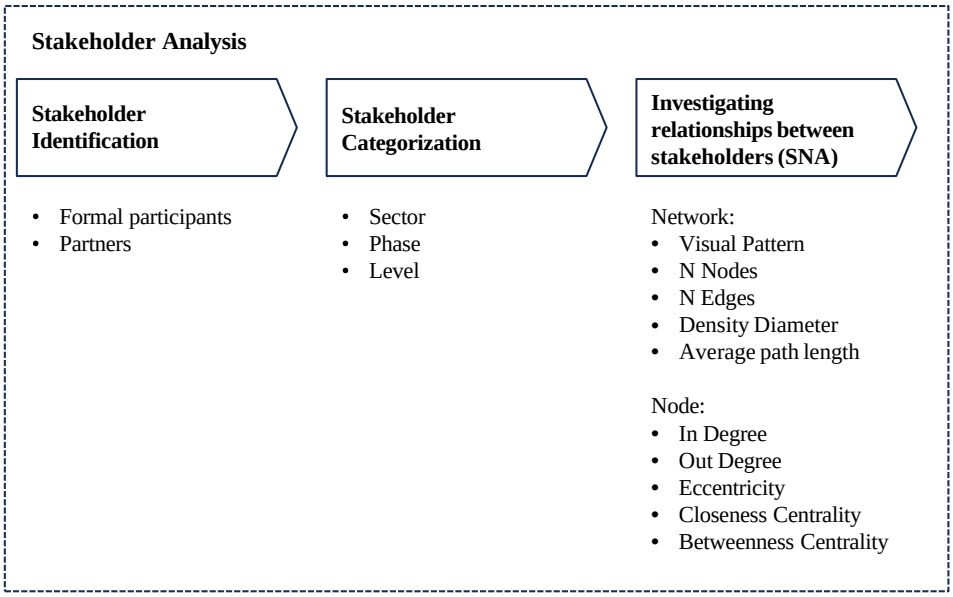

Figure 3. Stakeholder Analysis Method

Adapted from Reed et al., 2009.

Area of Study

The study was conducted as part of a Horizon 2020 project aimed at developing technological solutions to promote holistic wildfire management in the European Union. Technology development was performed in pilot regions where a stakeholder group or organization (henceforth "pilot leader") established a network of collaborators to achieve specific project objectives such as conductingexperiments, exercises, prototype testing, or developing risk management plans. Governmental institutions formally participated in all the pilots from their launch and new actors were engaged during implementation, with the networks growing as the project progressed.

The pilots are being implemented over a 42-month period between December 2022 and May 2026. For the purposes of this study, we selected the pilots with the five largest networks out of the eight project pilots. The pilots selected were in Austria, Greece, Italy, Norway, and Spain. These pilots comprise different scopes, landscapes, weather conditions, socio-economic characteristics, and wildfire management systems.

Table 1. Profiles of the Pilot Cases

Country	Leader Profile	Focus	Scope
Norway	Research Institution	Preparedness for wildfires in northern Europe	Field exercises on forest fires to enhance prevention and preparedness. Test fire protection technologies. Development of guidelines for safety zones and technical requirements.
Italy	Consultancy	Prevention, detection, and adaptation in densely populated areas	Feasibility study for the development of fire-resilient solutions for infrastructure. Analysis of the interactions between wildfire and critical infrastructure. Establish a resilient connection during wildfire occurrences, extending beyond traditional car accessibility.
Spain	Consultancy	Wide area wildfires in high-risk zones	Development of innovative tools for data collection, analysis as, and exploitation. Offer immediate post-fire information, assessing fire severity and recovery. Analysis of the environmental impact of fires in the region.
Austria	Rescue Service Provider	Prevention, protection, and fast response of (peri)-urban wildfire	Fire prevention and a fast response in peri-urban areas. Improve aerial-data use for prediction of fire evolution.
Greece	Research Institution	Human and animal evacuation	Enhance cross-sectorial collaboration and distribution of critical information. Facilitation of more effective rescue operations for humans and animals.

Stakeholder Identification

The first step of the stakeholder analysis process consisted of identifying the stakeholders participating in the local governance wildfire management networks at mapping workshops conducted between September and December 2022. Pilot leaders invited an initial group of stakeholders to workshops aimed at analyzing their local wildfire management context to identify the challenges, needs, and potential contribution of the stakeholders. The list of stakeholders in each pilot was completed through an iterative process with the pilot leaders and participants during the project. Participants finalized the lists after the workshops. The networks documented are unbounded, where membership is not set by a specific affiliation to a policy process, nor to formal engagement in the pilot.

Stakeholder Categorization

Stakeholder categorization aimed to identify the types of stakeholders participating in wildfire management networks. Categorization was performed directly after the initial workshops through a top-down approach where

the study team collaborated with the pilot leaders to identify the stakeholder groups according to three categories:

- Sector (government / civil society / private): categorization based on the governance mode and strategic objectives of each stakeholder group.
- Level (local / regional / national/ international): categorization based on the main level of operation for the stakeholder groups.
- Phase (review / risk reduction / readiness / response / recovery): categorization of phases based on Moore's framework of wildfire management phases (2019) where each stakeholder group is attributed a primary management phase according to their mission.

Stakeholder Relationship Mapping

The third and final step of the stakeholder analysis process involved investigating the relationships among stakeholders through social network analysis. Analysis was divided into two parts: a survey and a workshop. The survey aimed to identify active stakeholders in the region, their relationships, and connections requiring improvement. The workshop was designed to provide a preliminary analysis and validate the survey findings. In this part, stakeholders under the guidance of a pilot leader were asked to visually represent the survey results in a preliminary social network graph.

Data for the surveys and workshops was treated and analyzed in Gephi to create individual network graphs for each area of interest. The analysis process used information from the previous phases to characterize each network according to the attributes in Table 2.

Table 2. SNA variables

Network-level statistics	Node-level statistics
N Stakeholder Groups	In degree
N Connections	Eccentricity
N Stakeholders Groups per sector	Closeness Centrality
N Stakeholders Groups per level	Betweenness Centrality
N Stakeholders Groups per phase	
Network diameter	
Average degree	
Average) Weighted degree	
Average path length	

Ultimately, the study aims to provide empirical evidence to evaluate five European wildfire management contexts through networked governance models by analyzing the configuration of their stakeholder networks. This is measured by assessing network configurations and stakeholders. At the network level, the measurements assess the size, density, and diversity of sectors, in addition to scalar levels of operation and phases. At the stakeholder level, relevance is assessed by measurements such as in degree, eccentricity, closeness centrality , and betweenness centrality. Analysis is completed by a qualitative assessment of the network profile, leading to the discussion on the main factors determining the network configurations and the potential outcomes of these attributes.

RESULTS

Network Configuration Analysis

The first relevant result of the stakeholder analysis process are the profiles of each pilot network in terms of number of stakeholder groups, connections, average degree, network diameter, average path length, density , and the diversity of sectors, levels, and phases of operation. Analysis of network-level statistics allowed an in depth understanding of each network profile and the comparison of results across groups in information provided about the size, the interconnectedness, and the diversity of each pilot network.

The first relevant result of the SNA mapping is that the project is a building a diverse set of networks. The pilot

networks range from complex networks with dozens of stakeholders spanning three or four countries to very localized connections, where a handful of stakeholders interact to conduct specific experiments or test some of the technologies under development. Other attributes vary considerably such as interaction density, the diversity of sectors and scalar levels of operation represented, and the average degree.

Regarding network size statistics, the average number of stakeholders is 46, with the smallest network having 34 and the largest 79. The number of connections ranged from 80 to 295, with an average of 176. The diameter of networks ranges from 3 to 4, with an average of 3.4. The degree of interconnectedness of stakeholders within the networks ranges from 1.66 to 6.97, with an average score across the five pilots of 3.83. The average path length ranges from 1.42 to 2.38, with an average of 1.87. Finally, the graph density ranges from 0.04 to 0.21, with an average of 0.09.

Table 3. SNA Results Overview

Variable	Austria	Greece	Italy	Norway	Spain	TOTAL	AVG
Stakeholders Total	38	38	44	76	34	230	46,00
Connections Total	119	139	80	291	246	875	175,00

Avg Clustering Coef	0,68	0,35	0,31	0,25	0,55	NA	0,43

Data was processed according to the categories to access the diversity of sectors. On average, the pilot networks have 63% of representatives from government, 24% from civil society, and 13% of the private sector. Concentration of actors from government ranges from 74% to 59%. Civil society and private sector participation ranges from 34% to 11% and 18% to 3% respectively. All pilot networks in the study had at least one representative from each sector.

Information on the phases followed a similar pattern, with stakeholders more concentrated, on average, on the phases of response 32% and prevention 42%. Other phases average lower concentrations: review 10%, readiness 15% and recovery 1%. As for the distribution, the pilots that presented the highest concentration in one single phase were the Austrian and Italian pilot networks, with 47% and 43% of its stakeholders concentrated in the response phase respectively. Three out of the five pilot networks did not have stakeholders with priority focus on the recovery phase. Moreover, the Italian pilot did not have stakeholders in the review phase.

Network Composition Analysis.

The investigation of the network attributes of individual nodes complements the analysis across pilots by providing insights on the most well-connected types of stakeholders in each pilot, along with the identification of gaps identified by poorly connected stakeholders in key areas.

The first analysis identified of the most relevant stakeholder in each pilot according to the number of connections received. An investigation of the stakeholders with the highest in-degree scores indicates that NGV43 (Norway, 21), SGV27 (Spain, 17), DD Chania (Greece, 16), and IGV2 (Italy, 6) are the actors receiving the highest number of connections. In Austria, the AGV8, AGV13, ACS16 and AGV19 are tied for the most connections with five each. All stakeholders with the highest in-degree scores are from government, except for ACS16, which is a civil society entity providing public services. In terms of the phase focus, four out of five of the most highly ranked stakeholders perform functions in the "Risk Reduction – Prevention" phase, while one is in "Risk Reduction – Readiness" and two in "Response - Fire Fighting Operations."

The second analysis identified the stakeholder most strategically connected with betweenness centrality scores. Betweenness centrality is a measure of the dependency of other nodes on a given node (Brandes et al., 2016) and refers to the number of times a given node appears in the optimal connection between two other nodes in the graph. In our analysis, the pilot leaders in Spain (SGV14, 191), and Italy, (IGV2, 152) had the highest scores. In Austria, ACS10 (36), a stakeholder that specializes in networking for the improvement of wildfire management had the highest score. In Greece, HGV13 (116), a governmental agency responsible for coordinating emergency response, and in Norway, NCS47 (1013), a research center that partners with the pilot leaders, had the highest scores. In all cases the highest scores are attributed to actors that are central to the pilot's operation or to the management of networks of wildfire management in the implementation region.

A final investigation into the stakeholders' strategic placement was performed through closeness centrality measures. The results from this variable also indicate the strategic placement of the stakeholders in relation to the network but using its distance to all other nodes as a measure of interconnectivity. Here the lowest values are attributed to the most well-connected stakeholders, with only stakeholders that actively responded to the survey considered in the analysis. Of note, the highest scores in closeness centrality are attributed to stakeholders that might not be central to the network in terms of in-degree and out-degree scores, but are directed connected to them, as the case of SCS2 in Spain (0.40), HGV15 in Greece (0.42), ICS1 in Italy (0.46), AGV7 in Austria (0.49), and NGV64 (0.33) in Norway. These best scoring cases showcase the benefits of reaching out to network brokers not only to the performance of everyday duties but also to the development of integrated wildfire management actions.

Norway

The Norwegian pilot is led by a Norwegian center with expertise in fire resistance, reaction to fire, firefighting, fire tests, and fire simulations. The pilot conducted a hybrid SNA workshops, with stakeholders completing the survey prior to the on-site event in September 2023. The SNA survey yielded 30 responses resulting in the identification of 79 different stakeholders. The network of the Norwegian pilot is diverse and extensive , involving 44 stakeholders from the government, 25 from civil society, and 10 from the private sector. The stakeholders represent a broad spectrum, ranging from government bodies (e.g., local and regional authorities, fire brigade departments, and directorates) and educational institutions to agricultural associations and fire research organizations. The private sector also has a notable presence among the stakeholders, representing forest owner associations, technology development, and manufacturing companies, among others.

Connections within the network are intricate, linking entities involved in wood processing, fire safety, agriculture, meteorology, research, and technology innovation. Notably, the network includes international associations and research institutions, European agencies, and global non-profits, showcasing a comprehensive and multi-dimensional approach. The network appears to be well balanced, with various stakeholders able to contribute their expertise and resources to address fire-related issues comprehensively. This inclusive approach involves key players from different sectors, emphasizing a holistic strategy in managing and preventing wildfires.

The Norwegian pilot's activities were conducted in forested inland areas in the east and coastal landscapes with heather, grass, and scrub vegetation in the west. The exercises and experiments are designed and implemented in coordination with local authorities.

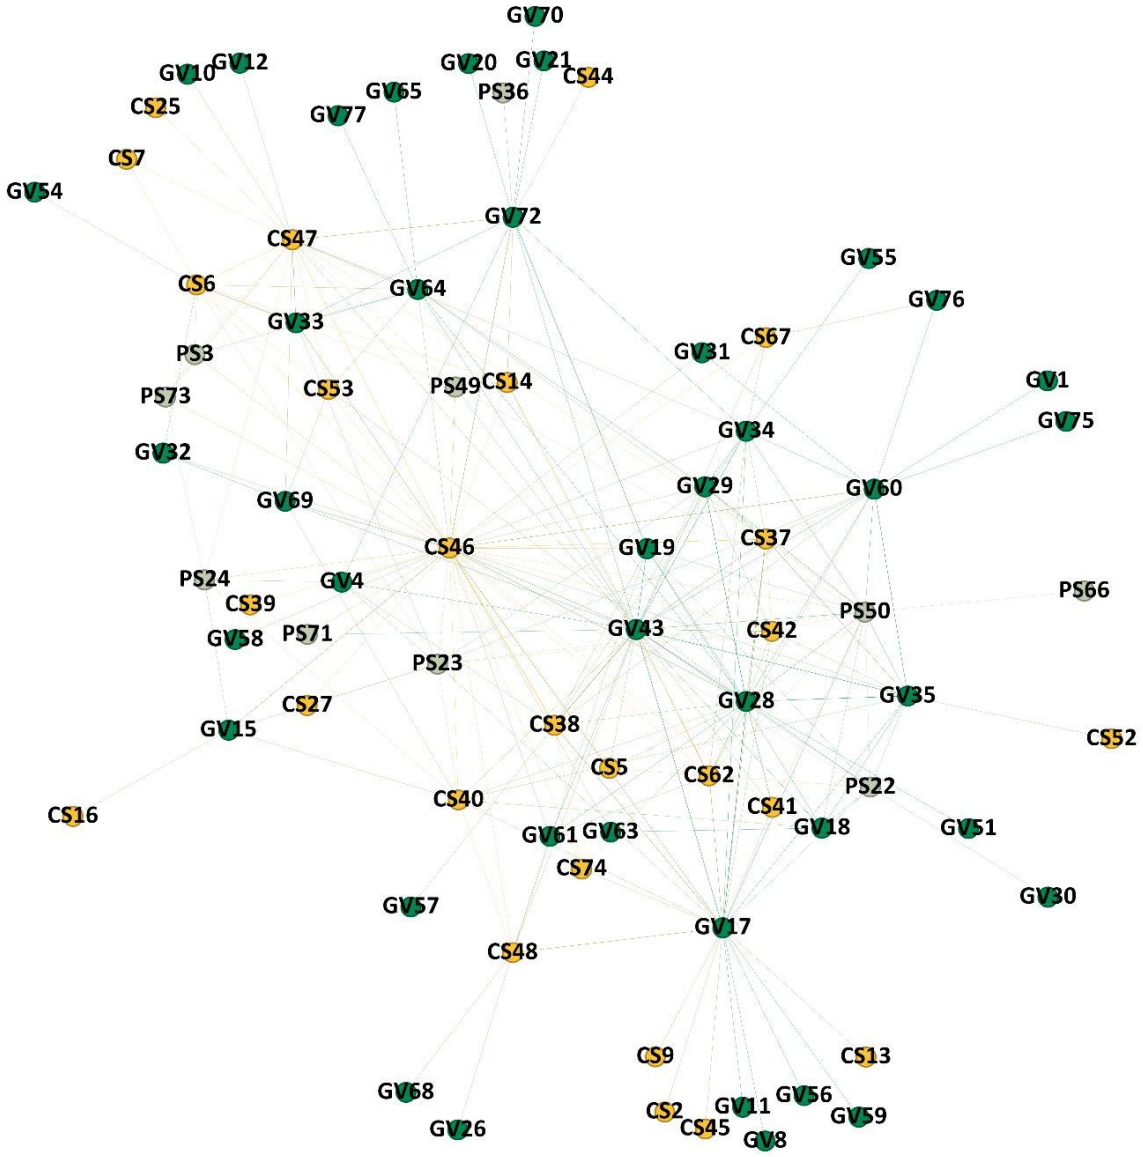

Figure 4. Norway Stakeholder Network

Italy

The Italian pilot is led by a private non-profit company engaged in research activities and the experimental demonstration of innovative technologies for the construction sector. The pilot leader organized an online SNA workshop in May 2023. The SNA survey was completed by 6 respondents from different organizations, resulting in the identification of 44 stakeholders.

The Italian network of stakeholders exhibits a comprehensive structure with robust connections to regional and local authorities. This is evident by the significant involvement of stakeholders from municipal, regional, and community levels. The identification of 26 stakeholders from government and 10 from civil protection emphasizes the active involvement of local entities in addressing wildfire management. The modest representation of private sector stakeholders (8) reinforces the idea that the predominant role in wildfire management is played by governmental and civil protection bodies. Such an approach emphasizes the vital role of community participation and collaboration at the local level in effectively managing and mitigating the impact of wildfires.

The Italian pilot focuses on the Sorento Peninsula, a densely populated area with urban areas and forests on the surrounding slopes.

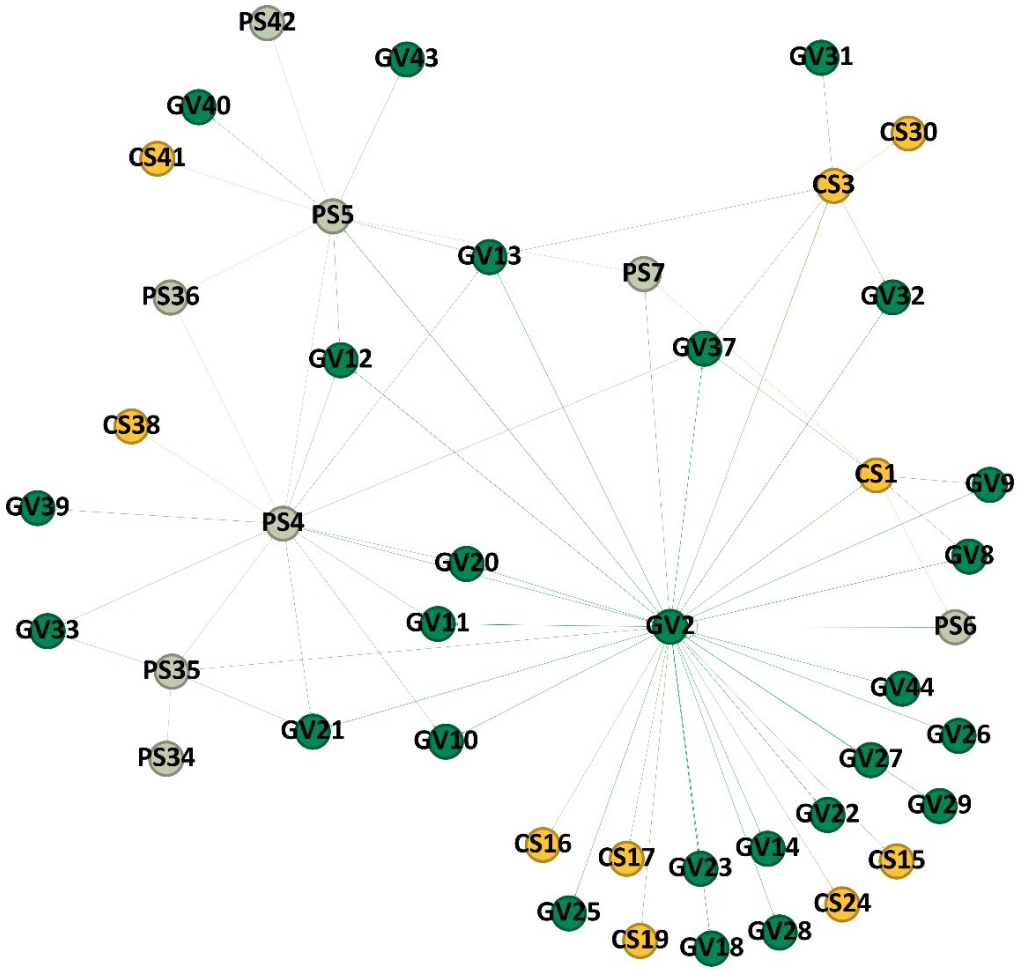

Figure 5. Italy stakeholder network

Spain

The Spanish pilot is led by an innovation and high-tech engineering consulting company. The SNA survey conducted in October 2023 had 21 respondents that identified 34 stakeholders across a diverse range.

The stakeholder types included 24 types of government entities, 3 from the private sector, 7 from the civil society. The governmental stakeholders appear to be the most common in the pilot network, including different municipalities of the autonomous community of Castile and León, and state environmental and forest protection services. Civil society is represented by environmental agencies and associations, forest management advisors, and forest owner associations. Lastly, the private sector brings stakeholders to the technological, innovation, and research fields.

While there is a substantial government presence, particularly of local authorities, firefighting, and forest management services, the involvement of civil society organizations, ecological associations, and private companies like Capgemini indicate a distributed network. This mix suggests a more balanced strategy rather than a purely top-down approach. The pilot is set to investigate the wildfire-prone Pinus species and mixed forest, recognized as high risk.

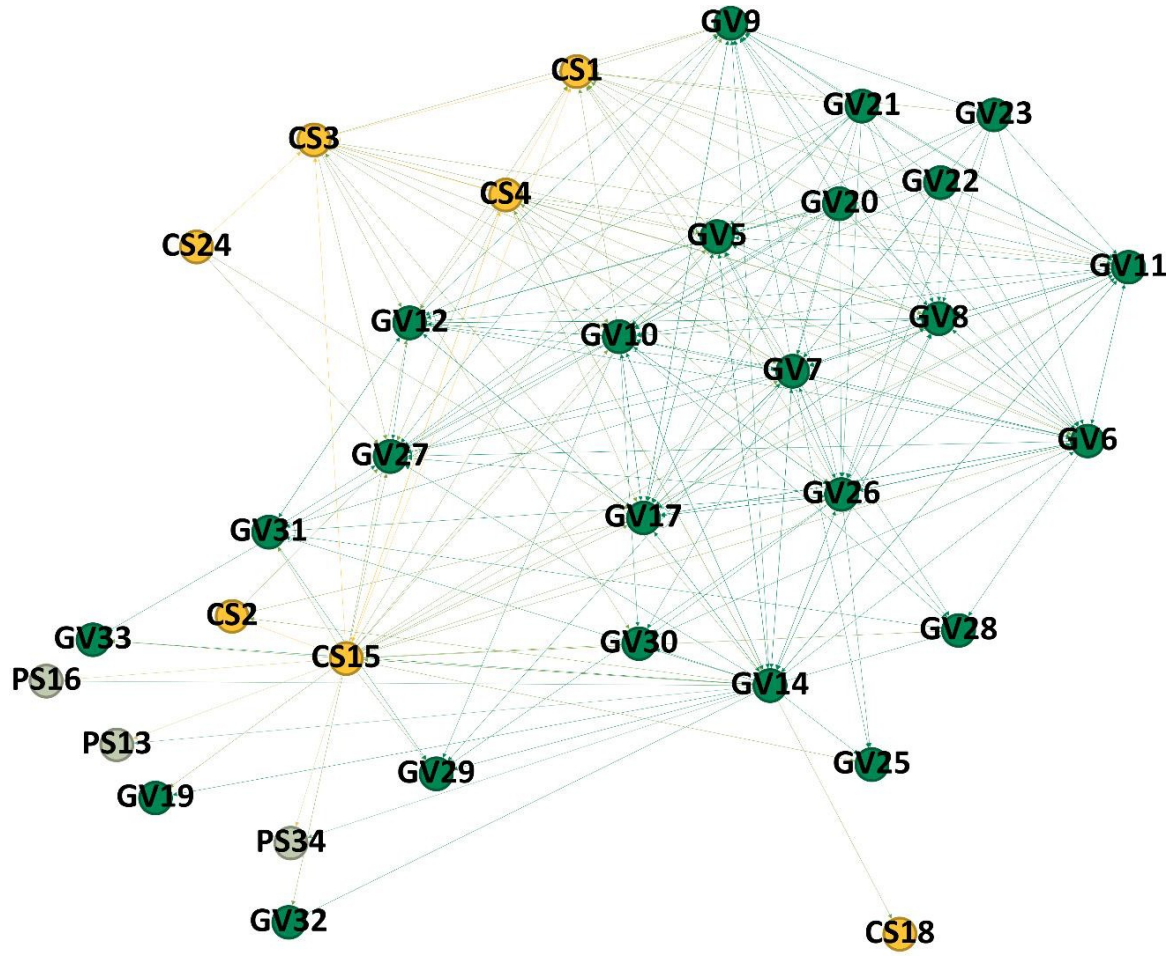

Figure 6. Spanish Stakeholder Network

Austria

The Austrian pilot is led by an organization that emphasizes health-related education and training. The pilot team

held a physical SNA workshop in October 2023. The SNA survey, conducted with 5 respondents, identified a total of 38 stakeholders, revealing a network predominantly composed of 28 government entities, 9 from civil society, and only 1 from the private sector.

Analysis reflects a blended approach, characterized by a significant top -down influence from governmental entities, coupled with engagement from civil society, but limited participation from the private sector. The pilot is set to evaluate the tools and solutions provided by the technical partners under realistic conditions and data with the end-users.

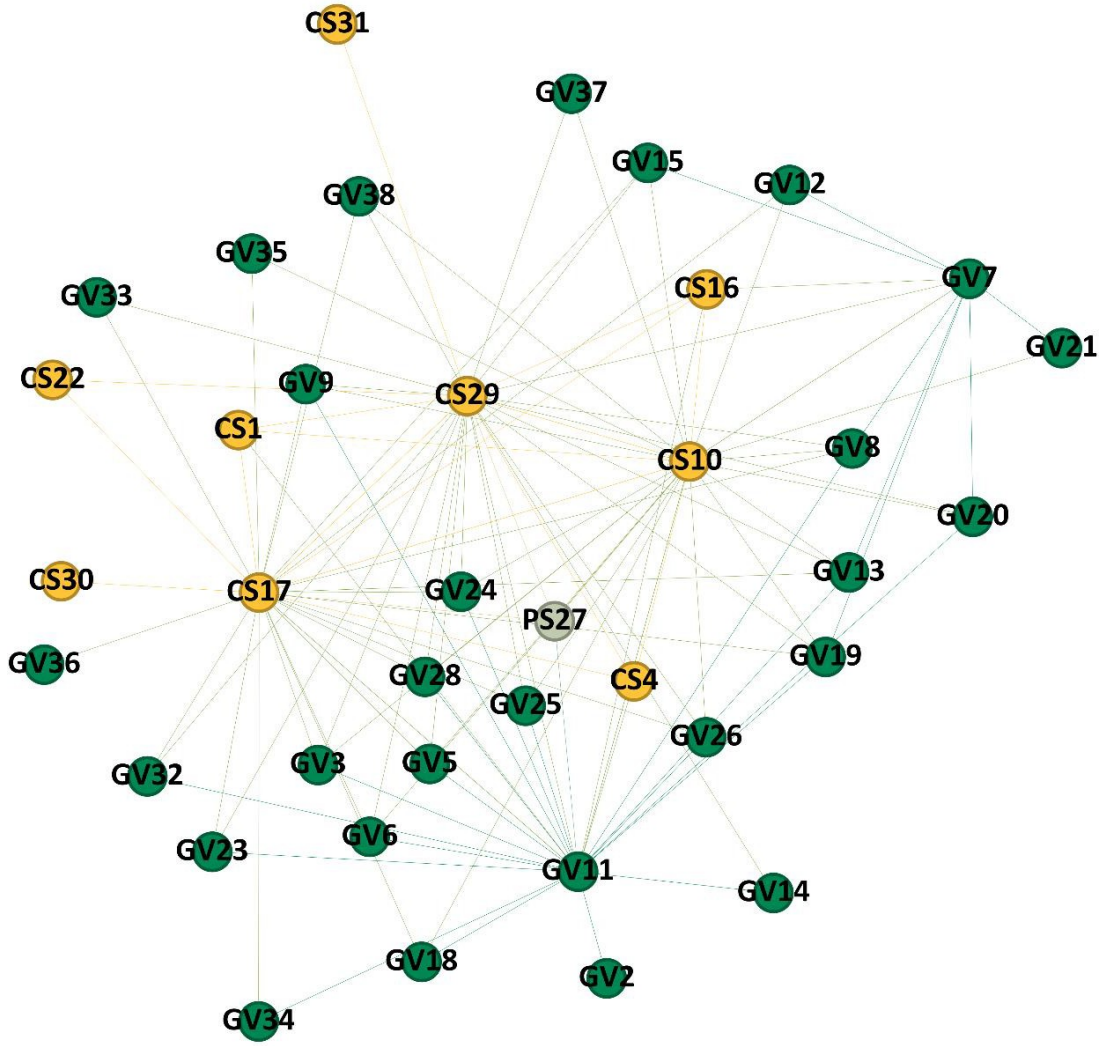

Figure 7. Austria Stakeholder Network

Greece

The Greek pilot is led by a university investigating wildfire management in the challenging terrain of the Samaria Gorge. The university organized a physical SNA workshop in October 2023. 15 participants completed the SNA survey, resulting in the identification of 38 stakeholders. The government sector, counting 27 stakeholders, takes a central position, involving fire brigade departments, local authorities, and public research centers, alongside entities like Police and forest services. The private sector is represented by 7 organizations, including research and innovation centers, and tourist and hospitality local companies that contribute cutting-edge technologies. 4 types of stakeholders represent civil society, with humanitarian organizations and mountaineering clubs in the network. The analysis reveals a harmonious top-down and bottom-up approach.

The use case is in southwest Crete in the regional unit of Chania, a closed canyon that limits the applicability of standard procedures.

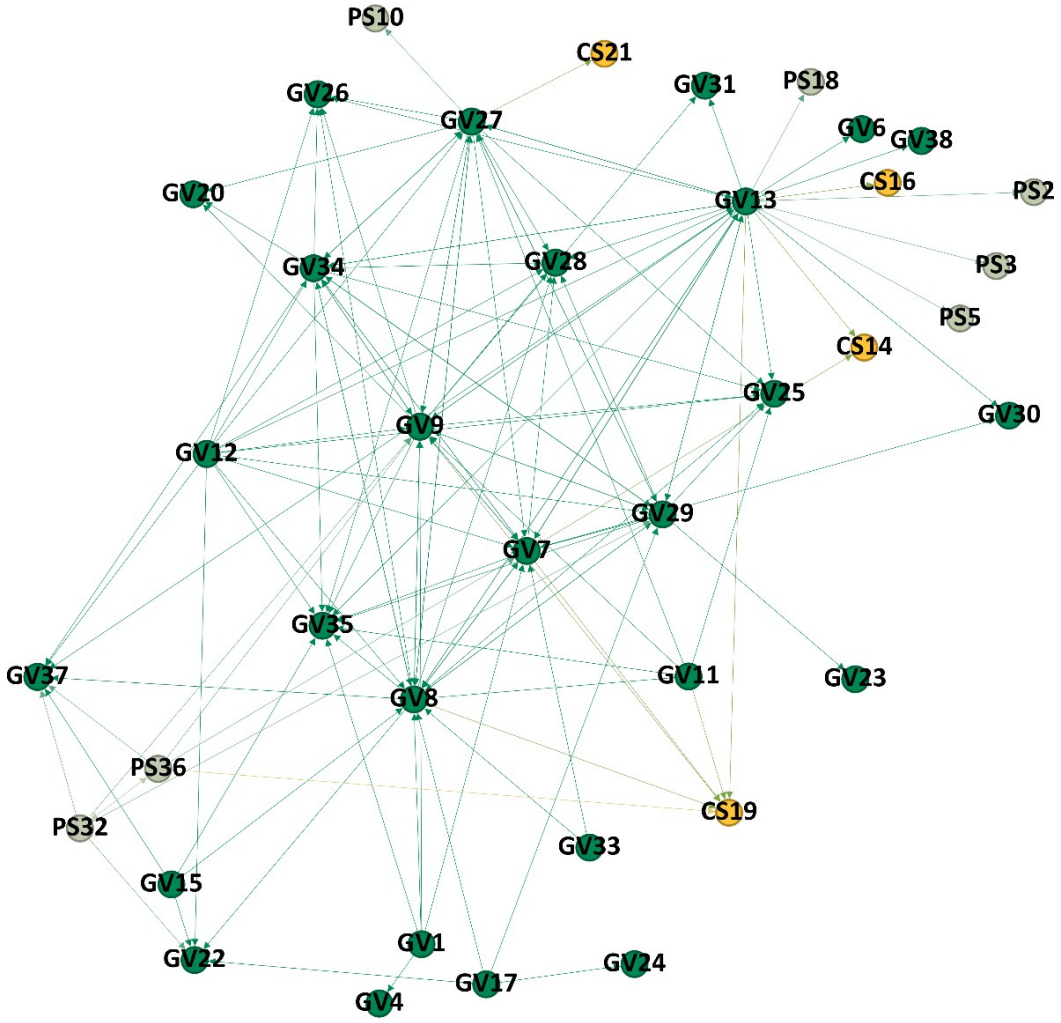

Figure 8. Greece Stakeholder Network

CONCLUSION

The project is designed to implement a holistic wildfire management approach. In practical terms, the approach involves the development of solutions across the wildfire management cycle and the coordination among different stakeholders and sectors. By profiling each of the eight pilots, the SNA first illustrates how this coordination is carried out. The scope of action, the profile of stakeholders and the density of connections are seen as evidence of this engagement.

The SNA analysis also identifies the key stakeholders in each pilot and provides insights on the connection gaps. The identification of these gaps provides two immediate inputs for the project: it supports local engagement in the pilot regions, and it assesses fit between technologies and local challenges.

In the wildfire management and disaster response policy debate, the analysis adds to the few empirical studies on natural resource governance networks in the European Union. It is relevant that the study is being performed while the project is under implementation, which allows the results to be shared with other similar EU fire projects and officials in the European commission. The results contribute to the fields of wildfire studies and networked governance by assessing how efforts such as the project contribute to improving governance in the territories of implementation.

ABSTRACT

Communities worldwide are increasingly facing severe impacts from natural hazards like wildfires, floods, and cyclones. Where a life-threatening hazard is imminent, and moving people is a safe option, large-scale evacuations of communities are often undertaken by authorities. In Australia, where evacuation is a recommendation to individuals and households, and not an enforceable order, community safety requires a collaborative approach: where communities take ownership of the risk and responsibility for their actions, and work closely with emergency management agencies for planning, preparedness, readiness, and response efforts. In this context, drawing examples from existing works, we present requirements for evacuation modelling from the perspectives of different end-users (the at-risk individuals and households, the town planner and developer, the risk analyst, the incident controller and response crew). We argue that this technology is useful, beyond its obvious use in planning and decision support, in building shared understanding among all stakeholders for improving community safety.

Keywords

Wildfires, Evacuation, Modelling, Simulation, Resilience

INTRODUCTION

With the increasing frequency and severity of extreme weather-induced natural hazards worldwide, large-scale evacuations of communities out of harm's way are becoming increasingly regular. Between 2017-19, in excess of one million people were evacuated from wildfires in California, USA (Wong & Broader, 2020). In 2023 alone, an estimated 200,000 people were evacuated during Canada's unprecedented fire season (Beverley, 2023), more than the combined total for the 1979-2007 period (Beverly & Bothwell, 2011). Hundreds of *bushfires*, the analogous term for wildfires in Australia, devastate vast landscapes in Australia every year, and can bring with them disastrous consequences for communities (Binskin et al., 2020; Teague et al., 2010). Against this backdrop, understanding evacuation-related human behaviour to inform choices in future events is becoming vital for all involved, from evacuating communities to emergency management agencies tasked with their timely egress to safety.

Recent years have seen significant advances in computer-based simulation technology for modelling large-scale evacuations, offering many benefits to planning and preparedness for future events. In the simplest use case, this technology can help improve understanding of traffic and timing when moving populations en masse (Goto et al., 2012; Wahlqvist et al., 2021). Combined with hazard progression modelling, it can allow evacuation policies to be stress tested under "what-if" scenarios (Goto et al., 2012; Wahlqvist et al., 2021), inform training of emergency personnel (Ronchi et al., 2017), improve community education and information (Goto et al., 2012), and bring a shared understanding of roles and responsibilities between authorities and communities (Chen et al., 2021). The ability to model complex human behaviour at a granular level, even down to every individual in a community, using techniques like agent-based modelling (Goto et al., 2012; Wahlqvist et al., 2021), are nothing short of impressive (Goto et al., 2012; Wahlqvist et al., 2021), and work to demonstrate that the technology is up to the challenge and abounds in academia (Ronchi et al., 2017).

Table 1. Evacuation modelling use cases.

	Planning	Preparedness	Readiness	Response
Decision timeline	Years ahead	Season ahead	Week ahead	Day of incident
Use cases	Integrated land use and transport planning, Risk reduction planning, Emergency planning for townships, Community education	Seasonal risk assessment and reduction, Adapting emergency plans, Preparedness exercises, Community information, Special events (e.g., festivals)	Emergency resources allocation, Community messaging, Special events arrangements	Evacuation options and messaging
Example actions	Constructing and upgrading community refuges, Identifying and upgrading roads and bridges for safe egress, Establishing standard operating procedures, roles and responsibilities	Pre-season incident management training, Community awareness programs, Adapting township emergency plans, informing traffic management arrangements	Community information, Leave early messaging, Event management, traffic management, emergency resources positioning and readiness	Evaluating if/when/how evacuations are conducted, Timing of leave or shelter messaging, Providing directions for safe egress, Placement of traffic management resources
End users	Agencies responsible for risk reduction, town and infrastructure planning, emergency management, Local / State / Federal governments, Building & construction industry	Emergency management agencies, Local / State governments, Township emergency planning committees, Community groups, Local residents, Event planners, Tourism agencies	Emergency management agencies, Community groups, Local residents, Event planners, Tourism agencies	Emergency management agencies

Despite improvements in computing software and hardware that have made evacuation simulation technology accessible today, these models continue to live largely in the domain of researchers and not practitioners. This sits in stark contrast to models of natural hazards, such as bushfires (Bally, 2023; Faggian et al., 2017), that are widely used in emergency management at all levels of operations and across all timescales from planning to response. Why so? In this paper we argue that the uptake of evacuation models is hindered today not as much due to technological challenges as it is due to social ones. What is lacking often is a clear understanding of the audience and a solution adapted for its needs. *Evacuation modelling for whom?* We argue for the need of a socio-technical approach: one that optimises not just the technological solution, but equally, and jointly, its use in society. In this setting there is no linear technology transfer from producer to consumer, rather an iterative process of co-production, co-learning, and product evolution.

While it is evident that evacuation related decisions must be made at the time of a bushfire, the timeline for evacuation decisions begins several years prior to the event. For many jurisdictions, emergency management arrangements relate to the timing of decisions before, during and after an emergency, and apply to the four broadly defined phases of Prevention, Preparedness, Response, and Recovery (PPRR) (Community Outcomes and Recovery Subcommittee (CORS), 2022). In this framing, evacuation decisions fall under the first three phases. When assessing how evacuation modelling can help inform decisions, it is useful to consider *when* decisions have to be made, *what* decisions can benefit from the outputs of the modelling, and *who* is making the decisions. Table 1 shows the timeline before and during a bushfire split into four phases: Planning that begins several years before the event and where related actions can take years to implement, Preparedness where actions align with the cycle of seasons every year, Readiness defined by actions in the days leading to an event, and Response relating to actions during the event. In this paper, and with a focus on Australia, we argue the need for a deeper appreciation of these use cases and end users and their requirements, when building evacuation modelling and simulation capability.

Consideration of community evacuations is a relatively new concern in Australia. As recently as the disastrous 2009 Black Saturday bushfires during which 173 lives were lost, Australia had no standing policy around evacuations. The subsequent 2009 Victorian Bushfires Royal Commission (Binskin et al., 2020) made 67 recommendations, of

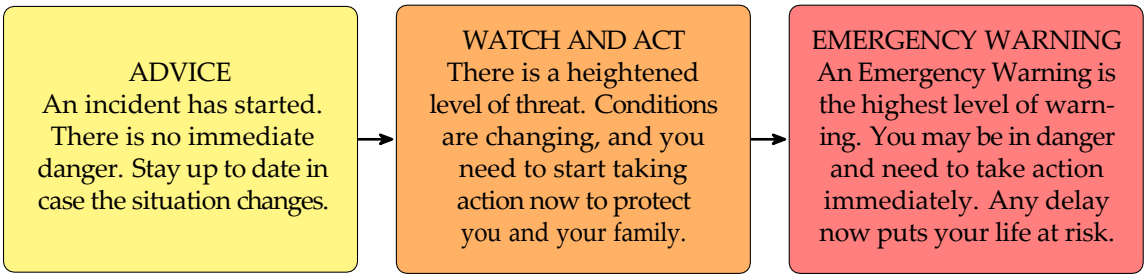

Figure 1. Warning levels under the new Australian Warning System.

which Recommendation 1, 3, and 5, sought a comprehensive approach to evacuations. A decade later, following the devastation of the Black Summer bushfires of 2019-20 that resulted in 34 direct casualties, and an estimated additional 417 deaths from bushfire smoke exposure (Borchers Arriagada et al., 2020), the Royal Commission into National Natural Disaster Arrangements (Binskin et al., 2020) expanded on the need for a national approach to evacuation planning and shelters. The evacuation context in Australia is one of vast landscapes prone to natural hazards and large numbers of relatively small and dispersed populations at their interface. During hazard events, such as bushfires that burn hundreds of thousands of hectares every year in Australia, limited resources exist within emergency services to attend to everyone in need. For the first few critical hours of an emergency until help arrives, it is the collective actions of impacted communities that have the biggest impact on lives saved.

Evacuations in Australia are additionally not mandatory. For this reason, improving community preparedness to take preventative action has been a focus of media campaigns from emergency agencies. Between 2009 and 2020, the nationally agreed Prepare Act Survive campaign saw the percentage of people who were prepared with a plan of action improve from 30 percent to 80 percent (NSW Rural Fire Service, 2023). However, residents who intend to leave have little in the way of knowing what conditions will be like once they become mobile. Evacuation simulation tools with map-based visualisations of expected behaviours and estimated traffic can show how decisions and actions of residents and emergency services translate to traffic and congestion on roads, and help improve individuals' understanding and planning.

The remainder of this paper is structured as follows. In the next section we describe important use cases and end users of evacuation modelling, focusing on Australia, then set out what we believe are key requirements for evacuation modelling capability from an applied perspective towards building understanding and improving community resilience. The subsequent section then covers current state-of-the-art in evacuation modelling capability in this context. Finally, in the discussion we reflect on what is required to get evacuation modelling tools to a level where they can confidently be used across bushfire planning, readiness, and response in Australia.

EVACUATION MODELLING FOR WHOM?

In this section we discuss evacuation modelling from an end user perspective across the decision timeline, in an attempt to highlight the importance of accounting for these perspectives when designing and implementing evacuation modelling technology.

The At-Risk Individual

The new Australian Warning System applies a nationally consistent approach to information and call to action for hazards like bushfire, flood, storm, cyclone, extreme heat and severe weather [1], and was established following recommendations from the Royal Commission into National Natural Disaster Arrangements (Binskin et al., 2020). Under this scheme, three warning levels communicate increasing risk to communities, as shown in Figure 1. Each warning level is associated with a set of action statements that give the community clear advice about what to do. Evacuation-related actions can accompany a Watch and Act warning with action calls including "Prepare to evacuate", or "Evacuate now," while for the more severe Emergency Warning the wording can include "Evacuate immediately" and "Seek shelter now".

An individual's awareness of the situation is a function of many factors, emergency warnings being one. Other important sources that contribute to awareness include visual cues such as the sight of smoke, embers, flames, and neighbours leaving, the sound of emergency vehicles and aircraft, communications from family and friends, and broadcasts through public information channels (Whittaker, 2019). Acknowledgement of the situation at a level that

1https://www.australianwarningsystem.com.au

Figure 2. Examples of the use of evacuation modelling for community information and education as shared by the Commonwealth Scientific and Industrial Research Organisation (CSIRO Evacuation Modelling Group, 2023).

warrants deliberation happens over time and via reinforcement of information from different sources. Individuals vary in their perceptions of risk which influences if and when they take action (McLennan et al., 2019).

Whether situation-aware individuals choose to evacuate varies significantly still. Extensive work by Strahan et al. on self-evacuation archetypes in Australian bushfires (K. Strahan et al., 2018; K. W. Strahan et al., 2019) shows that behaviours of resident individuals can be classified into one of seven distinct groups. A Threat Denier pays little heed to warnings because of the belief that their personal safety is not threatened by the bushfire, making evacuation unnecessary. Similarly, an Experienced Independent is also committed to remaining at home but for the reason that they are experienced and believe they are well prepared to fight the fire. In contrast, a Worried Worried Waverer hesitate between leaving and staying as they are not confident in their ability to defend their property despite prior training. A Community Guided person is constantly seeking information to stay informed, and values official advice when deciding to evacuate. A Responsibility Denier on the other hand is a committed evacuator who expects to be told what action to take when, effectively taking no responsibility for their own safety. Whereas, a Dependent Evacuator is incapable of taking protective action and relies on others for their safe evacuation. Finally, a Considered Evacuator is strongly committed to evacuate as soon as they become aware of the threat. While these self-evacuation archetypes give useful insights into behaviours of residents, they currently do not extend to households or seasonal visitors.

Even where a decision to leave or shelter nearby is made, there is still further variation in how decisions translate to trips. First, the distribution of departure times is skewed with a large number of people typically leaving sooner than the mean departure time, and a relatively smaller proportion leaving quite a long time after. Then a significant proportion of the population may undertake *intermediate* trips, which are trips to destinations other than the final evacuation destination, such as trips to pick up dependents from school or pets from homes. Finally, any trip, including the one to the evacuation destination may be disrupted by a change in the situation such as fire ahead, fallen tree over road, an accident, or redirection from traffic management authorities. In such situations, people may look for alternative routes to their destination, or failing that, look for alternative destinations. Lack of data on evacuation related behaviour and mobility are open challenges for evacuation modelling (Kuligowski, 2021).

Evacuation modelling capability should allow for heterogeneity and variation in behaviour expected during a real event towards more realistic estimates of egress times (Bulumulla et al., 2017; Robertson et al., 2021; Singh et al., 2021) and importantly of risk to communities. Simulations of evacuation can be extremely beneficial for community information, awareness, engagement, preparedness, and ultimately resilience to bushfire threat. Examples of this use case in Australia are seen in the evacuation modelling work being undertaken at the Commonwealth Scientific and Industrial Research Organisation (CSIRO). These include the use of evacuation modelling for information and education at community events (Atkin, 2023; Gamage, 2022, 2023), and for improving resilience through direct community engagement in the co-production of evacuation scenarios with support from the emergency services (Dennis, 2022) (see Figure 2).

The Town Planner and Builder

A recent high-profile case in Western Australia demonstrates the relevance of evacuation modelling in assessing the suitability of proposed new housing developments in high bushfire risk areas. Perth Hills in Western Australia suffered significant bushfires in 2011 (71 homes destroyed) (Keelty, 2011) and 2014 (48 homes destroyed) (Smith et al., 2015). Recently, concerns over a planning proposal for a township to accommodate approximately 1000 new dwellings there has seen significant government scrutiny (Government of Western Australia, 2023) and public protest (Perth Hills Action Group, 2023). The proponent developer submitted updated plans to address concerns, including a report on evacuation modelling for the proposed township. After final review, and hearing from public and experts, the planning committee recommended to the planning commission that the proposal be refused. In

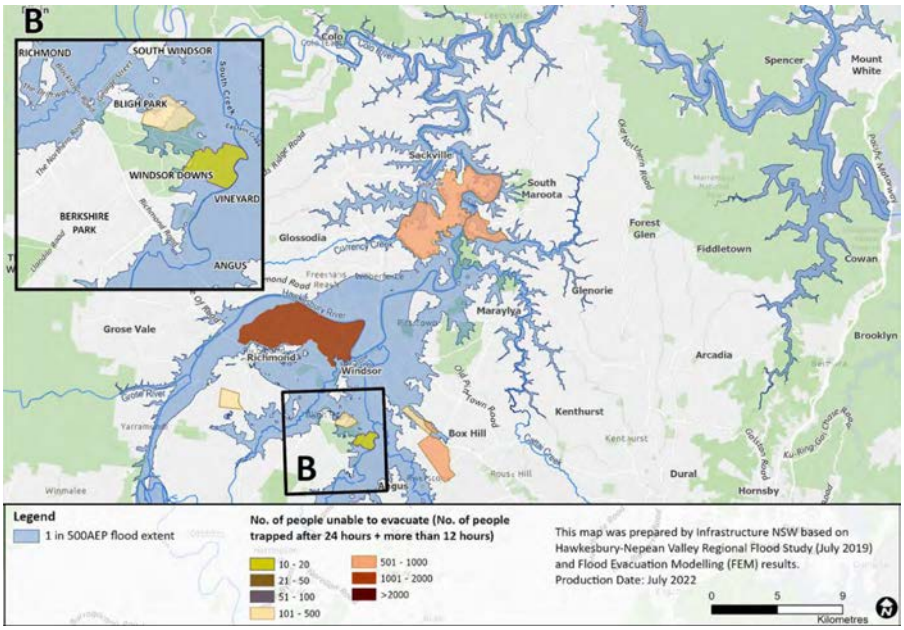

Figure 3. Extract of Figure 4.6 from NSW Government (2023) showing an estimated 6-fold increase in the number of people unable to evacuate in a 1 in 500 chance per year flood, under a medium mid-century climate change scenario with additional committed housing developments up to 2041, compared to the 2018 base case.

making its recommendation, the committee noted that the plan "does not demonstrate that the threat of bushfire risk to people, property and infrastructure can be appropriately mitigated [. . .] because: a. the technical information submitted in support [. . .], including traffic, evacuation and bushfire analysis and modelling, does not include adequate or accurate details to demonstrate that the risk of impacts from a bushfire, including safe evacuation in a bushfire emergency, is acceptable;" The case is significant because evacuation modelling played an essential role in the assessment of risk to a proposed future community from bushfires. It highlights the requirement for evacuation modelling to be "adequate and accurate" to be considered suitable for decision making. It emphasises the requirement for a tight integration between the fire progression modelling and evacuation modelling. Importantly, it demonstrates the demand for this capability for town planning in bushfire-prone areas.

An example of detailed evacuation modelling in Australia that was considered adequate and accurate for planning purposes, in this case by the State of New South Wales, including Infrastructure NSW, Transport for NSW, the NSW State Emergency Service, and the NSW Department of Planning and Environment, is the Flood Evacuation Model (FEM) developed by the CSIRO in collaboration with industry and academic partners (NSW Government, 2023). FEM was built to inform flood risk management planning in the Hawkesbury-Nepean river valley near Sydney, for use by government agencies and local councils responsible for integrated land use, transport and emergency planning in the area. FEM simulates the NSW State Emergency Service evacuation arrangements in current and future planned development scenarios (2018, 2026, and 2041) across a suite of representative flood events (from a 1-in-50 to 1-in-5000 chance per year). Through thorough analysis of results from a large ensemble of simulation runs, FEM provides an understanding of road network performance and capacity constraints for estimated evacuating traffic; assesses risk to life from saturated capacities and congested traffic flows against impending flooding; and estimates risk reduction from potential road upgrades (see Figure 3).

The Risk Analyst

Fire progression models like Phoenix, Aurora/Australis, and Spark are used within Australian emergency services (Faggian et al., 2017) at various levels of operation and time scales (see Table 1) from readiness to incident response. Personnel trained in the role of a fire behaviour analyst (FBAN) are responsible for collecting weather and fuel load information, simulating and studying fire progression under known and forecast conditions, and providing predictive insights to positioned or operational crews, towards reducing risk to lives, livelihoods, properties, and infrastructure. On days when fire danger is rated High, Extreme, or Catastrophic, an FBAN may run several fire progression simulations at the start of the day, prepare a summary on likely progression of select fires that had the potential to cause significant damage to communities and assets were they to ignite, and distribute the predictive insights to relevant teams. In ongoing fires, FBANs are installed in Incident management Teams and operate in

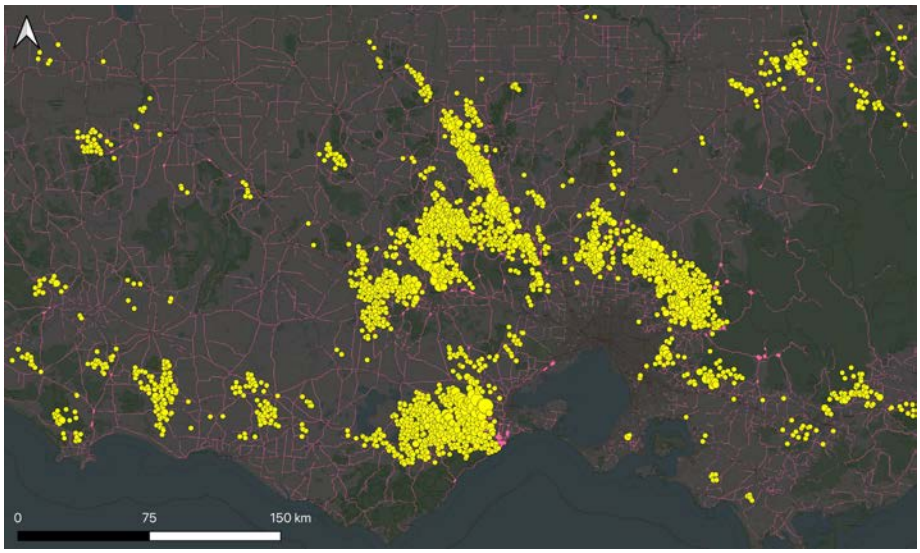

Figure 4. Example SAFER outputs showing evacuation hotspots in Victoria, Australia, as reported by Singh et al. (2023). Larger fire ignitions (yellow) are more problematic, while thicker road segments (pink) are more critical, for evacuating traffic.

Incident Control Centres at local, regional and state levels. Outside of Australia, the FBAN role is also employed in the USA. It is likely, under current emergency management arrangements, that the responsibility of running evacuation scenarios using outputs of fire progression models as inputs would fall initially on the FBAN. This highlights several important requirements for evacuation models: of timely, trusted, easily interpreted, explainable, and unambiguous outputs for accountable decision-making downstream.

Strategic long-term fire risk assessment is performed for large jurisdictions across a set of fire ignitions under different weather and wind conditions. Predictive Services within the Department of Energy, Environment, and Climate Action in Victoria, Australia, used "millions of fire simulations across the state to identify high risk areas, test different fire management scenarios and quantify risk reduction from delivered treatments" (Melero Blanca & Brien, 2023). Similarly, the Western Australian Department of Fire and Emergency Services used six million fire simulations to assess power network related fire risk from ignitions sparked at any power pole in the state's southwest (Parker & Allen, 2019). The CSIRO reported on the SAFER model, that consumes these very large sets of fire simulations to compute aggregate evacuation risk "hotspots" (see Figure 4 for Australian states (Singh et al., 2023). Noting the sheer size of the task, authors emphasise additional requirements for evacuation modelling capability in this context as: "The design goals for SAFER are (i) *scale*: supporting risk assessment for areas as large as Australian states and territories, and across hundreds of thousands of simulated fire ignitions, (ii) *speed*: computing state-wide evacuation risk metrics within hours, and (iii) *automation*: producing outputs automatically with no manual steps."

The Incident Controller and Response Crew

During a rapid-onset bushfire event, the Incident Management Team consisting of personnel representing all relevant emergency agencies is immediately activated in Australia, with explicit processes and protocols for emergency management and escalation. Within this team, it is the role of the Incident Controller (IC) to make the decision to evacuate or not, often under time pressure and with limited situation awareness. This is a decision that comes with enormous responsibility because if made incorrectly it can put people directly in harm's way.

Evacuation modelling capability that could provide fast and valuable insights into possible consequences for the community at risk, that the IC could take into account when considering the options, would be beneficial to the IMT as an additional source of assessment of the situation. However, for this to work, the technology must be trusted by the IC, allow exploration of emergency response scenarios the IC is considering in the situation, provide information on worst and likely consequences in forms that can be quickly understood by the IC, answer questions according to an explicit decision workflow the IC must follow, and highlight decision aspects that community safety outcomes are most sensitive to and may require careful attention. The reality is that the IC makes the decision to evacuate or not, for every bushfire that may interact with communities, evacuation models at hand or not. However, were such capability available, it would provide a valuable data-driven perspective to inform decisions. While this

Figure 5. Evacuation modelling use in Incident Management Team training as reported by Singh et al. (2022).

example is specific to one region and hazard, comparable emergency decision arrangements exist in many parts of the world and in the end a human is in charge of making the important decision on evacuation. The evacuation modelling capability must fundamentally cater to this user's requirements.

Singh et al. (2022) reported on the use of bushfire evacuation modelling in a multi-agency joint Incident Management Team training exercise organised by the Department of Environment, Land, Water and Planning at the dedicated Geelong Incident Control Centre in Victoria, in preparation for the 2021-22 bushfire season. During the live real-time training, evacuation modelling against the hypothetical fire was presented to the IMT in the form of analysis from several "what-if" evacuation scenarios of emergency response (see Figure 5). These scenarios included varying of timing and severity of warnings, partial or full implementation of manned traffic management points at intersections as per the local traffic management plan for emergencies, and combinations thereof. Outputs included map-based visualisations, videos of simulated evacuations against the fire progression, summaries of estimated consequences from each, and recommendations for the IC. Post-event reflection showed that evacuation modelling was a useful source of additional information for the IC who consulted the modelling on several occasions through the day. Authors noted that videos of evacuating vehicles were referenced by participants more than zone-based visualisations of evacuation metrics, hinting at the need for outputs that are fit-for-purpose. Post-event debriefing also identified areas of improvements including the ability to re-run scenarios in real-time to estimate reduction in risk to lives following IMT decisions.

EVACUATION MODELLING REQUIREMENTS FROM END USER PERSPECTIVES

We now return to an earlier point made in the Introduction that the adoption of evacuation models in disaster risk management requires addressing not just scientific or technological challenges, but societal barriers as well. In other words, the development of appropriate technological solutions must be guided by clearly articulated societal needs. Related to this point is the fact that, as is apparent from the previous section, different end users may have very different needs, and therefore it is imperative that modellers resist the temptation of a one-size-fit-all approach. Rather, each use case may call for a different approach, not just in the modelling techniques used, but also in the design of the corresponding software solution. At this point, an argument may be made that the term end users should be interpreted broadly, that is any individual or organization utilizing the outputs of a model in their decision making process. This does not necessarily imply that end users are responsible for executing the simulation scenarios themselves, but rather that the outputs of such scenarios should be made accessible to them.

As highlighted in the Introduction, the design process is inherently iterative, involving developers, researchers and end users. The objective during this phase should be to clarify the intended use of the model as much as possible, in order to create a solution that is fit for purpose. Relevant questions should include for example: What questions does the model need to be able to answer? What input data is required, and is it readily available? How fast does the model need to run? What kind of outputs does it need to produce, and in what form? Who is responsible for

running the models and producing results? If there is technology transfer, how is the risk of mishandling complex scientific software managed?

Irrespective of the specific use case considered, generally speaking a model of evacuation will need to address broad categories of key requirements, including:

- *Ability to set up multiple simulations scenarios*. This requirement includes the need for the model to easily ingest input data with minimal human intervention to miminimize time-consuming tasks, human errors, and enhance provenance processes and scenario reproducibility. An additional challenge specific to the use of these models in a response context is the ability to access live data, which may be challenging due to privacy reasons.
- *Capture of Important Evacuation Scenario Features*. The model should capture crucial features of the evacuation scenario under consideration. For instance, human behaviour modelling is critical for regional-scale evacuations but may be mostly irrelevant when identifying potential hotspots for evacuation risk at a larger scale (e.g. state-wide in Australia).
- *Reliability of models and outputs*. The issue of model validation for evacuation applications is an open question, as will be briefly discussed in the following section. Even if a full direct validation exercise may prove difficult to carry out, it is essential to consider quantification and adequate communication of uncertainty in the model outputs to prevent misrepresentation of scientific results with potentially devastating consequences.
- *Models as decision support systems*. Ultimately, an evacuation modelling tool is a decision support system, designed to assist end users in their decision-making process by providing them with the best available modelling data and is not intended as a replacement for human decisions. This implies that model outputs must be presented in a manner that facilitates a clear interpretation of results and minimizes the risk of judgment errors. For an IC for example, this means being able to easily compare the outputs of different simulation scenarios in a scientifically robust manner, to quickly gain an understanding of which plan may be the most effective under the conditions considered, taking into account any uncertainties and unknowns factors.

We argue that the process of identifying these requirements necessitates an extensive consultative approach well before any software development begins. Throughout this process, all parties involved should develop three essential design documents: a user requirements document, which lists all requirements that the technology needs to address, a risk register outlining roles, responsibilities, and risk mitigation strategies, and a strategic roadmap defining the development path with a clearly defined end goal. Finally, these documents should be revisited as the developments progress, with ongoing testing and feedback provided by end users. Only through such a thorough consultative process can we bridge the current gap in the use of computational modelling for evacuation management.

A BRIEF REVIEW OF MODELLING LARGE-SCALE EVACUATION

As the number of evacuation models continues to grow, user experiences and needs are pivotal for broader adoption, spanning community, government, and industry. Lovreglio et al., 2020 conducted a comprehensive international online survey in 2018, primarily focusing on pedestrian and indoor evacuation models but with implications for traffic evacuation. The survey highlighted key factors influencing model selection, emphasising validation and verification (V&V), data output, model documentation, continual development, and software usability. Notably, V&V emerged as a significant concern, reflecting users' demand for trustworthy model outputs. However, applying V&V to large-scale outdoor scenarios, especially in the context of wildfires, proves challenging due to the less constrained spatial and temporal behaviour compared to structured evacuations from buildings. While existing V&V documents provide guidelines for specific contexts, the lack of universally applicable procedures remains a challenge. Efforts by organisations like the National Institute of Standards and Technology (NIST) (Ronchi et al., 2013, 2016) and the International Standardisation Organisation (ISO) (ISO, 2020) are progressing toward standardised protocols, but challenges persist in defining comprehensive and universally applicable V&V processes for evacuation models. Ronchi et al., 2023 contribute to this with a verification protocol for wildfire evacuation models, acknowledging the difficulties and proposing tests for accurate implementation of modeling layers. It is important to note that the survey work by Lovreglio et al., 2020 is highly valuable for indoor fires but may require adaptation for large-scale evacuations. Additionally, the survey's utility is reinforced by the inclusion of respondents from diverse backgrounds, including end users outside of academia, accounting for 234 participants

from 41 countries and various professional domains. However, despite the insights provided by the survey, none of the covered models, including the pedestrian and building evacuation models, are currently being used for strategic planning, readiness, or response, underlining the ongoing challenges in applying these tools to real-world scenarios beyond academic and research contexts.

Notwithstanding, there are several simulation platforms for evacuation currently available. WUI-NITY, a modular simulation platform built on the Unity 3D game engine, effectively integrates fire, pedestrian, and traffic models to forecast evacuation behaviour during bushfire events (Kuligowski et al., 2022). This freely available platform allows for the simulation and visualisation of human behaviour, bushfire development, and evacuation scenarios. WUI-NITY's capability to import data from external wildfire models, such as FARSITE (Finney, 1998), and its implementation of a traffic model based on the Lighthill-Whitham-Richards (LHR) model (Li et al., 2012) contribute to its versatility. Recent studies, including a community drill in Roxborough, Colorado, and simulations of California wildfires, have validated WUI-NITY's performance, highlighting its potential for planning and real-time decision-making applications with its simplified yet effective models (Gwynne et al., 2023). The platform's modularity allows for the coupling of different sub-models, and its accessibility to a wide audience makes it a valuable tool for future model calibration and validation efforts.

There are other simulation platforms for evacuation currently available. SEEKER is a simulation platform integrated with an archetype-based behaviour model and employed by Victorian emergency services to understand community responses in bushfire evacuation scenarios (Marquez et al., 2022; Singh & Padgham, 2017; Singh et al., 2021). SEEKER takes as input fire progression simulation outputs from model like Phoenix and Spark (Faggian et al., 2017), a routable representation of the road network from Open Street Map, and a synthetic representation of individuals in the impacted area, and simulates community responses, considering various emergency response levers like warning messages and traffic control. Incorporating situation-based cognitive decision-making and MATSim traffic simulation, the platform provides detailed outputs on vehicles' trajectories and individuals' decisions during evacuations, including any intermediate trips to locations other than their final destinations. These outputs aid in identifying congestion bottlenecks, understanding diverse evacuation outcomes against a range of behaviour assumptions, and informing planning and preparedness. Simulation analysis supports operational decision-making, and the platform allows virtual testing of response strategies, including emergency messages and traffic control measures.

EXODUS is a suite of software tools designed for simulating the evacuation of large populations from various enclosures, including buildings, aircraft, and ships (Gwynne et al., 2006). Its core components include the Occupant, Movement, Behaviour, Toxicity, and Hazard sub-models (Galea & Galparsoro, 1994; Galea et al., 2000). The software employs rule-based descriptions, utilising heuristics to determine the progressive motion and behaviour of individuals. The Occupant sub-model in EXODUS characterises the response of individuals during evacuations based on their personal attributes (i.e., physical, positional, personal and hazard effects) influencing the individual's decision-making process and enabling the simulation to track their progress and behaviour during the evacuation process (Owen et al., 1996; Zhao et al., 2017). The Movement sub-model governs the travel speed of individuals during evacuations, taking into account factors such as terrain, obstacles, and queues (Gwynne et al., 2019). It assigns different travel speeds, such as run, walk, leap, and crawl, based on the specific conditions each evacuee encounters during the evacuation process. The Behaviour sub-model, influences occupants' responses and evacuation dynamics based on their attributes and environmental conditions (Galea et al., 1996). The Toxicity sub-model assesses the physiological impact of the environment on occupants, considering hazards like elevated temperature, thermal radiation, and toxic gases (Gwynne et al., 2001). The Hazard sub-model distributes hazards over time and location. EXODUS is well-suited for diverse applications, including planning, preparedness, readiness, response, emergency training, and community education. It provides valuable insights into evacuation scenarios and includes data analysis tools for effective result interpretation, as has been demonstrated in various publications (e.g., Galea, 1998; Gwynne et al., 2000).

DISCUSSION

Evacuation modelling is most useful for emergency management and planning when it supports the myriad of concerns of all stakeholders and incorporates realistic human behaviours and actions over idealised or optimised ones. Adoption of evacuation modelling capability for decision support involves a process of co-learning and co-production between emergency management stakeholders and technology providers. For emergency agencies to use evacuation models to inform decisions that impact lives, an often overlooked yet essential ingredient is time: required to understand, explore, adapt, and accept the modelling capability confidently into decision workflows. Model providers equally require time to shift evacuation modelling from a mathematical concept to a human-centred one.

The role of FBANs along with fire progression models in the emergency services is formalised and has existed for over a decade. FBANs are regarded with a high level of trust within teams, and that trust extends to the timeliness and quality of FBAN outputs (Begg et al., 2021). No such role exists in the predictive services for evacuation related modelling capability yet. This is partly because the need for evacuation planning is relatively new in Australia (Binskin et al., 2020; Teague et al., 2010) and current state-of-the-art evacuation modelling capability sits around Technology Readiness Level (TRL) 6 (technology demonstrated in a relevant environment), e.g., SEEKER (Singh et al., 2022), compared to fire progression models that have reached TRL9 (full system proven in operational environment), e.g., SPARK (Bally, 2023). Outside of technology readiness, other determinants of adoption of technology in emergency services include individual (e.g., perceived usefulness and ease of use, individual experience in emergency management), organisational (e.g., organisations IT infrastructure, interoperability and readiness, financial resources, decision-making processes), and contextual determinants (e.g., social norms and culture, and IT fitness for purpose) (Gulatee et al., 2020). Overcoming individual, organisational, and contextual challenges takes time, particularly in emergency management where reliance on technology for decisions that directly impact lives comes from trust, and the progression of technology over the final rungs to TRL9 is a necessarily slow process, and rightly so.

The Community-Based Bushfire Management program (Macken, 2019) is a successful example of a government funded program supporting emergency services and communities working together in Australia, in a community-led partnership to appreciate and plan for bushfire risk, understand roles and responsibilities, increase awareness and education, build trusting relationships, and ultimately improve safety in bushfires. Use of evacuation modelling to support these kinds of collaborative initiatives (see examples is Figure 2 and Dennis (2022)) shows promise in reaching a shared understanding and improving community resilience.

Compared with tools for modelling natural hazards like wildfires and floods, technology for modelling and simulating human behaviour during such hazards is relatively new. However, modern day computing infrastructure is rapidly enabling the use of this technology in tandem with natural systems modelling. We presented examples of the ways in which this technology is starting to be considered, beyond its obvious use in planning and preparedness, in also training and community education. What is unique here is a feedback loop that could positively alter community outcomes during natural hazards: since simulations of community and emergency responses today can help inform resilient behaviours of tomorrow.

ABSTRACT

The areas with high wildfire risk of wildfire are inhabited by multiple ethnic groups in China. In the event of a wildfire, there are many challenges for the government to release evacuation information to residents in multi - ethnic communities. Based on the Shannon-Weaver model of communication, a whole-process communication model of evacuation information is constructed to reflect the challenges during the whole process, including the dynamic variability, regional difference and cross-language expression of evacuation information at the stage of information generation, the inadequate communication capability of information carriers and instability of communication infrastructures at the stage of information transmission, and comprehension impairment and irrational perception at the stage of information perception. In response to these challenges, the authors also make some suggestions from the intelligent information technology, crisis response system and offline communication channels.

Keywords

Wildfire, evacuation, multi-ethnic, communication.

INTRODUCTION

Serious wildfires have occurred in many areas around the world recently. In addition to the result of ecological and environmental issues, such as declining air quality and vegetation destruction, they also pose a threat to human life and property safety. When a wildfire breaks out, except taking appropriate fire extinguishing, evacuating the residents around the fire in time is also important. The current research on wildfire evacuation is mainly carried out from the following aspects: (a) the influence factors on wildfire evacuation decisions. McCaffrey et al. (2018), McLennan et al. (2019), and Toledo et al. (2018) have analyzed the factors that affect residents' evacuation actions in wildfire scenarios. (b) the modeling and analysis of the evacuation process. Wang et al. (2021) constructed an evacuation model of forest tunnel fire based on the characteristics of smoke diffusion. Beloglazov et al. (2016) constructed a simulation of wildfire evacuation with dynamic factors and model composition, and evaluated the effectiveness of an evacuation. Cohn et al. (2006) analyzed the evacuation behavior during wildfires through case studies. (c) the evacuation risk from the perspective of local community and infrastructure. Cova et al. (2013) analyzed the limits of infrastructure on wildfire evacuation vulnerability, and Beverly et al. (2011) analyzed the impact of housing and roads during the wildfire evacuation process.

Some studies have also focused on the issue of information communication for wildfire evacuation. When a wildfire occurs, it is crucial for the public to receive timely information on evacuation (Stidham et al., 2011). McCaffrey et al. (2013) highlighted the importance of disseminating information in as timely a manner as possible

and through sources that allow as much interaction as possible with information providers. Li et al. (2021) demonstrated the efficacy of using social media to aid evacuations. Cao et al. (2016) believed that an optimal communication approach would be to couple map designs with several imperative textual descriptors, and Vélez et al. (2017) found that television is the primary source for information seeking during wildfires. Generally, these studies are conducted from the view of information receivers, namely the local residents at risk during a wildfire, and analyzed their attitudes and tendencies towards different information sources. However, there are few relevant research from the perspective of information communication process, and the information characteristics such as the timeliness and accuracy, which are also meaningful for wildfire evacuation, are not considered in-depth. Furthermore, community characteristics like multi-ethnic could also exert influence on the communication process, but relevant research is also lacked.

In this research, we will discuss the challenges of information communication during the wildfire. The study areas are the areas with high risk of forest fire in China, which are also the regions with multi-ethnic communities. Based on fire statistics, the current wildfire risk of China is presented. Then, from the perspective of evacuation information communication, this paper analyzes the challenges of information communication in these multi - ethnic areas with high wildfire risk. Finally, a whole-process communication model of evacuation information is constructed to reflect the challenges during the information communication process, and some suggestions are also provided.

THEORETICAL FOUNDATION

Getting the urgent information is the primary step before the public can take response actions. In general, whether the public can get the information in time is related to three factors: (1) The characteristics of the messages. The characteristics of the messages include the languages in which the messages are expressed and the forms of the messages (text, video, audio, etc.), which will have an impact on the accuracy, reliability and understandability of the information. (2) The transmission capacity of information carriers. For different information carriers, such as television, radio, online social media, and face-to-face communication, the speed and scale of information transmission are different, affecting the timeliness and population coverage of the information. (3) The comprehension capacity of the information receivers. The information needs to be understood and recognized after receiving it, and the comprehension capacity is related to the individual characteristics of the information receivers, including the age, career, education level, audio-visual condition, previous disaster experience and so on.

In this research, we mainly focus on the communication process of evacuation information during a wildfire. A classic theoretical model in communication research is the Shannon- Weaver Model (see Figure 1.), a process model of communication proposed by Claude Shannon and Warren Weaver in 1948 (Shannon, 1948). It is a transmission model consisting of six elements:

- Sender, the information source that produces a message;
- Encoder, the transmitter that encodes the message into signals;
- Channel, to which signals are adapted for transmission;
- Decoder, the reception that decodes (reconstructs) the message from the signal;
- Receiver, the destination where the message arrives.
- Noise, a dysfunctional factor.

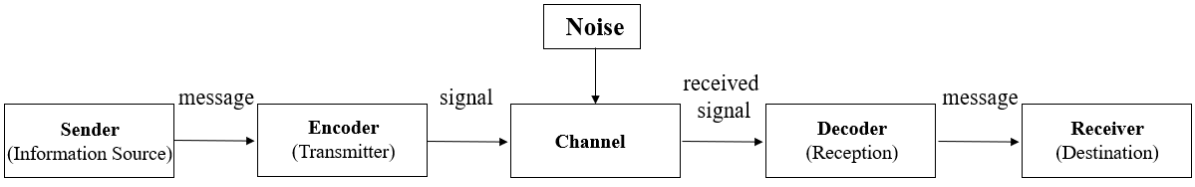

Figure 1. The Shannon-Weaver Model of Communication

The main feature of this model is the introduction of the concept of "noise", which refers to any interference with the message travelling along the channel and may lead to the signal received being different from that sent. It is a very linear model, and it does not even include a feedback loop. In our research, we focus on the linear process from official release to public reception of emergency information, so the Shannon-Weaver Model is adopted.

In this model, the sender will generate and send out the evacuation information to the receivers. For example, the local government or fire department can be considered as the sender during a wildfire, while the receivers are the

residents in the wildfire-affected regions. And the intermediate process from encoder to decoder can be regarded as the process of information transmission, including the channels of television, radio, SMS, online social media and so on. In addition, according to this theory, noise will occur in the process of information transmission, such as the unofficial and untrue rumors.

RESEARCH AREA

In this research, we will discuss the wildfire evacuation challenges in the regions with high risk of wildfire in China. There are great differences in natural conditions such as topography and climate among different regions in China, leading to the obvious regional differences in the risk of wildfire. Forest fire is a typical wildfire characterized by sudden and intense outbreaks, significant destruction, and challenging rescue efforts . The relevant data on forest fires in China from 2012 to 2021 provided by the *China Forestry Statistical Yearbooks* (2012-2021) reflects the occurrence of forest fires during this decade, and Figure 2 represents the total number of forest fires in each province of China according to the data. It can be observed that over the past decade, forest fires have predominantly occurred in the central and southern regions of the country, which is closely associated with differences in natural conditions such as topography and climate among these regions. In the north, the forest fire mainly occurs in Inner Mongolia. Specifically, Inner Mongolia, Shaanxi, Sichuan, Hubei, Hunan and Guangxi are identified as regions with a high incidence of forest fires and the total number of forest fires in Guangxi exceeded 4,000.

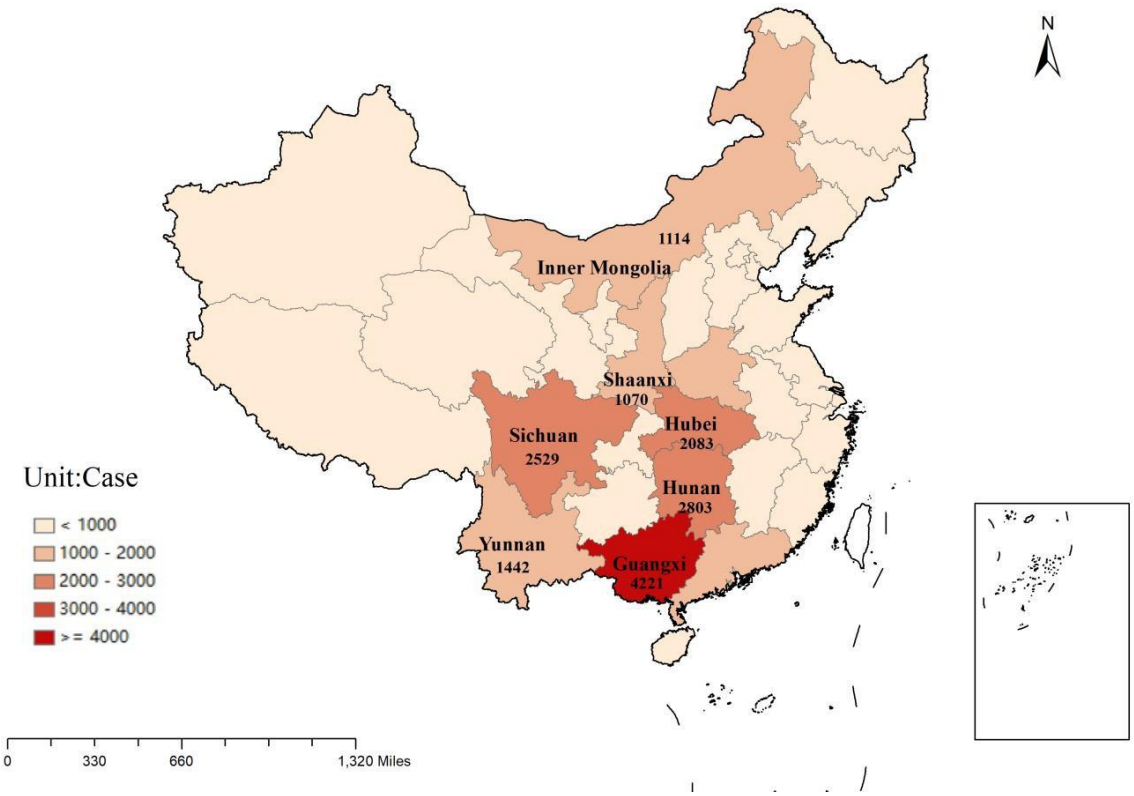

Figure 2. Total number of forest fires in each province of China (2012-2021)

The consequences of forest fires are serious. Figure 3 shows the number of forest fire casualties in China. Over the past decade, a total of 480 individuals have been reported to be injured or lost their lives due to forest fires, and the highest number of casualties was recorded in 2014, reaching 112 individuals. The provinces of Sichuan, Yunnan, Guangxi, Hunan, and Shaanxi have experienced a relatively higher number of casualties from forest fires. With regards to the damage to the ecology, the total damaged forest area has reached 133,000 hectares over the past decade. Figure 4 shows the affected forest area and total fire area in China. In 2014, the total fire area reached a peak of 55,341.4 hectares, and the affected forest area also reached a relatively high level of 19,111.1 hectares. In the subsequent years, both the affected forest area and total fire area showed a fluctuating decline and respectively reached 4,458 hectares and 14,125 hectares in 2021. Overall, the ecological damage caused by forest fires in China has been gradually decreasing, but the potential dangers still exist and should not be neglected.

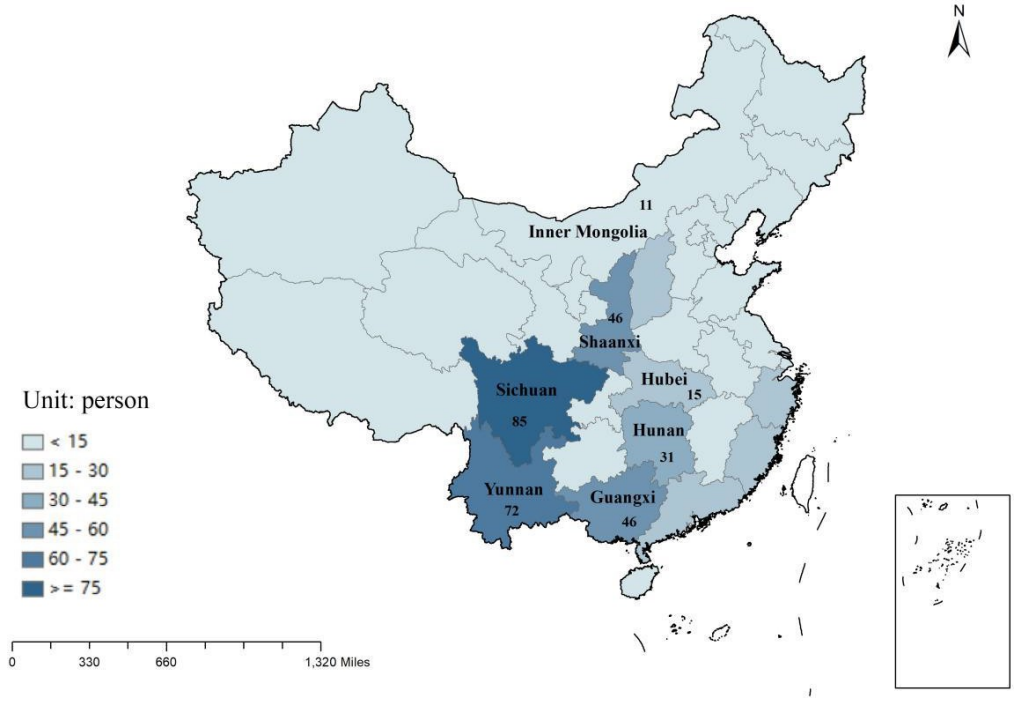

Figure 3. Total number of forest fire casualties in each province of China (2012-2021)

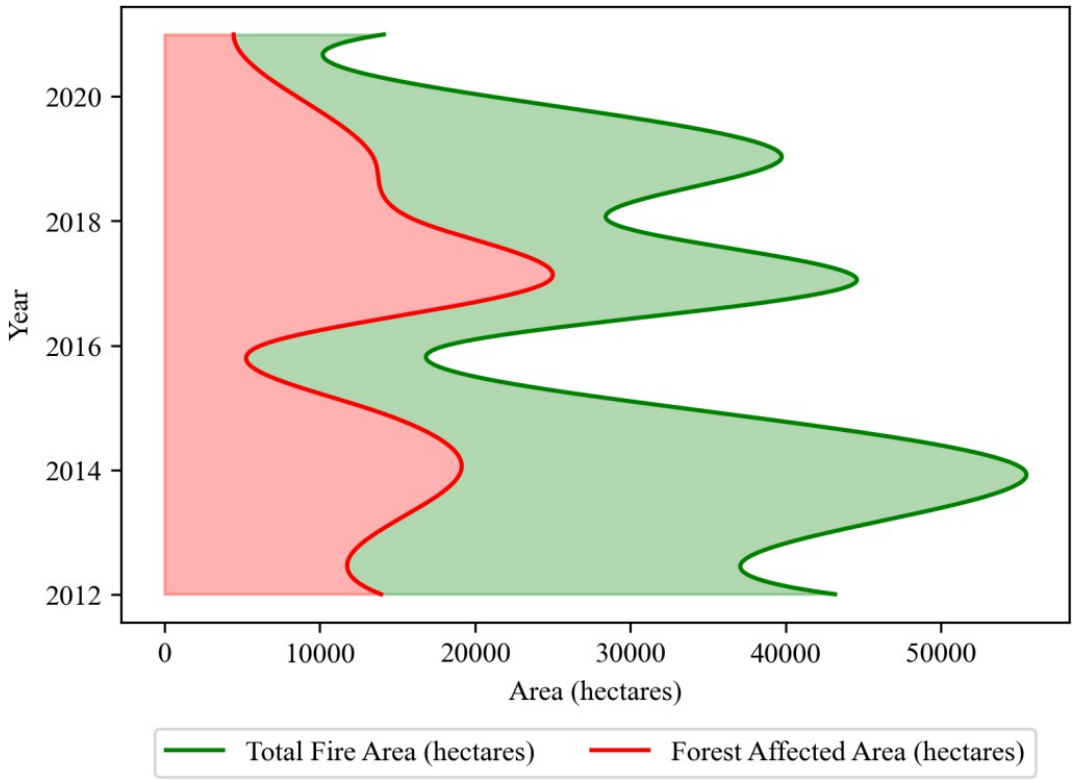

Figure 4. Total fire area and forest affected area over years (2012-2021)

Meanwhile, those serious and massive fire accidents should also be taken seriously, as they have caused serious casualties or losses. A serious case was happened in Liangshan, Sichuan Province, on March 30, 2019, which has caused 31 deaths. The brief information of several serious and massive large fire cases is shown in Table1.

Table 1. Cases of serious and massive forest fires happened in China (2012-2021)

Date	Location	Casualties or losses
Apr.16,2014	Kunming, Yunnan Province	210 hectares of forest burned
May.02,2017	Daxinganling, Inner Mongolia	About 8282.58 hectares of forest burned
Mar.30,2019	Liangshan, Sichuan Province	31 deaths
Dec.05,2019	Lianping, Guangdong Province	427.3 hectares of forest burned
Mar.30,2020	Liangshan, Sichuan Province	19 deaths and 3 wounded, 427.3 hectares of forest burned
Jun.07,2020	Changjiang, Hainan Province	About 358 hectares of forest burned

CHALLENGES: INFORMATION COMMUNICATION ON WILDFIRE EVACUATION

When a wildfire occurs, the timely information on evacuation is important to the public. The government will release evacuation information to residents in those communities which are deemed to be in need of evacuation to minimize potential casualties. However, there are many challenges in the actual implementation of the program.

Multi-ethnic Characteristics of Information Receivers

In the above section, we have analyzed the current situation of forest fire risk in China, and the areas with high wildfire risk include Inner Mongolia, Shaanxi, Sichuan, Hubei, Hunan, Yunnan and Guangxi provinces. In fact, these areas are also ethnically diverse. Figure 5 illustrates the current status of multicultural integration in these provinces according to *National Bureau of Statistics* (Office of the Leading Group of the State Council for the Seventh National Population Census, 2020). It can be seen that these provinces have a high proportion of ethnic minority populations apart from the Han, the largest population in China.

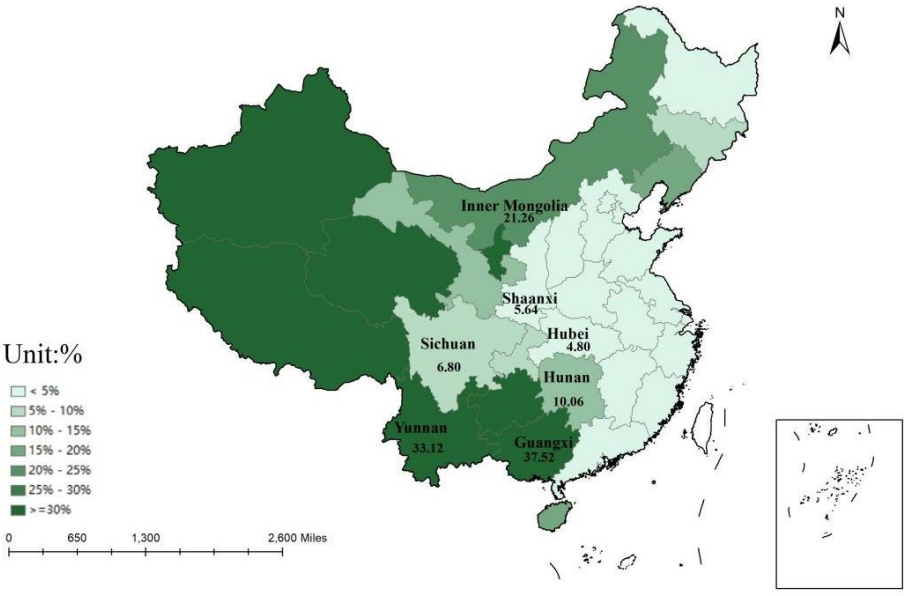

Figure 5. Proportion of ethnic minority population in China (2020)

Due to the small proportion of these ethnic groups, the emergency information is primarily published in Mandarin, the official Chinese language. For some ethnic minority residents, they may not speak or understand Mandarin clearly. This is a great challenge in the information communication on evacuation when a wildfire occurs. The diversity of ethnic minorities in these regions presents a requirement for the accurate information in their native languages.

Challenges for Communication of Evacuation information in Multi-ethnic Communities

According to the Shannon-Weaver model, the process of information communication can be divided into three

main stages: the generation and release of information, the transmission of information and the perception of information. When a wildfire occurs, there are some challenges for government departments to release evacuation information to residents in multi-ethnic communities. According to the process of information communication, the challenges are sorted as follows.

Generation of Information

At this stage, the government needs to generate a reasonable evacuation strategy for the public based on the real - time fire situation. In multi-ethnic areas, there is also a need to express in multiple languages. The challenges at this stage are:

- Dynamic variability of evacuation information. The accuracy of evacuation information is closely related to the real-time state of the fire. The development of the wildfire is dynamic, so it is necessary to dynamically update the evacuation information and release it to the public according to the real-time state, rather than a single information. For example, as the fire grows, the evacuation routes, available shelters, and available safe evacuation time in the information need to be modified.
- Regional difference of evacuation information. In the event of a wildfire, the risk exposure of residents in different regions is different, and in order to avoid possible evacuation congestion, the evacuation information (especially the evacuation routes) in different areas should be different.
- Cross-language expression of evacuation information. In multi-ethnic communities, considering the native language of different ethnic groups, it is also necessary to pay attention to the multilingual expression of evacuation information to meet the information requirements of different ethnic groups.

Transmission of Information

After the evacuation information is generated, the government will release the information through TV, radio, SMS, online social media and so on. Generally, when a wildfire occurs, government authorities use three main channels to release evacuation information to the public in the digital era: (a) Cable broadcasting and television (these two carriers are often reported together as an indicator in China). The emergency information was released through news bulletin or scrolling marquee in the television. In this channel, the length of the information is limited. (b) SMS (Short Messaging Service). When emergencies occur, the government departments compile the emergency information, and the mobile phone operator will release it to users through SMS (Short Messaging Service). This channel also has a limit on the number of words, but it supports the partitioned release of information, that is, the information for different regions can be targeted. (c) Online social media. Emergency information is released on online social networks by official accounts. The advantage of this channel is that there are fewer restrictions on the length of the information.

The popularity of these information carriers is investigated, and their penetration in the multi-ethnic areas with high risk of wildfire is shown in Figure 6, according to the statistics (National Bureau of Statistics, 2022; China Internet Network Information Center,2022). The penetration condition can represent the emergency information coverage in emergency scenarios to some extent.

It can be observed that the mobile phone and Internet are becoming mainstreams, while the penetration of traditional channel, the cable broadcasting and television are relatively low. The popularity of mobile phones is relatively high, and the rates in these high-risk provinces are all over 100%, which means that the use of SMS can achieve full information coverage statistically. However, it should be noted that the mobile phone penetration rate is calculated as the average number of mobile phones per 100 people, and some citizens have more than one mobile phone, while some may not have a mobile phone (especially for the elderly). So, it is improper to release information only with SMS. As for the Internet, the penetration rate in each province is more than half, but there are also differences among provinces, which is related to the level of economic development of the region. Regions with a low level of economic development, such as Yunnan Province, have low Internet penetration relatively.

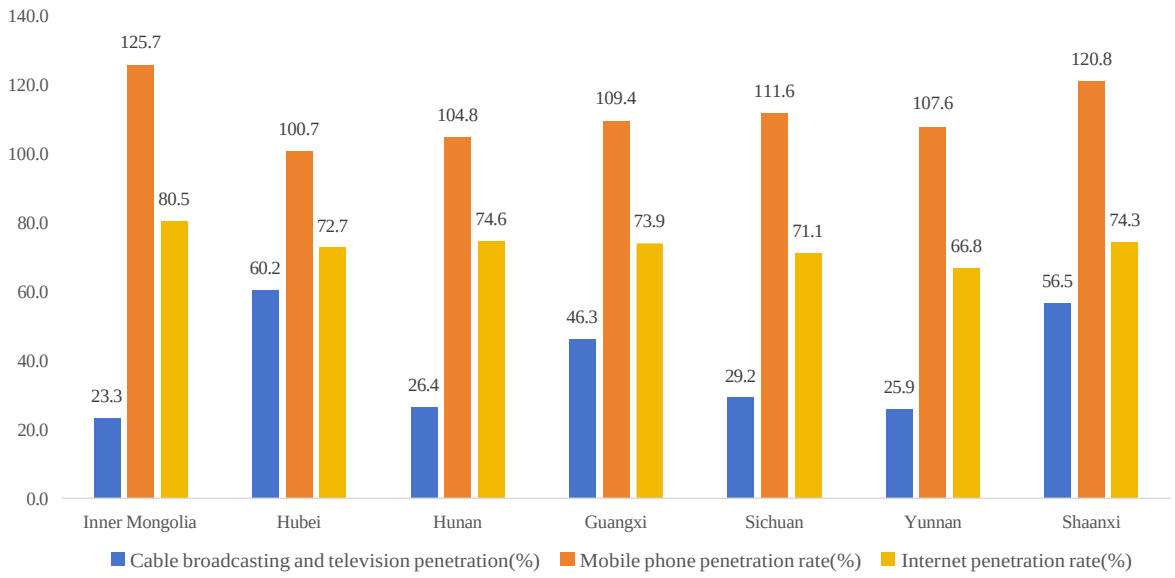

Figure 6. Penetration of Information Carriers in several provinces of China

To summarize, the challenges at the stage of information transmission are:

- Inadequate communication capability of evacuation information carriers. Unlike developed countries, the level of informatization in many developing countries, including China, still needs to be improved. The above analysis of penetration of several information carriers shows that the coverage and spread speed of information carriers in China are still insufficient. In the event of a wildfire, it is likely that not all the residents can receive evacuation information in time.
- Instability of communication infrastructures. In the case of wildfires, it is necessary to take into account the damage to communication infrastructures caused by the fire. Many communication infrastructures, such as the cell phone towers, are located in the wild, and they may be burned when a wildfire occurs, leading to the inability to receive the evacuation information from SMS in the local area.

Perception of Information

After receiving evacuation information through various channels, the residents still need to accurately understand the evacuation information. Apart from the individual differences, the following challenges still exist for the perception of evacuation information in multi-ethnic communities:

- Comprehension impairment due to non-native language or formalization. The evacuation information is primarily published in Mandarin, so the ethnic minority residents may not understand it clearly and rapidly if Mandarin is not their native language. Except for the language barrier, the difference between official expression and the colloquial expression will also make the public understand the emergency information differently. For example, the official naming of specific roads and locations mentioned in the evacuation information may be different from the naming of local residents, which will lead to a sense of unfamiliarity and misunderstanding of evacuation information for the public.
- Irrational perception in crisis situations. When a wildfire occurs, the evacuation information may be selectively ignored and filtered by the residents. Neuroscientists believe that the mechanism by which the human brain selectively ignores and filters information is closely related to the state of activity of neuronal networks. When the brain perceives a threat or an emergency situation, the state of activity of the neuronal network changes in order to better process and transmit information related to these situations. In a wildfire emergency, when the public receives the evacuation information, they may realize that they are in danger and "need to evacuate", but "how to evacuate" (the information on evacuation routes) mentioned in the evacuation message may be ignored, and the evacuation routes may be chosen according to personal experience.

MODEL AND SUGGESTIONS

On the basis of Shannon-Weaver Model, considering the characteristics of wildfire development and information

communication in multi-ethnic communities, a whole-process communication model of evacuation information in multi-ethnic communities is constructed as Figure 7, which also summarizes the challenges and possible responses in each segment. In this model, the official emergency evacuation information publisher, namely the local government or fire department, is considered to be the sender, which generate and send out the evacuation information to be transmitted; and the receivers are the residents in the wildfire-affected regions, who will receive the evacuation information during a wildfire. And the intermediate process from encoder to decoder can be regarded as the process of information transmission, including the channels of television, radio, SMS, online social media and so on. In addition, noise will occur in the process of information transmission, mainly in the form of unofficial and untrue rumors, as well as the interference to the accuracy of information by the dynamic wildfire condition.

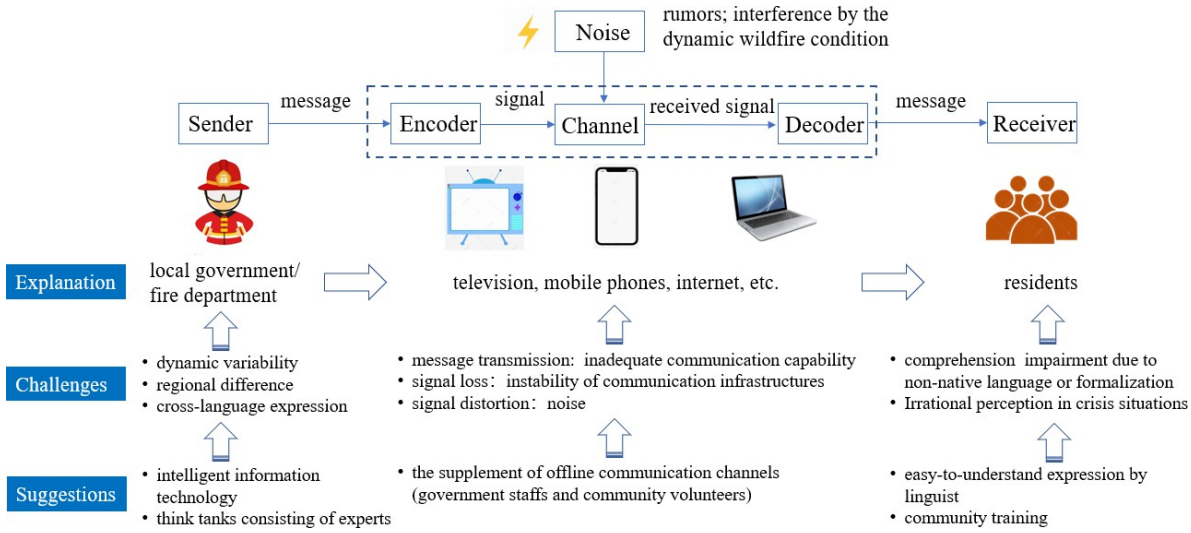

Figure 7. Whole-process communication model of evacuation information in multi-ethnic communities

In the process of communication, various challenges can affect specific segments, as evidenced by the following: when generating evacuation information from the sender, the dynamic variability and regional difference of evacuation information need to be considered, as well as the cross-language expression; in the process of information transmission, the communication capability varies among different information carriers (television, mobile phones, internet, etc.), and there may be regional signal loss or interruption due to damage of communication infrastructures, as well as information distortion due to the addition of noise; when the public receives the information, barriers to information comprehension due to non-native language, formalization, and the problem of irrational perception in crisis situations may make it hard to accurately and fully understand the evacuation information.

In response to these challenges, the authors make some suggestions:

First, the application of intelligent information technology. At present, with the development of artificial intelligence (AI) technology and the optimization of Large Language Models (LLM), the accuracy and speed of machine translation are constantly improving, and these intelligent technologies can be used to assist the release of information in emergency situations. Intelligent machine translation can utilize machine learning, deep learning, and other technologies to train models to recognize multilingual information and automatically generate the appropriate content for information release. With the help of intelligent machine translation, the time for translation of information can be reduced, ensuring the timely and rapid release of information, and the multi - language information can improve the comprehension of multi-ethnic receivers.

Second, the improvements to the crisis response system. China's crisis response system focuses on government-led and multi-party participation, relying on modern technological means and emphasizing early warning and prevention, rescue and relief, and post-disaster recovery, in order to safeguard the safety of public life and property and social stability. However, there are still some deficiencies in the way the current crisis response system operates for the issue of wildfire. For example, there is a lack of timely updated evacuation information and a lack of scientific basis for decision-making, all of which will affect the effectiveness of wildfire response in China. Therefore, we propose to start improving the way the system operates from the following two perspectives in order to increase its efficiency: a) strengthening the evacuation training of the community. Frequent training could help to reduce irrational behaviors of residents in critical situations, so that they can understand the evacuation information more calmly and accurately. b) Establishing organization of think tanks consisting of experts on fire

science, psychology and linguistics. The experts will cooperate with government departments and support decision-making in emergency scenarios, so that the dynamic scenarios of wildfires can be judged more accurately, and the evacuation information can be released and updated with a reasonable frequency and easy-to-understand expression.

Third, the supplement of offline communication channels. Many elderly people seldom use digital communication tools (mobile phones, laptops, etc.), especially for those from ethnic minorities, causing the barriers to receive emergency information. In addition, those with audio-visual impairments are unable to receive information in ordinary form. For these groups, offline face-to-face communication by government staffs and community volunteers is crucial. Meanwhile, the offline channels convey more accurate information, as the information provided by the government staffs and volunteers is official, avoiding the interference of possible rumors (noise). Therefore, despite the obvious disadvantage of inefficiency, the offline channels of information communication remain irreplaceable. In particular, in extreme cases where communication infrastructures are completely destroyed and wide-scale communication cannot be achieved through communication tools (mobile phones, telephones), door-to-door service by the government staffs and volunteers in the communities will be the most reliable form of information communication. At the same time, by carrying shouting or broadcasting equipment, drones can convey instructions, safety alerts and other information to the affected people, improving the public's ability to respond to emergencies.

CONCLUSION

The timely and accurate evacuation information is crucial for the residents during a wildfire. In China, the regions with high wildfire risk are also inhabited by multi-ethnic people, posing some challenges to the communication of evacuation information. In this research, the specific challenges are analyzed with a whole-process communication model, from the generation to the perception of evacuation information.

As a supplement to other research on the public evacuation behavior and decision, the challenges during the information communication are pointed out in this work, and some practical suggestions are also provided. In this work, the study areas are the multi-ethnic areas with high risk of wildfire in China, but the research is also applicable to other areas around the world, as some areas of the world with high wildfire risk are also inhabited by multi-ethnic residents. So, the discussion is helpful and can be served as a reference for the release of information in wildfire situations. Further research on how to solve these problems are still needed, especially on how to provide evacuation with regional difference and cross-language expression, and quantitative analysis on comprehension impairment due to non-native language and public perception in crisis situations.

Due to time constraints, it is not possible to obtain sufficient data at this time. However, we are conducting field studies to collect more specific data. We also plan to conduct an in-depth analysis using more quantitative communication science models, which will help to more accurately assess and explain the issues involved in the study.

ABSTRACT

Post-wildfire hot spots are a severe problem for fire fighters since they are hard to detect and can reignite fires. The tedious search can be greatly improved by using drones. However, developing and controlling an autonomous drone swarm is a challenging task. An assessment with domain experts reveals the suitability of drone swarms for hot spot detection. We develop a heterogeneous multi-drone system that can support fire fighters by creating thermal and visual aerial images and automating the hot spot detection process. During a joint exercise with a fire fighter brigade we demonstrate that the proposed system is able to autonomously search, detect, and report hot spots. Therefore it is able to speed up the search process while reducing the required number of personnel.

INTRODUCTION

The critical nature of disaster response missions make them ideal use cases for drone swarms. With climate change, the number and intensity of natural disasters is rapidly increasing. According to the "World Disasters Report – Trends in Disasters" 2022, the number of geological disasters increased from 19 in 2020 to 33 in 2021 (International Federation of Red Cross and Red Crescent Societies, 2022). According to a European Commission's report on wildfires, the number of wildfires in the EU increased by 48 % from 2021 to 2022, while the affected area increased by 86 % (Joint Research Centre, 2023). With an increase in number and intensity, wildfires are causing an increased havoc on the environment, human health, and infrastructure (United Nations Environment Programme, 2022).

Fighting wildfires requires a coordinated effort by fire fighters, emergency management, and specialized aircraft teams. In recent years, drones also known as unmanned aerial vehicles (UAVs) equipped with visual and thermal

*corresponding author

sensors have been used to support these efforts. Drones offer a cost-effective solution, compared to traditional methods for visual overview, such as using satellite imagery or aerial photography using helicopters. Fire departments equipped with drones may have a lot more flexibility in terms of operation time to generate and analyze such overview images. Additionally, drone swarms reduce the overall mission time significantly when compared to search using watch towers, ground robots, or ground personnel.

After wildfires are extinguished to a significant degree, fire fighters must search the affected area for hot spots that may be hidden inside burned tree trunks or buried out-of-sight. Sparks flying from these hot spots may lead to future fires. Therefore, the post-disaster phase of detecting hot spots, which may span over multiple weeks, is very important to prevent reignition. Currently, hot spot detection is mostly performed manually by fire fighters that are equipped with handheld thermal cameras. They may be supported by drones which are manually steered and do not provide automatic hot spot detection. These efforts require a lot of personnel. In this paper we describe a multi-drone system to aid fire fighters in hot spot detection in the post-disaster phase of wildfires.

Our proof of concept (PoC) system implementation uses a fixed-wing drone equipped with a visual camera, four multirotor drones equipped with thermal cameras, visual cameras, and communication interfaces (WiFi mesh and LTE/5G), two ground control stations (GCSs) for human interaction, and three servers for computing and data storage. The system is scalable in terms of the number of drones, and is designed with clear interfaces between humans and drones, while requiring minimum intervention from humans.

The system design takes into account feedback from first responders and emergency management experts gathered through questionnaires and expert interviews. It is noted from the feedback that current usage of drone imagery for hot spot detection puts a strain on the resources, requiring two persons per drone, a pilot and one person to analyze the images. The developed PoC by design requires two persons for the operation of the entire swarm. The purpose of this work is to demonstrate that an autonomous swarm is a feasible solution in terms of optimal resource usage in post-wildfire hot spot detection. The system is able to autonomously identify hot spots from the air over large areas, leaving the fire fighters free to tackle the task of extinguishing the fires. The focus of this paper, however, is not to provide quantitative results comparing the efficiency of manually-operated versus autonomous drones for hot spot detection.

The mission starts with the fixed-wing drone flying autonomously to generate a real-time aerial overview image of large areas. This provides the ground personnel with an up-to-date situation overview image to identify regions of interest (ROIs) for closer inspection. The ROIs can then be assigned to one or more multirotor drone swarms, which cover less area but provide greater detail. A single pilot can track the swarm status using a GCS. To synchronize takeoff in a swarm, the swarm pilot gives the mission start command. The swarm takes off, flies, searches, and lands autonomously. During search, the drones detect hot spots and transfer images and hot spot information to the ground, where they are geo-referenced. The location and intensity information of the hot spots is passed to the fire fighters who take necessary action to extinguish them.

Communication plays a critical role for successful swarm operation during the mission. The drones must avoid collisions autonomously. The swarm pilot must be able to track the swarm mobility and the hot spot images, and information must arrive in real-time manner at the GCSs. To support actions that benefit from device-to-device connectivity, e.g., collision avoidance, we use WiFi mesh; to support high-throughput real-time image transfer, LTE/5G networks are used. Thus, we are able to demonstrate a fire fighting mission aided by a drone swarm which makes the best use of two different communication technologies.

Our main contribution is the demonstration of a distributed swarm robotic system integrated from several sub-systems in a realistic environment including stakeholders. Compared to state of the art drone operations in wildfire scenarios, our system reduces the required ground personnel count while increasing the speed at which the situation overview is generated.

The rest of the paper is organized as follows: First, we list related work and report the outcome of the technology assessment. Then we describe the system architecture and its components, followed by details of the proof of concept demonstration and a conclusion.

RELATED WORK

There is no shortage of research work focusing on drone swarm or multi-drone use for search and rescue (SAR) (Arnold et al., 2020; Dominguez et al., 2017; Dong et al., 2021; Guo et al., 2019; Mbaitiga & Shosaku, 2022; Quan et al., 2019; Scherer et al., 2015; Steinha¨usler & Georgiou, 2022). A small number of these focus on real-world system implementation (Dong et al., 2021; Lauterbach et al., 2019; Quan et al., 2019; Scherer et al., 2015; Steinha¨usler & Georgiou, 2022; Terzi et al., 2019). Some work on system implementation highlights the

necessity for seamless integration of different technologies (Scherer et al., 2015; Tinetti & Riveros, 2021), which is a challenging task. The task becomes further complicated when using an autonomous drone swarm. In this paper, we present a multi-drone system to aid fire fighters. The drones fly completely autonomous to search an area and detect hot spots while avoiding collisions.

A drone swarm may support a team of fire fighters in many ways. One of the biggest advantages of using drone swarms is their ability to generate large-scale, near real-time, visual situational awareness by 3D area mapping (Lauterbach et al., 2019). The drones may additionally collect other valuable sensor data such as the levels of hazardous plumes in the air and reduce the risk to the fire fighters' lives (Seiber et al., 2018). Drone swarms are also ideal for victim detection and localization (Dong et al., 2021; Quan et al., 2019; Scherer et al., 2015; Steinha¨usler & Georgiou, 2022) as they provide a much faster area search as compared to ground personnel or robots. Finally, they help locate sources of disaster such as fires or toxic plumes (Seiber et al., 2018; Viseras et al., 2019). In our proposed system, the autonomous drone swarm locates hot spots in the post-disaster phase. Locating and extinguishing the hot spots mitigates the risk of future fires.

The increasing number of wildfires in recent years has seen an increased interest among the drone research community to develop systems aiding fire fighters. Pasini et al. developed a framework for cooperation between aerial and ground robots (Pasini et al., 2022). A drone is used to gather a visual overview of the area of interest while identifying hot spots. The overview image is transferred to a ground station, which generates a path to the identified hot spots for a rover. Viseras et al. performed a measurement campaign with three drones to collect visual and thermal images of wildfires and hot spots (Viseras et al., 2019). Hot spots with a minimum size of 15 cm could be identified during image analysis from a height of 90 m. Unlike the above two works, in our system, the drones are equipped with visual and thermal cameras to autonomously identify hot spots in a real-time manner during flight. Dong et al. used a similar approach for survivor detection post-disaster using YOLOV3-MobileNet on a single drone (Dong et al., 2021). However, the drone swarm system implementation was not the focus.

The agents in a drone swarm may make autonomous flight decisions either using visual information (Schilling et al., 2022) or using communication (Scherer et al., 2015). In this work, we rely on WiFi mesh communication for flight decisions due to the small drones' payload limitations. The drones are also equipped with 5G modems for sensor data transfer. The use of 802.11s mesh network to operate a drone swarms has been proposed in (Scherer et al., 2015), with related measurement campaigns performed in (Hayat et al., 2015). It was shown that in a multi-sender scenario (two drones generating traffic and sending to a ground station), the network offered fairness and an average throughput of 10 Mbit/s up to a distance of 450 m from the ground station. Scalability of wireless mesh networks is a known concern, mostly caused by link sharing (Lei et al., 2022). How mesh technologies such as WiFi fare in real-world drone swarms with more than ten agents depends on the amount of traffic needed to be exchanged among the agents, and is still an open topic.

For the transfer of high-throughput real-time payload data such as visual and thermal images, 5G networks are ideal. Experimental campaigns report drone-to-ground station throughput of up to 50 Mbit/s, with latency as low as 47 ms in a suburban environment (Fakhreddine et al., 2022). The average latency has been shown to vary with signal-to-interference and noise ratio, with its variance strongly impacted by handover frequency in both urban and suburban scenarios in (Luo et al., 2022).

TECHNOLOGY ASSESSMENT

In order to identify the most important application scenarios for a drone swarm and to gather initial requirements, we asked first responders and emergency management experts from Austrian ministries to complete a questionnaire. In total 33 experts replied. The majority (57.6 %) have more than 15 years of experience, 42.4 % are in senior command, 30.3 % in mid-level command and 24.2 % in operational service. Such a technology assessment is important, since it helps to determine the feasibility and suitability of the system for the specific needs and requirements of the first responders. The questionnaire introduced the general idea of autonomous drone swarms, equipped with different sensors, to support the emergency response. It contained questions to assess the experts' opinions concerning the suitability of such a system in different scenarios and specific use cases, the anticipated risks, dangers, advantages and disadvantages, both with closed Likert scale and open answers.

Due to space constraints, we only provide selected results of the user survey. In a series of questions, we asked the experts whether they a) believe that such a system introduces risks, b) disturbs the work of first responders, and c) brings them more disadvantages than advantages. Figure 1 shows the results for four application scenarios: wildfires, other natural disasters, person monitoring (e.g., at large events), and monitoring critical infrastructure. The majority of the experts agreed that a drone swarm introduces risks in person monitoring and wildfire scenarios. Most experts disagreed that such a system introduces risks for other natural disaster responses and monitoring

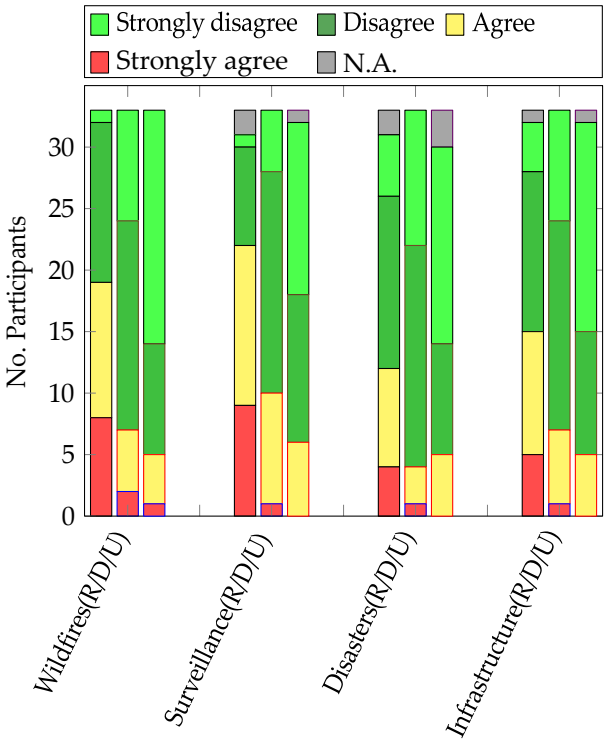

Figure 1. Does a drone system introduce more risks (R), dangers (D), or more disadvantages than advantages (U) to the use cases?

of critical infrastructure. The majority disagreed that a drone swarm disturbs the operation or introduces more disadvantages than advantages. It is safe to say that drone swarms are seen as beneficial in all scenarios.

We also asked the experts about specific use cases for drone swarms in the wildfire scenario, such as: detection of wildfires (e.g., after lightning strikes), monitoring the actual wildfire response, hot spot detection, and the post-disaster damage assessment. Figure 2 shows that hot spot detection and damage assessment are seen as the most suitable use cases to be supported by drone swarms.

The experts were also asked to identify the three most important/useful and the three most problematic/risky/negative factors when using such a system. Many experts mentioned cost as an important factor, both as a strength and as a weakness. Some experts were concerned with the initial investment costs, while others saw the potential for future cost savings due to a reduction in the number of first responders required. Similarly, the complexity of the system was seen as a crucial factor. While some experts were concerned with initial and ongoing training needs to operate the system, others saw a high degree of autonomy as a potential. Legal restrictions on the operation

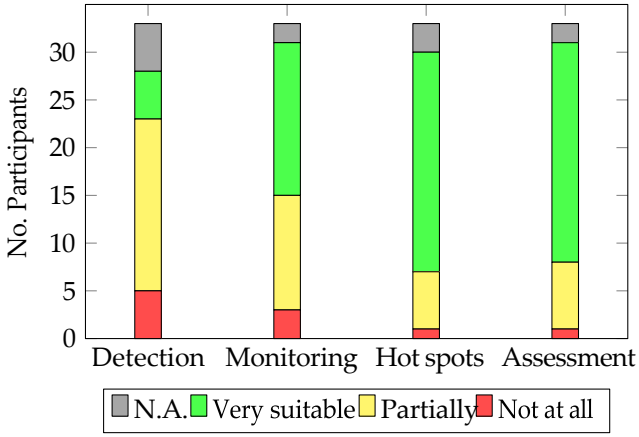

Figure 2. Is a drone swarm suitable for specific use cases in a wildfire scenario?

of autonomous drones and the impact of weather were seen as the biggest risks. Improved assessment times and situational awareness were cited as the biggest potential benefits.

Subsequent to the PoC demonstration, an evaluation was conducted to collect feedback from the first responders. The outcomes of this evaluation are elaborated in the proof of concept section.

Requirements

The experts were also asked about requirements towards such a system. The answers included: ease of use, both when controlling the system and when analyzing the gathered data; providing data interfaces to existing systems; well-defined safety regulations to ensure the safety of the personnel on ground and air forces. Furthermore, they mentioned important aspects such as flexibility (e.g., adapt the size of the swarm), quick setup, real-time monitoring, and robustness. Interestingly, there were conflicting opinions about the costs of such a system. While some experts see such a system as a way to reduce the response costs, other expect the system to increase costs.

SWOT Analysis

Based on the answers we performed a SWOT analysis with the following results.

Strengths: The system is seen to handle resources efficiently and hence to reduce cost regarding acquisition, operation, and maintenance. It can increase the speed of a mission, create increased situational awareness, and allow early detection of incidents. Its versatility allows it to be adapted and used for different applications.

Weaknesses: The complexity of the system is seen as its main weakness. This complicates the integration into existing systems, hence limiting its acceptance. Due to the complexity it might also be prone to failures and require regular maintenance, e.g., in changing weather conditions or crowded air space. Operating such a complex system requires training which could drive up costs, while current legislation does not allow a single swarm pilot but requires one pilot per drone.

Opportunities: The system can exploit already existing interfaces of other systems as well as existing, well-defined safety regulations to boost its acceptance. It can play out its flexibility in the challenging and changing conditions of rescue operations.

Threats: Outside influences that can threaten the system operation include incompatibilities with other systems, badly educated personnel, hacking attacks, external disturbance (e.g. interference on the communication channels), and mid-air collisions.

Concluding the assessment, we can say that most experts agree that drone swarms are a suitable technology for hot spot detection in wildfire scenarios. Therefore, we target this scenario with our drone swarm system. To address the concerns regarding system complexity we design our system with a focus on autonomy. Most steps, including mission execution, swarm coordination, communication, image analysis, and feature detection are automated to ease the system operation. This includes a collision avoidance algorithm to minimize the aforementioned risk of collisions in the air.

SYSTEM

In this work we propose a system consisting of several sub-systems that are interconnected using different technologies. An overview is given in Figure 3.

System Components

The proposed system can be organized into three technical sub-systems plus a user interface (UI) for interaction with users, i.e., pilots and fire fighters. The sub-systems are: the fixed-wing drone, the multirotor drone swarm and the server infrastructure for off-board analysis and storage.

The first subsystem consists of a fixed-wing drone (Skywalker EVE-2000) equipped with a visual camera (Sony IMX249 sensor with 2.3 megapixel mounted on a 1D gimbal for roll compensation) that creates an aerial image, a map server based on the open source implementation GeoServer[1] to store that image, and a custom build GCS that controls the mission of the drone and visualizes the progress (Fanta-Jende et al., 2023). The drone is controlled by a Pixhawk 2 flight controller running the Ardupilot firmware and localizes using a Cube Pilot Here3 RTK GPS. The onboard computation is performed by an NVIDIA Jetson Xavier NX. The drone has a maximum takeoff weight of 4.6 kg and a cruise speed of 75 km/h.

[1] https://geoserver.org/

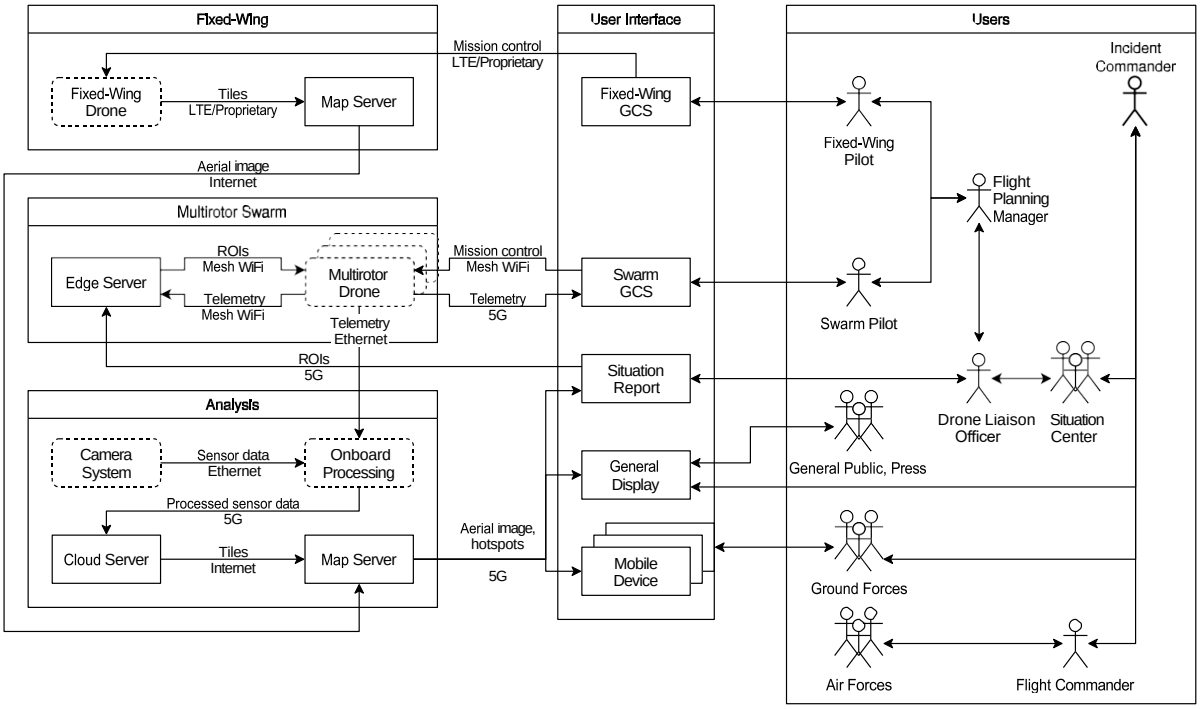

Figure 3. System Architecture with aerial components marked by dashed lines.

The second sub-system, the multirotor drone swarm, comprises several multirotor drones (twinFOLD KAT, twinFOLD GEO, twinFOLD SCIENCE)[2], an edge server that computationally supports the drone swarm, and a GCS for controlling the drone swarm. The drones are controlled by algorithms running in the Robot Operating System (ROS) on a Raspberry Pi 4 B connected to a Pixhawk flight controller that runs the Ardupilot firmware.

The third sub-system includes the components related to image analysis. Its main task is to locate the hot spots and provide a map server that manages the recorded images and the results of the hot spot detection. Onboard the multirotor drones are the following sensors: an RGB camera (Ximea CMV20000), two thermal infrared cameras (custom built by LEADER Photonics) and a GNSS/INS sensor (SBG Quanta). An NVIDIA JETSON AGV Xavier board is used for controlling the sensors and pre-processing sensor data onboard the drones. A custom built trigger box ensures that all sensor data (images and pose) is collected synchronously. The setup is shown in Figure 4. The takeoff weight including batteries for a flight time of roughly 15 min is around 14 kg. It should be noted, that the component weights have not been optimized, hence providing significant potential to extend the flight time. For further analyzing the sensor data, a cloud server allows computing intensive post-processing tasks.

The user interaction happens through the UI sub-system. Both fixed-wing drone and multirotor swarm have a GCS to control and monitor the mission. The main mission results are presented through the situation report terminal. It is a web front end that shows base maps, the real-time aerial image collected by the fixed-wing drone, the locations and state of hot spots and the location of fire fighters' ground forces and multirotor drones. It can also be used to define and send ROIs to be mapped by the swarm or to send commands to first responders that carry smart phones with a dedicated Android app. Additionally, there can be a non-interactive terminal (general display) to inform the general public about the mission.

The user side reflects the hierarchy of the fire fighter personnel. The main interaction points to the technical system are the pilots (fixed-wing and swarm) which are coordinated by the flight planning manager. He interacts with the drone liason officer who gets his information from the situation report terminal and gives instructions for the drone missions.

Communication

The system components are interconnected using different technologies. Communication between the fixed-wing drone and the GCS may use different technologies (Fanta-Jende et al., 2023). In most situations, 5G/LTE mobile networks provide sufficient bandwidth and a stable connection for transmitting the payload data to the GCS. For

2https://www.twins.co.at/en/multirotorsystems/

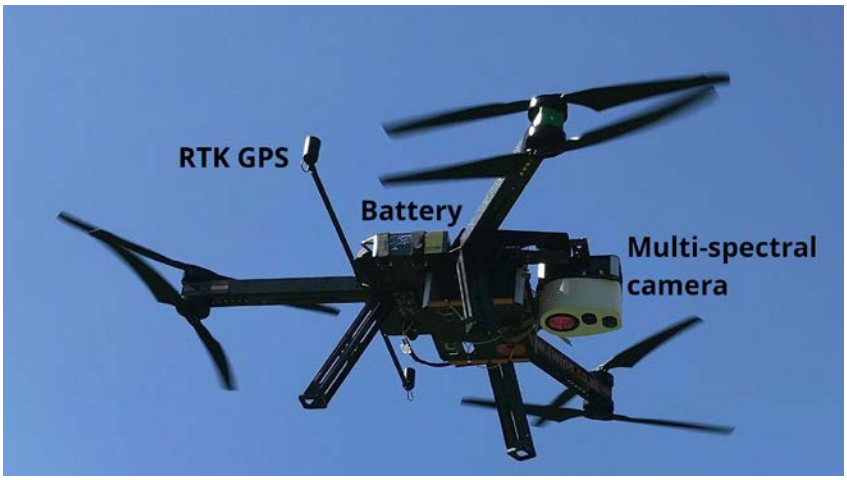

Figure 4. Multirotor drone setup (the processing boards are underneath the drone).

this purpose the drone and GCS are equipped with LTE routers (Teltonika RUT240 on the drone and RUTX11 on the GCS). Alternatively, a WiFi 802.11n network using a tracking antenna or a proprietary data link may be used. This alternative is important, as there may be a lack of mobile network coverage in the area of operation. Communication is used to control the mission from the GCS and transmit the recorded images to the map server on the ground. Coordination with the multirotor swarm is not needed at this stage since the fixed-wing drone mission is separated in time from the multirotor swarm mission.

The multirotor swarm uses a combination of WiFi mesh and LTE/5G mobile networks. Communication and coordination within the swarm is based on WiFi mesh to increase robustness in the absence of infrastructure. The mobile network is used to transmit payload data to the cloud server for processing and returning the result to the ground stations, and for receiving the ROIs to be searched.

Algorithms

The drones are programmed and controlled using ROS version 1[3]. Many of the software components are available as open source and links are given in the following.

A typical mission begins by fire fighters defining the mission area. The fixed-wing pilot enters it into the GCS which is a custom implementation connected to a locally running ROS master. When the fixed-wing pilot starts the mission, the drone autonomously surveys the mission area using its onboard camera to create an aerial image. It records images and performs visual simultaneous localization and mapping (SLAM) to localize itself while creating the aerial image. Being connected to the ROS master on the GCS, it transmits individual tiles of this aerial image to a map server located on the ground allowing the GCS to continuously update the visualization of the aerial image in real-time. This includes the steps of densification and stereo reconstruction[4], surface generation, semantic labeling[5], orthorectification[6], tileing[7][8], and object detection[9] (Fanta-Jende et al., 2023). Once the aerial image is complete, the fire fighters can define ROIs that should be covered in greater detail.

In the multirotor swarm, each drone, the edge server, and the swarm GCS run individual ROS instances that use the CPSwarm libraries[10]. They are connected using the swarmio bridge[11] (Sende et al., 2021) that forwards selected topics using the the ZeroMQ Message Transfer Protocol (ZMTP) over a (wireless) network. This increases the robustness of the system in unreliable networks. Hierarchical finite state machines (FSMs)[12] are used to model and implement complex behaviors controlling the drone from the onboard computer (Sende et al., 2021). The ROIs are received by the edge server that automatically assigns them to the available drones following a first-come,

first-served policy. As soon as a drone receives an ROI it computes a coverage path following a Bustrophedon back and forth pattern to search the given ROI[13]. The spacing between the different legs of this path is computed considering the characteristics of the camera system, i.e., field of view and altitude above ground. The swarm pilot uses the GCS to monitor the state of the drones and control the mission. He issues commands to start or stop the mission. For safety reasons, the drones wait for the mission start command before taking off.

After take off, a drone moves to the assigned ROI, activates the sensors and begins to autonomously search the ROI. Controlled by the onboard processor, the drone jointly captures thermal infrared and visual images and synchronizes them with its current pose.

The thermal images are analyzed on board and hot spots are detected if the temperature difference to the surroundings passes a given threshold. There can be an upper as well as a lower threshold. Hot spot detection using deep-learning neural networks or other AI approaches were dismissed due to the unavailability of suitable training data sets. The results are very small text-based data samples. Enriched with additional information such as temperature, size, and shape, they are sent to the cloud server for post-processing. The cloud server performs the more computationally expensive tasks of referencing the hot spots spatially and grouping neighboring detections using a morphological opening operator that also cleans up the data to smooth the detected polygons. The hot spots are labeled and linked with the meta data. Over the course of a mission, information about a hot spot is received multiple times in different image frames. This time series information is used for a scene analysis to improve and update the detection results.

The visual image data cannot be processed on board due to limited computing hardware and is instead transmitted to the cloud server for processing. For saving bandwidth, it is compressed losslessly on board the drone using the JPEG 2000 standard to guarantee that the transport does not influence the processing result. The cloud server generates a sharpened, orthorectified aerial image, both visual and thermal, containing the hot spots and their state (e.g., detected, assigned, extinguished). The result is stored on the map server which provides it to the user interface for further processing by the fire fighters.

While we also process the visual images on the cloud server for detection of humans and objects with YOLO deep-learning algorithms, it is not further described in this paper because it is out of its scope.

When a drone finishes the search, it returns, marks the ROI as completed and waits to be assigned to another ROI.

PROOF OF CONCEPT

To demonstrate the functionality of the proposed system, we performed a common exercise with the fire fighters in a closed stone quarry with an area of approximately 10 ha. The focus of the demonstration lies on the drone swarm component of the system which provides the main novelty and carries the greatest challenge. Besides showcasing the system capabilities to the main user group, the reason for the joined demonstration exercise was to test its usability during wildfire fighting missions. We assume the mission area to be a sub-part of the overall incident region surveyed by the fixed-wing drone. Compared to the fixed-wing drone, the multirotor drones cover a smaller area in greater detail. This helps firefighters deployed in the field to capture their direct surrounding at high detail without exposing them to the strain and risk involved in traditional, foot-based reconnaissance. While single-drone systems are already used for wildfire fighting, they are very personnel demanding (for each drone the fire fighters currently require one pilot and one person for mission planning and image observation). Our demonstration showed that a single operator can control four drones simultaneously by simply providing ROIs. Once the ROIs have been sent, the drones operate autonomously, executing their tasks without further human intervention. Due to resource limitations only four drones have been utilized for the demonstration. However, it is fair to assume that this number can be scaled up, as we performed mixed-reality experiments with simulated and physical drones to evaluate the coordination algorithm using up to 16 drones.

For this demonstration, the fire fighters created several hot spots of different types (burning wood or charcoal) shown in Figure 5a. For safety reasons the hot spots were deployed on rocky ground and not within forests. If hot spots provided a lower temperature footprint due to tree or bush cover, the detection threshold could be adapted accordingly.

Following the mission approval by the incident commander, the drone liaison officer defined four ROIs within the mission area using the situation report terminal, see Figure 5b. They cover a region of roughly 2 ha and are located at a distance up to 370 m from the command center. The ROIs were automatically transferred to the edge server and assigned to the four multirotor drones shown in Figure 5c. Once commanded from the flight planning manager, the swarm pilot started the mission using the swarm GCS. The drones computed flight paths as shown in Figure 5e to autonomously search the assigned ROIs. The drones then autonomously took off (Figure 5d) to altitudes between

[13] https://github.com/cpswarm/swarm_functions/tree/noetic-devel/coverage_path

30 m and 60 m and started moving to their designated ROI while autonomously avoiding collisions with other drones. Flying at a speed of 3 m/s and having a 30 ° camera field of view, they could cover an area of approximately 72 m^2/s while detecting all different types of hot spots. The low flying speed was selected for safety considerations, such as accommodating communication delays or outages that negatively impact collision avoidance. However, there is potential to increase the speed, particularly during ROI approach. During flight, the status of all drones could be monitored through the situation report terminal (blue symbols in Figures 5b and 5f) as well as the swarm GCS (red arrow in Figure 5e). The detected hot spots were visualized in the situation report terminal (warning triangle in Figure 5f) and reported to the incident commander. He then assigned them to individual fire fighters using a smart phone app shown in Figure 5g. The fire fighters moved to the location, confirmed (Figures 5h and 5i) and extinguished the hot spots (Figure 5j).

Based on the results of the initial survey and discussions with experts (see the technology assessment section), a second questionnaire was developed. The focus was on social science inquiries as well as the potential benefits of future market-ready systems based on the swarm technology.

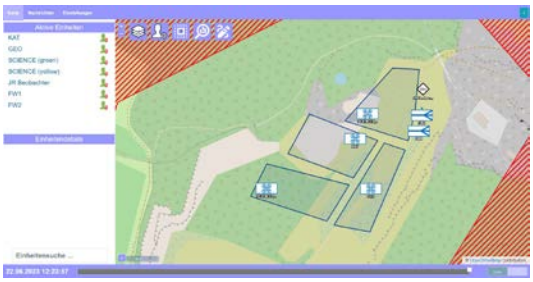
The experts identified several advantages of the system. Most experts consider the demonstrated system highly useful because it is anticipated to enable faster detection of hot spots, particularly through its autonomous operation. A (partially) autonomous swarm of drones will fundamentally expand the capabilities of the first responders by providing a larger and more valuable set of real-time mission data. This enables more precise planning of operations, more efficient firefighting procedures, and enhanced protection for emergency personnel, third parties, nature and wildlife. Two advantages have been named: 1) it accelerates the firefighting efforts, as a larger area can be searched in less time and 2) it reduces the need for manpower, as a single pilot can control multiple drones at once. In this sense, the system has been seen as an extension (not a replacement) of first responder personnel, which can be assigned with different tasks. The coordinated mission execution and the precision with which hot spots were detected are seen as an impressive demonstration of the system's strengths. Standard systems transmit images and videos, which lack the support for orientation. The presented system directly determines GPS positions of events (i.e., hot spots on the images are geo-referenced) and can lead emergency personnel straight to the point of interest.

Several disadvantages were identified. A significant risk is the potential for damage to third parties or objects due to faulty behavior. The greatest danger remains an uncontrolled crash, which can cause harm to people and materials. The lack of a legal framework for the deployment of a drone swarm is another weakness, mentioned by the first responders. Drones are already a substantial aid to all emergency services in dangerous and time-critical operations. However, the legislation and product maturity are seen as big challenges to be overcome. For efficient operation, comprehensive training of the emergency personnel is necessary. There is also a risk in a lack of acceptance of such systems by the emergency personnel themselves and in terms of public acceptance (e.g. privacy concerns).

CONCLUSION

In this paper we present a heterogeneous multi-drone system to support fire fighters with post-wildfire hot spot detection. According to a survey among domain experts, hot spot detection is a suitable application for such a system. They see the advantages in reduced mission time and increased situational awareness; the main disadvantage in its complexity. The system is still in an experimental phase and not yet ready to be deployed as a product. The system could be demonstrated in a controlled environment, with operation mainly performed by the research team, indicating a technology readiness level (TRL) of 4. It falls short in usability, reliability and security, which are critical aspects for effective oepration in actual fire fighting missions. Despite these limitations, we were able to demonstrate the system's capability to autonomously search for, successfully detect, and report hot spots in given ROIs. This outcome is encouraging and suggests potential for significant improvements in firefighting missions, particularly in addressing the increasingly pressing issue of forest fires.

ACKNOWLEDGMENTS



We would like to thank the volunteer fire fighter brigade Gumpoldskirchen, Austria for their support and IFR Ing. Richard Feischl for the task settings and the tactical and operational coordination.

This work received funding by the security research program KIRAS of the Austrian Federal Ministry of Finance (BMF) under grant agreement no. 879682 (UASwarm).

During the development of the communication system and the coordination and control algorithms, we used infrastructure provided by the 5G Playground Carinthia, which is funded by the Carinthian Agency for Investment Promotion and Public Shareholding (BABEG). The 5G Playground is operated by BABEG and financed by means of the Austrian Federal Ministry for Climate Action, Environment, Energy, Mobility, Innovation and Technology (BMK) and the government of the Carinthian provincial.

ABSTRACT

In disaster management, any relevant information about the situation can help decision makers to take the right decisions and initiate appropriate response measures. The digitalization of society offers more and more opportunities to gather information from the public. As instant messengers are one of the most widely used communication applications, they offer a broad user base for the collection of situational information. To minimize the effort involved, chatbots offer a promising option for the automated acquisition of specific information via instant messengers. In this paper we present an information system under development for the collection and reproduction of image information for disaster management. We also present the results of a first UTAUT-based evaluation of the current state of development to get an impression of the usability and perceived usefulness of the approach.

Keywords

Situational Awareness, Situation Picture, Chatbot, Public Sensoring, Crowdsourcing

INTRODUCTION

People share an extremely large amount of information in the event of a disaster/crisis via social media (Fathi and Fiedrich 2023). To have access to this information and to disseminate their own information quickly and directly to citizens, many civil protection authorities (CPAs) also use social media and operate their own social media accounts. In addition, there are innovative endeavors to deal more efficiently with information about future developments by implementing new technologies in acute operations (Schütte and Kox 2021). The large amount of different information and social media platforms means a great deal of effort for CPAs to use them effectively and efficiently. For this reason, scientists have been working for several years on approaches to make social media and their services more usable for disaster management purposes (Reuter and Kaufhold 2018). One challenge for which no approach has yet been widely established in practice is the targeted acquisition of situation information from the population.

So called information crowdsourcing is generally not a new topic. Information crowdsourcing approaches are examples where the citizens act as sensors, providing data to interpret and use by scientists or government agencies. The roles as sensors can be passive, for example, downloading an app that allows data gathering via a smartphone, or involve active participation, for example, taking photos or providing other information to the extent that their role can also take on that of an interpreter. For example, gathering data may entail the participants

performing some interpretation where basic training or guidance may be required. Beyond that, citizens involvement can go so far that the citizens play an active role in the problem definition or become part of the interpretation process (Haklay 2013; Vinnell et al. 2021).

Information crowdsourcing in disaster management offers the chance to gather previously unavailable data on e.g. meteorological phenomena (Kempf 2021) or earthquakes (Steed et al. 2019) and thus greatly add to existing observation capabilities of meteorological, geological or emergency services. In addition, crowdsourcing offers a low-cost approach to produce reliable and rapid results (Kox et al. 2021; Steed et al. 2019) and helping affected populations by providing geographic information for disaster response (Fathi and Fiedrich 2023). However, although promising approaches to targeted information crowdsourcing already exist, they are often limited by the reach of their users. For some approaches, users must have certain knowledge or skills, for example in dealing with geoinformation systems, but above all the approaches are mostly based on special software applications that must be installed separately and are not widely used. This means that much of the potential for obtaining information from the population cannot be utilized. Important aspects of the design of corresponding systems are user friendliness and simplicity of the implementation, as it is expected that most users will most likely not be able to accurately report desired phenomena on a professional scale (Kempf 2021).

One idea is therefore to make better use of systems that already have a large user base and enable information exchange, the social media. Instant messaging services such as WhatsApp, Facebook Messenger and Telegram are among the most frequently used applications worldwide (Kemp 2023). These enable simple and direct bidirectional communication with individuals and groups. However, not all CPAs can cope with the effort involved in communicating with many individual people, especially in highly stressful situations such as a disaster. The use of automation techniques in the form of conversational agents could therefore be an approach to ensure the practical applicability of instant messengers. Conversational agents (or chatbots) automatically respond to user input with suitable text messages and can support them in carrying out tasks or provide information themselves. In the area of crowdsourcing physical activities, there are already initial approaches to support the coordination of spontaneous volunteers in disaster response with chatbots (Gerstmann et al. 2019).

In this paper, we present the first steps in our research in progress on the development of targeted information crowdsourcing systems in disaster management using chatbots. To gain first impressions of the usefulness and accessibility of such systems, we have developed a simple chatbot with which a citizen can transmit photos of the situation taken with their smartphone with some meta information to CPAs. The CPA staff can access the information in the form of a dashboard. We have subjected this demonstrator to an initial expert evaluation based on a use case and present the results here. With this paper, we want to provide both scientists and practitioners with an initial assessment of the suitability of chatbot-based approaches for situational awareness and offer a simple solution for the implementation of a system in practical use. While doing so, we investigate the following research question:

RQ: Can chatbot-based situational awareness systems be a user-friendly addition to information retrieval in disaster management?

In the following sections, we first present related work in the field of chatbot-based approaches in disaster management, describe the implementation and features of the software artefact and show the results of an initial evaluation based on the UTAUT-method (Venkatesh et al., 2003). The paper ends with a conclusion summarizing the results and discussing the next steps of the research project.

RELATED WORK

Chatbots are text-based systems, which can communicate with their users via natural language (Gnewuch, Morana, Maedche 2017). They are particularly interesting due to their ability to integrate with other systems as they are mainly used on social media platforms, but also in other applications such as websites and mobile apps (Brandtzaeg and Følstad 2017). This makes them particularly valuable for use in disaster management, where communication via social media plays an important role (Reuter and Kaufhold, 2018). The application of chatbots for emergency and disaster management is an active field of research. In recent years, many different approaches for various use cases have been developed.

The approaches for chatbots in disaster management can be divided into two groups. The first group is concerned with informing and coordinating the general population. For example, Syed et al. (2020) designed an educational chatbot for small and medium sized companies to assist staff in learning about disaster preparedness, ranging from fires and blackouts to cyberattacks. The Richter chatbot on Facebook Messenger (Raymond 2016) provides users

with earthquake and tsunami preparedness information to help them draw up an emergency plan for their household. The “Flood Ai” chatbot (Sermet 2018) teaches users from the public about floods and provides up-to-date information on water levels. Other important use cases involve providing information and guidance to the general population during an emergency (Crook 2016, Ghosh 2019, Ahmady 2020, Boné 2020, Ohtake 2021, Ouerhani 2020, Ovando-Leon 2022) and allowing affected people to contact and communicate with emergency response forces (Clegg 2017, Crook 2016).

The second group focuses on supporting disaster response personnel and decision makers by e.g., facilitating data organization and access (Tsai 2019, Chen 2019, Tsai 2021a, Tsai 2021b). Another example for this is the coordination of spontaneous volunteers (Gerstmann et al. 2019, Ovando-Leon 2022). Furthermore, chatbots can also be applied for informational crowdsourcing. For instance, the chatbot 911bot, which was in practical use, (Crook 2016) was a Facebook Messenger based chatbot that allowed users to report emergencies to the authorities and provided information and advice to first responders. Additionally, it also allowed to send relevant pictures and videos to the authorities. Dharmapuri Sridhar (2017) investigated crowdsourcing situational information for flooding in Chennai, India and presented the web-based tool RiskMap for collecting and verifying crowdsourced information from social media. Participants can report flood-related information, such as location, flood height, and pictures of the flooding, by contacting chatbots on Twitter, Facebook, and Telegram. Tsai (2020) presented a system for the assessment of school building safety after natural hazards, such as earthquakes and typhoons, and for routine inspections. In this use case, people that are typically not structural engineering experts are assigned the task of assessing possible building damages. Hence, they are notified by a chatbot and guided through the inspection procedure and provided further assistance in the process. Furthermore, a dashboard showing the report results and assessed damages is used. This work is built upon in Kung (2020), where transfer learning is used to automatically extract the relevant information from the building damage reports. The chatbot SOCDA (Ohtake 2021) can be used to collect damage reports during natural disasters and can provide the public with relevant information, for example to aid in evacuations. SOCDA was tested in large-scale exercises in Japan in 2020 and 2021.

Despite the examples mentioned here along the entire disaster management lifecycle, the response to the refugee crisis in Germany has been characterized by the need for additional resources and the cooperation of various authorities and organizations under the leadership of a disaster management authority (Dittmer and Lorenz, 2019). Stieglitz et al. (2022) advise disaster managers not to rely on traditional chatbots, that simply gather information, but to deploy intelligent systems that ask information providers for more background information before passing it on to field teams.

Our work aims to build on these demands and previous chatbot implementations for data gathering during disasters and addresses the need to visualize the gathered data to disaster responders which can then be used to inform disaster response workers decision making processes. In the Research in Progress presented here, we explicitly do not consider any further features for analyzing and evaluating the information collected. In order to transfer the approach to practical use, it is important that the information collected is highly trustworthy. Possibilities for integrating existing methods that address this challenge on an organizational (e.g. Mehta et al., 2017) and technical level (e.g. Poblet et al., 2018) will be investigated in future publications.

SOFTWARE ARTIFACT

Our software demonstrator consists of two essential parts for the two user groups involved: A chatbot, the *BurningBot*, through which information providers from the population can transmit images of a situation including meta-information via the instant messenger Telegram, and a dashboard, called *Spell-Dashboard*, which visualizes this information on a situation map for disaster management. In the following, we explain the structure of the system before describing the features.

For a bot to be able to communicate via the Telegram Bot API, it must be registered with the Telegram internal tool BotFather. In the course of this, a name for the conversation ("spell-dashboard-burning-bot") and a username for linking ("@SpellDashboardBurningBot") are assigned and a token is created, which is required to authorize the bot and send requests to the Telegram Bot API. The bot is still active now and the given name can be used to find the chatbot in the Telegram search and to start a conversation. A *BurningBot* Listener Service, developed with Python, runs in the backend. This establishes a connection to the *BurningBot* via the bot token using the HTTP-based Telegram Bot API. The listener is also responsible for giving the *BurningBot* its functionality. All messages that the *BurningBot* sends to the user are defined in the service, such as requesting the image, location and direction. After all the necessary information has been received by the listener, it is converted into a JSON object together with some meta data (user ID, file ID, date and time) and forwarded to a PostgreSQL database. To enable the dashboard frontend to retrieve the data from the database, there is a *BurningBot* API service developed

with NodeJS. The dashboard is an Angular application (v15) and runs on the Red Hat OpenShift Container Platform. All backend services, including those of the *BurningBot*, are provided via OpenShift. Communication between the frontend and the *BurningBot* API takes place via HTTP requests. End users on the disaster management side access the dashboard via HTTPS. Figure 1 shows the components and information flows of the system.

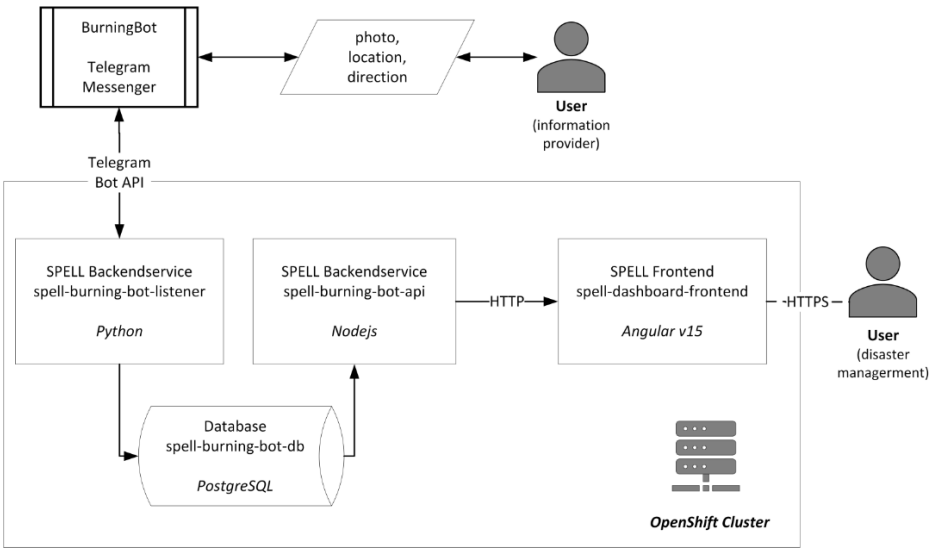

Figure 1. Component diagram of the BurningBot system demonstrator.

The *BurningBot* is a rule-based conversational agent that queries a photo and the corresponding location and direction of the shot in a three-stage conversation. The *BurningBot* first introduces itself and briefly explains how it works and the purpose of information retrieval. It then asks participants to upload an image that will be used as a source of information for CPAs. After the participant has uploaded a picture, the *BurningBot* asks for the participant's location and explains how to share it in the Telegram messenger. If the users have shared their location, the *BurningBot* asks for the cardinal direction in which the picture was taken and provides information on how this can be determined. After entering the cardinal direction, the *BurningBot* thanks the user and the entire conversation can be restarted to share more pictures. An example conversation in German is shown in Figure 2.

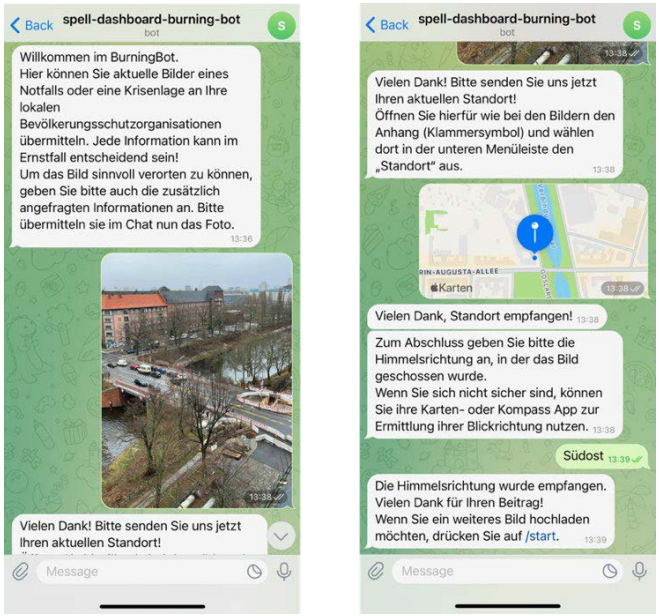

Figure 2. Screenshots of an example interaction with the BurningBot.

The second part of the evaluation involves the visualization of the results on a dashboard that was developed in the context of the SPELL project (https://spell-plattform.de/en/). The participants are provided with the internet address and login information for the dashboard. After login, the participants are presented with a dashboard

landing page, where they can select the "*Lage Berlin*" (translation: "situation picture Berlin") dashboard. They are presented with a panel that shows where participants submitted pictures. A screenshot of an exemplary map is shown in Figure 3.

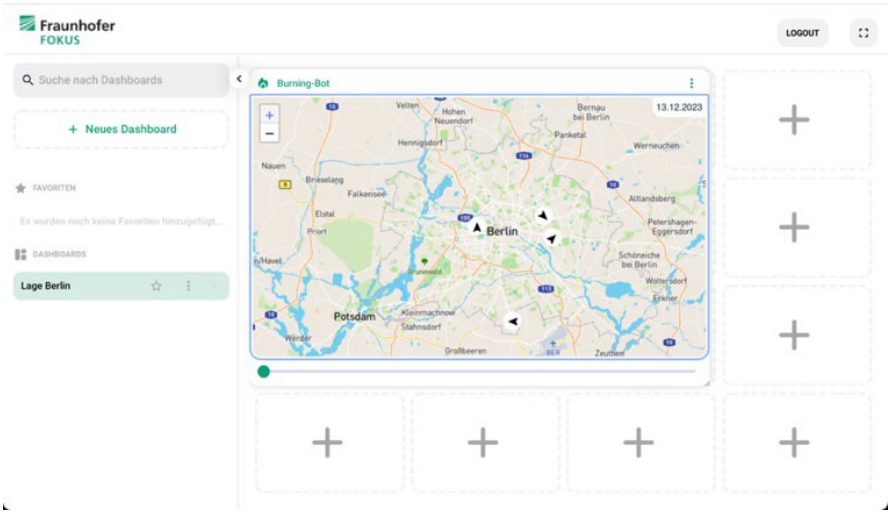

Figure 3. BurningBot panel with map showing locations of submissions.

The slider widget below the map can be used to display the submission status for different times. The positions of the submissions are shown with circle markers, which also indicate the viewing directions of the pictures. Detailed information of the single submissions can be seen by clicking on one of the markers. Figure 4 shows an example submission.

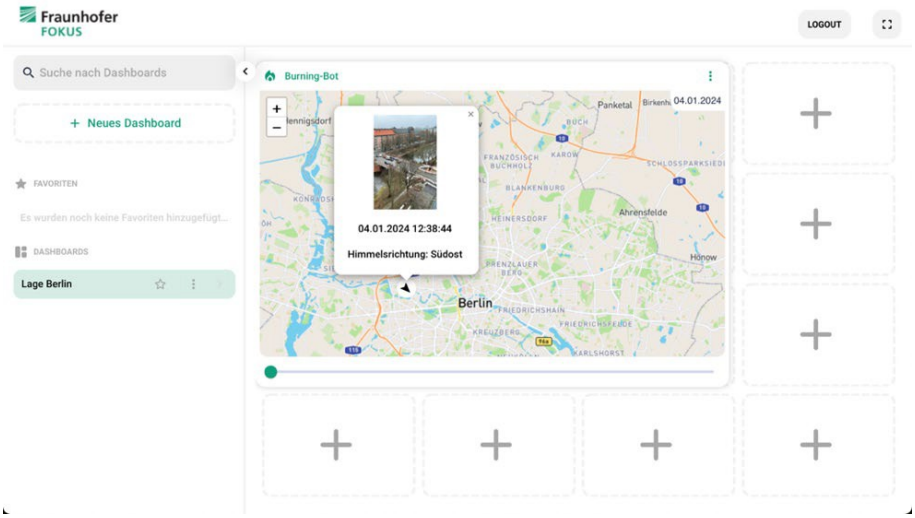

Figure 4. BurningBot panel with detailed information of an example submission.

EVALUATION

To get a first impression of the usability, the perceived usefulness, and user-friendliness of the *BurningBot* and the dashboard system demonstrator, we conducted a UTAUT-based evaluation (Unified Theory of Acceptance and Use of Technology; Venkatesh et al., 2003) of the current state of development. We surveyed people with a background in computer science and with a connection to disaster management as a proxy for the two actual user groups: volunteers, which contribute situational information, and disaster managers, who utilize the submitted information. The questionnaire is based on items and constructs from Venkatesh et al. (2003). The perceived likelihood of adopting the technology is dependent on the effect of four constructs: performance expectancy, effort expectancy, social influence, and facilitating conditions, moderated by age, gender, experience and voluntariness of use (Venkatesh et al., 2003). Certain UTAUT items that do not fit the context of our specific application were not included as they did not fit the purpose of the tool. For example, the item "*If I use the system, I will increase my chances of getting a raise*" was excluded since both the dashboard and the chatbot are not intended to provide economic benefits for the volunteers and disaster managers in our scenario. The items "*It scares me to think that*

I could lose a lot of information using the system by hitting the wrong key" and "*I could complete a job task using the system if I had just the built-in help facility for assistance*" were also omitted. Similarity, the item groups that measure the factors "*social influence*" and "*facilitating conditions*" do not transfer to the scenario at hand and were not used. The questionnaire contained 14 items of the UTAUT, measuring performance expectancy, attitude towards using technology, effort expectancy, self-efficacy, anxiety, and behavioral intent to use the technology. Eight additional items from a questionnaire from Sindhuja p and Dastidar, (2009), which is derived by the Purdue Usability Testing Questionnaire (PUTQ) by Lin et al. (1997) were included to obtain information about user satisfaction and perception of the software design.

The resulting questionnaire contained consequently 22 items for the dashboard and 22 items for the chatbot, which were translated to German. All thematic items consisted of 5-point Likert scales ranging from -2 (strongly disagree) to 2 (strongly agree). In addition, we added demographic items about age and gender. However, we did not include items about the level of education and profession of the participants. The survey was conducted online. Participants could answer items about the chatbot, the dashboard or both systems subsequently. In choosing the sample size, we followed the so-called "10±2 rule" (Hwang and Salvendy, 2010), which states that 8 to 12 respondents are sufficient for evalutation of usefulness of an artifact or technology The experts interviewed all had at least a bachelor's degree, with specialized knowledge in either disaster management, information systems design or both. Finally, 22 questionnaires were completed between December 2023 and January 2024. Ten of the completed questionnaires related to the dashboard while 12 referred to the chatbot. Participants were between 25 and 55 years old. Nine participants identified themselves as female and 13 as male. Due to the preliminary nature of this report, we are only reporting a selection of the data collected, with a focus on the items from UTAUT. All other analyses are currently work in progress.

Performance Expectancy

The performance expectations (Figure 5) for both the bot and the dashboard were generally reported as very high. 50% (dashboard) and 42% (bot) strongly agreed and an additional 40% (dashboard) and 50% (bot) agreed with the statement "*I would find the system useful in my job*" (median value dashboard: 1.5; bot: 1). In addition, 30% (dashboard) and 42% (bot) strongly agreed and additional 30% (dashboard) and 42% (bot) agreed with the statement "*Using the system enables me to accomplish tasks more quickly*" (median value dashboard and bot both: 1).

Figure 5. Survey results for performance expectancy.

Effort Expectancy

Also, effort expectancy (Figure 6) for both the bot and the dashboard were generally reported as very high. 70% (dashboard) and 75% (bot) of the participants strongly agreed and an additional 20% (dashboard) and 25% (bot) agreed with the statement "*It would be easy for me to become skillful at using the system*" (median value dashboard and bot both: 2). 50% (dashboard) and 83% (bot) of the participants strongly agreed and an additional 30% (dashboard) and 8% (bot) agreed with the statement "*I would find the system easy to use*" (median value dashboard:

1.5; bot: 2). 50% (dashboard) and 92% (bot) of the participants strongly agreed and an additional 30% (dashboard) and 8% (bot) agreed with the statement "*Learning to operate the system is easy for me*" (median value dashboard: 1.5; bot: 2).

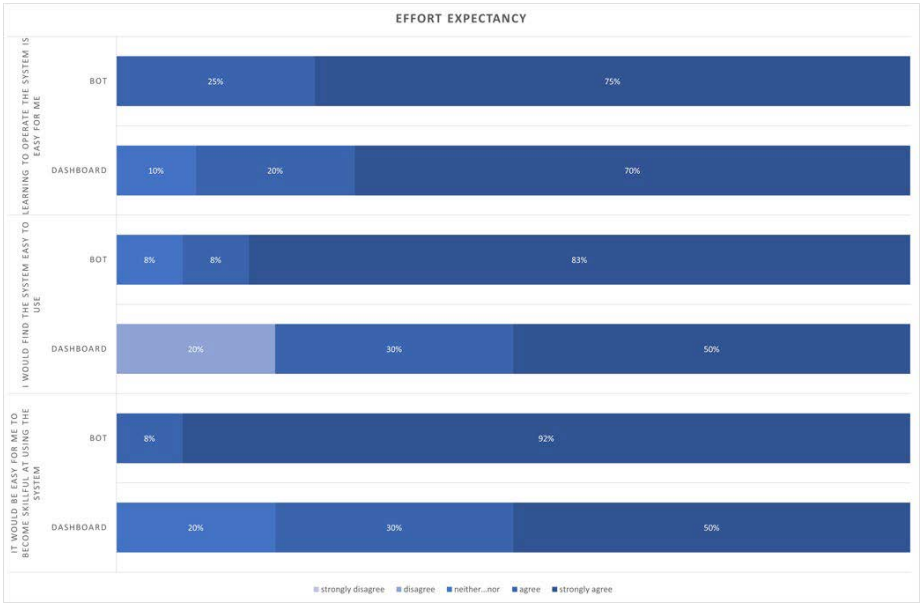

Figure 6. Survey results for effort expectancy.

Attitude Towards Technology

The attitude towards the presented technology (Figure 7) was to some degree indifferent: 50% (dashboard) and 25% (bot) of the participants agreed and an additional 8% (bot) strongly agreed with the statement "*Working with the system is fun*", while 40% (dashboard) and 58% (bot) neither agreed nor disagreed with the statement (median value dashboard: 0; bot: 0.5). However, 20% (dashboard) and 8% (bot) of the participants strongly agreed and an additional 60% (dashboard) and 67% (bot) agreed with the statement "*I like working with the system*" (median value dashboard and bot both: 1). 80% (dashboard) and 83% (bot) of the participants strongly disagreed and an additional 20% (dashboard) and 8% (bot) disagreed with the statement "*Using the system is a bad idea*". 8% of the participants who answered the questionnaire related to the bot, however, agreed with the statement (median value dashboard and bot both: -2).

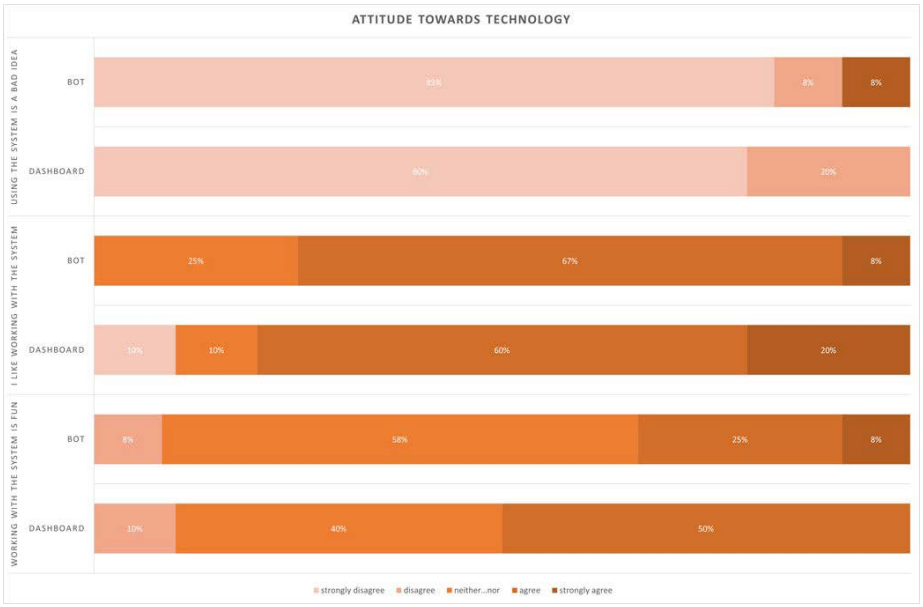

Figure 7. Survey results for attitude towards technology.

Self-Efficacy

Self-efficacy (Figure 8) was measured by asking three questions each starting with "*I could complete a job or task using the system...*" followed by a more specific statement. First, 50% (dashboard) and 67% (bot) of the participants strongly agreed and an additional 50% (dashboard) and 25% (bot) agreed, while 8% of the participants who answered the questionnaire related to the bot disagreed with the statement "*...if there was no one around to tell me what to do as I go*" (median value dashboard: 1.5; bot: 2). Second, 100% (dashboard) and 92% (bot) of the participants strongly agreed and an additional 8% (bot) agreed with the statement "*...if I could call someone for help if I got stuck*" (median value dashboard and bot both: 2). Third, 50% (dashboard) and 67% (bot) of the participants strongly agreed and an additional 30% (dashboard) and 25% (bot) agreed with the statement "*...if I had a lot of time to complete the job for which the software was provided*". However, of the participants who answered the questionnaire related to the dashboard 10% disagreed and an additional 10% strongly disagreed with the statement (median value dashboard: 1.5; bot: 2).

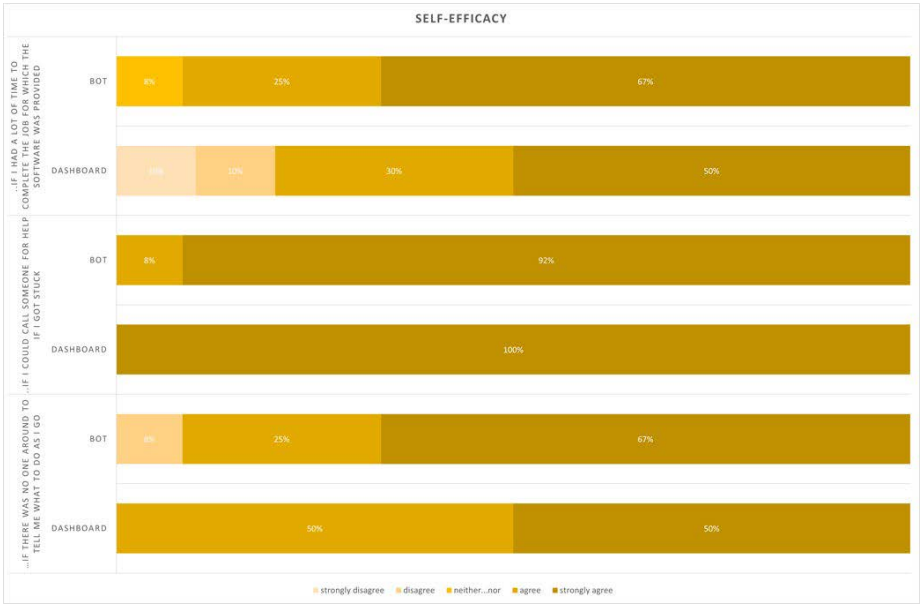

Figure 8. Survey results for self-efficacy.

Behavioral Intention to Use the System

The stated intention to use the bot was indifferent (Figure 10). 42% of the participants neither agreed nor disagreed, while 33% agreed and 17% disagreed with the statement "*I intend to use the system in the next 3 months*" (median value: 0). Regarding the stated intention to use the dashboard, 40% of the participants strongly agreed and an additional 40% agreed with the statement, while 10% each neither agreed nor disagreed or disagreed with the statement (median value bot: 0; dashboard: 1).

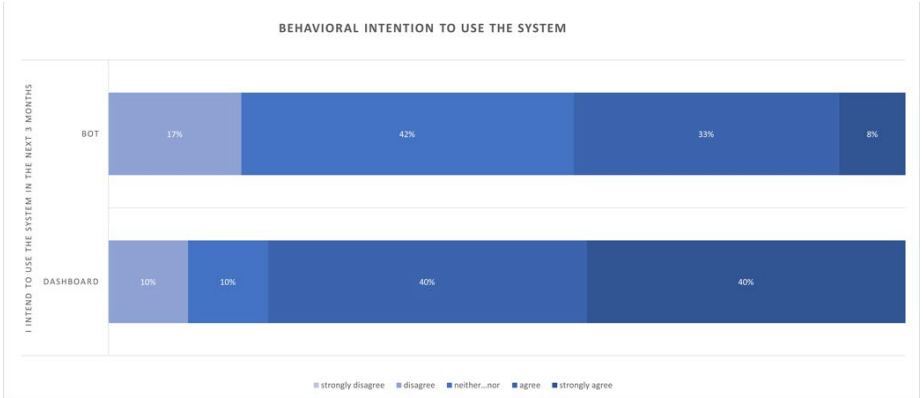

Figure 10. Survey results for behavioral intention to use the system.

Anxiety

Respondents showed no anxiety or concern (Figure 9) about using the dashboard or the bot. 50% (dashboard) and 67% (bot) of the participants strongly disagreed and an additional 40% (dashboard) and 17% (bot) disagreed, while 10% (dashboard) and 17% (bot) neither agreed nor disagreed with the statement "*I feel apprehensive about using the system*" (median value dashboard: -1.5; bot: -2). 50% (dashboard) and 92% (bot) of the participants strongly disagreed and an additional 40% (dashboard) and 8% (bot) disagreed, while 10% of the participants who answered the questionnaire related to the dashboard agreed with the statement "*The system is somewhat intimidating to me*" (median value dashboard: -1.5; bot: -2).

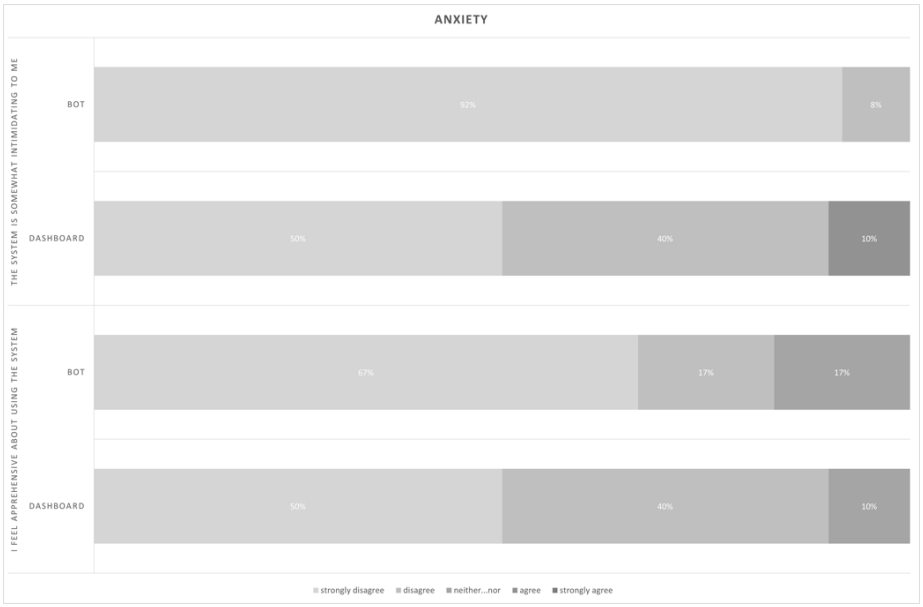

Figure 9. Survey results for anxiety.

Additional Items on Satisfaction and Perception of the Software Design

Regarding the questions on satisfaction with the software design of the dashboard and the bot, we present a selection of the items here (Figure 11). In general, the participants were satisfied with the software design. 40% of the participants strongly agreed and an additional 30% agreed with the statement "*I like the design of the dashboar*d." 10%, however, strongly disagreed with the statement and 20% were indecisive (median value: 1). In addition, 30% of the participants strongly agreed and an additional 30% agreed with the statement "*The dashboard provides clarity and consistency of wording*". Again, 10% strongly disagreed with the statement and 30% were indecisive (median value: 1).

Regarding the color scheme and the arrangement of the dashboard, participants gave positive feedback. First, 40% of the participants strongly agreed and an additional 50% agreed with the statement "*Color codes used in the dashboard are easily distinguishable*" (median value: 1). Second, 50% of the participants strongly agreed and an additional 40% agreed with the statement "G*rouping and ordering of menu options [in the dashboard] are logical*" (median value: 1.5). Third, 30% of the participants strongly agreed and an additional 40% agreed with the statement "*I can find easily what I'm looking for on the dashboard*", while 10% each strongly disagreed, disagreed or were indecisive (median value: 1).

The participants were not sure whether frequent and regular use of the dashboard and the bot was necessary to handle the technology. 20% (dashboard) of the participants strongly agreed and an additional 20% (dashboard) and 17% (bot) agreed with the statement "*The user needs to be a frequent user*", while 20% (dashboard) and 17% (bot) neither agreed nor disagreed with the statement. In contrast, 20% (dashboard) and 33% (bot) of the participants strongly disagreed and an additional 20% (dashboard) and 33% (bot) disagreed with the statement (median value dashboard: 0; bot: -1).

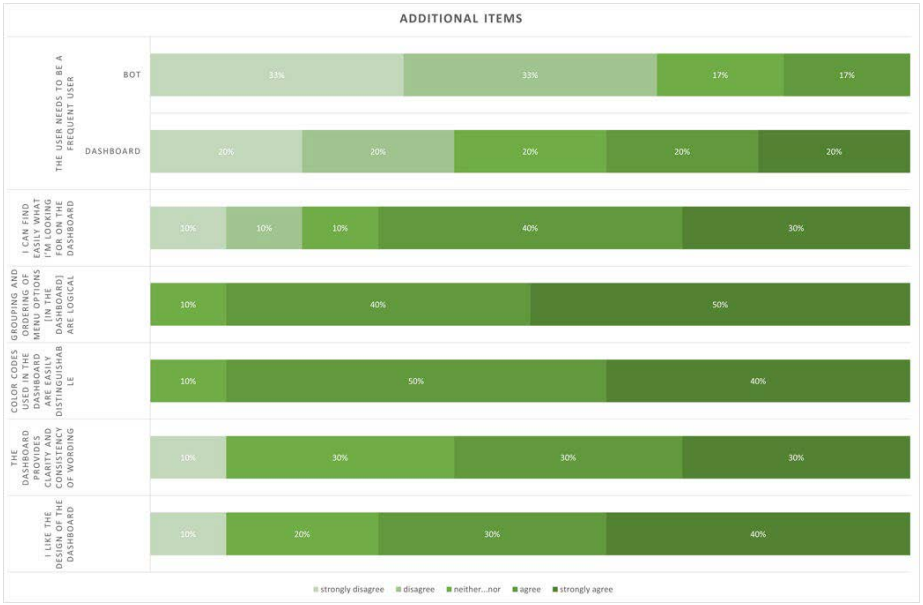

Figure 11. Survey results for additional items.

Limitations

Not just because of the provisional nature of the software, there are several limitations to this study: The evaluation only included part of the evaluation items, was conducted with only a few test persons and not under real-life conditions. It can be assumed that the statements will change under these conditions. The current prototype, for example, does not provide any information on the expected extent of contributions during a real-life crisis event. However, as lay persons networks made up of e.g. voluntary weather observers (Kox et al. 2021), or digital volunteers and professionalized digital volunteers institutionalized in established CPAs (Fathi and Fiedrich 2023) also form a community of practice and their willingness to engage in such a crowdsourcing task should not be underestimated (Kox et al. 2021). Additionally, in a real-life emergency context we would expect a bias between urban over rural areas, as it can be expected that the density of crowd observations will be higher in higher populated urban regions (Meier et al. 2017).

CONCLUSION

In this paper, we used a software demonstrator to investigate how potential users evaluate chatbot-based applications for situational awareness in disaster management. The approach presented here uses citizens and their mobile devices as sensors that interact with the object of interest to some extent, but do not provide any interpretative services. The participants in this use case mainly take the roles as *active sensors* by taking photos and providing context information. Images transmitted via chatbot with location and time stamp are displayed to decision-makers in disaster management in the form of a map-based dashboard. Both frontends were evaluated by expert groups based on established methods for evaluating technology acceptance after they had familiarized themselves with the system in a simple use case. The results showed a generally positive assessment of the user-friendliness and perceived usefulness of the system for both user groups.

Performance expectations and effort expectancy for both the bot and the dashboard were generally reported as very high. The respondents showed no anxiety or concern about using either of these technologies. The software design of the dashboard was generally evaluated positively. However, the stated intention to use the bot was indifferent, suggesting that other factors, which were not covered in this study, still might be affecting this variable. The factors "*social influence*" and "*facilitating conditions*" were omitted in this preliminary study and might be included in future research.

Despite the limitations of this work, such as the limited number of participants in the evaluation in the current research in progress and the fact that the software demonstrator only has basic functionalities, the clearly positive assessment of the system and the idea behind it suggests that corresponding solutions could offer significant practical added value and make further research in this area appear promising. In future research steps, we want to extend the existing demonstrator to investigate chatbot-based querying and dashboard-supported evaluation of different types of information. To better assess the added value and acceptance of such systems in practice, we

are aiming for an evaluation in the context of a larger disaster control exercise with more realistic operating conditions and a larger number of participants. We want to methodically summarize the design knowledge acquired in the course of this work for the implementation of such systems in a design theory to provide scientists and practitioners with a suitable starting point for the implementation of their own systems. Another research question that has been investigated for several years in the field of information gathering via social media concerns the IT-supported evaluation of the information collected. In addition, using sophisticated data analysis tools for automatic classification the crowdsourced information could help to build up databases of disaster impact that could not otherwise be created.

ACKNOWLEDGMENTS

This work is funded by the German Federal Ministry for Economic Affairs and Climate Action under grant No. FKZ 01MK21005B SPELL. The contribution of Thomas Kox was part of the joint project "Weizenbaum Institute for the Networked Society" (FKZ 16DII131), funded by the German Federal Ministry of Education and Research. We thank all people who participated in the evaluation of the dashboard and the chatbot.

ABSTRACT

Augmented Reality technologies can provide useful information to First Responders in rescue scenarios if their design is properly adapted to their cognitive and circumstantial requirements. Indeed, biosignals and environmental sensors can improve the situational awareness of the professionals working in emergency situations, supporting the decision-making process in critical moments. This study presents the architecture to create a Multi-Platform Interface to Enhance the Situational Awareness of First Responders that can be customized through an external dashboard. The key to individualizing the interface is the flexible configuration of sensor modules, normally manipulated by the Command Center according to the First Responders' rescue context.

Keywords

Augmented Reality, Cognitive Load, Situational Awareness, Angular, MQTT

INTRODUCTION

First Responders (FRs) operate in logistically demanding, mentally challenging, and time-sensitive circumstances. This is why, over the last few decades, there has been a growing interest in the development of technology that facilitates their rescue tasks. Augmented reality technologies, for instance, have been developed to provide important information to officers operating in catastrophic situations, as reflected in studies such as Arregui et al., 2022; Kapalo et al., 2018; Neustaedter et al., 2019. In this context, the International Forum to Advance First Responder Innovation (IFAFRI, 2023) has detected 10 FR common global capability gaps, a list that facilitates the characteristics of the innovative technologies to augment FR safety, efficiency, and effectiveness. Between those gaps, real-time information-sharing seems primordial to track the location of FRs, and monitor and analyze threats and hazards.

*xoregui@vicomtech.org

The incorporation of information available from multiple and nontraditional sources has been detected as an important capability gap, including the option to monitor physiological signs of FRs. Apart from sensor-based information, interoperable communications with FRs are supposed to enhance FRs safety and efficiency independent of environmental conditions.

Considering this circumstance, according to Arregui et al., 2022; Kapalo et al., 2018 appropriately designed Augmented Reality (AR) tools provide essential information to FRs to support decision-making and improve their Situational Awareness (SA) On top of this, The organization of the data in modules makes its processing more efficient. Indeed, the comprehension of the information processed by FRs in catastrophic circumstances varies according to their cognitive load as indicated by Meneguzzi et al., 2012. Despite enhancing the abilities of FRs, Gutie´rrez et al., 2023 highlights that the volume and manner in which these details are presented can impact their cognitive workload. The modulation of the amount of information displayed in AR interfaces facilitates focusing on the main goal of technology incorporation in emergency cases: the FRs' safety and minimizing risk exposures. The tracking and monitoring of biosignals allow for estimating the cognitive load and, therefore, adapting information exposure as already studied by Frederick et al., 2010; Kahneman and Beatty, 1966.

As identified by IFAFRI, 2023, another essential factor in catastrophic situations is the transmission of instantaneous information between agents present at the scene and the control center. The relevancy of this communication is reflected in the effort programmed by Canada in order to include the sharing of photos and videos between callers and 9-1-1 call centers within Next Generation 9-1-1 programs summarized in Camp et al., 2000; NG911, 2023. Ludwig et al., 2013; Neustaedter et al., 2019 indicate that real-time data exchange is equally significant between the RFs and the control center in emergency scenarios. In this way, the data collected by the sensors and devices of the FRs provides strategic advice in the control centers, as reminded in Ludwig et al., 2013.

Park et al., 2014 insists on the need for ergonomic tools that fit the usual equipment of FRs as a prerequisite for providing maximum efficiency and minimizing the difficulty of their task. A modality that facilitates the ergonomics of the FRs and the transmission of information between operators is voice communication, as remarked by Choong and Salvendy, 2021. When one of the essential tools is in the hands of the user in augmented or virtual reality situations, Monteiro et al., 2021 outlines the efficiency of voice as one of the most efficient interaction means. In this case, the use of voice can provide a double contribution: communication with external operators, and the ability to modulate the display, ensuring a completely hands-free context for the FRs. In this context, recent research as Arregui et al., 2022 shows the benefits of prototypes created according to these circumstances, such as the Smart Helmet presented by Ferna´ndez Garc´ıa et al., 2023. This tool combines sensors, artificial intelligence, AR, and personal protection to increase the situational awareness of FRs.

Within this context, this study aims to introduce an AR interface design characterized by the following objectives: modularity to adjust information exposure according to FRs' cognitive condition; ergonomic or hand-free adaptability; architecture flexibility to enable simultaneous deployment in interconnected distinct devices; and real-time data actualization capability. This presentation includes, on one hand, the description of the main architecture that provides a modular multi-device display, and it details the combination of operational modules connected through an MQTT-based communication protocol. On the other hand, it summarizes the generated prototype that demonstrates the versatility of the generated AR interface. This part includes its deployment inside a display added to an adapted FR helmet and the simultaneous visualization in the control center, which adjusts through a dashboard the tools to be displayed. The last section summarizes the impact of the experience of the pilots on the AR interface design, and finishes with the pending and future work perspectives.

DESCRIPTION OF THE SYSTEM

The Augmented Reality (AR) interface presented in this work, The Modular Multi-Platform Interface (MMPI), proposes a technology to aggregate and display essential information in order to enhance situational awareness and support decision-making. This mechanism improves the transfer of information between the agents in the emergency field and the technicians in the control center. All while keeping from overloading the users with information and preventing mistakes as a result of this extra-information exposure. This data comprises essential details such as the location and orientation direction of First Responders (FRs), the positioning of other FR team members, and noteworthy points of interest—such as targets or alerts regarding potential dangers or events tagged by other FRs or directly from the Command Center.

The design of the AR display is characterized according to the needs of the FRs in the emergency field since the main objective is to extend their capacities when working in crisis zones. Due to ergonomic reasons, the AR is engineered to be projected in the one-eyed transparent AR Head-Up Display (HUD) integrated into a standard helmet enhanced with a processing unit and camera, called Smart Helmet on the Ferna´ndez Garc´ıa et al., 2023;

but it is similarly displayable on an opaque screen of a mobile phone or a tablet. This is a result of the flexible design based on the dynamic web application framework Angular detailed by Jain et al., 2014, technology that facilitates the adjustment and duplicated reproduction of the interface on different displays. In this manner, all biosignal, sensor, and positional information displayed on the interface is available simultaneously to the rest of the FRs and the Command Center.

The procedure for transferring information across multiple devices is based on Message Queuing Telemetry Transport (MQTT), a lightweight messaging protocol designed for use in low-bandwidth, high-latency, or unreliable networks. The biosignal, contextual, and positional data recorded by distinct sensors or indicated by the FRs is published through previously defined topics in the MQTT broker. The subscription to those channels enables the real-time update of the information projected in the AR.

On the other hand, the FRs in emergency fields operate in dynamic and demanding operational scenarios, and therefore, it is crucial to equip the FR with comprehensive and adapted information facilitating real-time decision-making instead of over-saturating and complicating the situational awareness and decision-making processes. That is accomplished by adapting the modular configuration of the AR display through a dashboard manipulated in the control center. The cognitive load is the key indicator to avoid information saturation or overloading and provide an assumable data quantity. Gutie´rrez et al., 2023 provide measures to approximate it.

The following Global Architecture section includes all the technical requirements involved in the simultaneous deployment of the AR interface in distinct devices, which are distributed in two different physical environments: the Emergency Field and the Control Center.

Global Architecture

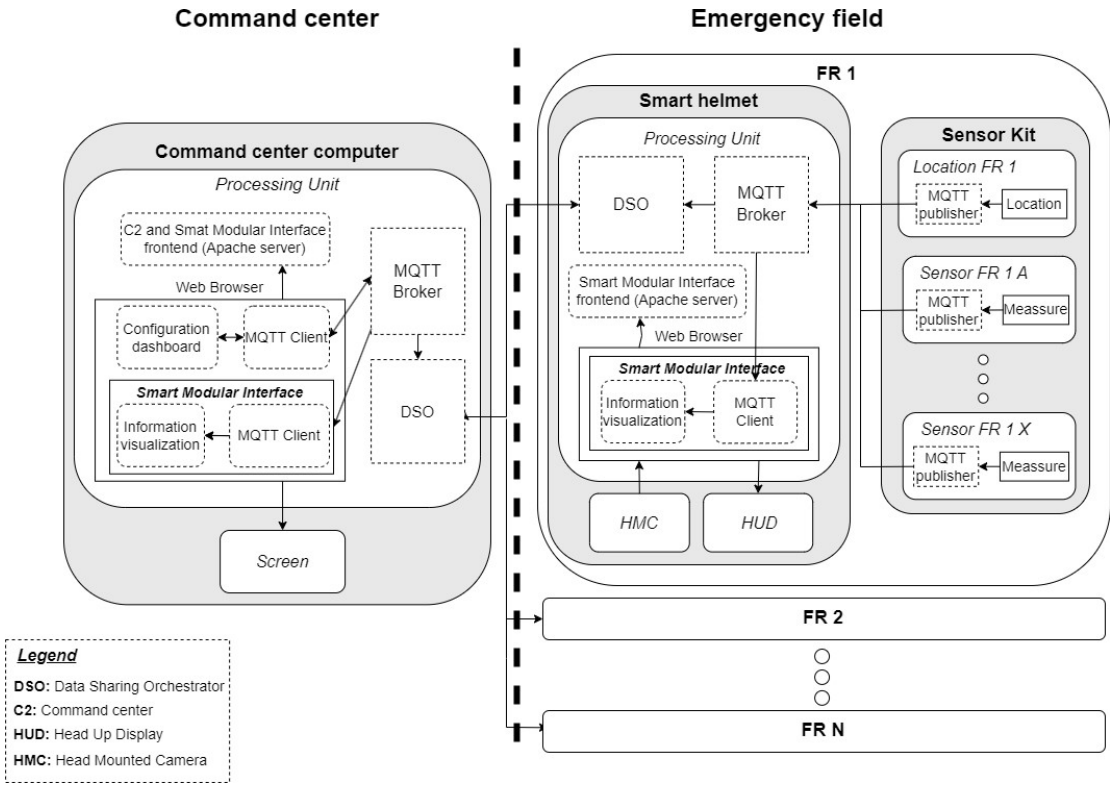

Figure 1. Use case architecture

The Modular Multi-Platform Interface (MMPI), an AR interface, has been designed to perform in a highly adaptable architecture resulting from different emergency scenarios, with changeable FR and Command Center (C2) organization. The presented architecture facilitates the intercommunication between multiple operational nodes in order to retrieve, process, and display information relevant to the FR. The architecture depicted in Figure 1 represents the main technology division that occurs in emergency response services, the digital frameworks corresponding to the Emergency Field and the Control Center. In the Emergency Field, the FRs illustrate the necessary digital configuration to display the AR in each deployed field operator. At the same time, the Central

Operation Computer symbolizes the Control Center and the required technology to overview the information of the FRs and the dashboard to customize their MMPI as depicted in Figure 4.

Both sides of the use case share many components. On the one hand, both contain a processing unit (Laptop, Raspberry, ...) that includes an MMPI, an MQTT broker, and a Data Sharing Orchestrator (DSO). The MQTT broker is responsible for collecting and managing the data flowing within the network established by the FRs and the control center. The MMPI consumes the messages available in the MQTT broker topics to supply the FR display or the control center screen with real-time data. Inside the processing unit, another common component is the Data Sharing Orchestrator. The DSO is a module that fulfills two tasks: forwarding the information from the sensors of each FR to the rest of the MQTT Brokers and filtering the data of other FRs based on the user's cognitive load to avoid overloading Gutie´rrez et al., 2023.

On the other hand, the control center and the emergency equipment differ in important characteristics. The Control Center includes a screen, in replacement of an AR device, and a Configuration Dashboard (CD) that personalizes the modular appearance MMPI of each FR. In addition, the CD can provide externally defined coordinates of points of interest in the Emergency field. Since the Smart Helmet does not offer the FR ways to interact with the MMPI, that is the unique manner to update information not registered by sensors. On the other hand, an FR in the Emergency Field carries, apart from a Smart Helmet that includes the Head Mounted Camera and Head Up Display, the necessary rescue equipment. This equipment contains an individualized collection of sensors, denoted as the Sensor Kit in this context. Indeed, the following list highlights the instruments considered within the RescueR project as part of the Sensor Kit:

* Smartwatches collecting the wearer's physiological signals
* Wireless signal detectors encompassing Bluetooth and WiFi frequencies, enabling potential victim localization in obstructed environments (e.g., under debris).
* Vital sign detectors designed to discern pulsation through solid barriers, facilitating life detection in scenarios where subjects are obscured by walls or similar impediments.
* Chemical sensors engineered to identify hazardous airborne constituents, such as methane or diminished oxygen levels, contributing to environmental safety monitoring.
* Localization devices employing GPS Galileo for outdoor positioning and leveraging inertial sensors, specifically mobile phone gyroscopes, for indoor localization purposes.

In order to ensure the transference of the data recorded by these sensors to the AR interface, the MMPI in this case, is necessary to publish those values in a previously agreed message format and topic for the MQTT. These topics shape the modules that are visualized in the MMPI, thus characterizing the modularity of the AR interface.

The Modular Multi-Platform Interface, the main contribution of this paper, is the technological cornerstone that facilitates the integration of all data gathered from different Sensor Kits. Its modularity, according to FR's cognitive load and adaptability to distinct devices, is characterized by its Angular-based front-end development. The main advantage of using Angular is its flexibility and structure that is specifically designed to generate individual components that can be grouped, nested or even replicated and reused in multiple sites. In addition, it is a widely used framework on which multiple libraries have been created (including a dependency inspector to facilitate their integration) that facilitates the development of more complex solutions. These characteristics fit the objectives of AR interface design, as mentioned above, a generation of an extensible and adaptable interface depending on the equipment assigned to each FR. Deployment options permit its installation on either an Apache server within the local device interfacing with the display or on a server interconnected within the shared network.

In addition to this, like many other JavaScript frameworks, its results are accessible from any modern web browser offering a lot of flexibility in terms of where to display the information. In this case, being an interface designed specifically for AR displays, the background of the application by default is a black background. Normally, AR displays interpret the black color as a transparent pixel allowing to combine reality with an artificial scenario. When the interface needs to show more information, such as a camera feed, the AR display can function as a regular opaque screen. Nonetheless, its functionality relies upon the interconnection between the display and the processing units, alongside the camera requisites delivering the camera feed.

Prototype

This section describes the different elements that conform complete architecture of the use case either on the Control Center side or in the emergency field side: The MMPI, the Configuration Dashboard and the Smart Helmet.

Modular Multi-Platform Interface (MMPI)

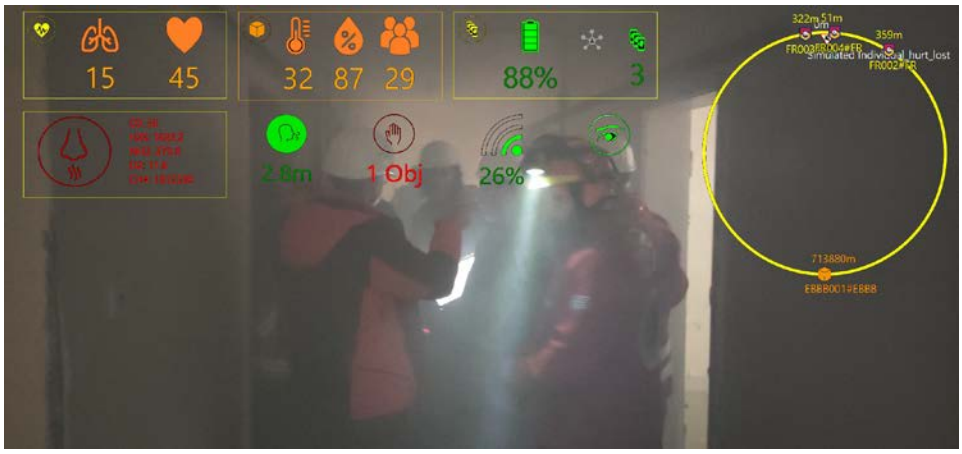

Figure 2. Example of the Modular Multi-Platform Interface (MMPI) visualization in a FR helmet HUD

The MMPI, has been generated to test its adaptability across the display in different devices, the implementation of the distinct-format data, as well as the connectivity of the components responsible for data management. As summarized in the Methodology section, the same AR interface is deployed on distinct displays: a laptop and a Head-Up Display (HUD) integrated into an FR Helmet, representing the communication segmentation of catastrophic circumstances. This duplication facilitates direct transmission of the information gathered by the FRs in the Emergency Field. The AR interface depicted in Figure 2 exhibits crucial information for First Responders (FRs) to navigate crisis scenarios effectively. Within this display, two distinct categories emerge: the passive data and the Tool-associated Information. The former encompasses data that is directly transmitted to the FR without requiring his interaction: for example, biosignals, location, or network status. Conversely, the Tool associated Information section includes the output of devices manipulated by the FRs during the rescue operation; for example such as radars or gas detectors (see Table 1 for further description of some examples applied during validation). The segmentation of all this information in modules facilitates a comprehensive overview of both passive and tool-related data, empowering FRs to make informed decisions while engaging with diverse tools and technologies. These Situational Awareness enhancing Modules and corresponding sensors are detailed in Table 1.

The information distribution on the screen is important to focus the attention of the user according to contextual needs. The focus of a First Responder (FR), for example, typically lies in the lower field of vision as they concentrate on locating victims. Therefore, in this case, the AR layer is required to be positioned at the top of the field of view to ensure the lower part remains unobstructed, as visualized in Figure 2.

During concrete moments in rescue operations, the FRs necessitate a distinct kind of information visualization, a configuration not summarizable with small icons and values in a small space fraction of the AR interface. Instead, this critical information needs to be displayed over the complete AR scene or screen. Therefore, two opaque interfaces have been included, display modes changeable from the Control Center. The two non-AR modes integrated are the Camera Feed mode, which allows the direct reproduction of camera output on the FR display (useful for infrared cameras or IA-generated image processing, Ferna´ndez Garc´ıa et al., 2023) or full-screen map mode that illustrates the position of the FRs and points of interest, as depicted in Figure 3.

Configuration Dashboard

This web tool has been designed to enable the Control Center to modify the depiction of modules for a specific FR and to facilitate the transmission of information updates necessary to keep the emergency field agent on track of their mission. This configuration could be adjusted further using communication via walkie-talkies with the Control Center for clarifications. The protocol established for this configuration operates as follows: The Control Center initiates a current status request to an FR identifier through the MQTT broker. If there exists an MMPI associated with that identifier on the network, it responds with an MQTT message containing its present configuration and the currently displayed points of interest on the screen. These parameters are integrated into the Configuration Dashboard, allowing modification by the Control Center. Subsequent alterations can then be transmitted to the FR using a new MQTT message.

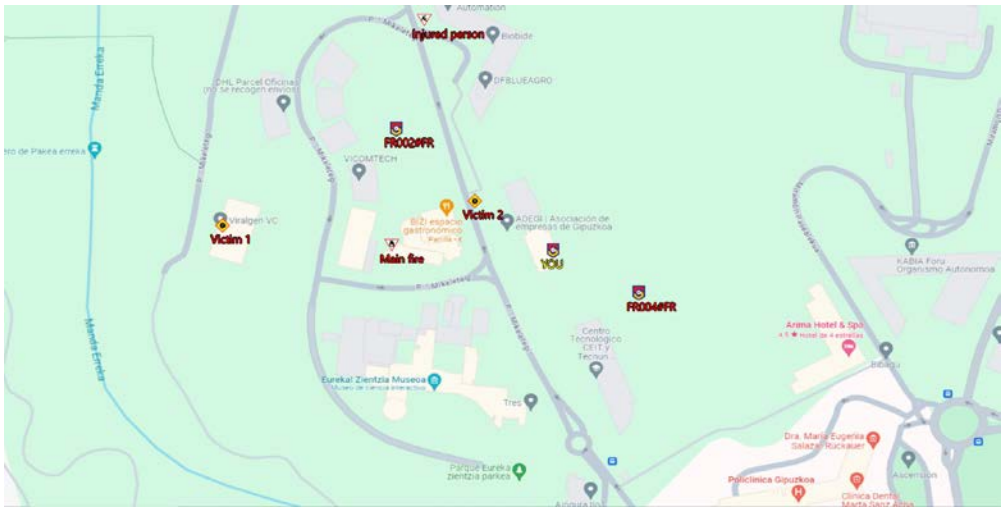

Figure 3. Map view

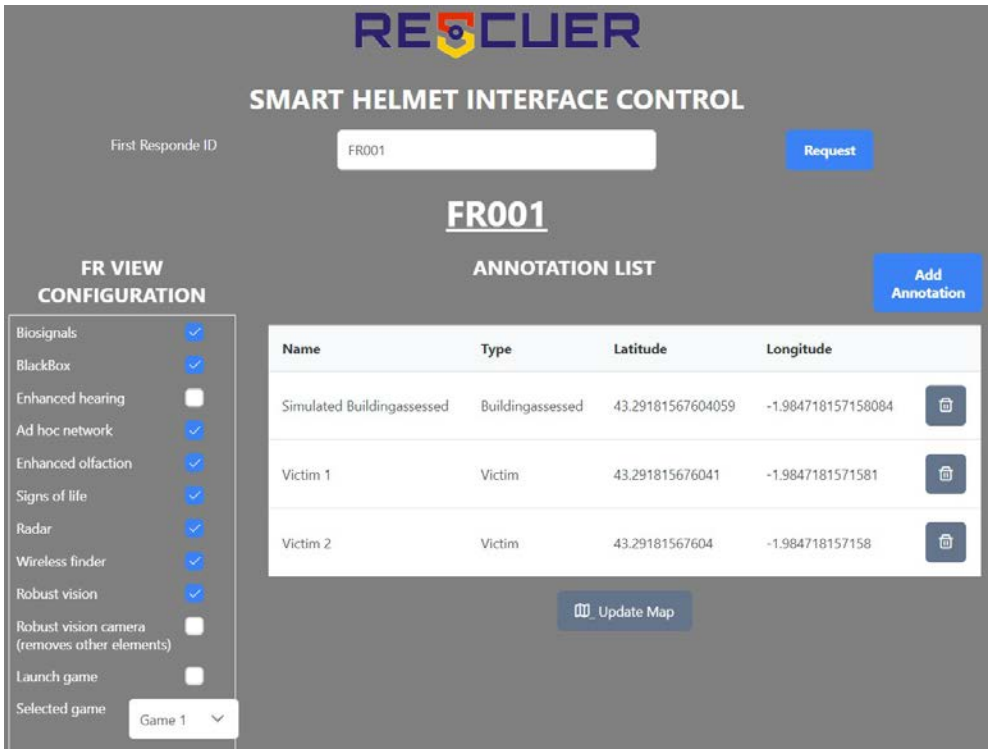

Figure 4. Interface configuration dashboard accessible from the Command Center

Smart Helmet

The Smart Helmet is a concept introduced in Ferna´ndez Garc´ıa et al., 2023 that refers to a regular FR helmet that has been enhanced with a display, a camera, and a processing unit in order to create a tool that can transmit information to the FR in the less invasive way possible. Each of these components has the following characteristics.

Head Up Display

A micro OLED transparent one-eyed display, integrated in a non-intrusive manner into the existing protective gear of the FR, capable of projecting AR information congruent with the environment. It includes a microcontroller in charge of controlling the brightness and orientation of the display. The HUD is mounted on a 5-degree-of-freedom mount that can be adjusted according to the user's ergonomics. This mount is affixed on the front side of the strap attached to the helmet.

Figure 5. Draft concept of the system installed on user's helmet and the final prototype in Ferna´ndez Garc´ıa et al., 2023

Helmet Mounted Camera

In some situations, such as search and rescue, cameras operating at different wave frequencies, such as infrared or ultrasound, are used to penetrate through debris or adverse conditions and detect the presence of trapped people. Similarly, thermal cameras detect heat emitted by objects and people rather than relying on visible light. They are essential in situations such as fires, earthquakes, or avalanches, as they can detect bodies or heat sources even in conditions of smoke, darkness, or debris. In this case, as the objective is to verify the transmission of the frames received from any type of camera, the considered prototype integrates a GoPro, and the flow of the received frames.

Processing Unit (Edge Unit) and an External Battery

Lightweight, energy-efficient, and integrated into the FR protective gear, it will provide an efficient processing platform with capabilities to develop rendered camera images and auxiliary sensory information, resulting in an AR processing unit.

Testing in Realistic Scenario

This prototype was tested as part of the RESCUER, 2023 project, where a series of pilots were planned in which the FRs tried first-hand the technology developed in the project in different use case scenarios. Three of these international events were located in Weeze (Germany) where an earthquake scenario was simulated, Navacerrada (Spain) for mountain rescue operations, and Modane (France) for tunnel rescue situations, in the consecutive months of November, January, and October of the period 2022-2023. Among other technologies, the AR interface was tested as a displaying tool for the Smart Helmet. These tests include a first phase to train the FRs to familiarize them with the interpretation of the display. In the second phase, the FRs operated in a simulated Emergency Field and performed a series of rescue tasks: dragging victims, detecting and transmitting the presence of dangerous products, and rescuing in smoke and darkness, among others. Finally, the FRs provided feedback evaluating their experience. The statistics of FRs feedback collected during the first two pilots are published in Ferna´ndez Garc´ıa et al., 2023, while the third round of Modane is in progress. This feedback has been essential to evolve the AR design according to the FRs requirements. The modules of data designed for this validation use case include the following information:

Location Information

The visualization of objectives and the positions of other First Responders (FRs) is a key parameter in rescue operations. In the RescueR project, this information is represented within an outer circle (depicted in Figure 2), illustrating the names and distances to the agents and objectives, such as other FRs, victims, and dangerous obstacles. This visual representation resembles the perspective commonly observed in video games. Notably, the orientation of the FR influences the adjustment of this circle, aligning it accordingly, and facilitating an intuitive orientation in the emergency field. For instance, when the object appears at the top of the circle, it signifies its location as being directly in front of the FR, establishing an intuitive and dynamic display mechanism for spatial awareness.

Sensor Kit Simulator

The modular development of the RescueR architecture enables simultaneous progress on various fronts, allowing each center to concentrate on advancing its own technology. Yet, particularly within a European project, coordinating for testing and validating distributed work from diverse consortium members demands considerable effort. This necessity sparked the inception of the Sensor Kit Simulator concept. This software is purpose-built to simulate messages from various sensors and tools used in the project within an MQTT broker. The paper focuses on the AR interface, where the relevance of the data simulated in the MQTT broker lies in its adherence to the original messages' structure, keywords, and frequency, rendering their origin inconsequential. To achieve this, the consortium standardized a common structure, enabling each partner to determine the requisite information to transmit from their sensors. This approach facilitated the independence of tool development and progress. The design of the icons-system as a representation of the distinct modules in Table 1 has been defined in collaboration with the *Ecole nationale supe´rieure des officiers de sapeurs-pompiers* (ENSOSP), in order to facilitate the comprehension and integration of this tool of firefighters within their rescuer tasks. Indeed, the icons in Table 1 are distinguished in two levels, since some modules provide information registered in more than one sensor. In these cases, as shown in Figure 2, the icons of the sensors are grouped in boxes, so that the symbols of the modules are in the upper left edge (Bio-signals, Black box, Ad-hoc network, and Augmented olfaction), and the symbols of the sensors (heart and breath rate, temperature, humidity, ...) inside the boxes. This distinction of these symbols is precise in Table 1: the left column contains the icons of the modules, while the right column incorporates the icons of the multi-sensor modules to the module descriptions.

In fact, the pilot of Mountain Rescue indicated the need to improve the AR interface in order to reduce the amount of information displayed and avoid distractions in the rescue tasks. To do this, one of the keys of the Rescuer project was to calculate the cognitive load and regulate the projection of information. Considering the recent results of Gutie´rrez et al., 2023, with the available sensor kit it was not possible to measure the cognitive load directly, but it is possible to derive it from bio-signals such as respiration, blood volume pulse, and electrocardiogram. Therefore, the modularity of the interface has been designed, i.e., the selected information can be projected from the entire data stream received (see Figure 6 in the Appendix for modularity explanation purposes). An automated modularity according to the cognitive load has also been considered in the project. But without robust and sufficient results to create such automation on the DSO, it was decided to use the Control Dashboard, through which, having direct communication with the FRs of the field plus their bio-signals, the Control Center operators customize the visualization of the AR. This AR has been tested in the Tunnel scenario pilot, but due to the processing status of the statistics, the present study is considered a work in progress.

CONCLUSION AND FUTURE WORK

This developed modular platform has already been tested, and the main conclusion has been that it provides real-time information to the FR that aims to facilitate their decision-making without augmenting the cognitive load of the user. Indeed, the modularity of the created interface allows the deployment of adapted information exposure respecting FRs' physiological limitations and capacities in the Emergency Field. Furthermore, the participation of the FRs in the definition of icons and colors to represent the situational awareness-enhancing modules facilitates the training process of the FRs. Integration of previously recognized symbols in rescuer vocabulary makes more innate the information understanding through an AR interface. All these characteristics made the MMPI an AR interface, in adequate circumstances, capable of augmenting the situational awareness of the FRs interfering in a minimal way in their rescuer maneuvers. However, there may also be situations in which the technology is not supportive. A blow can damage the equipment and disorient or confuse the FR, but these are inconveniences that, regardless of the technology, can not always be prevented.

One of the next objectives is the implementation of an automatized modular exposure based on the biosignals of the FRs. This smart modular adaptivity will be an optional display mode, in order to ensure that the AR does not overload the FRs and interfere with their operations. This should be an advanced Data Sharing Orchestrator version, considering the FR working team configurations in the Emergency Field and providing appropriate information distribution. For example, there may be three distinct configurations for situations such as exploration, rescue operation, and survival mode. Each one of those would provide a distinct data layout. For exploration or victim-finding operations, all FRs may receive the complete set of situational awareness modules, especially tools that facilitate the detection of people under low visibility circumstances. On the other hand, once victims are detected, for rescue operations, individual biosignals may be displayed, but there may be an information reduction in a manner that one FR may receive contextual information (temperature, humidity, and the number of surrounding people), while a team-mate obtains other specific tool derived data. In extreme situations, minimal data should be

Table 1. Symbol description of the situational awareness modules and sub-modules

Situational Awareness enhancing MODULES	Description of corresponding sensors
	Biosignals: Description of the biological signals of the FR. The color of the icons will change from green to red depending on if the values received are good or bad.  Heart rate: Measure of the heartbeat per minute.  Breath rate: Number of breaths per minutes done.
	Black Box: The black box is a device that has some environmental sensors inside; temperature, humidity and number of people around it.  Temperature: Temperature from the environment around the Black Box.  humidity: Humidity of the environment around the Black Box.  People: Number of people currently surrounding the Black Box.
	Ad-hoc network: Information of the wireless network generated by the gateways that each FR carries during an operation. It provides information about the battery level of the gateway and the status of communications between the C2 and other FRs.  Battery level: battery level of the gateway that both connects and is part of the generated network. The image is updated depending on the amount of battery left.  C2 connection: Flag showing if the control center is reachable through the Ad.hoc network. If so, the C2 could send coordinates of points of interest or modify the view on the interface.  FR connections: Number of FRs reachable within the Ad-hoc network.
	Augmented olfaction tool: It provides the concentration values on up to 5 type of gases, turning from green to yellow to red depending on if the gas levels are dangerous or not.
	Signs of life: This tools provides information if it detects life (through walls for example) it provides an estimated value of the distance to the found individual.
	Radar: This device shows the amount of objects that are approaching to the FR. The interface blinks when an object is approaching.
	Wireless finder: This device measures the distance to devices that produce wireless signals such as Bluetooth or Wi-Fi, that usually come from Mobile phones from victims under the rubble. The interface guides the FR in the initial calibration phase also.
	Robust vision: Displays the type and amount of objects detected by the object-detection module. It can be switched to a full camera view that will show the IR video feed with the red squares instead of the transparent view.

displayed in order to ensure the safety of the FRs, e.g. providing exit location points. Therefore, the priority of modules should be analyzed according to biosignals and the risky level of the circumstances of the Emergency Field.

In summary, this approach intends to replace the necessity for manual adaptation of information by the control center, thereby implementing an intelligent version of the current Modular Multi-Platform Interface.

APPENDIX

Figure 6 illustrates the reduced information exposure in the Modular Multi-Platform Interface (MMPI). This modular characteristic of the interface intends not to overload the First Responder when its cognitive load is high.

Figure 6. Example of the Modular Multi-Platform Interface (MMPI) visualization with high cognitive load and reduced information exposition

ABSTRACT

In recent years, drones have increasingly supported First Responders (FRs) in monitoring incidents and providing additional information. However, analysing drone footage is time-intensive and cognitively demanding. In this research, we investigate the use of AI models for the detection of humans in drone footage to aid FRs in tasks such as locating victims. Detecting small-scale objects, particularly humans from high altitudes, poses a challenge for AI systems. We present first steps of introducing and evaluating a series of YOLOv8 Convolutional Neural Networks (CNNs) for human detection from drone images. The models are fine-tuned on a created drone image dataset of the Dutch Fire Services and were able to achieve a 53.1% F1-Score, identifying 439 out of 825 humans in the test dataset. These preliminary findings, validated by an incident commander, highlight the promising utility of these models. Ongoing efforts aim to further refine the models and explore additional technologies.

Keywords

Human Detection, Computer Vision, Drones.

INTRODUCTION

In the last years, the use of drones to aid First Responders (FRs) has become more and more prevalent, including applications such as monitoring fires from an unobstructed perspective (e.g., (Georgiades et al., 2019)) and assessing building damage in difficult-to-access areas (e.g., (Adams et al., 2014)). The camera footage recorded by drones can also be used, for example, to help detect victims, solve logistical problems, and locate missing persons (e.g., (Khan & Neustaedter, 2019)). Currently, FRs usually fly the drones manually and interpret the camera footage without any system help. However, analysing drone images is time-intensive and cognitively demanding, making the interpretation of the camera footage prone to errors. Automating aspects of this analysis, e.g., the detection of humans, can help support FRs in their tasks and decision-making and possibly lead to an overall better understanding of the environment and reduce the time needed to provide aid to victims.

Past research focused on detecting objects like roofs, cars, debris, and vegetation from cameras in UAVs or helicopters (Pi et al., 2020) and also on detecting missing people in for example nature environments (Martinez-Alpiste et al., 2021). We aim to expand upon this by introducing more complex scenarios, like residential and industrial areas, with drones flying at varying heights, angles, and scales. For this, we created a custom dataset based on drone footage from the Dutch Safety Region *Rotterdam-Rijnmond*. This paper explores the use of a state-of-the-art object detection model for real-time long-range human detection in crisis scenarios. It should be noted that this explicitly differs from human identification, in which the goal is to exactly recognize individuals, and thus explicitly excludes surveillance. We only aim to locate humans present in the camera footage, and only during incidents. As such, the central question guiding this research is: *How can humans be located in drone camera footage in order to positively impact the decision-making of first responders?* As we are still in progress of investigating this question, our paper presents first steps and preliminary results.

WiP Paper – IT Solutions for Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

Identifying humans in drone data can benefit the decision-making process of FRs in different ways. First of all, locating and marking all humans present can help to determine whether humans require rescue or are located in potentially hazardous areas. Secondly, knowing the total number of humans present at a given moment can assist the FRs in addressing logistical challenges, such as determining the number of humans requiring evacuation or shelter. We analyse the preliminary findings together with an incident commander of the *Safety Region Rotterdam-Rijnmond*, to analyse the impact the current leading model can have on their decision-making process.

In this paper, we first explore some of the related background information and describe how we created and prepared our dataset, our model choice, and our evaluation methods. After this, we present our preliminary results, both the quantitative performance as well as qualitative results of an evaluation by an incident commander from the *Safety Region Rotterdam-Rijnmond*. Finally, we discuss our findings and describe future work.

BACKGROUND

In recent years, advancements in Computer Vision and Machine Learning have revolutionized the field of object detection (Zaidi et al., 2022), contributing to innovative solutions in various domains. Specifically, automatically detecting humans in images has been popular (Nguyen et al., 2016). Most of the time, this regards detecting humans from a short-range perspective at a relatively close distance (e.g., from CCTV footage or handheld mobile phone pictures). This is reflected by widely used datasets such as COCO (Lin et al., 2014), which contains many images of, amongst others, humans, from different angles, backgrounds, and poses. However, in these datasets, humans always make up a large part of the image by size. For our research, this is not the case, as humans in our footage take up a very small part of the images, meaning there are fewer pixels to describe the humans with, making their detection more difficult. There are also various long-range datasets. However, most of those do not contain humans (e.g., MOHR (Zhang et al., 2021) and DroneVehicle (Sun et al., 2022)). An example of a dataset that does allow long-range human detection is TinyPerson (Yu et al., 2020), which consists of helicopter footage, recorded above crowded beach scenes. Whilst the scale of the humans in the drone camera footage recorded by FRs resembles this dataset, the humans in the TinyPerson dataset are sometimes even smaller than the ones in our drone footage. In addition, the beach backgrounds in the TinyPerson dataset do not resemble ours, and they vary relatively little compared to the footage recorded by FRs.

Although these datasets have different characteristics compared to our dataset, we can still learn from these applications to inform our model choices. For example, Tang et al. (2023) trained a Faster R-CNN model along with several YOLO models on the TinyPerson dataset, achieving their best Average Precision of 9.5% with their modified version of YOLOv7. Additionally, YOLOv5 and Faster R–CNN have been trained and compared on drone footage recorded in nature backgrounds (Bachir & Memon, 2024), achieving mAP 0.5 scores of 96.9% and 91.0% respectively. Lastly, a skip-based Fully Convolutional Network (FCN) was trained on a set of long-range infrared images, resulting in an F1-Score of 98.93% (Haider et al., 2021). For this research, we analyse the performance of the YOLOv8 model, a leading model in the YOLO series.

DATA

In this paper, we train and evaluate our models on a custom-made dataset based on the drone footage of the *Safety Region Rotterdam-Rijnmond*. They have a historical record of some of the incidents where drones were used, going back to 2019. The footage is recorded in Full HD (1920 by 1080 pixels), 30 frames per second, by Zenmuse H20N cameras[1] on DJI Matrice 300 RTK drones[2]. The data contains a lot of variation, e.g., regarding light conditions (day and night), environmental background (e.g., industrial areas, rural, urban, indoor), and camera angles and distance (see Tables 1 and 2). For the creation of our dataset, we reduced the variation in the backgrounds by selecting exclusively daytime footage in industrial and residential areas, keeping only the video footage that was not zoomed in. From this, we only kept the 12 scenarios that contained humans and did not exclusively contain FRs. In the Methodology Section, we elaborate on the methods we used for preparing and labelling the footage from these scenarios to create a dataset. For examples of the selected footage, see Figure 1. In later stages of this research, we aim to incorporate more varied scenarios or train separate models for different situations.

METHODOLOGY

In this section, we go over the different steps we took to get to our preliminary results. Firstly, we elaborate on the methods used to prepare our custom dataset. Secondly, we explain our labelling process, after which we introduce our model choice. Lastly, we describe our evaluation set-up, where we differentiate between a quantitative and a qualitative evaluation.

Light condition	Frequency
day	104
night	53

Figure 1. Example images from the selected incidents, that cover a range of camera angles, backgrounds, and scales.

Data Preparation

In this section we explain the steps we took to go from the footage of the 12 selected incidents, as discussed in the Data Section, to an image dataset, containing 5,357 images. We also elaborate on the methods used to reduce this dataset into various representative and more balanced subsets.

The 12 incidents combined, contain a total of 87 videos with an average runtime of 7.5 minutes. We converted these videos into a set of images. We extracted the images at an interval of 150 frames (equivalent to 5 seconds) to mitigate redundancy, because the footage does not differ much from frame to frame, as the drones often move slowly or are stationary. This results in a total of 6,694 pictures. By filtering out the images without humans, 5,357 images were left (80.0%). We still noticed an overlap in some of the images, as well as an imbalance in the remaining data, as some incidents are over-represented by the number of images (due to different lengths of the original video footage).

In order to solve the imbalance problem, whilst simultaneously mitigating the perceived image overlap, we balanced the dataset by using a technique that reduces the entire dataset into a subset of x images. This needs to be done in such a way that the resulting subset is representative of the original dataset. A way to do this would be to not group the images by the scenario they stem from to create the reduced subset, but to cluster the data by using the backbone of a classification model, i.e., using a classification model to embed each image into a feature space, where all images that are similar as seen by the model will be close to each other. A classification model extracts certain features from an image, e.g., the relative frequency of green lines or the redness of the image, such that we can group the images on these features. A frequently used classification model is ResNet-50 (He et al., 2016). This model is pre-trained on the ImageNet 2012 classification dataset (Russakovsky et al., 2015), a dataset containing 1.28 million training images spread across 1000 classes, including animals, vehicles, common household objects, and more. The ResNet-50 backbone embeds each image into a 2,048 feature space. In this space, images that are close to each other are considered to be similar by ResNet-50. The classification step that follows the embedding is not needed, as the label does not help reduce the dataset.

Figure 2 is a visualisation of how all images with people were clustered, using t-distributed Stochastic Neighbour Embedding (t-SNE) (Van der Maaten & Hinton, 2008), which is a technique that reduces larger feature spaces into just two dimensions, trying to keep data points close together that are also close in the original space. It is clearly

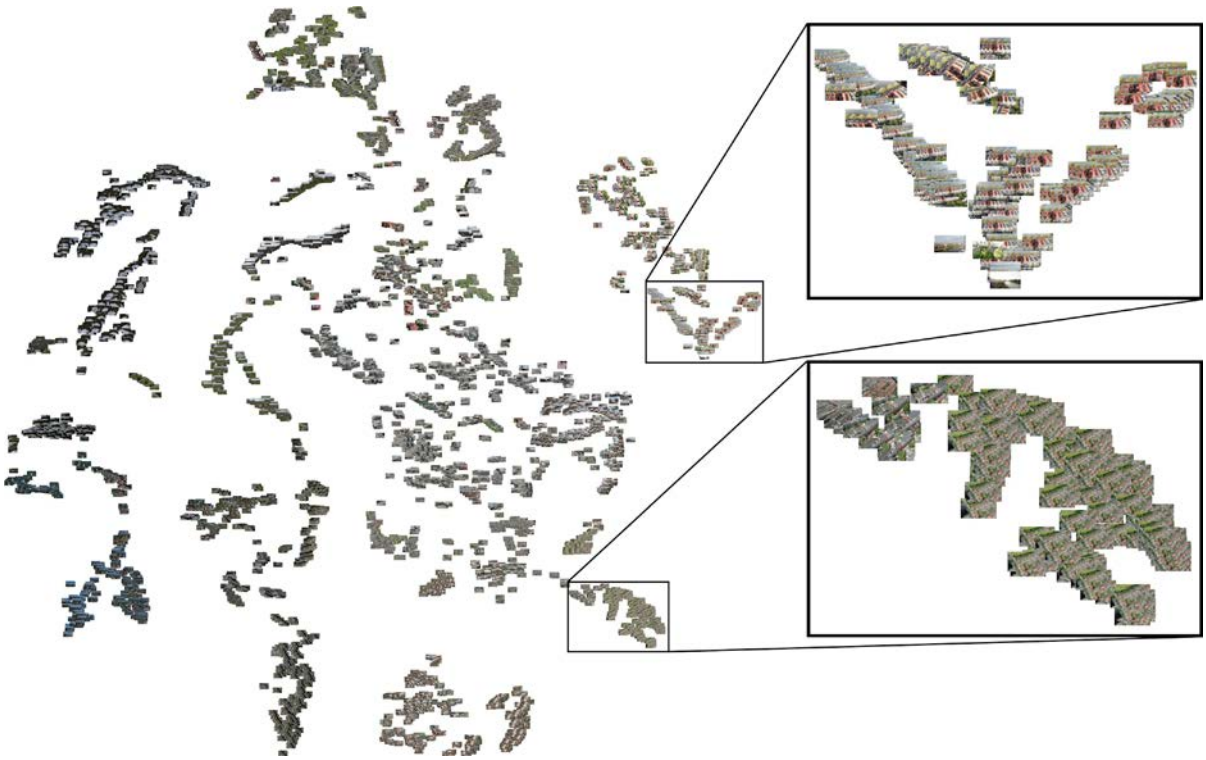

Figure 2. A t-SNE representation of the feature space, made by ResNet-50 on all the fire brigade's images that contain people.

visible in the zoomed-in regions of Figure 2 that the images with very similar structured content are close together and that the two regions are distinct from each other.

To generate a representative subset, the following heuristic was used. First, a random point was selected in the original feature space, after which the furthest possible point was selected as the second point. For this, the cosine similarity was used, to prevent the subset from primarily consisting of outliers. The third point is defined as the point that is the furthest possible point from both points, again using the cosine similarity. The next point is the furthest from all former points, and so on. Using this heuristic, multiple formations are repeatedly created, each with a different starting point. The formation that has the highest minimum cosine similarity will be kept. This is the formation that consists of the points that are the furthest possible from each other.

Using this technique, we created multiple subsets, decreasing in size, such that each subset is created from the closest bigger subset. This will make us able to easily increase the number of images in later stages of this research, knowing that the images we already prepared and labelled can be reused in bigger subsets. In Figure 3, a subset of 100 images, as selected from a subset of 200 images, is visualised in the entire feature space.

Data Labelling

For this paper, we have labelled a subset of 100 images. An example of a labelled image can be found in Figure 4. In the case of a crowd, we attempted to label every single human individually. We also labelled partially obstructed people, as they appear frequently and their detection might prove just as vital when it comes to detecting for example victims.

Model Choice

We trained the Machine Learning model YOLOv8[3] to detect humans in the fire brigade's footage. YOLOv8 is being regarded as state-of-the-art (Solawetz & Franchesco, 2023). Due to its multi-scale prediction method and anchor-free architecture (Jocher et al., 2024), it is specifically good at detecting small-scale objects, making it very applicable to the problem at hand. YOLOv8 is pre-trained on the COCO dataset (Lin et al., 2014). In this paper, we will fine-tune the pre-trained model.

[3] https://github.com/ultralytics/ultralytics

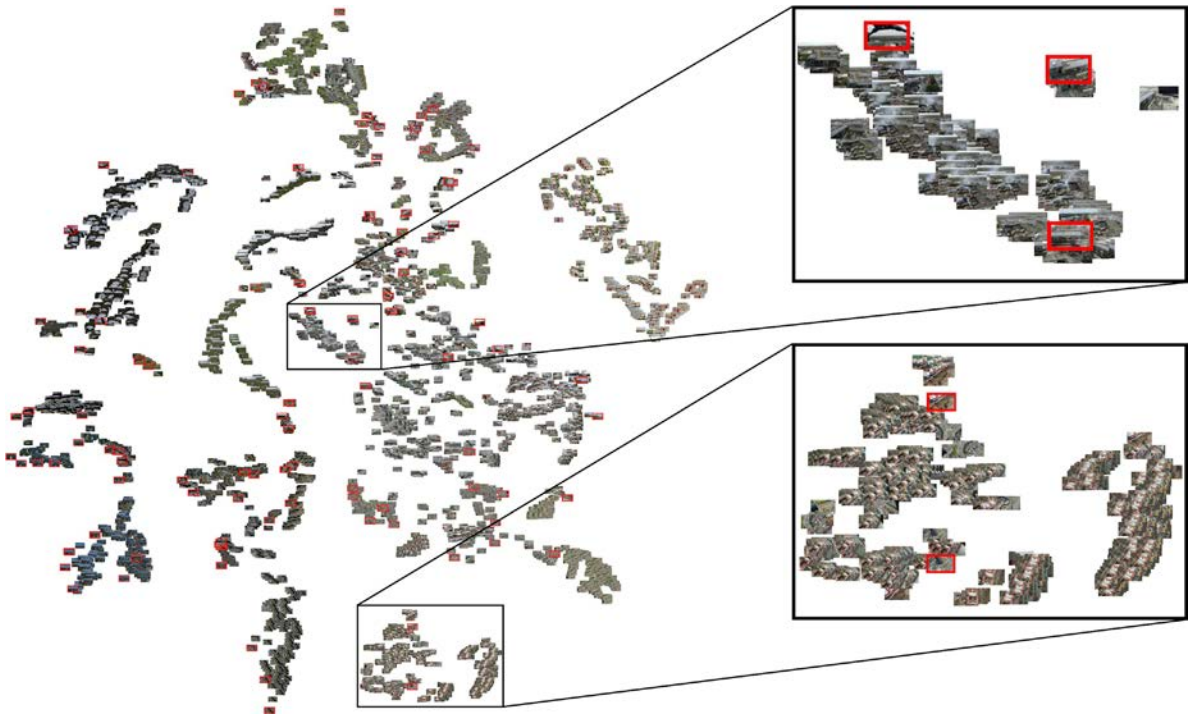

Figure 3. A t-SNE representation of the feature space, where the images with the red borders denote them as selected in the subset of 100.

Figure 4. An image with the labels overlaid. We zoomed in on some of the labelled humans.

Various versions of YOLOv8 are available, including *nano*, *small*, *medium*, *large*, and *extra large*, referring to the size of the model and its parameters. The larger the model, the more information it can store. A larger model has the capacity to learn more detailed representations of what a human is, but could also more easily overfit on smaller datasets. For our research, we decided to train these different versions and compared their results. We also explored the effects of different batch sizes, i.e., the number of images the model is exposed to before adjusting its weights. Larger batch sizes reduce the likelihood of the model overfitting the training data, but can negatively affect how long it takes the model to converge. In addition, we varied the input resolutions of the model, which have to be a multiple of the default 640 by 640 pixels, meaning we were only able to additionally analyse 1280 by 1280 pixels. The other parameters were left as default. The models' initial learning rates were 0.01. The stochastic gradient descent (SGD) optimization algorithm was used with a default momentum of 0.9 and attenuation coefficient of 0.0005. A constant seed of 42 was set for reproducibility purposes. The default mosaic augmentations were used. Each model was trained for 100 epochs, as we found this to be enough for all of the models to converge. The best scoring model, based on F1-Score, out of all these epochs was kept. Lastly, we randomly divided the 100 labelled images into a training, test, and validation set with a ratio of 8:1:1.

Evaluation Set-up

To evaluate our models, we use both quantitative and qualitative evaluation methods, which we describe in the following sections.

Quantitative Evaluation

To evaluate the performance of the model, we considered Precision, Recall, F1-Score, and mAP (Mean Average Precision). The precision and Recall of the model are calculated as follows:

$$Precision = \frac{TP}{TP + FP}, \qquad Recall = \frac{TP}{TP + FN},$$

where TP = True Positive, FP = False Positive, and FN = False Negative. Precision here quantifies the ratio of correctly predicted humans. Recall quantifies the proportion of actual humans that were correctly identified.

We combine recall and precision into an F1-Score to get a single score providing insight into both how often the model correctly identifies humans and how many humans it misses. A high F1-Score means the model is both accurate (with minimal False Positives) and thorough (with minimal False Negatives) in finding humans in images:

$$F1 = \frac{2 \cdot Precision \cdot Recall}{Precision + Recall}.$$

Since this score provides a balanced measurement of both False Positives and False Negatives, we primarily used this metric to intercompare models. For the best-performing model, based on the F1-Score, we will also analyse the exact number of True Positives, False Positives, and False Negatives, with the use of a confusion matrix. This gives us a more accurate and exact number to analyse if the best-performing model is business-acceptable or not.

Lastly, we used the mean Average Precision metric (mAP), which is commonly used in assessing the performance of object detection models. The Average Precision (AP) summarises the shape of the precision/recall curve, which shows how precision and recall change as we vary the threshold for what counts as a "correct" detection. The area under this curve gives us the average precision. This is done by taking the precision at each recall point and then averaging over all recall values. Mathematically, it's represented as:

$$AP = \sum_{r \in \text{recalls}} (r_i - r_{i-1}) \cdot p_i,$$

where r_i and r_{i-1} are consecutive recall values and p_i is the precision corresponding to the recall r_i.

The mAP is then computed as the average of AP over all classes:

$$mAP = \frac{1}{N} \sum_{k=1}^{N} AP_k,$$

where N is the number of classes and AP_k is the AP of class k. The mAP is a measure of accuracy for object detection models, typically assessed at various Intersection over Union (IoU) thresholds. IoU represents the percentage of overlap between the predicted bounding box and the ground truth bounding box:

$$IoU = \frac{A \cap B}{A \cup B},$$

where A is the actual bounding box and B is the bounding box as predicted by the model. For example, a mAP 0.5 score indicates the Mean Average Precision at an IoU threshold of 50%.

Qualitative Evaluation

Whilst these quantitative evaluation metrics enable us to intercompare models, they do not allow us to evaluate if any single model is business acceptable, i.e., can positively impact the decision-making of FRs. Relevant questions concern, for example, the potential effects of people being overlooked in the footage (False Negatives), people being marked multiple times, background objects being marked as people (False Positives), and the confidence values given for each detection. As a first step towards evaluating the model, we discussed the model results with an incident commander by presenting different scenarios with corresponding model output. The scenarios we presented differed in the number of humans that were present (e.g., a few humans or a crowd) and the setting of the incident (e.g., an industrial or residential area). The participant was asked to discuss the model output, including the impact on decisions, the desirability of different model behaviour, and other aspects relating to the understandability and usability of the model.

PRELIMINARY RESULTS

In this section, we describe the quantitative and qualitative preliminary results.

Quantitative Results

In this section, we present the preliminary results of the experiments we have run so far. We analyse the accuracy of all the different YOLOv8 models (i.e., *nano*, *small*, *medium*, *large*, and *extra large*) for a varying number of batch sizes and input resolutions. The training and testing was performed on a HP ZBook Studio 15.6 G8 laptop[4] with a Nvidia RTX A3000 GPU with 6GB of VRAM (Video Random-Access Memory). The relatively limited VRAM resulted in certain tests not being runnable, which explains why not every model is trained on every batch size.

640 by 640 resolution results

In order to analyse the effect different batch sizes have on the performance of the different models, we first ran them all with a 640 by 640 pixel input resolution, as we were not able to run larger batch sizes with higher input resolutions. This means that the images are scaled down, losing some detail in the progress. In return, we were able to train more model configurations. Due to potentially promising results, the YOLOV8s model on a batch size of 16 was trained on CPU.

In Table 3 we see that, judging by the F1-Scores, the two best-scoring models are YOLOv8s with a batch size of 12 and YOLOv8m with a batch size of 8. We do see a difference in Precision and Recall between the models. The YOLOv8s model seems to have a lower Precision score, but a higher Recall, which means that this model has more True Positives, at the cost of some extra False Positives.

1280 by 1280 resolution results

Due to our expectation that a higher input resolution would lead to better results, as there would be more pixels to describe the people with, we also tested the 1280 by 1280 input resolution. Not many of the tests would run on our hardware, which is why the larger batch sizes for the YOLOv8n model were trained on the CPU. In order to have a result for each model, we also introduced a batch size of 1. The 1280 by 1280 input resolution results in an overall higher performance compared to the 640 by 640 input resolution results (see Table 4). The YOLOv8n models show higher scores than the other models, with the batch size 16 model scoring the best in its F1-Score.

The validation set consists of 825 labelled people. This means that this is the worst possible False Negative score that can be reached, as well as the best possible True Positive score. In Table 5 we see that more than half (439/825) of the people are found. However, the model also marks 276 False Positives.

Qualitative Results

Based on the experimental results, for this evaluation, we used the output of the YOLOv8n model that was trained with an input resolution of 1280 by 1280 with a batch size of 16. During the discussions of the different scenarios and model outputs, the participant mentioned that it is important to differentiate between two aspects. First, the model can create False Positives, i.e., mark humans in the images where there are no humans (see examples in Figure 5). The participant mentioned that in general, False Positives should not be problematic, as having more False Positives probably also corresponds to having more True Positives and because it is better to find too many humans than too few, given that finding humans corresponds to the overall goal of the system. Also, the FR can

	12	**26.8**	**23.0**	**24.8**	**14.7**
	16	25.6	22.5	24.0	14.5
YOLOv8m	2	5.8	13.3	8.1	5.8
	4	37.0	18.4	24.6	16.3
	8	**34.6**	**19.3**	**24.8**	**16.4**
YOLOv8l	2	0	0	0	0
	4	7.9	13.1	9.8	6.6
YOLOv8x	2	7.1	3.6	4.8	1.9
	4	6.2	13.9	8.6	5.8

easily (visually) verify the result in the image. Second, the model can create False Negatives, i.e., not detecting humans in the image (see examples in Figure 6). The participant mentioned that this is more problematic, though it might not have a big impact if the humans are clearly visible. In any way, the participant mentioned that the model already provides output that is very helpful and would like to use it.

DISCUSSION

In this paper, we explored the use of state-of-the-art Object Detection models to detect people in long-range drone footage, to aid the decision-making process of FRs. We looked at the performance of different versions of the YOLOv8 model, for different batch sizes and input resolutions. Our best model (YOLOv8n with a batch size of 16 and an input resolution of 1280 by 1280 pixels) was able to detect 439/825 people in the test data, with 276 False Positives. This model had an F1-Score of 53.1%. An incident commander of the Dutch Fire Services feels confident, based on these preliminary results, that this model can aid the FRs' decision-making process for different use cases, such as locating people in the incident area faster and with less cognitive effort and aiding with decision-making regarding the deployment of teams and logistical efforts. The model can only be used to locate humans in the camera footage and cannot be used to identify (and monitor) individuals; furthermore, the model will only be used during incidents.

As a first start in this research, we reduced the variation in the drone footage and selected residential and industrial footage in daytime. In future iterations, we would like to expand the current model to include more different types of scenarios regarding environmental background and other light conditions. If this proves challenging, we alternatively will explore making specialized models for specific use cases or adding other sensor data, such as infrared.

Also, for now, we decided not to look at the effect of introducing images with no humans into the dataset. This may have caused the large number of False Positives of our model, as the model may have learned the number of people that should be present in each image. In the next steps, we will introduce different amounts of images without humans present to analyse the effect on the number of False Positives.

To create representative subsets of the selected dataset, we used a heuristic. Whilst we believe our approach to be grounded and methodical, we recognise that this approach has not yet been validated. It may also be the case that a different approach would result in a more applicable model. In the future, we will validate our approach and compare it to different techniques, using an already labelled dataset, to back up our claims.

Figure 5. Example predictions of the model. Each red box is a detected human, the number stands for the prediction certainty. We zoomed in on some False Positives (rooftop objects recognised as humans).

Figure 6. Example predictions of the model. Each red box is a detected human, the number stands for the prediction certainty. We zoomed in on some False Negatives (unfound humans by the model).

Table 4. Comparative results of the varied YOLOv8 models with different batch sizes for an input resolution of 1280 by 1280 (%). The best performing model, based on F1-Score, is highlighted in bold.

		Predicted Classes	
		Human	Background
Actual Classes	Human	439	386
	Background	276	-

In addition to selecting the data, we also labelled it. In the current stage of our research, we were only able to label 100 images. We recognise that this is not a lot. We expect the addition of extra labelled data to have a significantly positive impact on the accuracy of the models. We will continue to label data until we see diminishing returns and also explore the use of active learning to aid our labelling process. With this technique, an AI model decides which images should be next to be labelled. Another technique that we think could aid us in our labelling process is the use of semi-automated labelling. An Object Detection model like the one we built could provide the first iteration of labels, after which we would only need to correct the output. This could save a large amount of time spent on labelling images.

As mentioned above, we only had access to relatively limited VRAM to run our models and for that reason could not train every model on every batch size. Current efforts aim to access better hardware so that all of the models can be run to compare performances.

Moreover, for this research, we only analysed YOLOv8 models; we realize that other models might also perform well. In the future, we will explore different models, such as R-CNNs and Vision Transformers, and see whether these provide better alternatives.

Lastly, for this research, we were only able to speak with one incident commander, which means that our results might not accurately reflect the actual implications of our preliminary results. As next steps, we aim to expand upon this evaluation by interviewing multiple stakeholders from a variety of FR functions and by evaluating the use of the model in the field.

ABSTRACT

In the face of increasing frequency and severity of crises such as natural disasters, pandemics, and geopolitical conflicts, civil protection organizations are crucial for recovery and support for affected populations. However, the efficiency and effectiveness of these organizations in crisis response are often hindered by the manual generation of operation plans, characterized by cognitive overload and limited analytic overview. Existing systems focus on detecting crises or post-crisis analysis, overlooking proactive planning. We present GRETA, a graph-based operational planning approach utilizing semantic historical data for better decision support. GRETA uses Operational Scenario Patterns to model operations, mapping them onto a knowledge graph in JSON-LD format, thus creating a structured representation of past data to improve future crisis response planning. We tested GRETA with Germany's Federal Agency for Technical Relief, analyzing over 157,450 historic operations from 2012-2022. Results show GRETA enhances plan efficiency, accuracy, and comprehensiveness, aiding especially inexperienced planners.

Keywords

Operations Planning, Civil Protection, Decision Support Systems, Knowledge Graph, Operational Scenario Patterns

INTRODUCTION

In recent years crises like natural disasters, pandemics or political conflicts are becoming more frequent with critical impacts on people's private and public lives, finances, economy and politics, for instance the COVID-19 pandemic, the Turkey–Syria earthquakes in 2023 or the Russian Ukrainian war. In such crisis situations, civil protection organizations like the German Federal Agency for Technical Relief (THW), French Civil Protection, Corps of the Italian Civil Protection or the Austrian Red Cross restore order, rebuild affected areas and provide support for civilians and crisis victims (Chehade et al., 2018; Habib et al., 2018; Idris and Soh, 2014; Wrona et al., 2019). To ensure efficient and effective operations on-site, accurate and complete operation plans for task-driven allocation of

*corresponding author

resources and qualified personnel are needed as fast as possible (Idris and Soh, 2014). Currently, those operation plans are generated manually by experts including all related disadvantages of human cognitive overload under time pressure as well as limited analytic overview due to heterogeneous large-scale data (Correia et al., 2018). Up til now, data-driven decision support systems are not applied within operations planning of civil protection organizations in Germany.
This leads to an inefficient use of resources, delayed responses by civil protection organizations and, in the worst case, less saved lives (Ali, 2015; Idris and Soh, 2014).
Existing approaches on decision support systems for operations planning focus on early detection of crisis signals (e.g, Bompotas et al., 2022), post-crisis planning recommendations (e.g., Krstikj et al., 2021; Lindner et al., 2018; Rauchecker and Schryen, 2018), logistical topics such as optimized route planning for resource deployment (Lim et al., 2017), evacuation plans (Lee et al., 2017), or usage of robots and drones (Habib et al., 2018). Supporting the upfront planning process of operations is beyond the scope of these approaches. In our research, we investigate decision support systems for operations planning for upcoming crisis events.
In this work-in-progress paper, we present GRETA - a graph-based approach for operations planning based on semantically enhanced historical data. GRETA introduces Operational Scenario Patterns that extend existing approaches on representing crisis events (e.g., Janzen et al., 2023) with respect to domain knowledge about operations in civil protection. Those patterns are used for mapping and aggregating large-scale data on historical crisis operations onto a knowledge graph operationalized on JSON-LD. Framed as a kind of episodic knowledge representation of past operations, the resulting knowledge graph can be used in a decision support system to generate recommendations for operation plans for upcoming crisis events.
GRETA was instantiated and evaluated in a concrete use case with the civil protection organization THW addressing planning officers on regional and supraregional levels. The applied data set covered #157,450 historic THW operations within Germany (2012-2022), including details on crisis events with respect to location and type, requester and planner of operation, date, planned duration, report on tasks, number of helpers etc. Within the case study, we showed the potential of GRETA for supporting operations planning in civil protection in terms of required time (efficiency), accuracy and completeness of resulting plans (effectiveness) as well as the empowerment of less-experienced planning officers.

RELATED WORK

Related work on graph-based decision support in crisis management (Kontopoulos et al., 2018) focus on semantic representations of specific crisis domains, e.g., fire, hazard crises or earthquakes, but not on operations (Chehade et al., 2018; Gaur et al., 2019; Hassan and Chen-Burger, 2016). Existing ontologies in the crises domain like EMERGEL[1] and MOAC[2] are not available online. Other graph-based approaches focus on natural language processing for knowledge extraction from unstructured operation descriptions in the context of military operations Zhao et al., 2022. The generation of recommendations for upcoming operations with respect to required personnel, equipment, tasks, duration etc. is beyond the scope of those approaches; as well as the usage of structured and unstructured data in decision-making for improving operations planning and thereby resilience of civil protection organizations (Shittu et al., 2018).

GRAPH-BASED APPROACH FOR OPERATIONS PLANNING IN CIVIL PROTECTION

We present GRETA, a graph-based approach for operations planning in civil protection consisting of four main modules (cf. Fig. 1): **Mapper, Neo4j Inserter, Query Builder,** and **Recommender**. Core concept of GRETA are graph-based operational scenario patterns following Chehade et al., 2018; Gaur et al., 2019; Hassan and Chen-Burger, 2016; Janzen et al., 2023; Kontopoulos et al., 2018; Mescherin et al., 2013 (cf. Fig. 2). Fig. 3 shows all entities and attributes of the operational scenario pattern as well as applied concepts of foundational ontologies and the transfer to domain-specific items in the use case (THW data). As an **identifier** of an operation, an ID or the date of the operation is used. In addition to a description of the crisis event, the pattern covers a **context** entity for specifying the event type of the crisis (e.g., natural distasters) and the concrete event (e.g., flood) (cf. Fig. 2). As defined in Janzen et al., 2023, the operational scenario pattern includes a **provenance** entity for capturing the source of crisis information and operation request as well as an entity for the **location** of the operation. If an operation was part of a greater project, this information is represented within the precondition attribute in the **reason** entity (cf. Fig. 3). **Impact** of an operation is described by the attributes duration of the operation, post-conditions (e.g., final report of operation) and the severity of the operation. The **actors** entity covers information on the total amount of actors (helpers) of the operation, their conducted working hours as well as deployed units with their strengths, roles

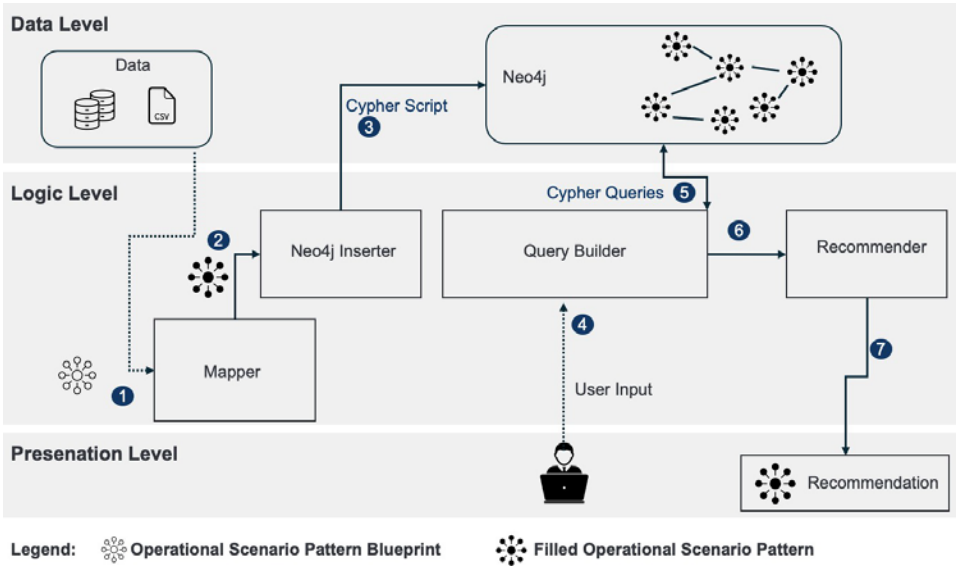

Figure 1. Graph-based Approach for Operations Planning in Civil Protection (GRETA)

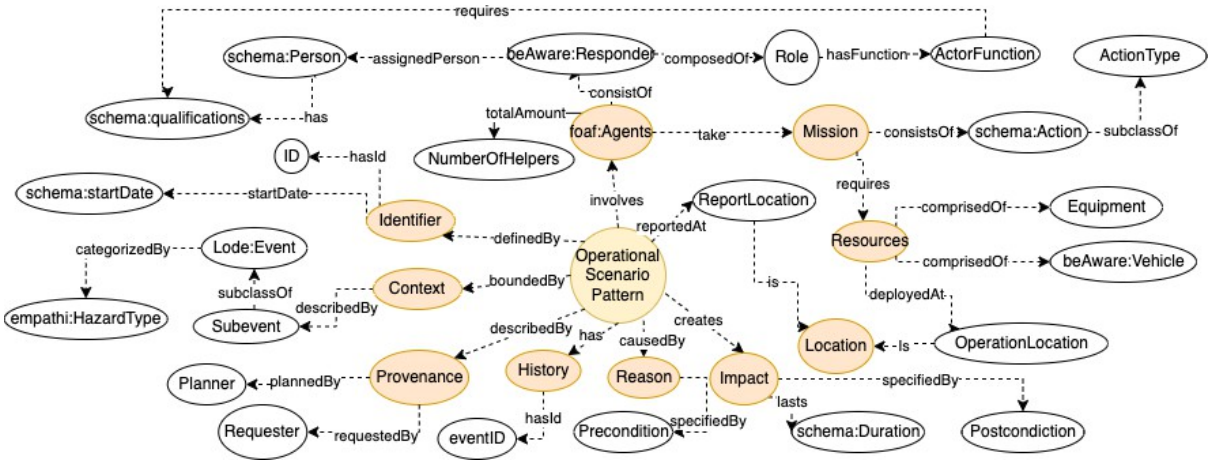

Figure 2. Graph-based view of Operational Scenario Pattern (Extract)

and assigned helpers per role (cf. Fig. 2). Furthermore, actions to be fulfilled in the operation are captured by the **missions** entity in form of action types as well as action sets per type. Vehicles required in operations are covered by the entity **resources**. Last, based on event type and location of the crisis (context), operational scenario patterns are interlinked by their identifiers within the **history** entity. All entities are anchored in and mapped onto existing vocabularies and ontologies (e.g. foaf[3], beAware[4], LODE[5], Empathi[6], DCAT[7], schema.org[8]) (cf. Fig. 3). GRETA applies the operational scenario pattern blueprint for mapping historic data on past operations on a knowledge graph with episodic operational knowledge (cf. Fig. 1). First, pre-processed data of historic operations in csv-format are mapped onto an operational scenario pattern blueprint in JSON-LD format by the Mapper component (cf. Fig. 1, step 1). Thereby, filled operational scenario pattern, means interlinked historic data are generated that are pushed to the Neo4j Inserter (cf. Fig. 1, step 2). By means of a cypher script the filled operational scenario patterns are inserted into Neo4j as knowledge base repository (cf. Fig. 1, step 3). Using JSON-LD as format has several advantages. First, the data entered into the knowledge graph can be easily expanded using other available data sets described by existing ontological standards. In addition, data of civil protection organizations such as the German Federal Agency for Technical Relief (THW) is currently only available in CSV format. However, CSV is not suitable

Figure 3. Operational Scenario Pattern

for mapping nested tree-like structures as presented by civil protection units. JSON-LD enables to keep important structural and semantic information between units, functions, their tasks to be performed and required qualifications that are transferred to the knowledge graph. This in turn enables further completion of meanwhile unconnected individual datasets through inferencing and a deeper analysis of the data records with regard to graph metrics, e.g. to recognize key personnel via the number of connected nodes and edges for certain events. The episodic representation of operational knowledge can then be requested using cypher queries by means of the Query Builder (cf. Fig. 1, step 4 and 5). To give an example, the following query extracts information on actors connected to a specified event: `MATCH (osp:OperationalScenarioPattern)-[:t_bounded_by]-(c:Context)-[:t_described_by]-(s:Subevent) WHERE s.name =~ "(?i).*$SUBEVENT_NAME.*") WITH sp MATCH (sp)-[:t_involves]-(i:Actors) RETURN distinct(i)`.The resulting output is processed by the Query Builder and aggregated to planning recommendations by the Recommender (cf. Fig. 1, step 6 and 7). Recommendations are structured according to a subset of operational scenario patterns; here the entities Actors and Impact are used to present results (cf. Fig. 4). GRETA was implemented as a web-based service using HTML, JavaScript, JSON-LD, Neo4j[9] [10].

USE CASE

We instantiated and evaluated GRETA in a concrete use case with the German Federal Agency for Technical Relief (THW) - an agency of the German Federal Ministry of Interior and Community. THW operations include for instance debris clearance, electricity supply, bridge building or logistics, serving the purpose of maintaining public structures and critical infrastructure. Currently, the operations planning process at THW is deployed manually by experts. Although, THW collects data on larger missions, data about included operations differ with respect to formats and details of fulfilled operation tasks etc. Up til now, available data are therefore of limited usefulness for planning experts when allocating tasks and personnel to upcoming operations. Furthermore, structured data on historic operations including allocated units and tasks are not accessible at all via the internal IT infrastructure. This information is embedded in heterogeneous, unstructured textual documentations that do not offer direct added value in the effective and efficient planning of operations under time pressure of an expected crisis event. Within the use case, a data set covering #157,450 historic THW operations within Germany (2012-2022) was used as input for GRETA, including details on crisis events with respect to location and type, requester and planner of operation, date, planned duration, report on tasks, number of helpers etc.

		135
	Responders	'Debris Clearance', 'Technical Unit Waterdamage/Pumping', 'Diving Group', 'Bridge Construction Group', 'Emergency supply and repair', 'Locating group', 'Technical Platoon'
Impact	Duration	0:10:32:08

Figure 4. Recommendation for operation plan for upcoming crisis event based on user input "flood" as *event type* and "secure operation site" as *action type*

Data Preparation

In order to enable the mapping of the historic operations data to operational scenarios patterns (cf. Fig. 2), the data set was prepared, i.e., we (1) collected, (2) cleaned, and (3) merged the data entries to generate a comprised data set.

(1) Collecting data: Initially, the data set included details on the crisis event such as location and type, the fulfilled operation, requester and planner, date, planned duration, a short report (description), number of deployed helpers, internal operation ID, provided service and assigned service project. For adding missing information on involved units and vehicles of the historic operations, an available tool developed by THW was used for extraction[11]. The extracted data covered details about tasks associated with over 40 units and details on 57 vehicle types. Additionally, 47 strength and equipment certification documents (StAN) were transformed into a structured data set for extending the data set with information on assigned roles and vehicles per unit.
(2) Cleaning data: The resulting data set was cleaned by deleting rows with missing features, merging operations with the same internal ID and correcting features with deviant formats and broken entries (e.g., dates, planned duration). As a result, the cleaned data set covered #31,118 operations.
(3) Merging data: In order to be able to inference on deployed units, tasks and vehicles per historic operation, collected data sets were merged using the BERT model (Reimers and Gurevych, 2019). Embeddings of operation descriptions and tasks associated with units as well as vehicles were generated. Furthermore, cosine similarity was used to establish a relationship between operations units based on unit's potential tasks and the tasks conducted within the operations. By testing diverse thresholds, we found an acceptable trade-off between the number of data entries and an accurate allocation of units per operation (confidence score: 60%). As a result, the integrated data set consisted of #15,274 historic operations.

THW Operations Planning Supported by GRETA

The pre-processed data set of #15,274 THW operations was mapped onto the operational scenario pattern blueprint in JSON-LD by the Mapper component of GRETA. Fig. 3 shows the mapping relations between entities of the pattern to THW data features. Resulting filled operational scenario patterns, i.e., historic THW operations are generated, pushed to the Neo4j Inserter and inserted into a knowledge graph (cf. Fig. 1). Giving an exemplary user request for planning an operation of the *event type:"flood"* and the *action type:"secure operation site"*, this input is translated into a cypher query by means of the Query Builder. The resulting output covers #306 relevant historic operations that are processed by the Query Builder, e.g., for inferencing the appropriate number of helpers, planned duration for the operation to be planned based on the historic data. The extracted data are aggregated to an operations plan recommendation based on the structure of the operations scenario pattern by the Recommender component, i.e., the entities actors and impact are used to present recommendation results (cf. Fig. 4). Given the exemplary user input, GRETA recommended to staff the planned operation with 12 helpers with 135 hours potential working time based on an expected operation duration of 10 hours and 32 minutes. Furthermore, units are listed that are required for conducting the operation, e.g., debris clearance, and bridge construction group (cf. Fig. 4). Generated results are represented within a first prototypical service, that is available as open source code on Github[12]. The user interface comprises four tabs (cf. Fig. 5). Two tabs are used to describe the service and applied Operational Scenario Patterns (1) Introduction & Data, (2) Background Information, while the remaining two tabs serve as the main functionalities of the service (3) Event Prediction, (4) Recommendations. Based on the amount of data per individual crisis event, that was available to train our predictive machine learning forecasting model, the event prediction focuses on weather-based events, in particular floods, heavy rainfall and snowfall within Germany.

Figure 5. Overview of the user interface for the implemented web service of GRETA

After selecting the desired location, the user receives information on the occurrence (red dots) of predicted events for the next 7 days, as well as a risk assessment for the forecast via the confidence of the forecasting model and a threshold value (orange line). In addition, a map-based area overview provides topographical information and current weather information on selected locations. Planning recommendations are generated for the selected location and predicted crisis events and an additionally selected task category. The recommendations include a classification of the event, contextual information on similar past incidents, recommendations for action, personnel recommendations and resource recommendations per unit. A demo of the service is also available on Youtube [13]. Within the case study, we showed the potential of GRETA for supporting operations planning in civil protection in terms of required time (efficiency), accuracy and completeness of resulting plans (effectiveness) as well as the empowerment of less-experienced planning officers. In contrast to actual dispersed data and isolated documents at THW, operational scenario patterns supports structuring available data of past operations by means of a linked data approach (JSON-LD) and improves the accessibility of existing operational knowledge. Furthermore, GRETA offers the opportunity to interlink operational knowledge by diverse civil protection organization by applying operational scenario patterns on their data enabling a cross-organizational operational knowledge space for more efficient collaboration in operations planning and conduction.

LIMITATIONS AND FUTURE WORK

While GRETA demonstrates promising results in enhancing operations planning for civil protection organizations, there are also several limitations. The effectiveness of GRETA heavily relies on the quality and completeness of historical data. Incomplete or inaccurate data may lead to suboptimal recommendations. Future work should focus on improving the data collection methods and ensuring data accuracy to enhance the reliability of GRETA (cf. section on data preparation for the use case). The scalability of GRETA in handling larger datasets and diverse crisis scenarios needs further investigation. As the volume and complexity of crisis events increase, the scalability of GRETA's knowledge graph construction and recommendation generation processes may become a bottleneck. Future research should explore strategies for optimizing GRETA's performance on larger datasets also with respect to cross-organizational operation planning based on shared data on historic operations.

While GRETA utilizes operational scenario patterns to represent domain knowledge, there may still be nuances specific to civil protection operations that are currently not adequately captured. Enhancing the domain-specific knowledge representation within GRETA could lead to more accurate and tailored recommendations for operations planning. Those aspects will be investigated in an empirical user study with the resulting prototype with experienced planning officers by THW. In this study also the usability and adoption of GRETA by planning officers will be evaluated in real-world settings as those are crucial factors for its practical utility.

Furthermore, GRETA primarily relies on historic data for generating operation plans. Integrating real-time data streams, such as weather data, social media feeds or sensor data (e.g., water level of rivers), could further enhance GRETA's capabilities by providing up-to-date information on unfolding crisis events and potentially required operations. Future research will explore methods for integrating real-time data and generate predictions for potential crisis events by applying machine learning methods (e.g., XGBoost) into the decision support system based on GRETA.

[13] https://www.youtube.com/watch?v=ohWVGATnjZM&t=1s

CONCLUSION

In this paper, we introduced GRETA, a graph-based approach for enhancing operations planning in civil protection organizations. By leveraging semantically enhanced historic data and operational scenario patterns with linked data, GRETA provides decision support for generating operation plans for upcoming crisis events. Through a case study with the German Federal Agency for Technical Relief (THW), we demonstrated the potential of GRETA in improving the efficiency, accuracy, and completeness of operation plans, while empowering especially less-experienced planning officers.

ABSTRACT:

Is running the Propagation of Local Undamped Motion (PLUM) algorithm in a community-engaged earthquake early warning (EEW) network feasible, and can it function effectively at the node level without centralised processing units? This study investigates the practicality of deploying the PLUM algorithm within a node-level architecture, shifting away from traditional centralised seismic data processing methods. The study uses cost-effective MEMS-based seismographs to decentralise EEW. The preliminary phase of the research included the deployment of sensors and the establishment of a two-tiered Primary-Secondary node structure for node-level intensity prediction and alert generation, with the sensors functioning as independent prediction points. Future work includes threshold calibration for optimal alert issuance, and network expansion to reduce blind spots. This work-in-progress paper discusses progress towards a scalable, efficient EEW system that could serve as a replicable model for earthquake-prone regions globally, aiming for operational readiness that empowers communities against the threat of earthquakes.

Keywords

Earthquake Early Warning (EEW), Node-Level Processing, PLUM Algorithm, Citizen Seismology, Low-cost sensors

INTRODUCTION

Earthquake Early Warning System (EEWS) has been recognised as a vital advancement towards mitigating the impacts of seismic events (Allen & Melgar, 2019; Chandrakumar et al., 2022). The evolution of EEWS has been propelled by technological advancements and research breakthroughs, resulting in the implementation of systems across various regions and countries (Chandrakumar et al., 2022; Cremen & Galasso, 2020; McBride et al., 2022). These systems are designed to provide advanced alerts, enabling individuals and authorities to take preventive measures to safeguard lives and infrastructure. The effectiveness of EEWS in reducing damages and injuries associated with seismic activities has been well documented globally (e.g., Fujinawa & Noda, 2013; Nakayachi et al., 2019; Suárez et al., 2009).

Despite the pronounced seismic hazard in Aotearoa New Zealand (NZ), the country lacks an official national EEWS, a critical gap in preparedness underscored by Becker et al. in their 2020 study. The country relies predominantly on the GeoNet programme, managed by GNS Science, for rapid earthquake information. GeoNet provides earthquake source parameters and ground-shaking data through a website and mobile app but lacks dedicated Earthquake Early Warning (EEW) capabilities (GeoNet, 2017).

The absence of an official EEWS in NZ is primarily due to various technical and non-technical challenges, with the high cost of advanced systems representing a considerable obstacle (Brooks et al., 2021; Prasanna et al., 2022). For cost-effective earthquake preparedness solutions, there has been a marked global trend towards adopting low-cost alternatives. Micro-electromechanical systems (MEMS) based ground motion sensors have gained prominence among these. Demonstrating a successful track record in seismic applications since the early 1990s, MEMS-based ground motion sensors have been effectively integrated into EEWS in various regions, facilitating real-time public alerting systems (Anthony et al., 2019; Holland, 2003).

In pursuing a cost-effective EEWS in NZ, Prasanna et al. (2022) have initiated and deployed an experimental, community-engaged network in the Greater Wellington region. As depicted in Figure 1, this innovative system leverages Raspberry Shake 4D (RS4D) seismographs equipped with MEMS-based accelerometers, signifying a pivotal development in earthquake detection and alert technology. This network adopts a node-level processing approach to analyse and process ground motion data, diverging from the centralised processing approaches predominant in established EEWS globally. The experimental network uses the propagation of local undamped motion (PLUM) algorithm (Kodera et al., 2018) for its EEW capabilities, optimised for low-cost sensors with limited computational resources, to facilitate this node-level processing.

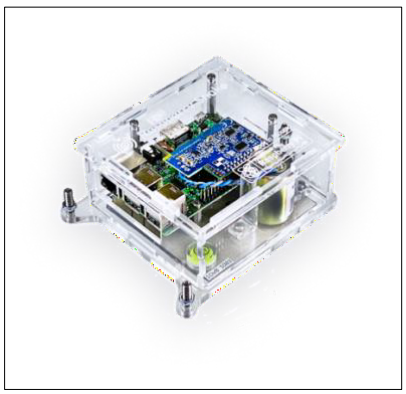

Figure 1: The RS4D Seismograph.

The effectiveness of node-level processing has been compared to conventional centralised approaches. This assessment was conducted by applying the PLUM algorithm to a selected array of sensors within a simulated environment (Prasanna et al., 2022). Chandrakumar et al. (2023) have also validated this approach's earthquake detection capabilities within a community-engaged network, focusing on a particular earthquake event. This work-in-progress paper builds on past research and addresses the ongoing progression and practical application of the PLUM algorithm within a real-life operational context, including adaptation processes of the original PLUM algorithm for node-level processing.

The article is structured as follows: The Background section outlines the node-level processing architecture and PLUM algorithm. The Work-in-Progress section details the ongoing adaptation of the PLUM algorithm to a node-level processing architecture within the community-engaged EEWS. Finally, the Discussion section presents the insights from the preliminary findings, outlines future research work, and concludes by highlighting the importance and potential impact of this research.

BACKGROUND

Node-Level Processing Architecture

Two principal methodologies dominate the landscape in data processing: centralised and node-level processing (Xi, 2020). Centralised processing gathers data from diverse sources into a unified, centralised facility undergoing analysis and processing. Conversely, node-level processing adopts a decentralised approach, wherein individual nodes or sensors independently execute data analysis and processing tasks (Santamaria et al., 2019). This distinction primarily revolves around allocating computational responsibilities; centralised systems centralise data processing in a singular hub, whereas node-level systems distribute these tasks across each node within the

network, potentially augmenting the system's responsiveness and robustness against widespread failures.

Most EEWS operates on a centralised model, where a central facility receives and processes seismic data. While this centralised approach offers superior control and consistency in data handling, it is susceptible to critical delays and communication failures, particularly when major seismic events compromise infrastructure (Prasanna et al., 2022).

Recent technological advances have led to the enhancement of low-cost, MEMS-based sensors with in-built processing capabilities. These advancements enable data processing directly at the sensor nodes, allowing a transition from centralised to node-level processing (Chandrakumar et al., 2022). Node-level processing empowers the system to analyse seismic information and issue alerts where the data is collected, utilising the built-in computational power of the sensors. Aside from Prasanna et al.' (2022) publication on community-engaged EEW network, there is minimal documentation of node-level processing for EEW.

The shift toward node-level processing is motivated by multiple benefits. It reduces the time to issue alerts by removing the necessity for data to travel to a central server, allowing the system to provide a longer warning window for the end users. It also strengthens the resilience of the EEWS against central system failures caused by earthquakes. Furthermore, processing at the node level can decrease the operational costs associated with the upkeep of sophisticated central processing systems (Fischer et al., 2012; Prasanna et al., 2022).

The PLUM Algorithm

Over the past three decades, significant advancements have been made in EEWSs (Chen et al., 2015; Clinton et al., 2016). These advancements have primarily focused on network-based[1] approaches, utilising source-based[2] models to estimate earthquake parameters like hypocentre locations and magnitudes (Kuyuk et al., 2014; Satriano et al., 2011). Traditional EEW systems analyse seismic data, including P-wave onsets and maximum displacement amplitudes (Meier et al., 2015; Noda et al., 2016). However, the accuracy of these predictions heavily depends on the precision of the estimated parameters, which poses challenges, particularly during complex seismic events like large magnitude earthquakes and simultaneous aftershocks (Hoshiba, 2013; Hoshiba et al., 2011).

Recognising these limitations, Kodera et al. (2018) introduced an alternative approach known as the PLUM method. Based on Hoshiba (2013) work, this method offers a more direct ground motion estimation approach, emphasising cost-effectiveness and ease of implementation.

The PLUM algorithm operates by forecasting seismic intensity using real-time ground motion data. Its operation involves collecting pseudo-seismic intensities from observation stations within a predefined radius around a target station. The forecasted seismic intensity is then determined based on the highest value among these real-time observations. This method assumes that ground motion, responsible for significant seismic intensity, travels within the specified radius without notable attenuation. Figure 2 illustrates the PLUM algorithm's operation, demonstrating the intensity prediction at a prediction point using intensity data from surrounding observation stations.

[1] A network-based approach in EEWS involves deploying a network of sensors across various locations within a geographical area. Earthquake detection is achieved by collectively processing the data gathered from this interconnected sensor network.

[2] Source-based EEWS models are designed to detect earthquakes and alert stakeholders, providing detailed information about the seismic event.

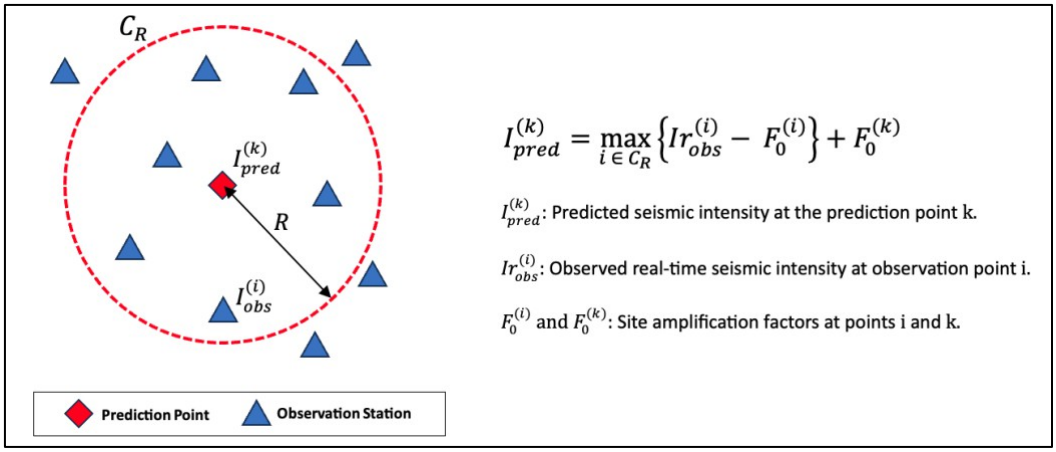

Figure 2: Illustration of the PLUM Algorithm's Operation, Demonstrating Intensity Prediction at a Target Station Based on Observations from Peripheral Stations (Adapted from Kodera, 2018).

A key component in the operation of the PLUM method is monitoring the observed intensity at each observation station. The PLUM method triggers an EEW alert when the real-time ground motion predictions from two or more monitoring stations exceed a specified threshold. This alert is generated explicitly for the region surrounding the target station, ensuring timely warning dissemination.

The PLUM method's distinct advantage lies in its ability to continuously monitor ground motion distribution in real-time, addressing the overprediction issues and false alarms prevalent in traditional ground-motion-based systems. This was particularly evident following the Mw 9.0 Tohoku earthquake, where PLUM issued more reliable early warnings (Hoshiba, 2021). Further validation with the 2016 Kumamoto earthquake data reinforced PLUM's superiority, consistently providing earlier warnings and effectively reducing blind zones (Kodera et al., 2016).

Moreover, the PLUM method has shown resilience in handling multiple simultaneous earthquakes and predicting strong motion by monitoring real-time seismic intensities. This capability sidesteps technical issues associated with source-based models and suggests a potential for further improvements with denser seismic networks, including low-cost sensors (Kodera et al., 2016).

Despite its advantages, the PLUM method has limitations. Its effectiveness is contingent upon a dense observational network, as it is limited by the short prediction radius and site amplification factors that significantly influence seismic ground motion (Kodera et al., 2016). Additionally, the PLUM algorithm tends to provide shorter warning durations than source-based methods. While it excels in predicting ground motion in complex seismic scenarios, the maximum warning time it offers is limited by the radius of observation.

WORK IN PROGRESS

This section highlights the work-in-progress of this study's implementation of an EEWS with node-level processing for the PLUM algorithm.

Installation of Seismic Sensors and Validation of Ground Motion Data

The initial phase of seismic sensor installation was carried out in 2020 and 2021, utilising MEMS-based RS4D sensors for their affordability, accuracy, and processing power, aligning with the objectives of a community-engaged EEWS (Prasanna et al., 2022). Community participants were recruited to host these ground motion sensors within their households. An workshop was conducted to gain insights into user perspectives and to develop strategies for distributing sensors to the general public, promoting a citizen seismology approach (Tan et al., 2021).

Following that, the network expansion in 2023 aimed to increase sensor density, leveraging social media campaigns to gather community interest in hosting additional RS4D sensors. The campaign resulted in 80 expressions of interest, informing the strategic selection of sensor locations through geographical data analysis. By mapping the geographical spread of these responses, 25 locations were identified from the pool to install additional sensors. This expansion strategy aligns with insights from a recent study, which explores the necessity of a comprehensive approach to developing a community-engaged EEWS for NZ, addressing the technological, societal, and cultural challenges (Tan et al., 2023). The criteria for site selection encompassed algorithm coverage, seismic activity, proximity to fault lines, population density, and other technical and environmental considerations. This careful selection has contributed to a network comprising approximately 60 ground motion

sensors across NZ, with a significant concentration of around 45 sensors within the Greater Wellington area.

The performance of the community-engaged EEW network was evaluated through a dedicated study focusing on P-wave detection capabilities utilising the collected ground motion data (Chandrakumar et al., 2023). This evaluation centred on data obtained within 48 hours surrounding a magnitude 5.8 earthquake on 22 September 2022. The analysis involved a detailed assessment of recorded seismic data by the stations, specifically focusing on identifying any false detections or missed detections of seismic events within the dataset. The findings from this investigation underscore the effectiveness of a citizen seismology-based EEWS in identifying seismic occurrences relevant to early warning objectives.

These results affirm the operational capability of the newly implemented network, demonstrating its potential to contribute meaningfully to earthquake early warning efforts.

Adaptation of PLUM for Node-Level Architecture

Reason for Choosing PLUM for Node-level Processing.

In developing the node-level architecture for EEWS, the crucial task was to select an algorithm that conforms to the computational limits of the RS4D sensor nodes. These nodes are limited by their processing capabilities, necessitating an EEW algorithm that is both lightweight and effective. Through benchmarking existing EEW algorithms, the PLUM algorithm stood out as the optimal solution with its robustness, lightweight design, and ease of implementation (Prasanna et al., 2022). Its successful deployment in Japan's EEWS and validation across various global contexts affirm its appropriateness (Kodera et al., 2018). With its proven effectiveness with EEWSs worldwide, the PLUM algorithm was chosen for node-level operation for this study.

Processing Method of the Original PLUM Algorithm

The PLUM method predicts seismic intensities at designated prediction points, distributed across various areas based on seismic risk. For each area, the predicted seismic intensity is computed as the highest forecasted value among all its prediction points. This computation involves selecting the maximum observed real-time seismic intensity within a radius R from each prediction point, incorporating site effect corrections with a continuous one-second update interval (Kodera et al., 2018).

Real-time ground motion data processing in PLUM is centralised; observation stations transmit their data to a central unit, which issues intensity predictions to the target sites. This system has pre-programmed prediction points and corresponding observation stations for streamlined processing (Kodera et al., 2018). However, the adaptation to node-level processing necessitates a fundamental reconfiguration. In this architecture, each sensor node assumes the role of processing, effectively rejecting the need for a centralised processing unit. This shift ensures that the PLUM algorithm's calculations are conducted within the individual sensor nodes, thus fully embracing the decentralised nature of node-level architecture.

Defining Prediction Points for Node-level Architecture

The next objective focused on enabling the functionality of the PLUM algorithm at the node level. Defining prediction points is a foundational step in the methodology for adapting the PLUM algorithm to node-level architecture. The current implemented EEW network is depicted in Figure 3. In the original implementation of the PLUM method, authorities selected prediction points based on regional seismic activity to disseminate alerts to those areas (Kodera et al., 2018). These regions had various prediction points, reflecting the seismic activities observed.

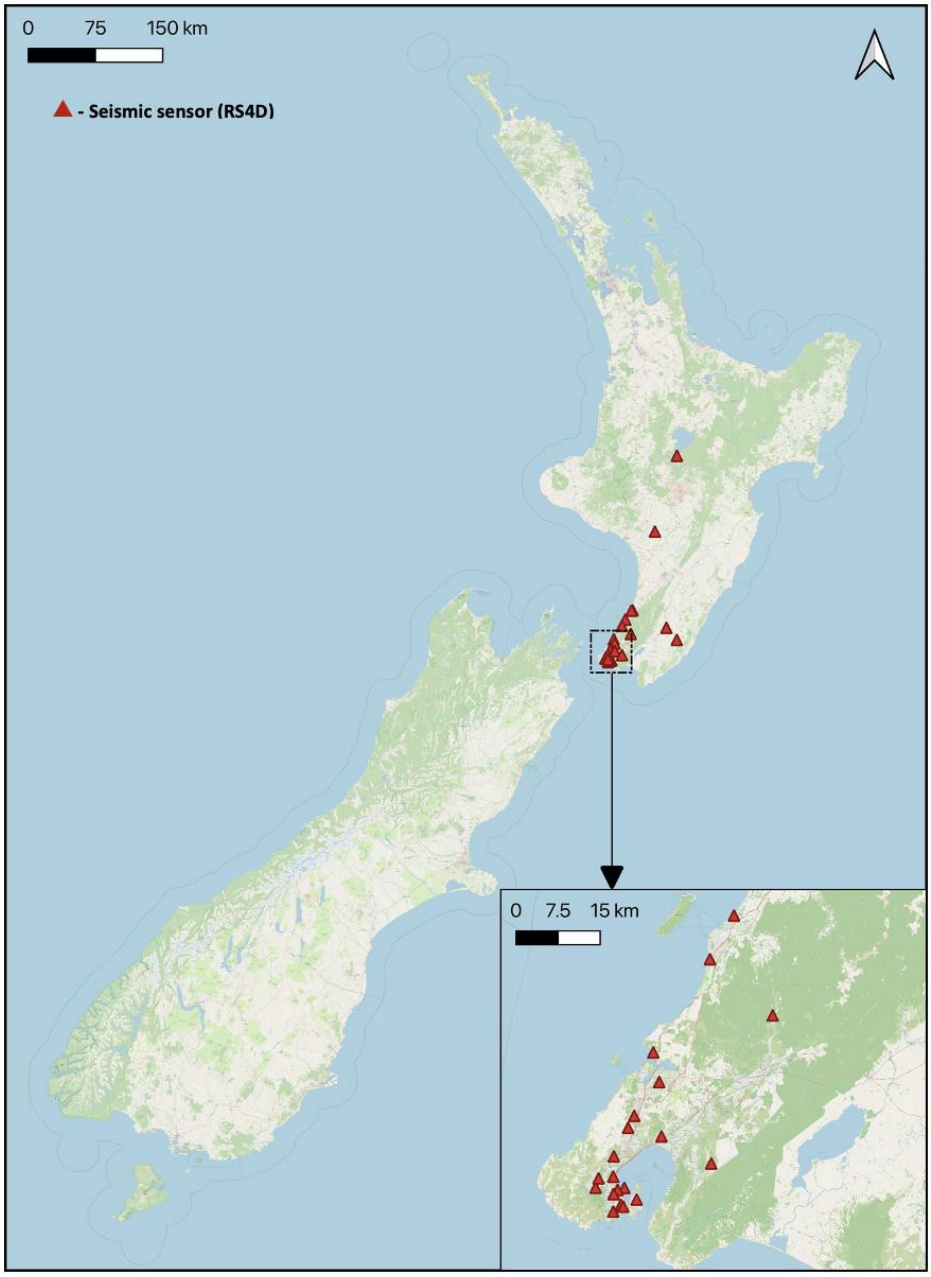

Figure 3: Overview of the EEW Network Deployed by the CRISiSLab Team.

Compared to the original PLUM implementation, our approach differs by designating the sensors as prediction points. Figure 4 presents four different prediction points as an example; each sensor marked in red represents a prediction point with a 30 km prediction radius consistent with the original PLUM specifications. Sensors within this radius serve as observation stations around the prediction point and are responsible for predicting the seismic intensity at the prediction point. Currently, our focus is not on issuing EEW alerts for broader regions but on generating alerts specifically for the prediction point - the RS4D sensor. This strategy is rooted in the concept of a community-engaged EEW network, ensuring that each sensor host receives EEW alerts directly through their installed RS4D sensor. However, it is essential to note that, in future, the network has the potential to be augmented with additional passive nodes. These nodes would also function as prediction points but receive alerts without estimating the intensity, enhancing the system's reach and effectiveness.

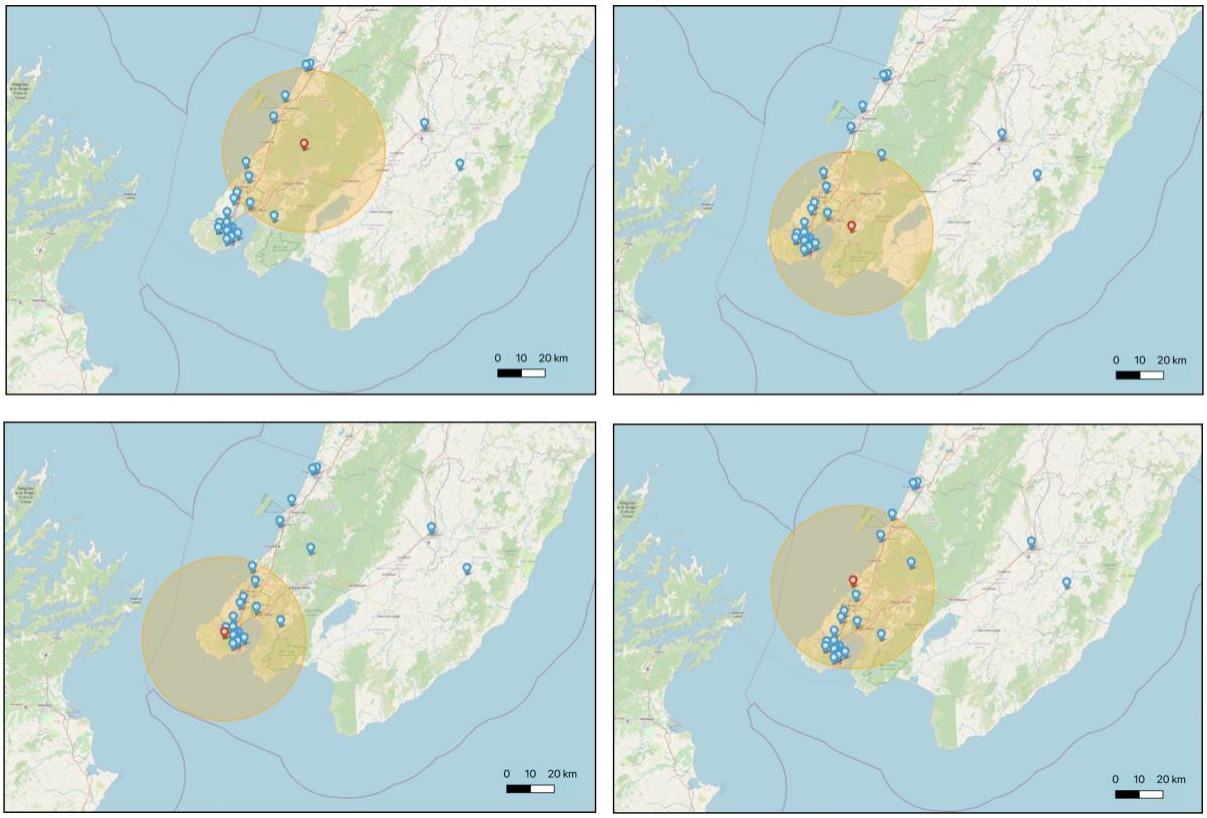

Figure 4: Illustration of Four Prediction Points with 30 km Prediction Radii, Highlighting Sensors in Red as Designated Prediction Points.

Implementing Node-Level Processing in the EEWS

Upon designating prediction points within the EEWS, the node-level implementation of the PLUM algorithm was initiated, establishing a dual-tiered structure of RS4D sensors: Primary and Secondary. Each prediction point, with a 30 km radius, is approached as a distinct scenario where one RS4D sensor is appointed as the Primary sensor, entrusted with two key functionalities: **intensity prediction** and **alert generation** for its specific prediction site. Concurrently, the surrounding sensors, classified as Secondary sensors within the same radius, are tasked with transmitting real-time intensity data to the Primary sensor for analysis. It is essential to highlight that a single sensor may serve multiple roles, acting as a Primary sensor for one prediction point while simultaneously functioning as a Secondary sensor for another, especially in areas where prediction radii overlap. The selection of a Primary sensor is strategically based on its current processing load, favouring sensors with minimal existing commitments to other prediction points. This strategic allocation and distribution of processing responsibilities ensure the efficiency and effectiveness of the node-level processing within our EEWS. Figure 5 illustrates how node-level processing utilises the PLUM algorithm, showcasing a prediction radius (Orange circle) scenario and the prediction point (Red icon), Primary (Purple icon) and Secondary stations (Blue icons).

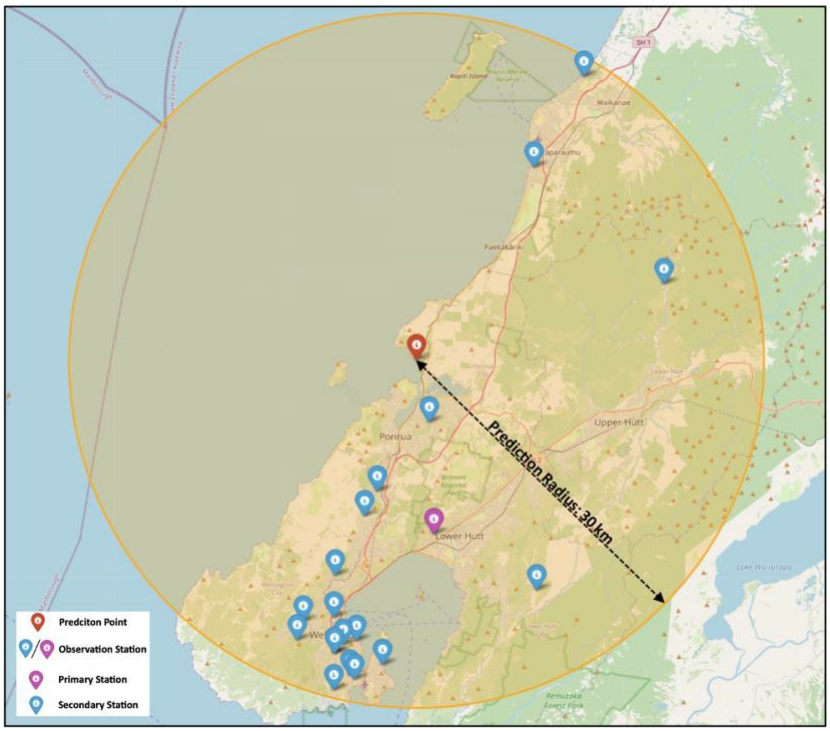

Figure 5: An Illustration of the PLUM Algorithm Adopted for Node-level processing, Featuring a Prediction Point, Primary Station, and Secondary Stations within a Specified Prediction Radius.

To address the potential failure of a Primary sensor, our system allocates at least three sensors to the Primary sensor role - one serves as the active Primary sensor, while the other two are on standby as backups. These backups also function as Secondary sensors, springing into action as the Primary sensor should the main one fail. This redundancy is crucial for maintaining continuous and uninterrupted seismic intensity predictions at each prediction point.

In contrast to the original PLUM methodology, which requires that all observation stations within the prediction radius update their real-time intensity to a centralised processing unit each second, our approach modifies the interaction between Secondary and Primary sensors. In our system, Secondary sensors independently process initial data, forwarding intensity updates to the Primary sensor only upon surpassing an internal threshold. Each sensor within our network is programmed to estimate real-time intensity, including Peak Ground Acceleration (PGA), Peak Ground Velocity (PGV), and Peak Ground Displacement (PGD) on a second-by-second basis, assessing whether the PGA exceeds a specified internal threshold.

The Primary sensor undertakes the task of predicting the intensity at the prediction point solely under two conditions: if its internal threshold is exceeded or if it receives an intensity update from any Secondary sensor within the prediction radius that has surpassed the internal threshold. Secondary sensors are programmed to transmit real-time intensity data (PGA, PGV, and PGD) to the Primary sensor only after crossing this pre-determined internal threshold; the specifics of determining the internal threshold are detailed in a separate subsection. This strategic introduction of an internal threshold diverges from the original PLUM's approach by aiming to minimise the processing load on the Primary sensor. By reducing the influx of data packets during PLUM operation, this internal threshold mechanism ensures the Primary sensor maintains optimal performance, marking a significant adaptation in our node-level implementation to streamline processing and enhance efficiency. Figures 6 illustrates the overall working flow of Primary sensor in terms of predicting the intensity to a given prediction point according to our PLUM approach adopted for node-level processing. The comprehensive operation of the Primary sensor's alert generation is detailed in the next section.

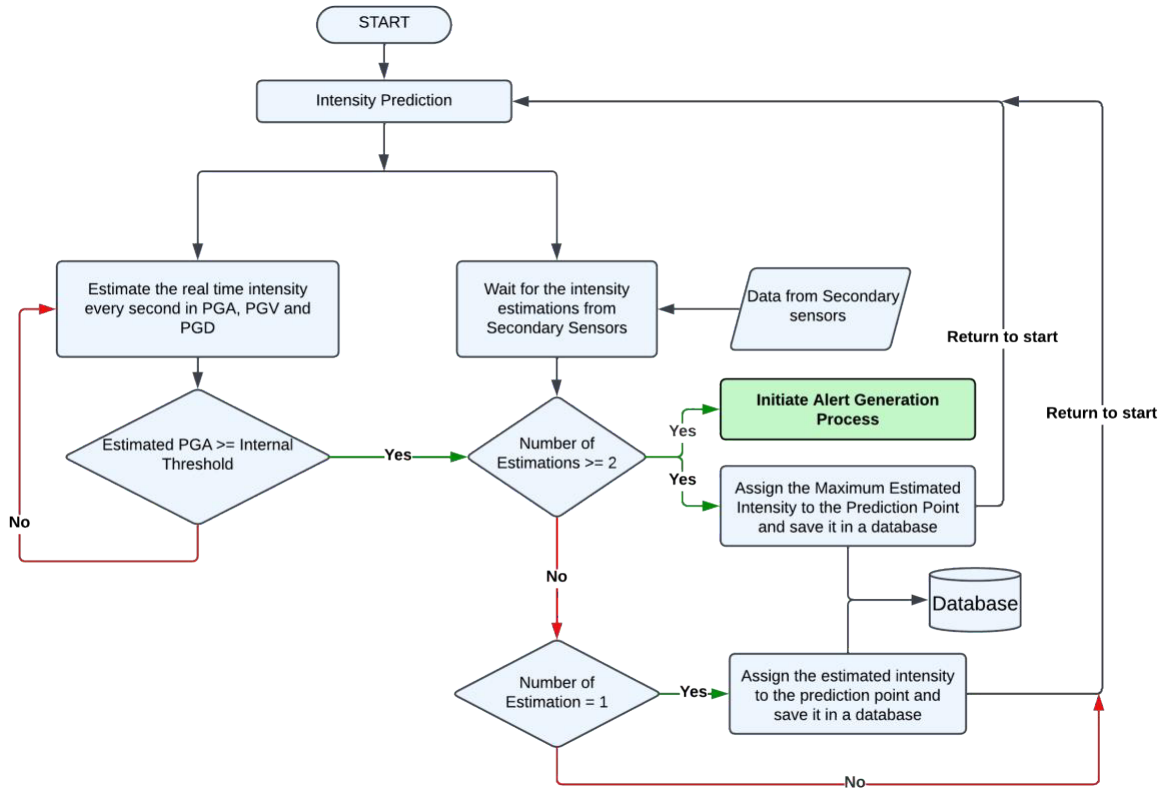

Figure 6: Flow Chart Explains the Intensity Prediction Flow of the Primary Sensor for the Assigned Prediction Point.

Defining the Internal Threshold for Secondary-Primary Communication

An internal threshold mechanism has been introduced to streamline communication between Secondary and Primary sensors, thereby reducing the processing load on the Primary sensor. This threshold determines when Secondary sensors should transmit real-time intensity updates. The formulation of this internal threshold began with establishing a specific Modified Mercalli Intensity[3] (MMI) range that effectively signals the necessity for an update without indicating considerable ground shaking.

The selection of an appropriate MMI range was based on the descriptions provided by GeoNet (Dowrick, 1996; GeoNet, n.d.). This choice ensures that our system's criteria for triggering intensity updates are well-tuned to the regional seismic activity profiles, thereby maintaining the system's accuracy and relevance. After careful consideration, MMI 3 was selected as the internal threshold. MMI 3 is characterised by indoor light vibrations, where hanging objects might sway slightly. This level of intensity serves as a pragmatic threshold, allowing Secondary sensors to initiate communication with the Primary sensor early in the event of significant seismic activity or at the onset of a large earthquake, thereby optimising the timing of alert dissemination.

Following the selection of MMI 3 as the internal threshold, the challenge was addressed by translating this MMI value into measurable parameters for the sensors, specifically PGA, PGV, and PGD. Since our sensors estimate intensity through these physical measures every second, determining an equivalent PGA value for MMI 3 was essential. To accomplish this, Ground Motion Intensity Conversion Equations (GMICEs), as outlined by Moratalla et al. (2020), were utilised. Figure 7 visually illustrates the correlation between MMI levels and PGA values, as defined by the GMICEs. In the figure, the MMI threshold of 3 or above is marked with a green vertical line, setting a clear benchmark for triggering communication from Secondary to Primary sensors based on real-time seismic data.

[3] The Modified Mercalli Intensity scale is a qualitative tool used to describe the intensity and effects of an earthquake on the Earth's surface, structures, and inhabitants. It ranges from I (imperceptible) to XII (destruction), describing the impact on structures, the environment, and human perception and response.

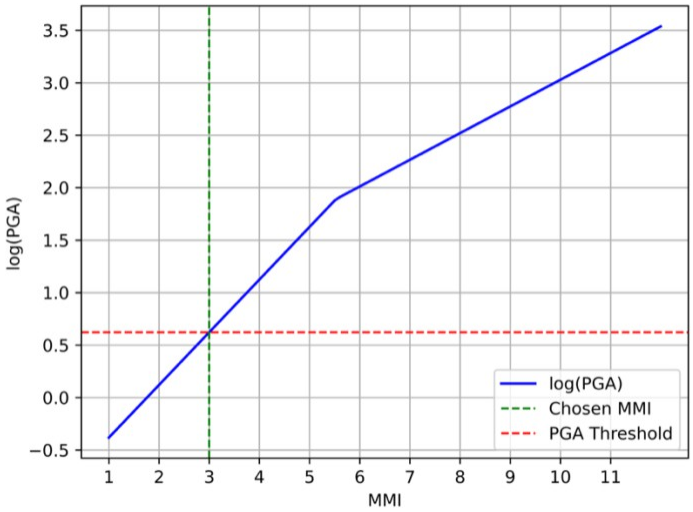

Figure 7: Correlation Between MMI Levels and PGA Values as Defined by GMICEs, Featuring a Green Vertical Line to Indicate the MMI Threshold of 3 and a Horizontal Red Dotted Line Representing the log(PGA) Threshold for Transferring Intensity Estimations from Secondary to Primary Sensor

Subsequently, the log(PGA) threshold was identified by analysing the intersection point depicted in Figure 7. The chosen log(PGA) value, serving as the internal threshold for Secondary sensors, was identified as 0.62, as represented by a red dashed horizontal line within the figure. After converting the logarithmic value to its original scale, the PGA internal threshold was determined to be 4.2 cm/s².

Alert Generation

In our EEWS, the generation of alerts for a specific prediction point, typically another RS4D sensor installed in a household, is managed by the Primary sensor designated for that point. The key requirement for a Primary sensor to trigger an alert is the reception of at least two intensity predictions that surpass a predefined threshold. These predictions can originate from the Primary sensor and one or more Secondary stations or exclusively from Secondary stations. The surpassing of this threshold by the predictions is critical, as it indicates a level of seismic intensity warranting generating an alert.

In the experimental network designed for testing, an intensity threshold of MMI level 5 has been provisionally selected. According to the GeoNet MMI descriptions, this intensity level corresponds to shaking typically felt outside, capable of awakening most sleepers and causing alarm among a few people indoors. However, establishing an ideal alert activation threshold requires carefully evaluating societal impacts and technical capabilities. Determining such a threshold is part of a broader, ongoing conversation to formulate a comprehensive set of guidelines specific to NZ's unique needs and circumstances.

The MMI 5 was translated into a PGA value of 42.3 cm/s² to quantify this threshold, utilising the same method for establishing the internal threshold for Primary-Secondary sensor communication. Therefore, if the predicted intensity from two or more observation stations within a prediction radius exceeds this PGA threshold of 42.3 cm/s^2, the Primary station will initiate an alert to the prediction point.

DISCUSSION

Launching a node-level EEWS using the PLUM algorithm in NZ seismically varied landscape represents a significant shift from conventional centralised models. Table 1 summarises the key differences between the traditional PLUM methodology and this research's approach. This proposed approach has optimised the processing capability of RS4D sensors for real-time seismic intensity prediction and alert dissemination. Transitioning to a decentralised architecture enhances the resilience of the EEWS by minimising the risks associated with a single point of failure, a potential issue in centralised systems.

Table 1: Comparative Overview of Traditional Plum Approach Versus Node-Level PLUM Adaptation Proposed in this Study.

Characteristics	Traditional PLUM implementation	Experimental Node-Level PLUM adaptation
Processing Approach	Centralised processing	Node-level processing with a two-tiered Primary-Secondary structure
Prediction Point Determination	Selected based on areas of interest reflecting observed seismic activities	Sensors themselves are used as prediction points
Data Handling Method	All observations within a prediction radius are sent to a centralised unit in real time.	Secondary sensors process data independently, sending updates to a Primary sensor only if internal threshold is surpassed.
Intensity Predicting Method	Observations are collected and processed at a central location to predict the intensity at prediction points.	The Primary sensor is responsible for predicting the intensity when its threshold is exceeded or upon receiving data from Secondary sensors.
Alert Generation	Centralised system issues alerts to the prediction points.	The Primary sensor issues an alert for its prediction point.

Adapting the PLUM algorithm for node-level application showcases the system's adaptability and the algorithm's suitability for environments with limited resources, particularly with the constraints of RS4D sensors. Identifying sensors as prediction points facilitates a community-centric warning system, ensuring swift alert delivery directly where needed. The classification of sensors into Primary and Secondary roles optimises task distribution, streamlining the network's operation.

A key focus for this proposed architecture was to minimise network traffic coming from the frequent intensity updates from Secondary sensors. Implementing an internal threshold curtails unnecessary data transfers, minimising the processing burden on Primary sensors. This threshold, determined by NZ's specific MMI scale and GMICEs, enhances network efficiency.

The MMI scale was utilised for alert generation, with MMI level 5 selected as an illustrative threshold to demonstrate the alerting process. However, establishing a definitive threshold needs further research for both societal impacts and technical capabilities, underscoring the need for a comprehensive discussion on this topic.

Future Work

In the next phase of our research, we will concentrate on a sequence of strategic undertakings designed to strengthen the capabilities of an operational node-level processing EEWS:

1. **Pilot Implementation and Performance Assessment:** The proposed concept will be piloted by integrating it into several RS4D sensors. We will focus on investigating the PLUM algorithm's performance at the node level, with particular attention to the accuracy of intensity estimations. Data collected from these sensors will be stored in a dedicated database for subsequent analysis to evaluate the system's performance metrics thoroughly.
2. **Network-Wide Implementation:** Upon completing the initial tests and refinements, the algorithm will be rolled out across the entirety of the operational network (45 sensors in the Wellington Region). This crucial step will mark the transition from a controlled testing environment to a real-world application, setting the stage for comprehensive system evaluation.
3. **Alert generation and threshold calibration:** Research efforts will be directed toward fine-tuning the parameters that trigger alert generation. This task will entail a deep dive into alerts' societal impact and the technical nuances associated with threshold calibration, tailored to NZ's unique seismic profile.

4. **Communication Technology Exploration:** Pursuing alternative communication methodologies, such as LoRa, is essential, particularly as an alternative strategy to ensure network operability during traditional communication infrastructure failures.

The conceptual framework detailed in this work-in-progress paper will undergo operational testing, refinement, and expansion. Future results from the experimental network are planned for journal publication to validate the system's effectiveness and provide guidance for similar deployments in seismically active areas.

CONCLUSION

This work represents a notable contribution to EEWSs by integrating node-level processing with the PLUM algorithm. The system's design, emphasising redundancy, cost-efficiency, and reduced latency, addresses the critical need for resilient seismic warning capabilities. Furthermore, the node-level approach emerges as a viable solution following significant earthquakes, where standard communication networks may fail. The potential for sensors to utilise alternative communication methods, such as LoRa, highlights a forward-looking strategy for ensuring continuous alert delivery during aftershocks, enhancing community safety and preparedness. In conclusion, our endeavour to develop a community-engaged node-level EEWS in NZ signifies a step forward in seismic risk management.

ABSTRACT

Located in the southern coastal region of China, Guangdong Province is perennially threatened by typhoons originating from the Northwest Pacific Ocean. Compared to studies focusing on typhoon intensity, paths, and catastrophic effects, research on typhoon landing frequency features remains relatively limited. This study systematically constructs a dataset based on the landing typhoon frequency of Guangdong over 71 years (as the target variable) and a set of 88 atmospheric circulation indices as well as 26 sea surface temperature indices (as the potential feature variables). Two machine learning models, including Random Forest Regression (RR) and Support Vector Regression (SVR), are used to predict the frequency of typhoons making landfall in Guangdong, and the results show that both models have good characterisation ability while the RR model has slightly better fitting performance on the training set. This study provides scientific support for understanding the characteristics of typhoons in Guangdong and better responding to typhoon disasters.

Keywords

Tropical cyclone, frequency characteristics, machine learning, vulnerability functions.

INTRODUCTION

According to the definition of the World Meteorological Organization, a tropical cyclone with sustained wind speeds above level 12 (i.e. 32.7 to 41.4 meters per second) at its center is called a typhoon or hurricane, where generally the former is used to refer to tropical cyclones generated in the Pacific Ocean, while the latter is used to refer to those generated in the Atlantic Ocean. According to the traditional Chinese custom of naming tropical cyclones, tropical cyclones are collectively referred to as typhoons in the following. The 2022 Global Natural Disaster Assessment Report points out that there are a total of 66 major storm disasters (typhoons and hurricanes) worldwide in 2022, accounting for approximately 21% of the total frequency of major disasters; 16.93 million people are affected, resulting in direct economic losses of approximately 131 billion US dollars (Academy of Disaster Reduction and Emergency Management et al., 2023). The impact and challenges caused by typhoon disasters cannot be ignored and are a global problem facing humanity. China is located in the northwestern part of the Pacific Ocean, which is a high risk area for typhoon disasters. In the 71 years from 1949 to 2019, there are 2,333 typhoons in the Northwest Pacific, of which 636 have landed in China, accounting for 27.3% of the total (Liu et al., 2012; Su et al., 2021). Guangdong Province is located in the coastal area of southern China and is the main region where typhoon makes landfall in China, making it one of the provinces most severely affected by typhoons (Zhang et al., 2009; Chou et al., 2018). In 2018, Typhoon Mangkhut makes landfall in Guangdong with 14 gusts of wind, affecting 3.066 million people, causing the collapse of 200,000 houses and direct economic losses of 13.29 billion yuan. In early September 2023, Typhoon Sura and Haikui make landfall in Guangdong, causing record-breaking rainfall in various parts of the province. The disasters have caused serious consequences, including road collapses, interruptions in communication and power supply, house collapses, fallen trees, and damage to water conservancy projects, particularly in Shenzhen and Yangjiang.

With the severity of global climate change, the increasing intensity of worldwide natural disasters such as typhoons is causing progressively greater losses globally. Typhoon characteristics prediction has become a major focus of research. In general, the studies on typhoon characteristics prediction include typhoon frequency prediction (Jia et al., 2014; Hai et al., 2019), track prediction (Murakami et al., 2010; Hsan et al., 2021), landfall prediction (Wahiduzzaman et al., 2017; Kumar et al., 2021), wind field strength prediction (Kotal et al., 2020; Chen et al., 2023), rain field strength prediction (Matyas, 2010), and so on. The study of the characteristics of typhoon landing frequency can understand the law and mechanism of typhoon activities and the impact of climate change on typhoon activities, better early warning and risk management, so this paper mainly focuses on the prediction of typhoon landing frequency.

The traditional methods for studying the characteristics of typhoon landing frequency mainly include two categories: statistical analysis methods and numerical analysis methods. Statistical methods do not focus on physical principles but on the exploration of data patterns in historical disasters. Yang et al. find that the landfall typhoons numbers as well as the south-north range of landfall typhoons have decreased by using the data from the Tropical Cyclone Yearbooks (Yang et al., 2009). Numerical analysis methods are built based on principles of atmospheric dynamics and thermodynamics to discretize and simulate the atmosphere for weather forecasting. Nie et al. find that the average intensity and number of typhoons landing in China under three RCPs will increase in varying degrees in the future, based on outputs from the global climate model HadGEM2-ES in CMIP5 (Nie et al., 2023). With the popularization of artificial intelligence technology, machine learning has gradually become a popular method in typhoon characteristics prediction research due to their ability to process large amounts of complex meteorological data and capture their nonlinear and non parametric relationships. Richman et al. implement a Support Vector Regression model based on the May-September Nino index, a novel El Nino, a quasi-biennial oscillation in the stratosphere, and a Southern Hemisphere ring mode to estimate the frequency of typhoons in the Australian typhoon season from December to April (Richman et al., 2012). Tan et al. select environmental fields such as sea surface temperature, sea level pressure, Nino 3.4 index, wind shear, vorticity, subtropical high pressure and sea ice cover, and establish a random forest model based on the prediction of tropical cyclone frequency in the Northwest Pacific Ocean (Tan et al., 2018). Chen chooses six types of forecast elements, including temperature field, altitude field, sea-level pressure, specific humidity field, meridional wind field vertical shear, and sea surface temperature field to perform single machine learning model predictions and integrated predictions (Chen, 2022).

Overall, compared to traditional weather prediction methods such as numerical models, machine learning methods are still in the exploratory stage of typhoon characteristics prediction research. Its application research scope is wide, but it mainly focuses on the study of typhoon intensity, weather and its catastrophic effects such as wind speed and rain intensity (Chen et al., 2020). There is still relatively little research on typhoon landing frequency. Studying the frequency of landfall can help understand the characteristics and trends of typhoon frequency in different regions, help governments and communities better prepare and respond to possible typhoon disasters, conduct more effective meteorological disaster risk assessments, and reduce the impact of disasters on people's

lives and property. Therefore, studying the frequency of typhoons is of great significance for guiding regional disaster prevention and reduction.

THE OVERALL STRUCTURE

The general structure of this study is shown in Figure 1. Guangdong Province has been selected as the study area, which is one of the most typhoon-prone provinces in mainland China. Typhoon track data from 1952 to 2022 and a potential set of feature variables have been collected. Through data processing, datasets of both feature variables and target variables have been obtained, used for training two machine learning models. The ability of the two models to characterise and predict the frequency of typhoons making landfall in Guangdong Province is compared. The results of this paper help to understand the characteristics of typhoons in Guangdong Province and provide reference and technical support for subsequent studies on typhoon landing frequency predicion, as well as help to improve the government's capabilities in response to typhoons.

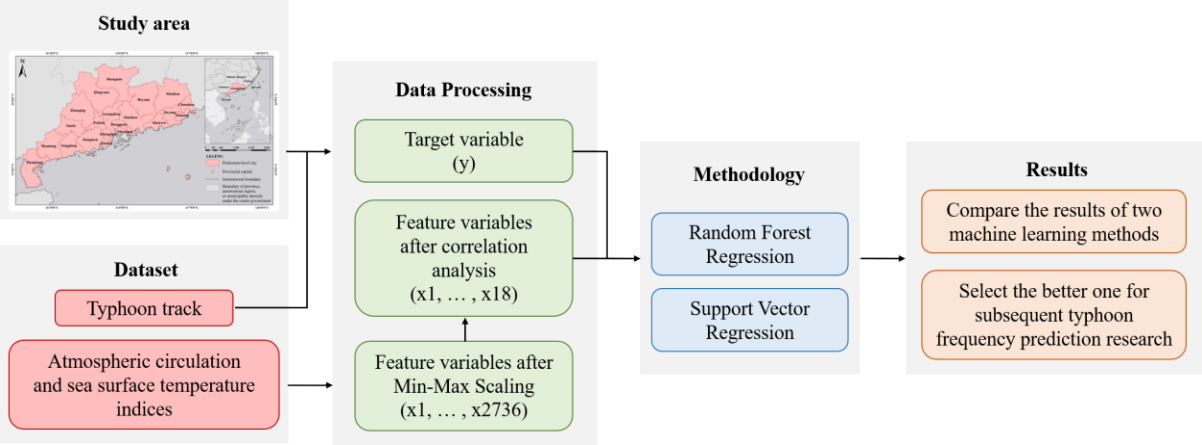

Figure 1. The Overall Structure of This Study

STUDY AREA AND DATASETS

Study Area

Guangdong Province is a provincial-level administrative region in China. It is located along the coast of the South China Sea, bordered by Hong Kong, Macau, Guangxi, Hunan, Jiangxi and Fujian, and across the sea from Hainan Province, with a total land area of 179,800 square kilometers. As of October 2022, Guangdong is composed of 21 prefecture-level cities, 65 districts, 20 county-level cities, 34 counties, and 3 autonomous counties. In 2022, the gross domestic product (GDP) of Guangdong Province reached 12,911.86 billion yuan, with a per capita GDP of 101,905 yuan. At the end of 2022, the permanent population of Guangdong was 126.568 million, with an urbanization rate of 74.79%. Figure 2 illustrates the study area in this paper.

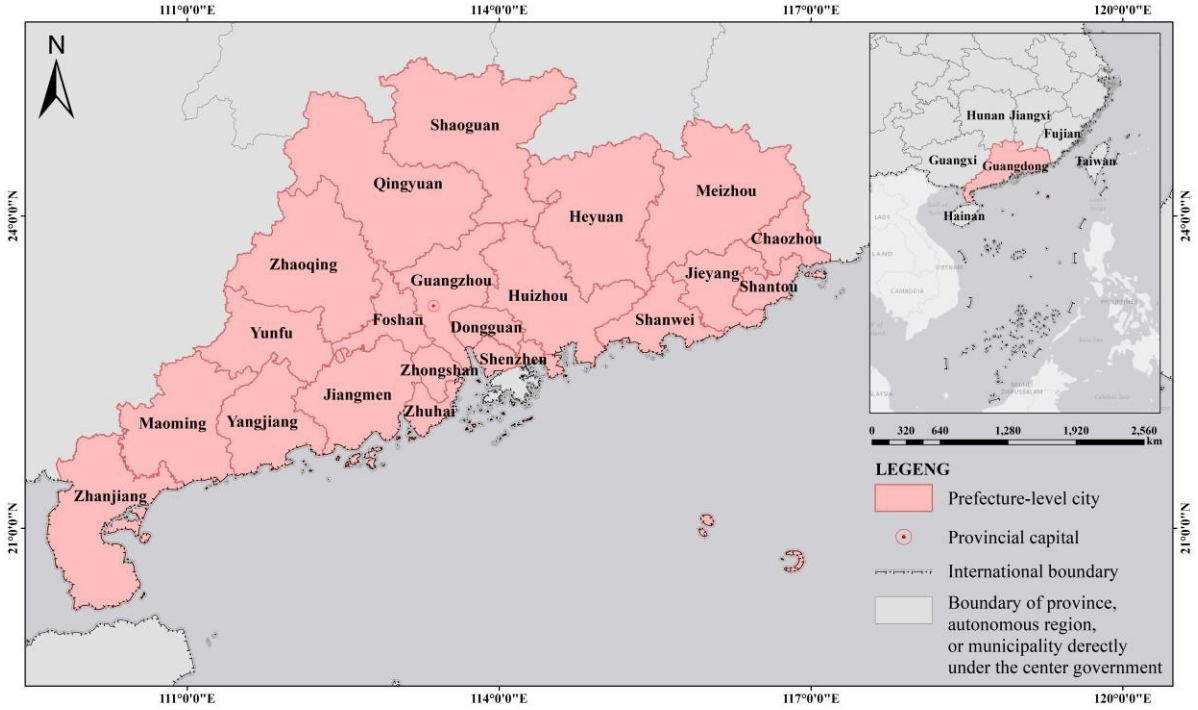

Figure 2. The Study Area in This Study

Data Sources

The typhoon track data is sourced from the Best Track Data provided by the China Meteorological Administration Tropical Cyclone Data Center (CMA, 2023; Ying et al., 2014; Lu et al., 2021). This dataset provides basic information on the position and intensity of tropical cyclones in the northwest Pacific (including the South China Sea, north of the equator, and west of 180°E longitude) every 6 hours since 1949. Starting from 2017, for typhoons that make landfall in China, the time frequency of the best track data has been increased to once every 3 hours within the 24-hour period before their landfall. Since 2018, for typhoons making landfall in China, the time frequency of the best track data is increased to every 3 hours within the 24 hours before their landfall and during their land activities In China.

Regarding the potential feature factors influencing typhoon frequency, the monthly data of 88 atmospheric circulation indices and 26 sea surface temperature indices provided by the National Climate Center from 1951 to 2022 are considered by this study, mainly based on the research of Rong et al. (National Climate Center, 2023; Rong et al., 2023).

Raw Data Processing

Feature Variables Processing

For the feature variables, this study utilizes monthly atmospheric circulation indices and sea surface temperature indices for the years 1951-2022. The entire feature variable dataset comprises 71 entries (an entry per year from 1952 to 2022), with each entry including 88 atmospheric circulation indices such as the Northern Hemisphere Subtropical High Area Index, as well as 26 sea surface temperature indices like the NINO 1+2 SSTA Index, for a total of 24 months corresponding to the target variable's current year and previous year, resulting in a total of 2736 [=(88+26)*24] feature variables per entry.

In the feature variable dataset, the differences in meanings of various variables and units of measurement can affect the performance of machine learning algorithms. Therefore, it is necessary to normalize data from different dimensions, allowing for comparison and interpretation on the same scale. In this study, Min-Max Scaling is employed to normalize the feature variable dataset.

The Min-Max Scaling method scales the original data proportionally to fit within the range [0, 1]. The specific formula for this process is as follows:

$$x_{ij} = \frac{x_{ij} - \min(x_j)}{\max(x_j) - \min(x_j)} \quad (1)$$

Here, x_{ij} denotes the value of the j-th variable for the i-th year, $\min(x_j)$ and $\max(x_j)$ are the minimum and maximum values of the j-th variable in the whole dataset, and x'_{ij} denotes the normalized value after processing.

Acquisition and Analysis of the Target Variable

Based on the best track data of tropical cyclones, which provides latitude and longitude information at regular intervals for each typhoon, combined with the longitude and latitude range of Guangdong Province, whether the typhoon made landfall in mainland China from Guangdong Province is determined. Here, landing in Guangdong refers to the first landfall location of a typhoon in China being Guangdong, the situation where a typhoon lands in other provinces of China first and then makes a secondary landfall in Guangdong is not considered. Summarizing the typhoons landing in Guangdong each year, the frequency data of typhoons making landfall in Guangdong from 1952 to 2022 (target variable) is obtained. It reveals that a total of 250 typhoons made landfall in Guangdong during this period, with an average of 3.52 typhoons per year and a standard deviation of 1.71. The highest annual typhoon frequency reached seven, while the lowest was one. Figure 3 reflects the annual changes in the frequency of typhoons landing in Guangdong Province. The linear trendline indicates a significant downward trend in the number of typhoons making landfall in Guangdong Province over the 71 years. The 5-year moving average curve shows that the landing typhoon frequency exhibits overall fluctuating characteristics, entering a period of reduced frequency starting from the late 20th century.

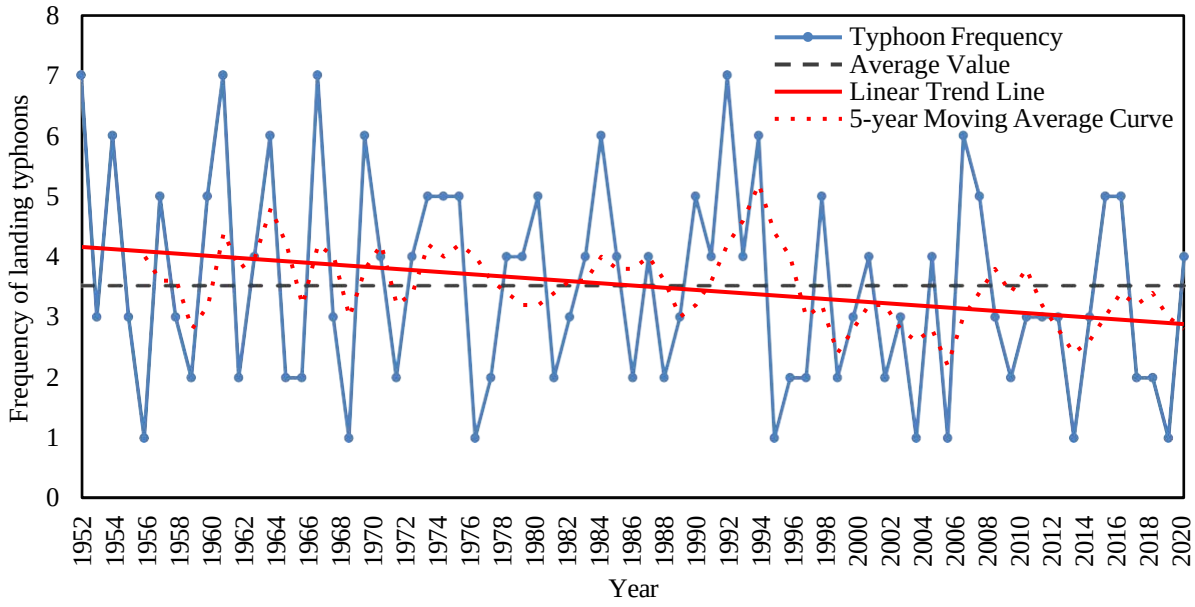

Figure 3. The Annual Distribution of Landing Typhoon Frequency in Guangdong Province

METHODOLOGY

Random Forest Regression

Random Forest Regression (RR) is an important application branch of Random Forest. The RR model builds multiple unrelated decision trees by randomly extracting samples and features, following the principles of Bagging, and obtains predictions in parallel. Each decision tree can produce a prediction result from the extracted samples and features, and the regression prediction result of the whole forest is obtained by averaging the results of all trees. This model improves the Bagging ensemble algorithm by incorporating random attribute selection alongside the bootstrap sampling method during the training of decision trees. This introduces diversity among weak learners, enhancing the model's generalization performance.

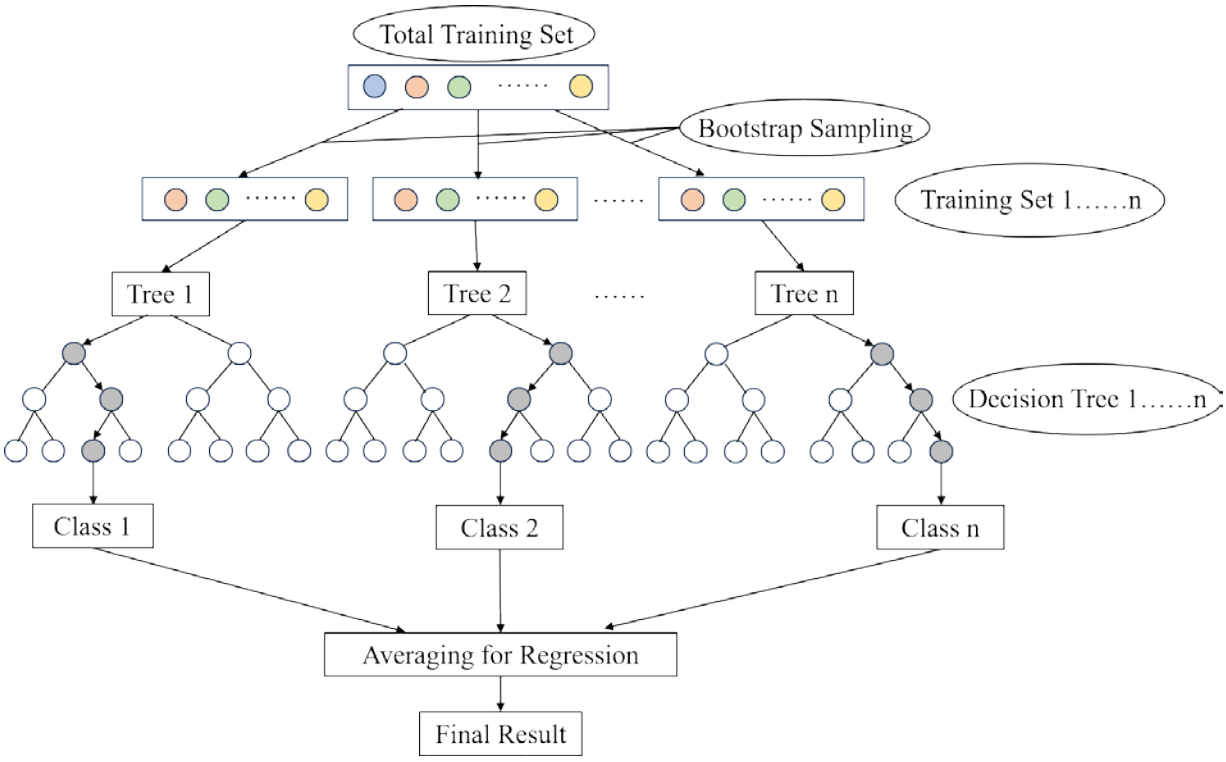

Figure 4. Flowchart of Random Forest Regression Algorithm

Support Vector Regression

Support Vector Regression (SVR) is a supervised learning method that uses Support Vector Machines (SVM) for regression analysis. The goal of SVR is to find the optimal hyperplane, allowing for a certain amount of error, such that the sample points are as close to this hyperplane as possible. SVR achieves this by optimizing the following convex quadratic programming problem:

$$\min_{\omega,b,\xi,\xi} \frac{1}{2}||\omega||^2 + C\sum_{i=1}^{N}(\xi_i + \xi_i) \tag{2}$$

Here, ω denotes the weight vector of the hyperplane, b denotes the intercept, ξ and ξ denote slack variables allowing some data points to be within the margin or error range, respectively, and C denotes the regularization parameter controlling the trade-off between margin size and error.

The objective of SVR is to minimize the loss function mentioned above while satisfying the following constraints:

$$yi - \langle \omega, \phi(x_i) \rangle - b \leq \epsilon + \xi_i \tag{3}$$

$$\langle \omega, \phi(x_i) \rangle + b - yi \leq \epsilon + \xi_i \tag{4}$$

$$\xi_i, \xi_i \geq 0 \tag{5}$$

These constraints ensure that data points are within the margin or error range. The parameter ϵ controls the size of the margin. SVR finds the optimal hyperplane by minimizing the loss function, enabling it to make predictions.

Metrics for Evaluating Machine Learning Performance

In order to compare the learning effects of the two machine learning models, Mean Squared Error (MSE), Root Mean Squard Error (RMSE) and Mean Absolute Error (MAE) are chosen as the evaluation metrics for the training results. Smaller MSE, MAE and RMSE suggest better fit of the model to the data. The formulas to calculate MSE, RMSE and MAE are as follows:

$$\text{MSE} = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \tag{6}$$

$$\mathrm{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{7}$$

$$\mathrm{MAE} = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \tag{8}$$

In which, n denotes the number of samples, y_i denotes the actual values, and $\hat{y}_i$ denotes the predicted values of the model.

RESULTS

Correlation Analysis

To prevent overfitting and reduce redundant information caused by numerous feature variables, a correlation analysis between the target variable and feature variables is performed, yielding correlation coefficients of each feature variable to the target variable. Based on the correlation coefficients, features with a strong correlation with the target variable have higher priority to be selected thereby simplifying the feature variables dataset, which is recommended by Rong et al. as a simple but effective way of parameter selection (Rong et al., 2023). Given a dataset D = $\{(X_K, Y_K)\}$, where $K \in n$, the correlation coefficient r is defined as:

$$r = \frac{\sum_{K=1}^{n}(X_K - \bar{X})(Y_K - \bar{Y})}{\sqrt{\sum_{K=1}^{n}(X_K - \bar{X})^2}\sqrt{\sum_{K=1}^{n}(Y_K - \bar{Y})^2}} \tag{9}$$

where $\bar{X}$ denotes the mean of X and $\bar{Y}$ denotes the mean of Y.

After calculating the correlation coefficients for each feature variable to the target variable, those with missing values (originally marked as -999 in the raw data) are removed. The remaining features are sorted in descending order based on the absolute values of their correlation coefficients. Subsequently, multiple tests are conducted based on the changing dataset, where every three sequential cumulative increases in the number of feature variables, and the dataset composed of the first 18 feature variables is discovered to have the better prediction effect. Therefore, in this paper, 18 feature variables are set as shown in Table 1, and due to space limitations, the process of selecting the number of feature variables is omitted. These 18 feature variables respectively represent the sea surface temperature indices (x2723, x2734, x1902, x2620, x2724, x1580, x2609, x2718, x2610, x2604, x2506, x1694, x2512) and atmospheric pressure indices (x2575, x2573, x2337, x411, x1605) related to typhoon formation (For detailed explanations of these indices, please refer to the National Climate Center's website). Furthermore, only x411 is a feature variable from the previous year, affecting this year's frequency of typhoon landing. Therefore, it can be observed that sea surface temperature factors have a greater impact on the frequency of typhoon landing in Guangdong, and the index of the same year has more influence compared to the index of the previous year. The dataset of feature variables together with the target variable will serve as the initial dataset for machine learning models. The dataset is split into 80% for training and 20% for testing.

Table 1. The Top Eighteen Feature Variables Ranked by the Absolute Values of Their Correlation Coefficients

Number	Feature variable identifier	Feature variable name	Absolute value of the correlation coefficient
1	x2723	Indian Ocean Warm Pool Area Index in December of the same year	0.4015
2	x2734	Indian Ocean Basin-Wide Index in December of the same year	0.3995
3	x1902	Scandinavia Pattern , SCA in May of the same year	0.3949
4	x2620	Indian Ocean Basin-Wide Index in November of the same year	0.3766
5	x2724	Indian Ocean Warm Pool Strength Index in December of the same year	0.3731

6	x1580	Tropical Northern Atlantic SST Index in February of the same year	0.3659
7	x2609	Indian Ocean Warm Pool Area Index in November of the same year	0.3605
8	x2575	India-Burma Trough Intensity Index in November of the same year	0.3564
9	x2718	NINO B SSTA Index in December of the same year	0.3514
10	x2610	Indian Ocean Warm Pool Strength Index in Novermber of the same year	0.3483
11	x2604	NINO B SSTA Index in Novermber of the same year	0.3385
12	x2573	Tibet Plateau Region 1 Index in Novermber of the same year	0.3376
13	x2337	Northern Hemisphere Polar Vortex Central Latitude Index in September of the same year	0.3373
14	x2506	Indian Ocean Basin-Wide Index in October of the same year	0.3373
15	x411	Antarctic Oscillation, AAO in April of the previous year	0.3334
16	x1605	South China Sea Subtropical High Area Index in March of the same year	0.3332
17	x1694	Tropical Northern Atlantic SST Index in March of the same year	0.3298
18	x2152	Western Hemisphere Warm Pool Index in July of the same year	0.3293

Random Forest Regression Model Prediction

Key parameters affecting the fitting performance of the RR model, namely n_estimators (number of trees), max_depth (maximum depth of the tree), min_samples_split (minimum samples required for a node to split), and min_samples_leaf (minimum samples required for a leaf node), are performed parameter tuning by using a parameter grid which is formed by commonly used numerical values respectively. After multiple rounds of optimization and combining the fitting results, the values 200, 20, 10, and 4 are chosen for the respective parameters.

Due to the random features inherent in the RR model, the results obtained from each training iteration are not entirely consistent. Therefore, Table 2 represents the average training results after 20 repetitions. The model exhibites good performance on the training set, where the prediction deviation for typhoon landing frequency is around 1. However, the performance on the test set is relatively poor, with the values of three metrics significantly higher than on the training set. Comparison of the actual and predicted values for the training and test sets from the 20th training iteration is shown in Figure 5. The RR model demonstrates a consistent trend with the actual values in the training set, showing relatively high concordance with peak and trough values in certain years. On the other hand, the results for the test set, highlighted with a deep red background in the Figure 5, exhibites suboptimal trends and extreme value predictions. The maximum prediction error for the number of landing typhoons reaches 2.4.

Table 2. The Results of RR Training Evaluation Metrics

Type of dataset	Evaluation indicators	Values
Training set	MSE	1.0857 ± 0.0152
	RMSE	1.0419 ± 0.0073

	MAE	0.8758 ± 0.0096
	MSE	1.8042 ± 0.0511
Test set	RMSE	1.3431 ± 0.0192
	MAE	1.1669 ± 0.0178

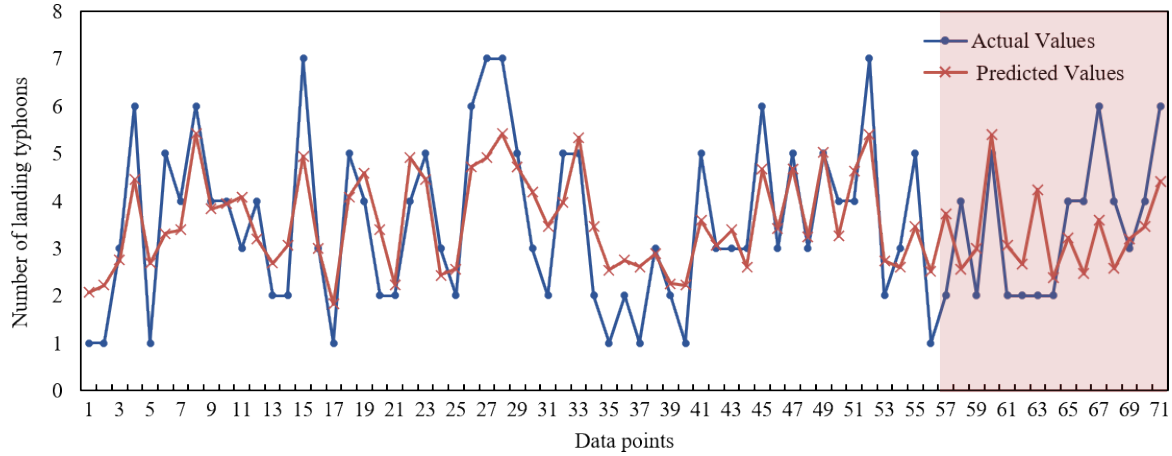

Figure 5. RR Training Results Plot for Training and Test Sets (Highlighted in Deep Red Background for Test Set Training Results)

The average feature importance values from the 20 training iterations are illustrated in Figure 6. Among them, the four feature variables, Scandinavia Pattern, SCA in May of the same year (x1902), Antarctic Oscillation, AAO in April of the previous year (x411), Tropical Northern Atlantic SST Index in February of the same year (x1580), and Tibet Plateau Region 1 Index in Novermber of the same year (x2573), demonstrate higher importance in influencing the overall training performance of the model, with importance values of 0.2097, 0.1159, 0.1154, and 0.0899, respectively. The relevant results show that time coefficients of the ninth mode from empirical orthogonal function analysis (EOF) of the normalised 500hPa height field in the region 20°N-90°N, 0-360°in May as well as regional average of sea surface temperature distance levels in the region 5.5°N-23.5°N, 57.5°W-15°W in February of the same year (x1902, x1580) and normalised series of time coefficients of the first mode from EOF of the anomalous field at 700hPa height in the region 20°-90°S, 0-360°in April of the previous year (x411) will have a relatively important impact on the number of typhoon landing in Guangdong Province in a year.

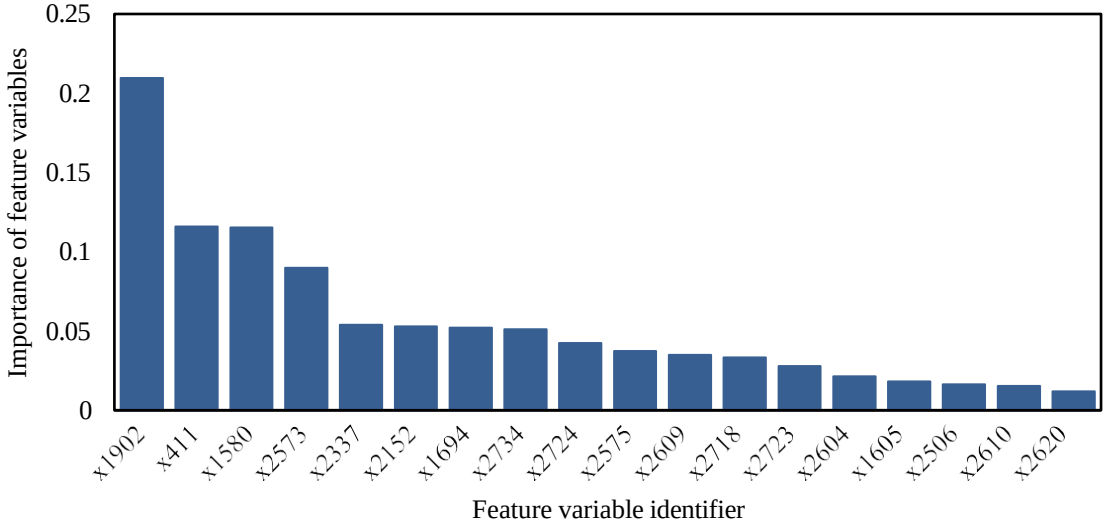

Figure 6. Importance Level of Eighteen Feature Variables

Support Vector Regression Model Prediction

In SVR model, the parameters affecting training performance include kernel (kernel function), C (penalty term), epsilon (tolerance), and gamma (affecting the width of the kernel function). Similar to Random Forest Regression, common values for these parameters are selected to form a parameter grid, picking the best parameter combination through exhaustive methods. SVR does not involve the concept of "random" features like Random Forest, so the optimal parameter set is obtained through one training: C is set to 10, epsilon is set to 1, gamma is set to 0.1, and the kernel is set to sigmoid.

The training results for the training set and test set are shown in Table 3. It can be observed that the training performance of SVR on the training set composed of these 18 feature variables is not very ideal compared to RR, with an average of 1.18 typhoon landing frequency prediction errors according to MAE, which is higher than RR. However, the test set fitting effect is good, with the values of three metrics lower than RR. Combining Figure 7, SVR's prediction values on the training set align well with the overall trend of the actual values, but the fitting performance for the peak and trough values is relatively poor, even showing completely opposite predicted values to the actual values in some years. The test set results highlighted with a deep green background show suboptimal trend and extreme value performance, with a maximum prediction error of 2.29 for the number of landing typhoons.

Table 3. The Results of SVR Training Evaluation Metrics

Type of dataset	Evaluation indicators	Values
Training set	MSE	1.9894
	RMSE	1.4105
	MAE	1.1840
Test set	MSE	1.5054
	RMSE	1.2269
	MAE	1.0259

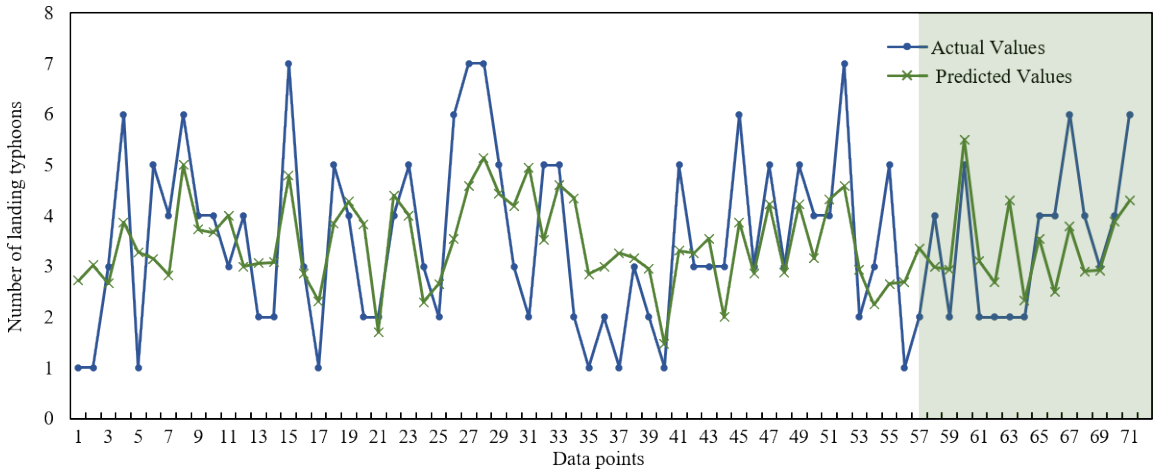

Figure 7. SVR Training Results Plot for Training and Test Sets (Highlighted in Deep Green Background for Test Set Training Results)

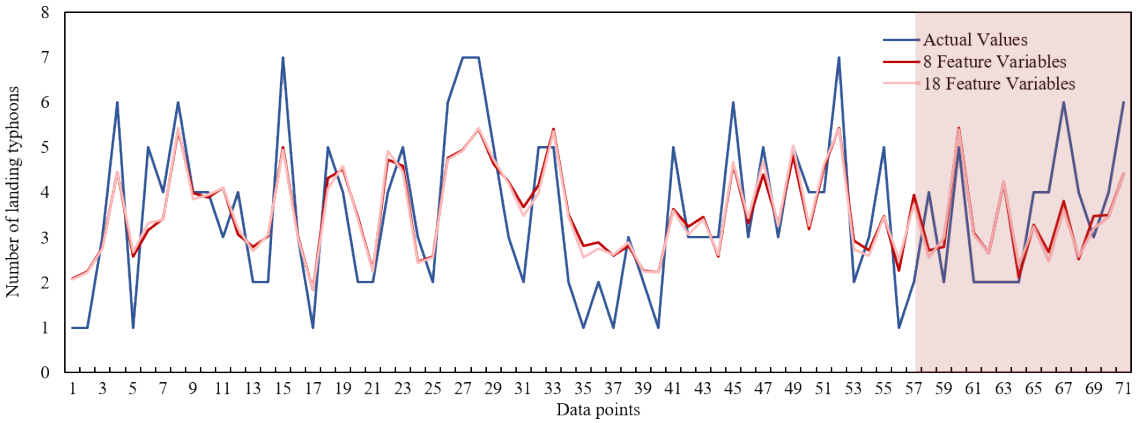
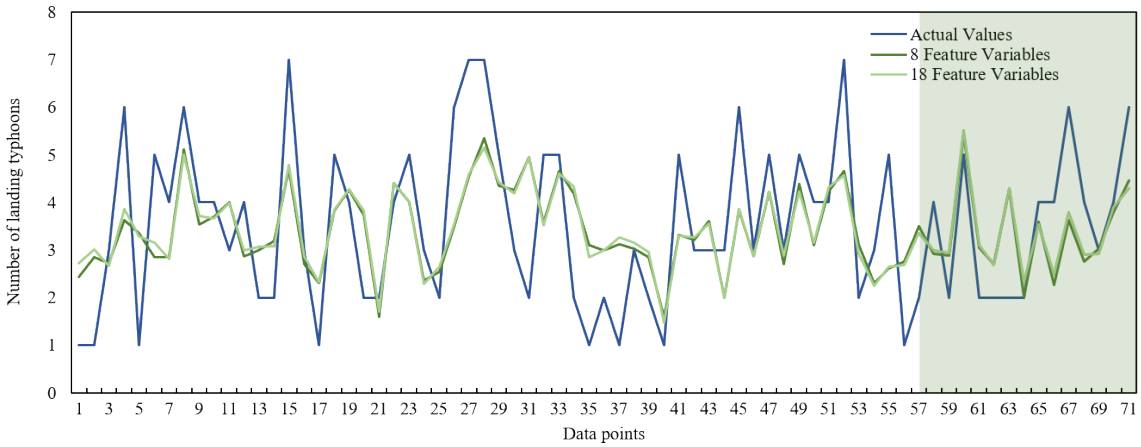
Comparison of Model Performance after Simple Secondary Selection

Usually, multicollinearity among feature variables can lead to model instability and excessive sensitivity to input variables. It is necessary to adopt methods to select optimal feature variables from a pre-selected set to enhance model performance and interpretability. Based on the idea of Rong et al., the author's team proposes a new approach: conducting preliminary selection of feature variable dataset by correlation analysis and secondary selection based on importance obtained through the RR method mentioned earlier to simplify the number of feature variables in the dataset, and then performing regression training based on two machine learning models. Table 4 below shows the 8 feature variables with importance values exceeding 0.05, which will constitute a new feature variable dataset for training both models.



Based on this idea, the author's team does a preliminary exploration The training results of the two models are shown in Table 5. Compared to the dataset with 18 feature variables, the values of MSE, RMSE, and MAE on the test set all decrease, indicating that the dataset with 8 feature variables shows some improvement in the RR model's fitting performance on the test set. However, in the training set, the simplified dataset has slightly worse model fitting performance than the original dataset. For the SVR model, the simplified dataset does not improve its fitting performance. Comparing the actual and predicted values of the two models on the training and test sets with different feature variable datasets, the simplified dataset does not play much role in two model fitting performances.

Table 4. The Eight Feature Variables with Importance Values Exceeding 0.05



Number	Feature variable identifier	Feature variable name	Importance value of the characteristic indicator
1	x1902	Scandinavia Pattern , SCA in May of the same year	0.2097
2	x411	Antarctic Oscillation, AAO in April of the previous year	0.1159
3	x1580	Tropical Northern Atlantic SST Index in February of the same year	0.1154
4	x2573	Tibet Plateau Region 1 Index in Novermber of the same year	0.0899
5	x2337	Northern Hemisphere Polar Vortex Central Latitude Index in September of the same year	0.0540
6	x2152	Western Hemisphere Warm Pool Index in July of the same year	0.0530
7	x1694	Tropical Northern Atlantic SST Index in March of the same year	0.0521
8	x2734	Indian Ocean Basin-Wide Index in December of the same year	0.0511

Table 5. The Training Evaluation Results of the Two Models

Type of dataset	Evaluation indicators	RR		SVR	
		18 feature variables	8 feature variables	18 feature variables	8 feature variables
Training set	MSE	1.0857 ± 0.0152	1.1033 ± 0.0163	1.9894	2.0137
	RMSE	1.0419 ± 0.0073	1.0504 ± 0.0078	1.4105	1.4191
	MAE	0.8758 ± 0.0096	0.8832 ± 0.0060	1.1840	1.1913
Test set	MSE	1.8042 ± 0.0511	1.7534 ± 0.0382	1.5054	1.5912
	RMSE	1.3431 ± 0.0192	1.3241 ± 0.0144	1.2269	1.2614
	MAE	1.1669 ± 0.0178	1.1426 ± 0.0139	1.0259	1.0301

(a) RR

(b) SVR

Figure 8. The Training Results of the Two Models on the Training Set and Test Set Based on Two Datasets (Highlighted in Background for Test Set Training Results)

The results show that the simplification method described above applied to the feature variable dataset does slightly improve the model fitting performance, but the improvement is limited. This suggests that the combined indicator selection approach of initial screening based on relevance and secondary selection based on importance has some potential, but its utility needs further exploration.

LIMITATIONS AND FUTURE WORK

In the selection of machine learning prediction models, due to time and space constraints, this paper only utilizes common machine learning regression models-Random Forest Regression and Support Vector Regression. However, there are many different regression models in machine learning, and for a more comprehensive and refined application to train and predict the landing typhoon frequency in Guangdong Province, other machine learning methods and even deep learning or large model learning methods can be considered as future research methods. By comparing the training results, the optimal method for predicting the landing typhoon frequency in Guangdong Province may be identified. After continuous optimization of the model, further practice can be considered - translating research findings into an information system. This system would display the predicted typhoon landing frequency for each region based on input atmospheric and sea temperature indices. We briefly conceptualized the initial interface and functionality of the system as shown in the figure below (the image results displayed are not accurate). The development of this visualization system can help for typhoon crisis management.

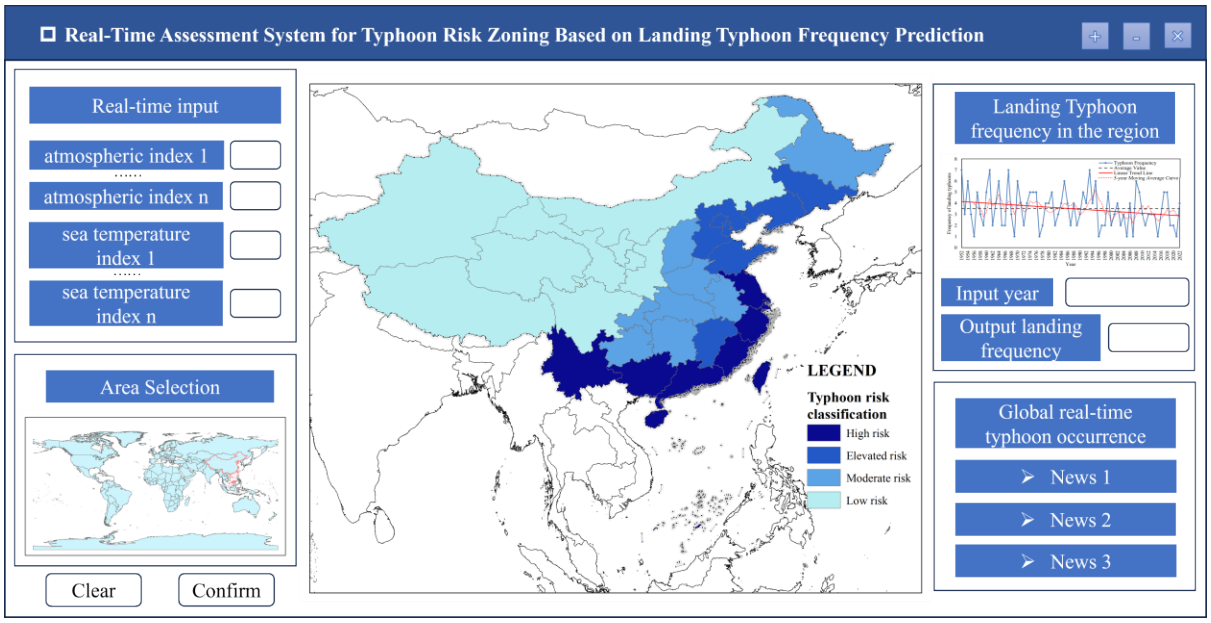


Figure 9. The Initial Concepts for the System Interface

CONCLUSION

Tropical cyclones are one of the destructive and globally impactful natural disasters. With the increasingly severe global climate change, the frequency of extreme weather events is rising, and tropical cyclone disasters have become a significant global concern. This study is based on collected data of the best tracks of typhoons from 1952 to 2022 and monthly atmospheric circulation and sea surface temperature indices from 1951 to 2022, constructing target variable and feature variable datasets separately. These datasets are used for training Random Forest Regression (RR) and Support Vector Regression (SVR) models, allowing a comparison of the fitting performance of the two machine learning models.

The research findings show that the frequency of typhoons making landfall in Guangdong Province has shown a decreasing trend from 1952 to 2022, particularly entering an interdecadal period of scarcity began at the end of the 20th century. Based on the training results of RR and SVR models on the dataset with 18 feature variables, RR demonstrates better fitting performance on the training set compared to SVR, while the opposite is observed on the test set. Both models exhibit good fitting trends on the training set, but RR shows higher sensitivity to peaks and valleys than SVR. On the test set, both models demonstrate relatively less-than-ideal fitting in terms of trends and extreme values. Generally speaking, the values of MSE, RMSE and MAE are small, so it can be seen that the prediction of the number of landing typhoons in this paper is accurate, basically able to predict the exact number of landing typhoon, with a possible error of no more than 2 typhoons. Additionally, analysis of the importance of the feature variables by RR model shows that SCA in May and Tropical Northern Atlantic SST Index in February of the same year and AAO in April of the previous year have a relatively important impact on the number of typhoon landing in Guangdong Province in a year. After the second screening and simplification of the dataset using the RR method, there is not a significant improvement in the fitting performance of the two models. The RR model shows some improvement, but it has the opposite effect on the SVR model, leading to a decrease in performance. Therefore, the combined indicator selection approach of initial screening based on relevance and secondary selection based on importance has some potential, which needs further exploration.

The research process and related results provide some references and guidance for further research and prediction of landing typhoon frequency and other characteristics of typhoons. This paper also helps the government departments to assess the risk of typhoons in the region and to improve the capabilities of emergency response management to disaster risks.

ABSTRACT

For more than two decades, satellite-based emergency mapping (SEM) supports authorities and responders in the rapid assessment of disaster situations. Although automation has been advanced, particularly in the field of satellite image analysis, the standard SEM workflow of the Copernicus Emergency Mapping Service (CEMS) is mostly user-driven at crucial steps. The 2021 flood events in western Germany show, as an example, the strong influence of manual interaction on the timely provision of satellite-based crisis products to emergency managers. We examine where latencies occur in the CEMS workflow and show a concept for the automation of processes and the usage of primarily open web data for process triggering to overcome delays. Our assumption is that a combination of both components is key for a faster SEM workflow, which we discuss along further benefits and challenges. A prototypical information system demonstrates the practical applicability of the concept.

Keywords

Earth observation, disaster management, satellite-based emergency mapping, web data analysis.

INTRODUCTION

Large-scale natural disasters such as the severe floods in western Germany in 2021 (e.g. Ahr valley) or Pakistan in 2022, the extensive wildfires in Portugal in 2017, Spain in 2022, Chile in 2023 and 2024 or the devastating earthquake in the bordering region of Turkey and Syria in 2023 require an effective, fast and coordinated disaster management (DM). When a disaster strikes, rapid, timely situation assessment is key for an adequate operational planning, so that available resources can be used effectively, shown by the example of the Ahr valley flood (Holzheimer et al., 2022). Earth observation (EO) data products have proven highly valuable in providing an up-to-date overview of an affected region and valuable information on the extent and distribution of damage (Gstaiger et al., 2022). Satellite-based emergency mapping (SEM) services such as the Copernicus Emergency Management Service (CEMS) rapid mapping service (RMS) (CEMS, 2024) provide geospatial information on demand and fast in support of DM activities before, during or immediately following a disaster (Voigt et al., 2016).

In contrast to sudden-onset disasters like earthquakes, the availability of early warnings, e.g. for meteorological events, may enlarge the time window for an improved DM support with EO data. Recent undertakings to accelerate SEM in terms of delivery timeliness of the crisis information by utilizing early warning systems have proven effective (Wania et al., 2021), however the process remains user-driven at crucial steps. In this paper, we investigate possible enhancements for the SEM process and propose a concept for automation of manual steps to improve both, timely provision and accuracy of EO-based crisis information. Afterwards, we show how our approach is applied in a prototypical implementation as a proof-of-concept.

Our work is based on design science research (Hevner et al., 2004). The presented artifacts, an improved SEM process and an information system prototype, are the first results of an ongoing development process with practice and state-of-the-art research in mind. This is made possible in particular by the authors' position as employees of an RMS (Center for Satellite-Based Crisis Information (ZKI)) based at a research organization (German Aerospace Center (DLR)). Both the relevance and rigor of the artifacts can thus be iteratively ensured.

RELATED WORK

Since 2003, ZKI has established one of the first rapid mapping mechanisms that continued to evolve with concurrent advances in satellite technology to provide users with precise EO-based crisis information (Gähler, 2016). Among other RMS providers, DLR has contributed to the predecessor of the CEMS (Schneiderhan et al., 2010). Today, the standard SEM process of the CEMS starts with a user-driven activation, which on average is requested 20h after the user-defined event time. Upon activation, the state-of-the-art process follows the steps 1) satellite tasking (optional, see chapter “Satellite Acquisitions”) 2) image acquisition, 3) image delivery and 4) map product delivery including image analysis (Wania et al., 2021) (Figure 1).

The timeline for the severe Ahr valley flooding was reconstructed to illustrate this SEM process. Figure 2 shows early warnings by the European Flood Awareness System (EFAS, https://www.efas.eu) and the German National Meteorological Service (DWD, 2021a, 2021b) four, respectively, one day before the CEMS activation by the German Joint Information and Situation Centre (GMLZ). Upon the activation, cloud cover prevented the use of optical satellite imagery for damage assessment during the initial flooding days. The ZKI became active at request of the Bavarian Red Cross given the DWD warnings and by chance was able to provide timely aerial imagery (Holzheimer et al., 2022). An automatic flood detection based on Sentinel-1 radar satellite images was also published (ZKI, 2021). This case exemplifies the time delays in the current SEM workflow due to manual activation responsibilities and handover procedures. It is important to note that the disaster response cannot be reconstructed for a theoretical case in which the SEM would have been activated at an earlier stage.

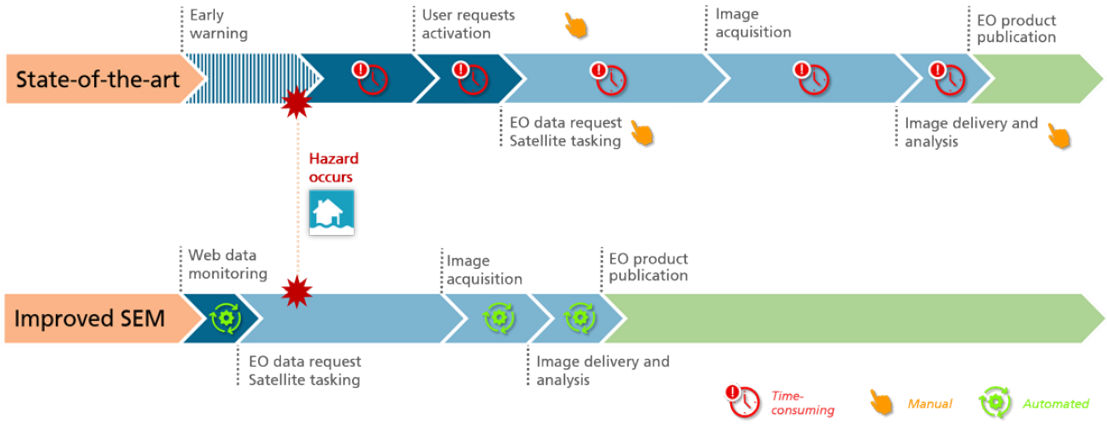

Figure 1. Comparison between state-of-the-art and proposed automated SEM workflow

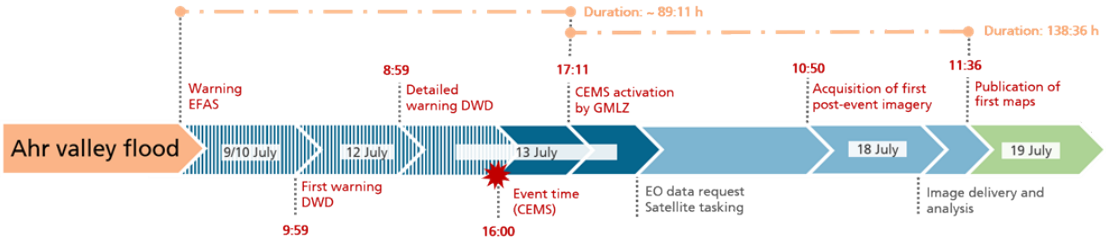

Figure 2. Condensed timeline of the RMS activation EMSR517 for Bad Neuenahr-Ahrweiler with time in UTC (based on CEMS, 2021a, 2021b; Weidinger, 2022)

Overall, we can identify several significant gaps in time delay 1) between the initial early warning and the SEM activation, being manually performed by an authorized user, and 2) between the activation and satellite tasking. Furthermore, 3) the latency between satellite sensing and image delivery (e.g. on Copernicus Open Access Hub, https://scihub.copernicus.eu) and 4) the time- and labor-intense manual and semi-automatic visual image interpretation delay the SEM process at later steps. Most attention has been given to optimizing the latter gap, which remains an area for ongoing improvements, such as fully automated flood detection (Wieland & Martinis, 2019; Bereczky et al., 2022), and burnt area derivation (Nolde et al., 2020; Knopp et al., 2020).

Considering the first two gaps, mental workload and initial uncertainties affect both users and SEM providers during disasters. Authorities must be aware of the event location to define the area of interest (AOI) for a SEM activation. End users are often unaware of possible and upcoming satellite data acquisitions, including Copernicus and very high-resolution (VHR) satellites, and the time until map product availability. SEM service providers are engaged in a time-consuming search and coordination for suitable satellite data sources. Reducing manual activation time delay is crucial given past delays in RMS activation of, for instance, 36h after disasters in Bosnia and Herzegovina (CEMS, 2014). Since 2016, EFAS has been linked to the CEMS SEM process to anticipate satellite tasking for riverine floods. Wania et al. (2021) found that EFAS pre-tasking reduced delivery time for the first map product from 28:47 h to 16:05 h on average considering 14 flood events in Europe from 2016 to 2020. Similarly, Ajmar et al. (2019) proposed to include early warning alerts like those of the Global Disaster Alert and Coordination System (GDACS, https://www.gdacs.org), which also integrates tsunami models to reduce acquisition times by up to one day (GDACS, n.d.).

THE PROPOSED CONCEPT

The SEM workflow described above reveals that manual interaction and latency are the main reasons for a delayed provision of EO-based data products for DM, particularly the triggering step and the search for suitable satellite data sources. There are already approaches in place that shorten the time for triggering, but these are limited to specific natural events, and in some cases are not commonly accessible. Thus, we propose an approach that substitutes manual interaction and latency with a) the automation of processes and b) the usage of primarily open data from the WWW. Our assumption is that combining both components is key for an accelerated and therefore substantially improved SEM workflow.

AOI Definition

Figure 1 shows our proposed workflow for automating the initial steps of a SEM activation, which requires two types of input data: a) data that allows us to determine an AOI and b) data that contains information on future satellite data acquisitions. In our approach, the AOI is defined as an automatically derived area in which an event is likely to happen in the near future or has just happened. An event can be anything that might require an observation with remote sensing technologies, such as a natural or man-made disaster. While the AOI is currently determined manually by the entity that requests the satellite data, we propose a process that automatically retrieves the AOI by monitoring crisis-related data from the WWW. Monitoring involves continuously analyzing heterogeneous data to detect spatiotemporal anomalies in a given context.

Sometimes web data contain such anomalies implicitly. In case of natural disasters, for example, numerous national and international entities issue official alert messages already including an AOI (e.g. MeteoAlarm, https://www.meteoalarm.org). For predictable events, such as storms, these alerts can be early warnings. For sudden-onset disasters, such as earthquakes, these alerts are usually published in a short time frame after the event.

Another example of publicly available spatiotemporal anomalies are event databases like the Global Database of Events, Language, and Tone (https://www.gdeltproject.org). These databases may contain conflict-related events, such as air raids. Technically, we can directly use the spatiotemporal information from alerts and event databases for building an AOI. Yet, trustworthiness of the sources must be considered. Warnings issued by widely accepted institutions such as GDACS can be regarded as very reliable. We can trust the expertise of the specialists and integrate the provided AOIs into our process. However, sometimes there are no official warnings or up-to-date event databases for the region or the event type we are interested in. As an example, quickly emerging refugee camps or natural disasters in countries without warning infrastructure can be mentioned. In such cases, or when the information derived from alerts and event databases is not satisfactory, other data sources should be considered, for example media monitors (e.g. Europe Media Monitor, https://emm.newsbrief.eu) and social media platforms. Here, the challenges are data access, data reliability and the fact that the spatiotemporal anomaly detection has to be performed by ourselves. An automated event detection approach (see Li et al. (2022) for examples) can be applied to turn unstructured textual data into well-structured events that describe the location, the time and the type of a disaster (Resch et al., 2018; Havas & Resch, 2021).

In summary, we can assume that in certain situations only one data source might be sufficient for the definition of an AOI. Even more, this applies to situations where a) the size of the footprint of the satellite is much bigger than the AOI, b) the satellite data are available free of charge and c) the satellite data will be analyzed automatically. In other situations, we cannot rely on only one data source. For instance, an official alert might cover a vast administrative entity. However, an RMS provider is primarily interested in the situation in populated areas. In such cases, we propose the fusion of as many data sources as necessary to determine a sensible AOI. In this scenario, together with the official alert(s), we could use a population distribution dataset and social media analysis for refinement (Lorini et al., 2019). The efforts pay off particularly when a) the size of the footprint of the satellite is smaller or approximately of the same size as the AOI, b) the satellite data are only available commercially at a high price and c) the satellite data will be analyzed manually.

Satellite Acquisitions

Besides the definition of AOIs for specific events, information on satellite acquisitions is essential in our approach. We have to distinguish three different satellite categories depending on the availability of satellite data. 1) Some EO satellites collect data permanently. The data are made available free of charge on platforms on the WWW. Besides the actual imagery, acquisition planning data are sometimes published on the WWW. Hence, we know when and where a satellite will acquire data in the coming days. Examples for this category are the Copernicus Sentinel (e.g. Sentinel-2, see European Space Agency, n.d.) or Landsat missions. 2) Some EO satellites offer a direct data broadcast. These satellites still collect data permanently. However, ground stations can directly receive the data when the satellite passes over and before the data is published on official platforms. Alongside the sometimes publicly available acquisition planning data, information from and about ground stations is required to assess data availability. Examples of this category are Sentinel-1, Aqua, Terra and Suomi NPP. 3) Some EO satellites do not collect data on a permanent basis. Instead, these satellites have to be tasked by an authorized entity. For acquisition planning, a ground station has to uplink information to the satellite, such as where and when data have to be acquired. Examples of this category are commercial VHR optical satellites (e.g. WorldView-3) and radar satellites (e.g. TerraSAR-X).

Data Intersection

For satellites from category one, as defined in chapter “Satellite Acquisitions”, each of the derived AOIs can be intersected with the potential sensing areas. No manual interaction is required and all the necessary data can be downloaded from the WWW. For satellites from category two, we additionally have to consider the direct acquisition capacities of ground stations. For satellites from category three an interface with commercial satellite operators has to be established in order to ensure that the requested AOIs can be considered in acquisition planning. The overall goal remains the same in all three cases: We want to know which satellite data will be available for our AOIs at what time. This information is of great value to decision makers in crisis situations based on experience gathered from previous ZKI activations and research projects, e.g. EU FP7 PHAROS (Community Research and Development Information Service (CORDIS), 2023) and EU H2020 HEIMDALL (CORDIS, 2022). At this point of the workflow, users can quickly be informed by means of decision proposals, for instance short email notifications, about their options for their customized satellite-based product. Thus, decision proposals are a further means to strengthen situational awareness (Endsley, 1995). While our system is intended to function fully automatically until this step, the relevance of decision proposals becomes evident if the acquisition of possibly expensive commercial data is proposed.

When EO analyses are based on publicly available data, further automation is possible and intended. In our approach, as soon as the EO data for the derived AOI are available, automatic thematic processors would instantly start analyzing these data. After a manual expert-based quality control, the EO product can be delivered to users. Besides the important EO product validation, we envisage an equally important step of AOI validation. Above we have shown that AOI derivation might be based on our own spatiotemporal anomaly detections. In such cases, we have to ensure that thresholds are calibrated correctly in order to constantly improve the quality of derived AOIs.

PROTOTYPE AND EXAMPLE

In order to demonstrate the feasibility of our concept we have implemented an experimental application based on disaster alerts from various official international (e.g. GDACS) and national (e.g. German DWD) sources as well as acquisition data of Sentinel-1A, Sentinel-2A, Sentinel-2B und Landsat-8. The prototype automatically collects the alerts from the WWW and calculates when the potential sensing area of a satellite intersects with an AOI. The results are saved in a database that can be queried by a graphical user interface for visualization purposes. Additionally, a dissemination service automatically generates textual notifications with current disaster events and matching satellite acquisition options.

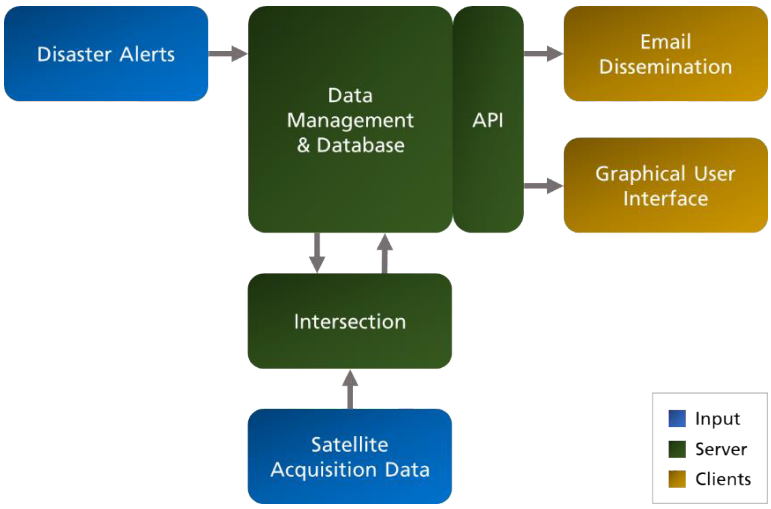

Figure 3. Major components of the prototype. The arrows indicate the direction of the data flow.

Figure 3 illustrates the major components of the developed prototype and their interactions. The prototype is designed as a client-server web application (Gallaugher & Ramanathan, 1996). The server comprises a data management component, an intersection component, a database and an API. The data management component is built with Python. Its tasks are, for instance, the download of alerts and the triggering of the intersection component. The spatiotemporal intersection component is a Java-based extension of the operational PSM (Processing System Management) (Böttcher, 2001) deployed at DLR's ground station for satellite data reception in Neustrelitz, Germany. It selects those satellite acquisitions within the next 7 days that spatially and temporally overlap with the AOIs from the alerts and returns the results to the data management. The communication between data management and intersection runs via gRPC (gRPC Remote Procedure Calls) (https://grpc.io). Next, the results are stored in a PostgreSQL database. A GraphQL API (https://graphql.org) built with Hasura (https://hasura.io) delivers the requested results to clients. The server part runs automatically at regular intervals, e.g. once per hour. A dissemination service written in Python generates brief email notifications based on the intersection results. For a more detailed insight into the collected and generated data, there's a web-based graphical user interface with an interactive map and various sorting and filter options. The graphical user interface is implemented with DLR's open source software for geoscientific web applications UKIS (Environmental and Crisis Information Systems) (Muehlbauer, n.d.; https://github.com/dlr-eoc/ukis-frontend-libraries).

The following screenshots of the prototype's graphical user interface show exemplarily how our system worked in the context of a predicted flood in northern Germany in November 2023. The "Warnings" view in Figure 4 gives an overview on all disaster alerts currently registered in the system. After selecting one particular alert, the system displays the AOI together with the matching satellite acquisitions. See "Detail" view in Figure 5.

Due to automation, the prototype was able to generate these results within minutes after the official warning was issued. As the underlying alert was an early warning, we could predict which satellite data would be available at what point of time before the actual event had happened.

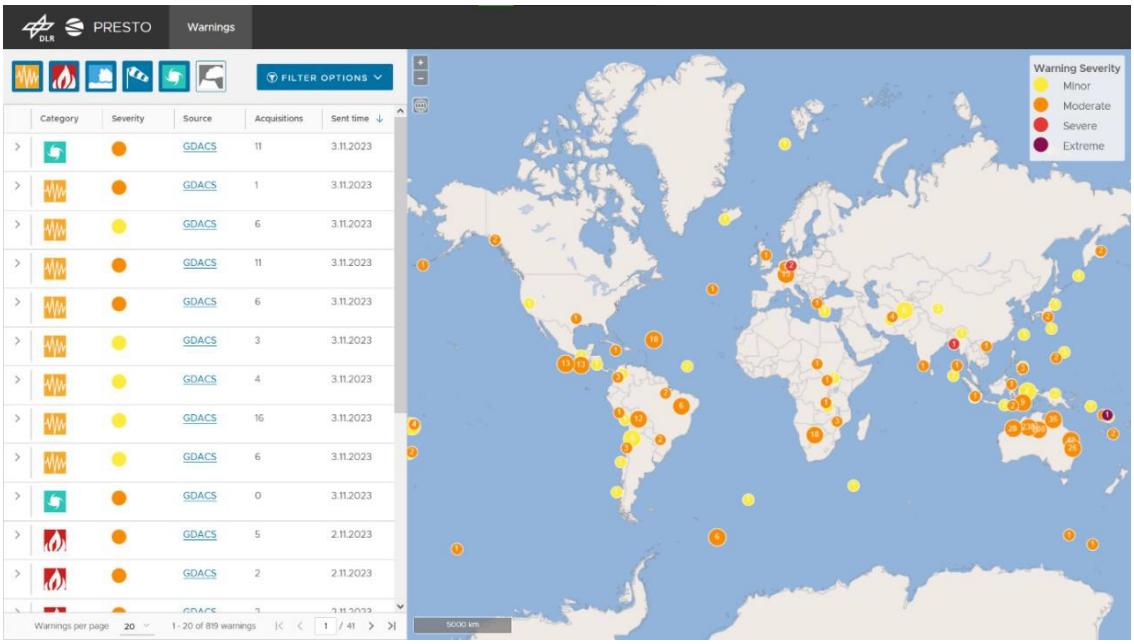

Figure 4. "Warnings" view of the prototype: The list at the left shows alerts for natural disasters with some of their attributes. The column "Acquisitions" contains the number of possible satellite data acquisitions for the respective AOI. The list can be filtered (here: source equals "GDACS") and ordered (here: time stamp descending) by the user. The map at the right shows the locations of the alerts, with colors indicating the severity of an alert.

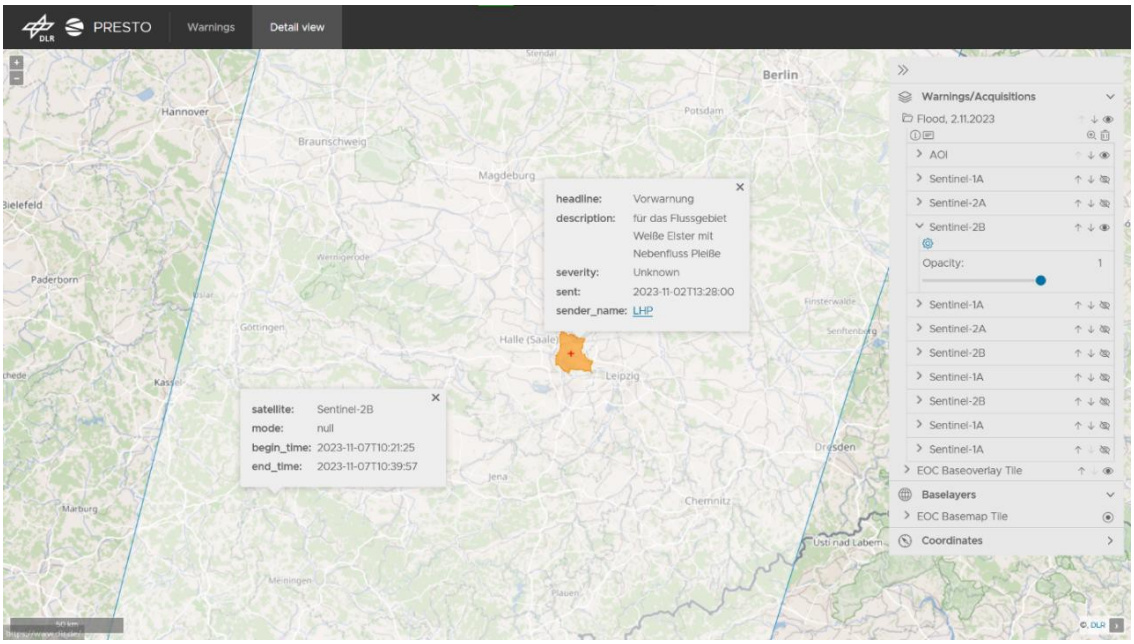

Figure 5. "Details" view of the prototype: The layer control element at the right contains entries for the AOI as well as all matching satellite acquisitions. A click on the AOI displays information such as the source of the alert and the original alert description. A click on an acquisition segment shows attributes such as the satellite name or the sensing time(s).

DISCUSSION

We consider our approach as a possible advancement of well-established SEM workflows addressing different kinds of natural or man-made disasters. Proven SEM process steps are combined with automation and primarily open data in order to satisfy the prevalent requirement of users of SEM products: faster information and product availability. The main objective is to improve the timeliness, but we also anticipate improved quality in the final EO products. If data interpretation cannot be fully automated, an EO expert will have additional time for analysis. Also, alerts, media articles etc. used to trigger the workflow can enrich the final product. Our approach improves the user's situational awareness by automatically generating decision proposals regarding EO data and product availability. This can also comprise crucial information such as the expected cloud coverage. Besides the user's benefits, there are advantages on the RMS provider's side. The monitoring of trigger data on a continental or global scale can lead to useful products that would not have been possible with human triggers alone. Cost is another factor. As long as no commercial data acquisition is involved, the workflow is based on free input data. Of course, we acknowledge the significant challenges associated with automation and open data. We heavily rely on trusted data sources such as official alerts. Yet, even official alerts might contain errors. Other possible data sources for the AOI generation, particularly media and social media, must be treated even more carefully. We try to eliminate as many inaccuracies as possible with a fusion of a reasonable amount of data sources in the respective use case. To achieve this fusion, the heterogeneous data sources first could be aggregated geometrically e.g. by incorporating the discrete global grid system H3 (https://h3geo.org). Afterwards, rule-based criteria can be applied to further validate and refine the AOI as much as possible (Roll, 2024). Moreover, a manual validation step for the AOI generation should be in place. The fusion approach also tries to absorb the loss of web data sources in course of time. Given that, for example, official alerts, events from online news and events from social media were used to define AOIs, the system would continue to function if social media were removed. Certainly, we cannot eliminate an inherent problem of satellite-based EO: the satellite most likely is not at the position over a disaster event or has just passed by. Latency is the result. Also, cloud coverage might further delay the assessment of optical imagery.

An automatic trigger can generate the decisive advantage in time, for example, by allowing data reception via direct broadcast. While automatically intersecting publicly available AOIs and acquisition plans is straightforward, including ground stations and commercial data providers may appear technically and administratively obstructive. However, an interface with DLR's ground station for satellite data reception in Neustrelitz, Germany could be established for our prototype. Finally, we want to emphasize the importance of the human factor in our approach. Crucial decisions will still – and have to – be made by humans based on their experience and transparent decision proposals. Expert knowledge from specialists at the disaster site is, once available, of utmost significance and we treat it as yet another – but very trustworthy – data source of the system.

SUMMARY AND FUTURE WORK

In this paper, we presented our vision of an enhanced SEM workflow as well as a first proof-of-concept implementation. We believe that our workflow can help to narrow down some gaps in the current state-of-the-art SEM. An accelerated process, better transparency, and more high-quality EO products can be achieved by automated processes and the combination of existing data. First experiments based on publicly available alerts and satellite acquisition data from DLR's ground station have demonstrated promising results: The prototype shows that satellite data availabilities can automatically be determined for areas potentially affected by a crisis. Our future work will focus on the transformation of our vision into a stable software that reliably supports future SEM activities. This includes a logic that considers the suitability of each satellite for each disaster type. Also, we aim at automatically generating more refined AOIs by aggregating available warning sources and filtering relevant attributes. Eventually, we plan to link our system to processing chains for satellite data in order to automate a further process step. Not only the 2021 Ahr valley flood in Germany has shown that an improvement of existing processes is relevant and possible.

ACKNOWLEDGMENTS

We certify that there is no actual or potential conflict of interest in relation to this article. This work is part of the two projects TEMA (Trusted Extremely Precise Mapping and Prediction for Emergency Management) and IFAS (Indicator Monitoring for Early Acquisition of Innovative Satellite Sensors in Natural Disasters). TEMA receives funding from the European Union's Horizon Europe research and innovation program under grant agreement No 101093003. IFAS is funded by the Bavarian Ministry of Economic Affairs, Regional Development and Energy in the Bavarian Collaborative Research Program (BayVFP) framework.

ABSTRACT

The world is constantly exposed to the negative effects of wildfires, which occur for various reasons, often beyond human control. In such a case, it is highly advisable to develop appropriate countermeasures that will comprehensively approach the problem of wildfires. In response to these needs, the SILVANUS project was created. The goal of SILVANUS is to use new and existing technologies in the field of fire management, such as mobile applications for citizens, dedicated user interfaces or special applica tions for training firefighters in VR. The set of these tools is intended to support Integrated Fire Management. In this paper, we propose a web -based interface which facilitates crisis management during fires, especially wildfires. The Dashboard is an interactive map for monitored areas, with layers corresponding to different sources of data. It also supports communication between citizens and firefighters through mobile applications and social media. The main objective of the system is to help with decision making process so that the user will ultimately decide whether data is relevant or not. The solution is directed mainly at firefighters, analysts, and public administration entities. The presented Dashboard is a work in progress.

Keywords

Dashboard, wildfire, decision support system, map.

INTRODUCTION

Climate changes, voluntary or involuntary human activities, natural causes like lightning, are main reasons of wildfires that have a negative ecological and socio-economic impact on different countries. “Every year about 45000 forest fires occur in southern Europe, burning approximately 0.5 million hectares of forests and other rural lands.” (Moreira et al., 2011). Forests in Europe cover over 35% of total land area (FOREST EUROPE, 2020) and are responsible for many ecosystem services necessary for human we ll-being such as purifying the air, filtering water supplies, controlling floods and erosion, and many more. Unfortunately, when facing wildfires, forests are losing their ability to adapt and become more vulnerable to other dangers (Forzieri et al., 2021). We distinguish

controlled and unplanned forest fires. The purpose of a controlled burning, among other things, is to reduce the risk of uncontrolled fire and to initiate it intentionally to support the forestry and agricultural sectors or to reduce greenhouse gas emissions (Grebner et al., 2013). An unplanned forest fire is unwanted wildland fire which affects an increasing number of countries, therefore the need to take remedial actions is also growing.

While researching countermeasures to prevent the increasing number of wildfires, more and more authorities are turning to IT solutions. They are flexible, relatively easy to use and low cost, and can potentially be customized with information the user considers most necessary (Hunter & Westerman, 2009). The prevention and management of forest fires, restoration of areas destroyed by fire are the topics that the Horizon 2020 -funded project SILVANUS addresses. It aims to create a stable forest management platform that is resistant to climate change. It is intended not only to effectively prevent and suppress uncontrolled and dangerous forest fires, but also to help plan prescribed burning. As part of the project, SILVANUS uses the expertise of specialists in t he areas of environmental, technical and social sciences. Scientists and engineers are supporting civil protection authorities by helping to effectively monitor forest resources, assess biodiversity, create accurate fire risk indicators and promote safety regulations among local fire-affected communities through awareness campaigns. The project lasts 42 months and, with the involvement of 49 partners from around the world, is to develop the best possible solution in the fight against wildfires (SILVANUS, 2021).

One of the tools developed as part of the SILVANUS project is the Dashboard. It is an interactive panel that represents various data graphically, often through the use of charts, tables, maps, and other visual elements. The main purpose of this interface is to facilitate timely and easy user access to important information, as well as to enable monitoring of key indicators or metrics (Few, 2013). The SILVANUS Dashboard consists mainly of a map and corresponding layers intended to assist relevant authorities in making important decisions. The platform obtains information from various sources, such as robots, drones, computer analysis and even from residents who have the Citizen Engagement Application installed on their phones, which is another tool of the SIL VANUS project prepared to increase citizens' awareness about forest fires. The aim of this article is to provide information about the Dashboard prepared for the SILVANUS Project.

The article is structured as follows: the first two sections outline the context of the problem and present the current state of knowledge in the field of fire crisis management. The next section defines the SILVANUS Dashboard system requirements, presents the system description and its architecture. Finally, conclusions are presented, summarizing the contribution of this work to solving the original problem and presenting plans for further works.

STATE OF THE ART

Dashboard is a useful tool which is being used and analyzed for emergency management in various areas to help with the decision support process. Mordecai & Kantsepolsky (2018) prepared a framework to improve management in extreme weather conditions. They propose a system to effectively use data for decision making processes through open to change deployment and visualization of data streams and indicators. The functiona lity was developed on the basis of clear system requirements, received from real end -user needs. Another example is the ELD-BS tool suite which, among other things, is a web-based dashboard developed to help with the administration work in the event of a disaster. It also supports the exchange of information between the authorized units (Hellmund et al., 2022).

Numerous works are also being undertaken to analyze the problem of forest fires and their effects. The Sanborn Map Company proposed a commercial solution called Forestry in which they focus mainly on mapping, land modeling and spatial analytics. This tool supports urban tree canopy management, heat island mitigation and the work of wildfire fighting agencies (The Sanborn Map Company, Inc., n.d.). A different platform developed by a company Technosylva is a software called Wildfire Analyst™ for real-time analysis and simulation of fire behavior, with particular emphasis on performance. The user receives various useful information in the form of charts, reports or GIS maps. It is also cloud based which makes it very flexible. Examples of three Technosylva dashboard views can be found in Figure 1. (Technosylva, Inc., n.d.).

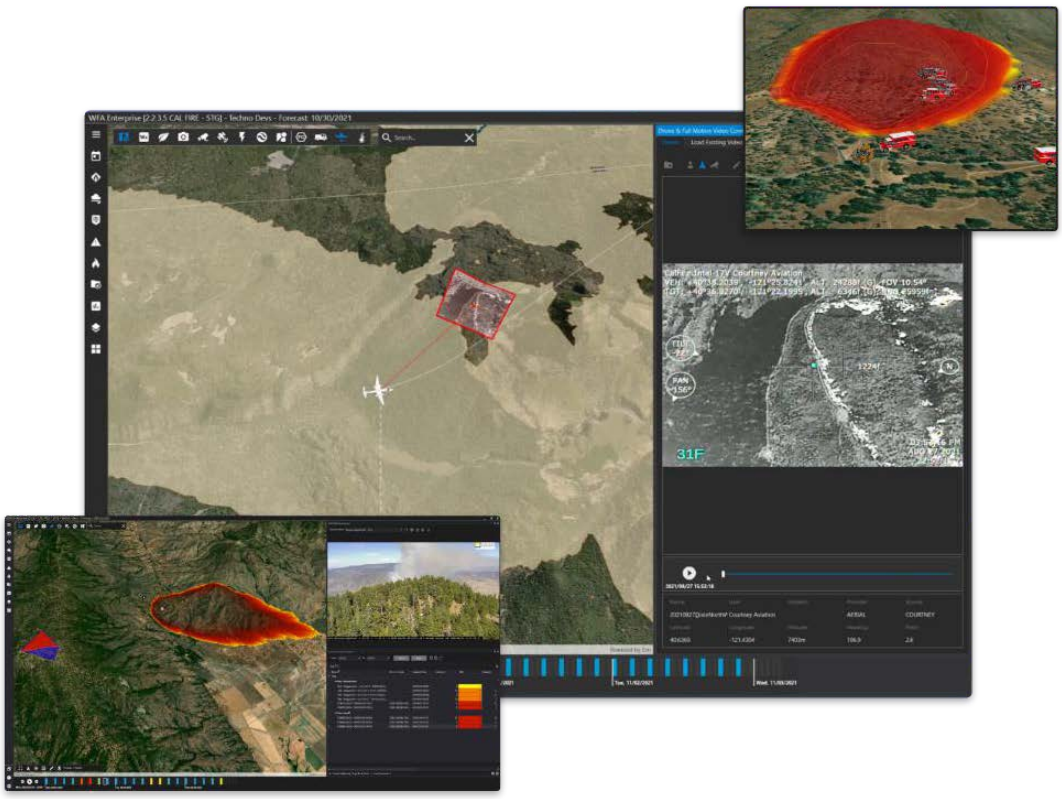

Figure 1. Technosylva dashboard (Technosylva, Inc., n.d.)

Another example is EMXSYS owned by Bruce Schubert and their CPS Wildfire Management Tool. It is free to use software for fire forecasting. Wildfire Management Tool uses the logical structure contained in Campbe **l** Prediction System, which is a fireground-specific language system that wildland firefighters learn from (Schubert, n.d.). An example of the EMXSYS dashboard view is shown in Figure 2.

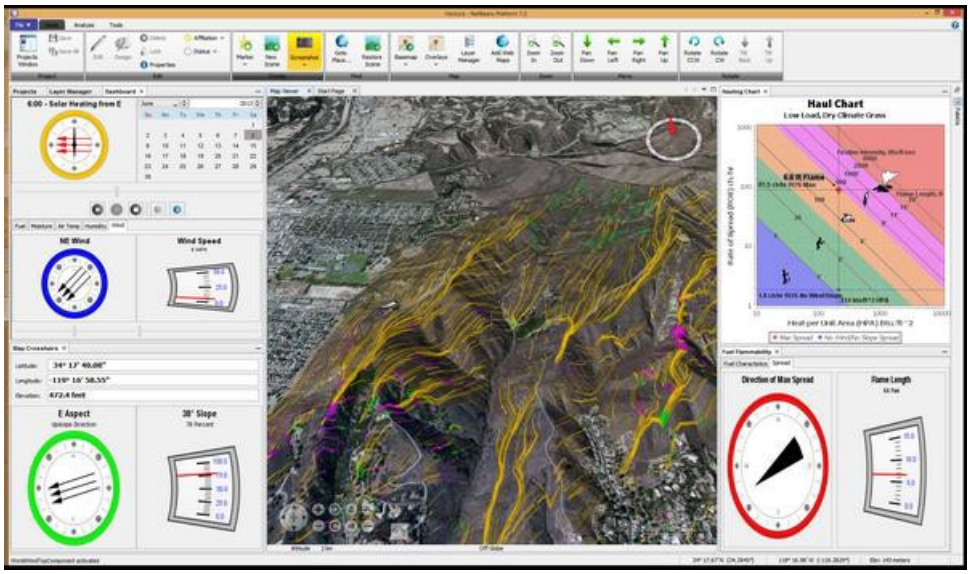

Figure 2. EMXSYS dashboard (Schubert, n.d.)

A comprehensive review of the literature shows that works on forest fires have been a topic often undertaken by specialists. One of the examples is the online GIS platform named AEGIS, which is a tool supporting the decision - making process in managing fire risk in Greece. It uses both spatial and non-spatial data to present the most useful information for the user about fires. The user can also conduct a fire simulation to understand how the fire will behave. Authors also used artificial neural networks to assess the risk of fire outbreaks, taking into account various parameters, learning methods, activation functions, data pre-processing techniques and network structures

(Battiston et al., 2019).

Another Horizon 2020 project called HEIMDALL also works on the problem of wildfires. It aims to enhance both immediate and long-term collaborative strategic planning at the regional level for the multiple stakeholders involved in disaster risk management a nd response. Their main goal was to create for decision-makers and other interested parties a platform that offers various tools to support crisis management. Many specialists from various specializations were engaged in the project. HEIMDALL platform predicts the spread and behavior of fire under a variety of fire conditions (Battiston et al., 2019).

Despite the large number of already existing solutions in the field of fire crisis management, the need to deal with the problem of wildfires is still urgent. According to our research and experience - it is important to use existing data to create new tools. The solutions do not have to be competitive, but rather complementary. For this reason, work on the SILVANUS project was started. This platform aims to minimize the number of fires, detect them faster and to help manage forest restoration better.

SILVANUS DASHBOARD

SILVANUS Dashboard is a web-based interface which is created to provide useful information, enabling users to quickly understand the situation on the field to make informed and good decisions. The interface is designed to be used mainly by trained personnel e.g. firefighters, analysts or public administration representatives to facilitate Integrated Fire Management. It combines prevention and firefighting strategies, taking into account social, economic, cultural and ecological analyses. Its goal is to minimize losses caused by fires and maximize the benefits that may come from them. In addition, it also covers four stages of crisis management: mitigation, preparedness, response and recovery. To use the Dashboard, a person must successfully undergo training conducted by a specialist. They also must demonstrate an understanding of fires, forest fires, legal regulations and how firefighting units operate in the served area.

To understand the needs of future users and to decide on the technology, contributors asked for opinion partners, firefighters and specialists through meetings, dashboard demonstrations and participation in pilots organized as part of the project. The whole process is shown in Figure 3.

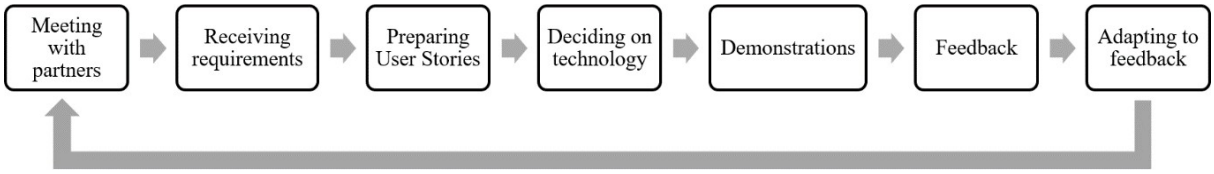

Figure 3. Process of developing Dashboard functionalities

The requirements collected at all meetings and levels were divided into functional and non -functional. They describe the constraints with which the system should perform its functions. All requirements are presented in Table 1 together with their descriptions.

Table 1. SILVANUS Dashboard functional and non-functional requirements

SRS-ID	Requirement	Description
SRS-F-1	Log in/out	A user must be able to log in/out to the existing account.
SRS-F-2	Displaying Layers	A user should be able to turn on/off the GIS layer while being in a map view.
SRS-F-3	Displaying Notifications	When the system gets an update about a new event the user must be notified about it on the map and on the notification bar.
SRS-F-4	Displaying right information drawer	When the user sees the new event on the map, he will be able to interact with it to see more information about it.
SRS-F-5	Displaying left information drawer	The left drawer must display layers, pin list, map typer, filter options.
SRS-F-6	Filtering	A user must be able to filter different layers by date and time range and different variables (depending on the layer).
SRS-F-7	Zooming in/out	A user must be able to zoom in/out the map.

SRS-F-8	Displaying Smoke/fire detection layer	A user must be able to browse pins with smoke/fire detection on the map.
SRS-F-9	Displaying Social Media Fire Events layer	A user must be able to browse pins from social media posts such as platform X with information about probable fires.
SRS-F-10	Displaying ID Social Media layer	The Dashboard must display a layer with area scope (set of coordinates) with information about it from social media in 3+ different languages.
SRS-F-11	Displaying Unmanned Ground Vehicles layer (UGV)	The Dashboard must display a set of pins on a map to show the route of UGV with photos and information gathered.
SRS-F-12	Displaying ID DSS layer	The Dashboard must display a layer with area scope (set of coordinates) with analytical information about it in different time ranges.
SRS-F-13	Displaying Fire Spread Simulation layer	The Dashboard must display a fire spread simulation as a polygon (set of coordinates).
SRS-F-14	Sending warnings	The user must be able to send warnings to citizen using Citizen Engagement Mobile App after clicking on a map and filling out the form.
SRS-F-15	Mapping a fire	The user must be able to draw a polygon on a map which will mirror the ongoing fire.
SRS-NF-1	Security	The Dashboard must be secured against unauthorized access.
SRS-NF-2	Performance	The Dashboard must be able to handle the required number of users with a constant flow of new information from the backend without compromising performance.
SRS-NF-3	Maintenance	The Dashboard should be easy to maintain and update.
SRS-NF-4	Simplicity	The interface would be used by people who have different knowledge in IT solutions so it should be easy to use.
SRS-NF-5	Verification	The Dashboard must meet with all applicable laws, terms and regulations, including Horizon 2020 terms (for example privacy by design).
SRS-NF-6	Reliability	The interface must be reliable and compliant with user requirements.
SRS-NF-7	Availability	The Dashboard must be available during system maintenance.

Main goals for this platform are to be transparent, intuitive and tailored to the needs of future users. After analyzing the collected requirements, a list of basic dashboard functionalities was created which are presented in Table 2.

Table 2. SILVANUS Dashboard functions

Function	Description
Layers	All data gathered from partners are displayed as layers in the form of highlighted areas, a collection of pins or a slider to show different images.
Pins	A pin is a feature to show a specific location. The user can interact with the pin by clicking on it to see more information about the event.
Area scope	This is a layer where the information concerns an area, i.e. a set of coordinates. The user can interact with the area by clicking on it to see more information.
Zoom in/out	The Dashboard allows to zoom in/out the map for better

	understanding by using a scroll on the mouse.
Notifications	When new data is delivered to the Dashboard, the user receives a notification. The user can delete the notification.
Filtering	All pins layers can be filtered by date and time.
Log in/out	Users can log in/out using an authorized account prepared by the admin.
Slider	The slider is used to quickly change the displayed graphics on the map (heatmap, fire spread simulation).
Drawing on the map	The user can specify an area on the map by placing points on the map. It can be edited or deleted.
Sending a poll to citizens	The Dashboard allows communication with Citizens Engagement App. The user of a Dashboard can send a warning or an announcement for specific area and time.
Map types	The map can be displayed in different types (satellite, street map).

Technical Information

This section describes the technologies used in the Dashboard interface and the general reasoning behind usage of said solutions. There is also a description of the data flow in the Dashboard as well as general architecture of integration of Dashboard with rest of SILVANUS through SAL (Storage Abstraction Layer).

Technologies

The core of the interface is written in ReactJS, which is one of the more recognizable, opensource libraries for building user interfaces based on components - standardized, interchangeable building blocks of UIs. It is being constantly developed and supported by a wide community of individual developers and companies. The library being open source ensures there will not be additional costs hidden in solution for SILVANUS being used and further developed in the future. Moreover, a wide variety of places where ReactJS is being currently used (ie. Facebook, Instagram, Netflix) can guarantee that it will be constantly improved and updated in the foreseeable future. These factors were considered as well in all libraries listed below, for keeping solution viable and without unnecessary costs.

Dashboard makes use of TypeScript - a free and open-source high-level programming language that adds static typing with optional type annotations to Java Script. TypeScript speeds up development experience by catching errors and providing fixes.
Following libraries are being used in dashboard:

- REACT – Redux Toolkit – Redux is a library implementing Flux pattern, for managing and updating application state, using events called "actions". It serves as a centralized store for state that needs to be used across entire application, with rules ensuring that the state can only be updated in a predictable fashion. It allows more efficient control and testing of the application.
- Leaflet - an opensource Java Script library used to build web mapping applications. Leaflet's goal is to be a tool focused on ease of development, focused on efficiency and user-centric design. It seamlessly operates across various platforms, both mobile and desktop, offering comprehensive documentation and extensive plugin options for customization.
- Material UI - an open-source React component library that implements Google's Material Design , Material Design aims to reflect the way objects react to the light and cast shadows in the physical world, operate with bold, intentional elements from print typography and introduce fluidity of movement for their interactions. Material Design uses more grid-based layouts, responsive animations and transitions, padding, and depth effects such as lighting and shadows.
- KeyCloak JS - As an OAuth2, OpenID Connect, and SAML compliant server, Keycloak can secure any application and service as long as the technology stack they are using supports any of these protocols. For some programming languages, Keycloak provides libraries that try to fill the gap for the lack of support of a particular security protocol or to provide a richer and tightly coupled integration with the server.

General SILVANUS Architecture Overview

SAL is the module of SILVANUS responsible for transferring data between different components in SILVANUS. The primary function of SAL is to abstract the object store, offering two key advantages. Firstly, it enables flexibility in managing data at rest, allowing for efficient data management practices. Secondly, it decouples data from user products in a multi-source, multi-client environment, providing support for security, policy, privacy, and business constraints. From the perspective of Dashboard, the ma in purpose of SAL is to store and provide access to data produced by User Products.

Figure 4. showcases the flow of ingestion and provision of data by SAL from external and internal sources, as well as user products. Each ingestion method requires a distinct SAL interface to facilitate communication.

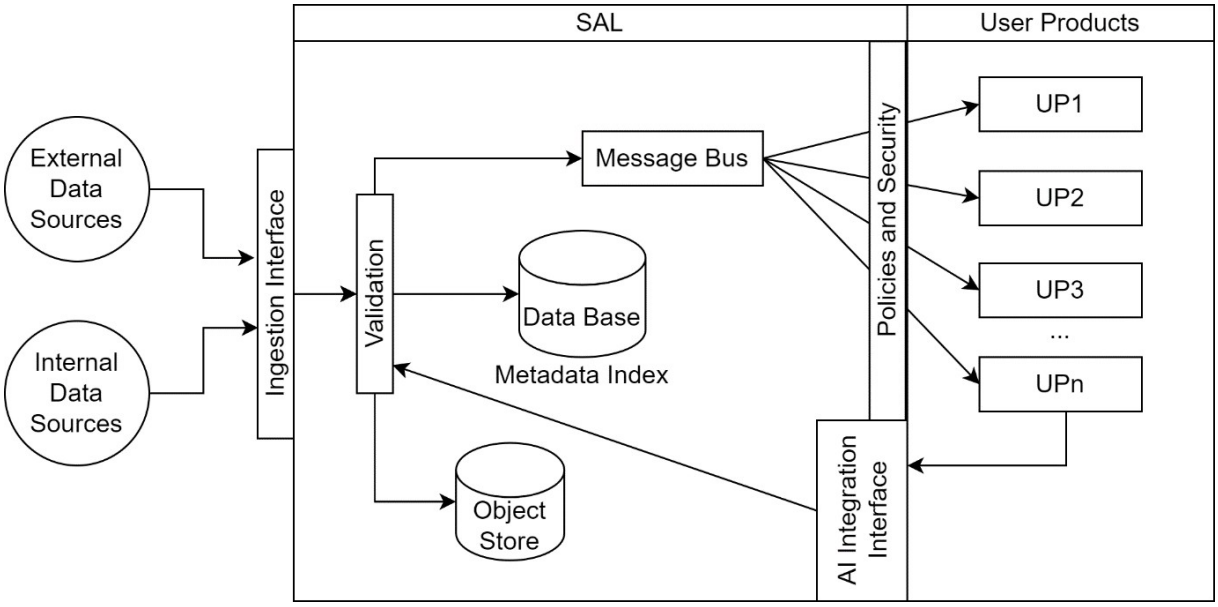

Figure 4. The interaction between SAL and other components in SILVANUS platform

Integration with SAL

The data is produced by the UPs (User Products) and stored in SAL. Between the UI and SAL the middleware exists in the form of Proxy Backend, which is responsible for downloading and transferring the data from SAL to the dashboard. Connection between Proxy Backend and UI is being authorized through Keycloak.

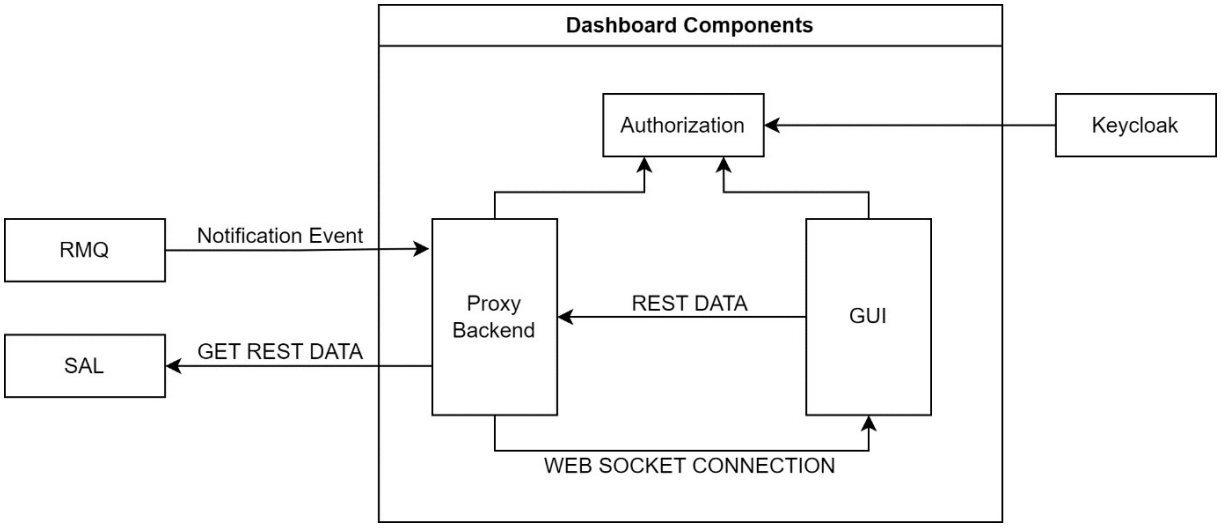

Figure 5. Dashboard – SAL integration general architecture

Proxy Backend – the component performs the task of communicating with the SAL component via a REST API by fetching data and transforming it into the final format that is delivered to UIF. In addition, it receives

notifications from the RabbitMQ queue and forwards them via WebSocket.

Data

There are two different types of data which could be digested by dashboard:

- Geolocalised events (visualised via pins)
- State of the area (visualised via polygon/raster)

Both of those data types are standardized throughout SILVANUS in a certain form of geojson. The data are either static or live, which determines the way in which they are downloaded from SAL. Static data are being downloaded through REST API and live through WebSockets.

Dashboard is able to work with outside GIS servers to manage data flow for less complex layers with static data. The advantage of such a solution is that there is no need to handle data on the side of dashboard and multiple different sources of such data could be applied to the dashboard. On the other hand, there is limited customization and interaction from the dashboard available in such cases.

Dashboard Layers

The SILVANUS dashboard displays a map with several layers representing the work of different User Products (UP). UPs are users' creation in the form of products, content or services. The list with names of UPs and corresponding layers is presented below in Table 3.

Table 3. User Products - Dashboard Layers

UP	Dashboard layer
Fire detection based on social sensing	Social Media Sensing Layer
	ID Social Media Sensing Layer
Fire detection from IoT devices	IoT Layer
Fire detection based on UAV/UGV	UGV Layer
Fire spread forecast	Fire Spread Forecast Layer
Citizens engagement programme and mobile apps	Mobile Subscribers Layer

Depending on the data collected, layers are divided into those displayed in the form of pins and those that represent a certain area. All layers can be enabled simultaneously and each separately. Figure 6 represents a use case diagram of all layers with pins. A pin is a point on the map which geolocation was sent along with other necessary data by a specific device. Currently, there are four layers of this type: Unmanned Ground Vehicle (UGV), Internet of Things (IoT), Social Media Sensing, Mobile Subscribers.

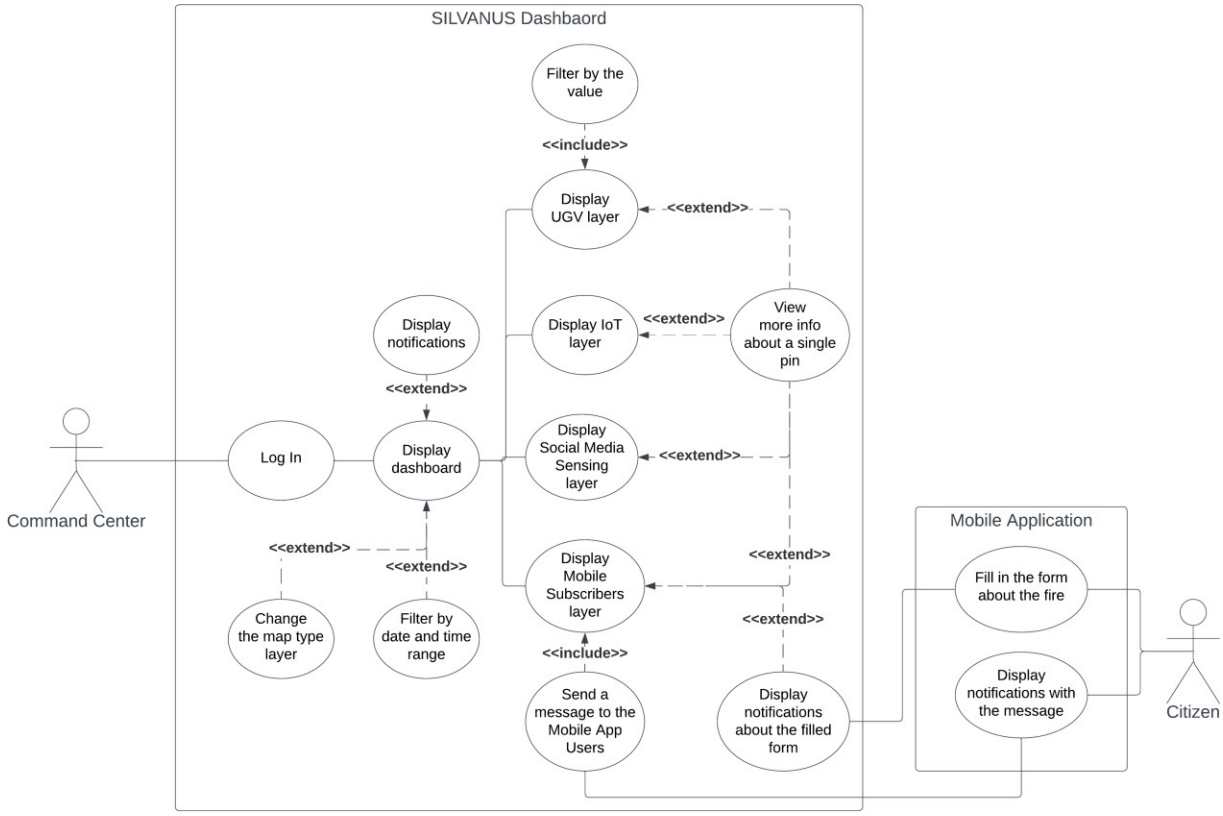

Figure 6. Use Case for SILVANUS Dashboard layers with pins

UGV is a vehicle that operates on the surface of the earth without human intervention on board. These devices move along the previously indicated route, collecting photos and indicators that are sent to the SILVANUS Dashboard every few minutes. They help, among other things, understand the actual state of the field in order to possibly detect a fire. It can be filtered by date, time and value.

IoT is a layer where the device is attached to a fixed and stable place, for example a tree, equipped with sensors and a camera. Similarly, to UGV, it periodically sends data along with photos to the SILVANUS platform. When fire or smoke is detected, it is appropriately recorded with an indicator that affects the color of the pin, thanks to which the dashboard user obtains information about a possible threat faster. The user can filter it by date and time.

Social Media Sensing layer receives alerts from social media, which are generated based on data from social media such as the X platform (formerly Twitter) or Facebook. They contain information about fire, smoke and other fire hazards. It can be filtered by date and time.

Mobile Subscribers is the layer where information comes from citizens who are using mobile devices with the SILVANUS mobile application installed. When they face a fire threat, they can send a photo along with information about it. Moreover, the SILVANUS Dashboard user, having already learned about a fire in a specific area, can send a warning to users of the mobile application. It is possible to filter by date and time.

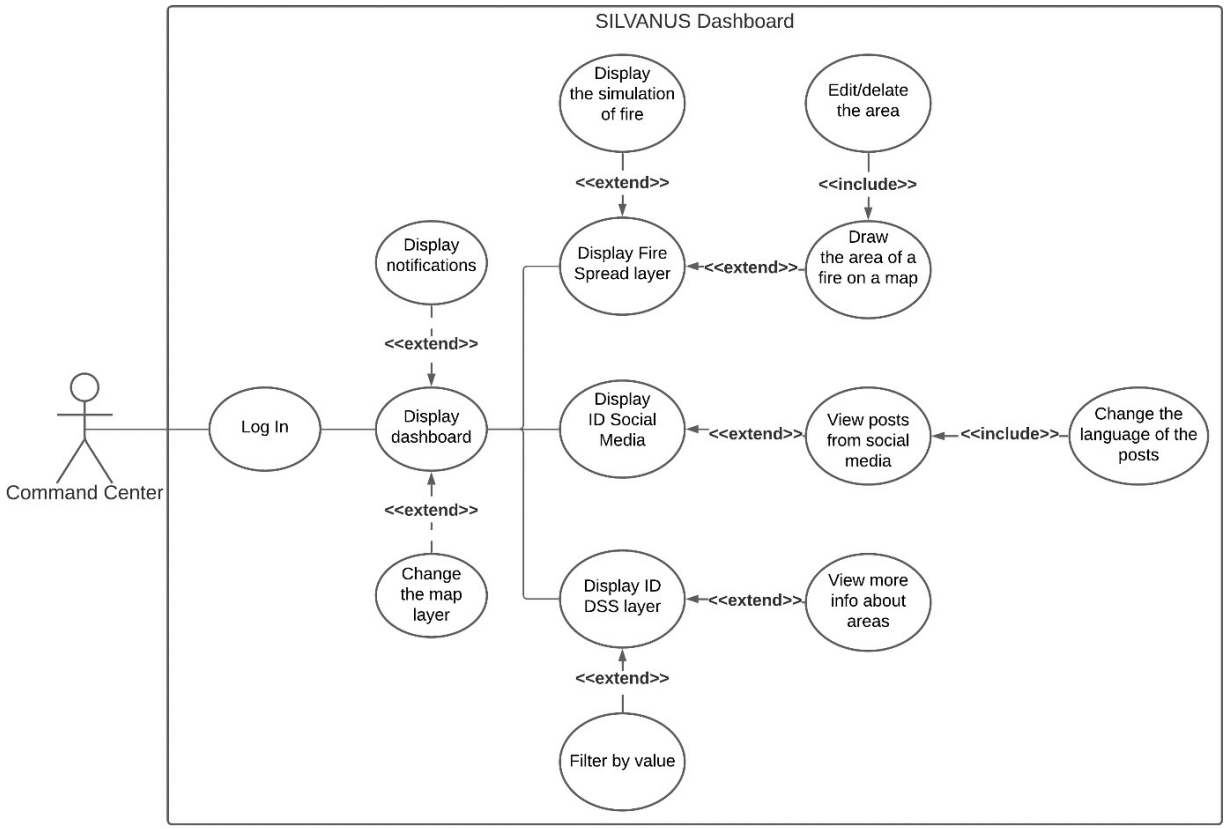

Figure 7. Use Case for SILVANUS Dashboard layers with areas

The next type of layer represents data on areas which is shown on the use case diagram in Figure 7. We distinguish Fire Spread layer (FS), ID Social Media Sensing and Decision Support System for analytics purpose (ID DSS) both prepared for Indonesia region. FS is a layer with simulation of fire spread. The user can view simulation results for a given time in future by moving the slider to a different time range given in minutes. This will display the simulated fire spread, which is shown on the map in the form of a grid. Next, we have layers focusing on the Indonesian area. ID Social Media Sensing layer is very similar to the layer mentioned earlier, they differ primarily in the form of data presentation, in this case they are not pins but areas. ID DSS is the analytical layer that collects statistical data for easy comparison, where the data is presented in the form of charts. Most of the layers can be seen in use on the SILVANUS Dashboard screenshot in Figure 8.

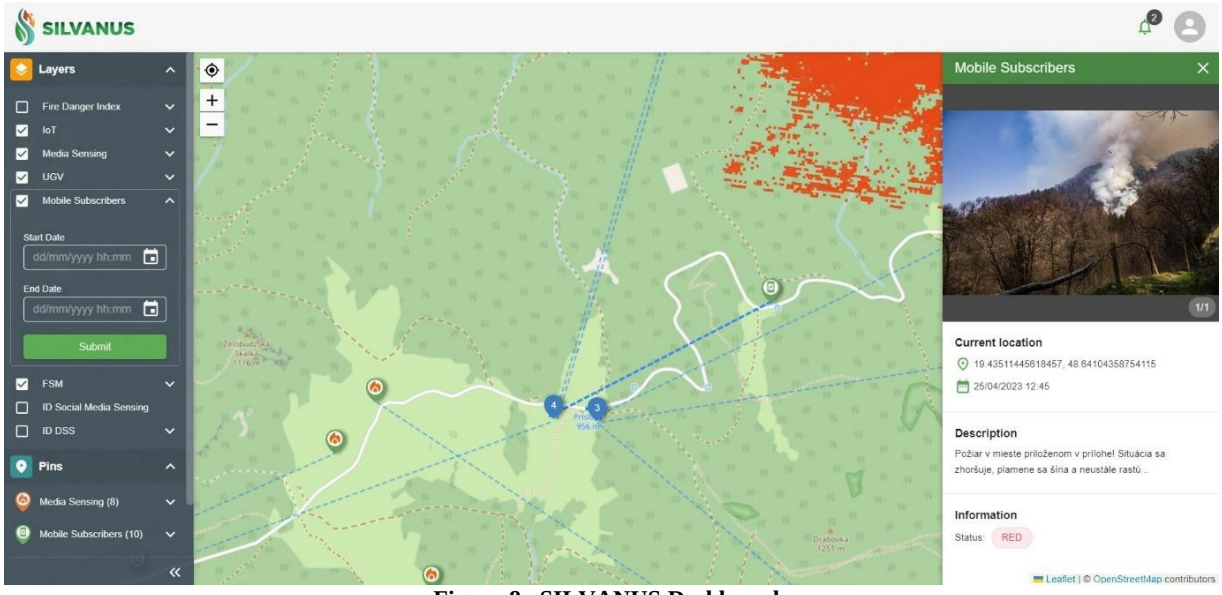

Figure 8. SILVANUS Dashboard

On the left side of the interface there is a panel that allows the user to select the layer with filtering option and the

list of all displayed pins. The main view of the platform is a map which, after selecting a layer, displays the data of interest to the user. Each pin contains information that the user can read by clicking on the pin icon, which will cause the panel to slide out on the right side of the dashboard.

INTEGRATION WITH THE CITIZEN ENGAGEMENT MOBILE APP

The Citizen Engagement Mobile App (CEA) is a specialized mobile application featuring various modules designed to involve citizens in combating forest fires. In addition to citizen engagement modules, such as Guidelines, Quizes, Practical Tips or News, a "Situational awareness and information sharing" module for receiving alerts and sharing event reports in direct communication with firefighters deployed at the scene is also being implemented. The idea is to provide tools for citizens to communicate with firefighters as close to the incidence site as possible. The two main supported use cases are "Fire Warning" and "Fire Reporting". The following Figure depicts the basic actors and use cases.

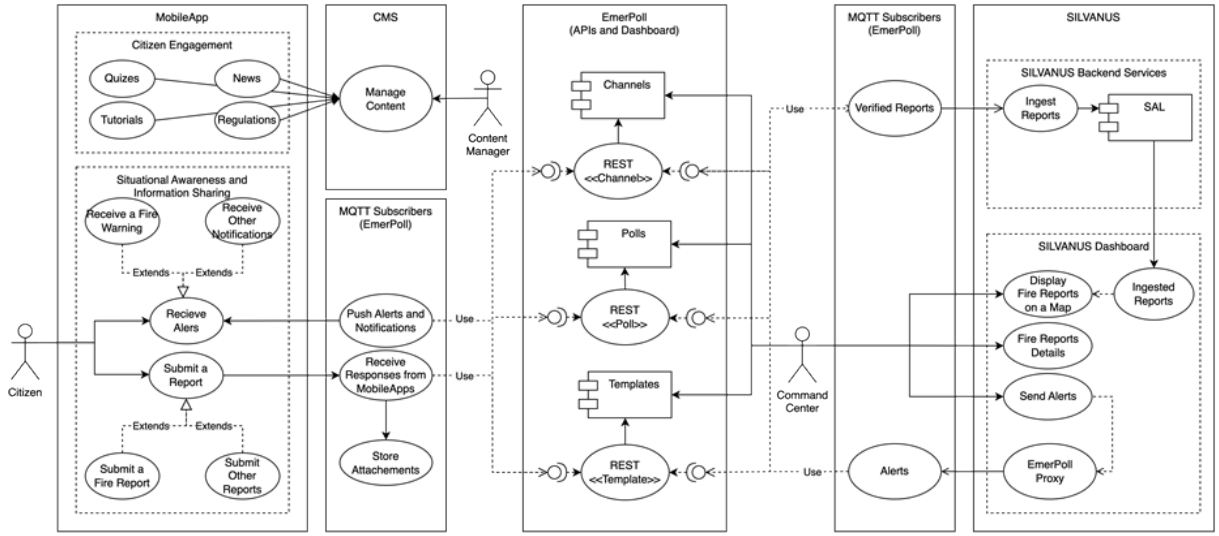

Figure 9. Use Case for the SILVANUS Mobile App and the EmerPoll backend

The main systems involved in the use cases are the mobile application (MobileApp), a content management system (CMS), the SILVANUS platform and the EmerPoll system.

The MobileApp encompasses the "Citizen Engagement" subsystem in which a Content Manager can manage and update the content of the citizen engagement modules and the "Situational Awareness and Sharing" subsystem in which functionalities for receiving alerts and notification as well as for submitting reports about a spotted fire or other events are supported.

EmerPoll is a response collection and aggregation framework which is based on the concept of Polls, Channels and Templates, proposed and described in (Balogh, 2016), for which it exposes both REST APIs for actions as well as a dedicated web-based Dashboard. EmerPoll is the main backend engine making possible the submission, aggregation and validation of individual reports or alerts. MQTT Subscribers are special services which facilitate communication between EmerPoll and other systems by compiling and forwa rding MQTT messages.

The involved SILVANUS system comprises the Backend Services and the SILVANUS Dashboard subsystems. Verified reports coming from the EmerPoll system are ingested using the publish/subscribe paradigm to a storage abstraction layer component (SAL). Subsequently the SILVANUS Dashboard uses such ingested verified reports and displays them on a specialized map layer. Forms are used to send alerts or warnings from the SILVANUS Dashboard via the EmerPoll APIs to the Mobile App users.

Figure 10. Screen of CEA app receiving fire warning region

The CEA application serves as a mobile platform enabling citizens to report sightings of fires (Balogh, 2023) during outdoor activities. In addition to sending the information, users of CEA may receive updates on the severity of fires in their vicinity. Specifically, a polygon marked with a warning icon is displayed on the user's map (shown in Figure 10) to indicate areas of concern. These warning messages are relayed from the EmerPoll service initiated by the SILVANUS Dashboard, where responsible fire-rescue personnel, upon confirming a fire, designate the dangerous area requiring a response. Subsequently, the message is distributed to users through their registered channels as an MQTT message containing a GeoJSON payload with metadata describing the fire incident. In a similar manner, the CEA is also prepared to display evacuation routes from the endangered area, ensuring users have access to critical information for their safety.

CONCLUSIONS AND FUTURE WORKS

Dashboard is a web-based, graphical interface created for SILVANUS platform, which is the main access point for the user to obtain and interact with outcomes of data produced by SILVANUS' various modules. Panel is meant to be used both by representatives from authorities managing fire prevention and regular operators derived from firefighters. Data from different User Products is presented on separate layers in a way which is clear and easy to navigate. Dashboard facilitates timely and easy user access to important information. It provides a variety of tools and parameters upon which the operator is able to determine geolocated occurrences of smoke and fire to put adequate countermeasures to them.

It is important to know that for interface there is no single all-in-a ll solution, or design, which will answer every need from every partner. Each case should be considered separately and be customized based on the individual needs of every partner and characteristics of their region. Final solution will be applied case by case to different regions considering local challenges and accommodate them appropriately.

Dashboard is currently aimed to be visual representation of combined works undergoing in SILVANUS for the partners, authorities and representatives from different regions during pilots and field presentations. In 2023 it was presented during pilots in Podpolanie (Slovakia), Limoges (France), Palangka Raya (Indonesia) and Brisbane (Australia). During those presentations the feedback from possible end users was gathered and is currently being analyzed and considered for further improvements.

Dashboard is constantly evolving upon continuous testing and gathered feedback from actual environments involved in fire prevention, both from perspective of offered functionalities and undergoing improvements in design, usability and user experience. As for 2024 Dashboard is being prepared for upcoming pilots in Czech Republic, Brazil and Italy and the changes identified during previous pilots are being applied.

ACKNOWLEDGMENTS

This work is made under the SILVANUS project which is funded by the EU Horizon 2020 Green Deal program under grant agreement ID: 101037247, Slovak national project iControl APVV-20-0571.

ABSTRACT

Terrorist attacks are a significant threat to global security as they can cause a large number of deaths, economic losses, and trigger public panic. This paper focuses on the Gulf states as the survey region. This study comprehensively investigates the correlation between national-scale terrorist attacks and various potential factors in the social, political, economic, and military fields, based on the Spearman rank coefficient and gray correlation analysis. The potential factors are divided into two categories: those with a positive correlation and those with a negative correlation to terrorist attacks. The study shows a strong correlation between the adolescent fertility rate (births per 1,000 women aged 15-19) and the occurrence of terrorist attacks. This correlation has not been previously noted in relevant studies, indicating a need for greater attention to be paid to the impact of terrorist attacks on the human rights of children and adolescents.

Keywords

Terrorist attack, Gulf states, characteristic analysis, correlation analysis.

INTRODUCTION

Terrorist attacks involve violent acts against non-military targets, often motivated by political, religious, or ideological goals (Kydd & Walter, 2006; Richards, 2014). The definition used by the Global Terrorism Database (GTD) is adopted in this study, defining terrorist attacks as "the threatened or actual use of illegal force and violence by a non-state actor to achieve political, economic, religious, or social goals through fear, coercion, or intimidation." Terrorist attacks, characterized by obvious violence and inhumanity, can not only cause huge casualties and property losses but also create a panic atmosphere within a certain area for a long time (Holman et

al., 2008; Roy et al., 2011; Yaya, 2009). Moreover, these attacks seriously affect and threaten political security and social stability of all the countries and regions globally, posing a huge threat to international relations and the global economy through ripple effects (Mun et al., 2021). Globally, we have experienced a variety of tragic terrorist attacks. For example, the September 11 attacks were the worst terrorist attacks happened in the United States, resulting in 3,025 deaths and missing. This incident seriously weakened American people's sense of security and formed severe psychological impact on American people who experienced the terrorist attack firsthand (Tong et al., 2016). In 2004, 190 people were killed and more than 1,500 were injured in the Madrid metro bombings (Buesa et al., 2007). On the night of November 13, 2015, a series of terrorist attacks took place in Paris, France, killing 132 people and injuring more than 300, which induced a state of emergency declaration in France. In another well-known case, the multiple bomb attacks in Sri Lanka on April 21, 2019 , resulted in more than 250 deaths and more than 500 injuries. The identification of 42 foreign nationals among the victims caused global shock and widespread concern. Although the GTD indicates a general decrease in the number of terrorist attacks worldwide in recent years, the overall volume remains substantial, with approximately 8,000 attacks recorded in 2020, equating to an average of 22 attacks per day (GTD, 2023). Considering the global impact of terrorist attacks and the serious humanitarian disaster they may bring, research on the characteristics of terrorist attacks itself and the potential related factors are in urgent need.

Terrorist attacks can indeed happen suddenly, but when analyzed on a regional level, patterns and risks of terrorist attacks can often be identified. The academic community has dedicated significant efforts to researching the spatiotemporal evolution and driving mechanisms of terrorism, which can provide valuable insights into the root causes and trends of terrorist attacks. Among the numerous studies, several commonly mentioned factors that are highly correlated with terrorist attacks have been frequently identified, including imperialism, political systems, race and religion, and social factors such as income inequality and unemployment rates (Leite et al., 2019; Sharma, 2013; Tin et al., 2022). Specifically speaking, most of the existing studies engaged in in-depth mining of GTD. Part of the research is the data rearrangement and statistical presentation of the GTD. For example, some scholars searched the GTD for all terrorist attacks against nuclear facilities, nuclear scientists, nuclear transport, and other nuclear industry-related targets in the period from 1970-2020, and found that terrorist attacks carried out by non-state perpetrators were rare, and none of the attacks finally resulted in radioactive fallout or environmental contamination (De Cauwer et al., 2023). Part of the research is knowledge mining or knowledge discovery based on GTD datasets. For example, in terms of temporal and spatial characteristics, a study discovered countries located in a hot spot neighborhood of terrorist attacks are likely to experience a large increase in the number of terrorist attacks in the next period. This suggests that the spatial distribution of terrorist attacks is an important feature, and indicates that terrorist attacks have a characteristic of spatial transmission (Braithwaite et al., 2007). In terms of influencing factors, it has been suggested by some studies that states that fail to respond to internal political strife, ethnic conflict, or "stateless areas" are more susceptible to terrorist attacks (Piazza, 2007). This highlights the importance of governance in a country or region when it comes to preventing terrorism. Of course, some other factors like religiosity (Varenia et al., 2021), the ethnicism (Cho, 2010), democracy and civil conflicts (Kim et al., 2020; Morris et al., 2021), the popularity of the national leaders (Krueger et al., 2009) were also revealed to be highly related to terrorist attacks.

As to the terrorist attacks themselves, GTD provides detailed information on the location, type of attack, weapons used, and target type of terrorist incidents. Researchers have employed hierarchical analysis and K-means clustering analysis to categorize these terrorist attacks (Li et al., 2021). Additionally, studies have evaluated the heterogeneity of attack types worldwide using methods such as chi-square tests (De Cauwer et al., 2022; Ulmer et al., 2022). For instance, Pan conducted a quantitative analysis, fully exploring the correlations between terrorist organizations and other event attributes in the GTD. Based on machine learning techniques, he proposed a method to predict terrorist organizations using other indicators (Pan, 2021). Last but not least, some studies aim to provide additional information beyond the GTD dataset. For instance, an evaluation index system for the harmfulness of terrorist attacks could be constructed using the projection pursuit model. This system could be used to score all terrorist attacks in the GTD based on their consequences. This information wa s a valuable addition to the GTD dataset. Time series methods, such as the grey metabolic model (Deng et al., 2021), can be used to predict the future risk of terrorist attacks. These studies enriched and deepened our understanding of the GTD dataset. However, the factors linked to terrorist attacks usually intertwine to form a complex network. It's sometimes hard to distinguish which factors are the causes of terrorist attacks and which are the effect of terrorist attacks, since some factors are mutually causal with terrorist attacks, which is also a point worth further study.

The Middle East is a region with a high-incidence of terrorism. According to the GTD, the Middle East has an average of 1,165 terrorist attacks per year from 1970 to 2020, accounting for 27% of the global total. The Gulf region has long been the focus of geopolitics and conflicts, which has created a breeding ground for terrorism and seriously affected the security and stability of local countries and regions. From 2014 to 2021, the Islamic State (ISIS) carried out several terrorist attacks in the region, including violence in areas controlled by Iraq and Syria, as well as terrorist attacks in other countries. This has resulted in a severe security situation in relevant areas.

Multiple factors, including political conflicts, wars, terrorism, social inequality, and natural disasters, have continuously caused unrest in the Middle East, leading to humanitarian disasters and crises in many countries. The issue is also highlighted by the adolescent fertility rate indicator studied in this research. According to the World Bank data, the countries and regions with the highest rankings are mainly concentrated in Africa and the Middle East. Taking Iraq as an example, the adolescent fertility rate in 2021 reached 62.19‰, which although has decreased compared to previous years, is still significantly higher than the world average of 42 ‰. As a foundation for subsequent global-scale studies, this paper selects the Gulf states as the survey region, including Bahrain, Iran, Iraq, Kuwait, Qatar, Saudi Arabia, the United Arab Emirates and Oman. Spearman correlation analysis and Gray correlation analysis were used to explore the characteristics of terrorist attacks and related factors. It should be noted that correlation analysis in this paper is distinct from causation analysis, which means that causality cannot be strictly inferred. The causation analysis of terrorist attacks is relatively more complex and will be furtherly studied in the future. However, the authors believe that the paper could still have a great contribution. To the best of the authors' knowledge, this paper makes the first attempt to reveal the correlation of social multi-source data and terrorist attacks in the Gulf states. Also, some of the key findings provided by this paper are original and represent the first proposals.

OVERALL STRUCTRUE

As a preliminary study in the authors' research plan, the overall framework of this paper is straightforward. In this study, the Gulf states are selected as the survey region. Two main datasets, GTD and the World Bank dataset, are utilized in this study. The basic characteristics of terrorist attacks are analyzed in depth using the GTD, while additional associated factors are retrieved from the World Bank dataset. The Spearman's rank coefficient analysis and Grey relation analysis are two well-known and commonly used methods. They are employed in this study to investigate the correlations between terrorist attacks and related factors. Several important findings could be obtained by this study by quantitatively defining the relationship between terrorist attacks and the factors of socio-economic system, such as identifying which factors are most relevant to terrorist attacks. The results from this study are crucial for addressing the risk of terrorist attacks and assisting the communities in making targeted preparations.

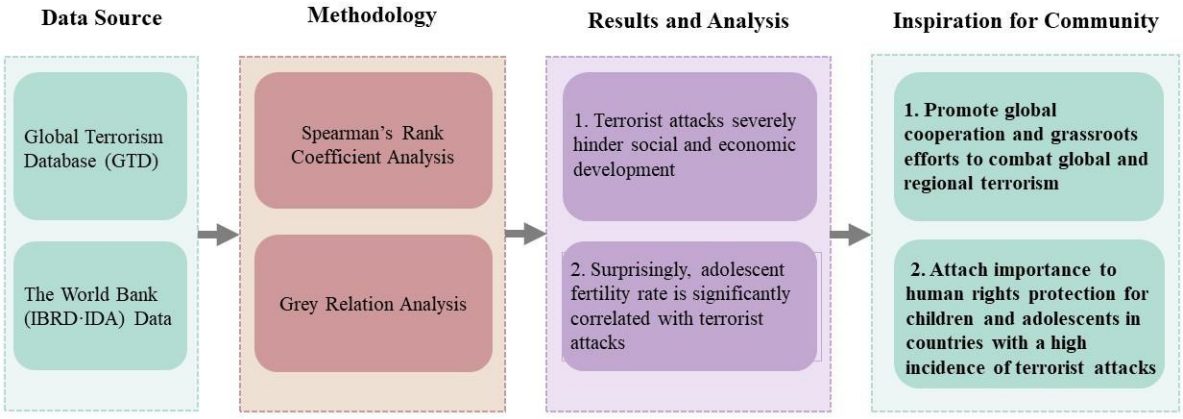

Figure 1. The overall structure of this paper

STUDY AREA AND DATASET

Survey Region

The Persian Gulf, abbreviated as "the Gulf", is one of the most important inland seas in the world, located in southwestern Asia between the Arabian Peninsula and Iran. The term "Gulf States" is a widely accepted concept, rather than a strictly defined geographic term with clear boundaries. In this study, the "Gulf States" refer to the eight countries along the Persian Gulf coast: Bahrain, Iran, Iraq, Kuwait, Qatar, Saudi Arabia, United Arab Emirates and Oman (Figure 2). The profiles of the eight countries were collected and briefly organized (Table 1), comprising information on area, population, religion, language, political system, economy, as well as military affairs.

Dataset

The datasets utilized in this study include the GTD, which covers records of terrorist attacks in the Gulf States region from 2001 to 2020 (the latest available data is updated to June 2021). GTD is an open-source database operated by the National Center for Terrorism at the University of Maryland and the Consortium for the Study and Research of Terrorism. It is widely recognized as the most comprehensive and sophisticated database on terrorism worldwide. The database incorporates data from reports published by authoritative media organizations. It includes information on the time and location of terrorist attacks, targets, attackers, and the number of people killed, injured and so on. Statistics show that there were 28,264 attacks in the Gulf States from 2001 to 2020. To ensure accuracy, data records with incomplete latitude and longitude information were excluded, ultimately 28,091 terrorist attacks in the Gulf states region were involved in this study.

This study selects eight socio-economic indicators as related factors (Table 2), based on the relevant studies mentioned in the introduction section and using the World Bank database as a reference. These indicators are:

- Per capita GDP (constant 2015 dollars);
- Unemployment rate (the ratio of the total number of unemployed to the total number of labor force);
- Net migration (net migration is the total number of net migrants during the period, i.e., the total number of migrants who migrated abroad minus the number of migrants who migrated into the country each year, including both permanent and non-permanent residents. The number of net migrants in that year is then divided by the country's population in that year);
- Adolescent fertility rate (the number of births per 1,000 15~19-year-old females);
- Military strength (armed forces personnel as a percentage of the total labor force);
- Urban population (the percentage of the urban population compared to the total population);
- Agricultural land (per capita agricultural land refers to land used for short-term cropping, short-term pasture for mowing or grazing, vegetable gardens for supplying the market, and gardens for own use, as defined by the Food and Agriculture Organization of the United Nations (FAO). Recreational land resulting from the conversion of farming practices is not included);
- Commodity trade (as a percentage of GDP).

In addition, considering the differences in each country's population, economy, etc., the Terrorist incident rate is defined as the number of terrorist attacks in a given year divided by the population of that country in the same year.

Table 2. Basic information on related socio-economic indicators to terrorist attacks

Index	Socio-economic variable	Abbreviation
x_1	Per capita GDP ($)	PCG
x_2	Unemployment rate (%)	UR
x_3	Net migration (%)	NM
x_4	Adolescent fertility rate (persons/1000)	AFR

x_6	Urban population (%)	UP
x_7	Agricultural land (hectares)	AL
x_8	Commodity trade (%)	CT
y	Terrorist incident rate (cases/million people)	TIR

METHODOLOGY

The Correlation Analysis Method

Correlation analysis is a straightforward and accessible analytical method for measuring how quantitative data are related to each other, and it is commonly used to determine the degree of correlation between variables. To

calculate the strength of correlation between two different factors, a correlation coefficient is introduced below, that is the Spearman Correlation Coefficient (R_S), as shown in Eq. (1). The Spearman's Rank Correlation Coefficient (R_S) offers greater flexibility compared to the Pearson Correlation Coefficient (R_p), which is typically limited to describing linear relationships assuming a normal distribution. R_S is often used to assess the ranking of relationships, particularly in scenarios where variables possess ordinal properties, do not follow a normal distribution, or when the distribution type is unknown. The flexibility arises from its less restrictive data requirements. Current research often focuses on investigating ordinal relationships between variables, specifically examining whether an increase in one variable is accompanied by an increase in another. Therefore, the formula for calculating Spearman's correlation coefficient is chosen based on research needs. To calculate the Spearman's rank correlation coefficient (R_S), define two data sequences, $\{x_i\}$ and $\{y_i\}$, of equal length, where n is the number of data points in each sequence. Assign rank values (denoted as $\{p_i\}$ and $\{q_i\}$) to each data point in $\{x_i\}$ and $\{y_i\}$ respectively, based on their position from smallest to largest. Then, for each corresponding data point in the two sequences, calculate the difference $\{d_i\}$ between their rank values. Note that variables with the same value should be assigned the same rank, and in case of ties, the average rank is commonly used. The variables $\bar{p}$ and $\bar{q}$ are denoted as the mean ranks, respectively.

$$R_s = \frac{\sum_{i=1}^{n}(p_i - \bar{p})(q_i - \bar{q})}{\sqrt{\sum_{i=1}^{n}(p_i - \bar{p})^2}\sqrt{\sum_{i=1}^{n}(q_i - \bar{q})^2}} = 1 - \frac{6 * \sum_{i=1}^{n} d_i^2}{n\,(n^2 - 1)} \quad (1)$$

R_s is an index that quantifies the strength of correlation in the range of [-1, 1]. The closer the value of R_s is to either 1 or -1, the stronger the correlation. R_s >0 indicates a positive correlation, while R_s <0 indicates a negative correlation.

When performing correlation analysis, significance level tests are routinely conducted to assess whether the observed correlation is statistically meaningful. This means that the correlation is unlikely to be due to random factors. In statistics, the p-value is used to assess the probability of the sample data appearing under the null hypothesis, thus testing the statistical significance of an effect. The Spearman's rank correlation coefficient, for example, can be used to measure the strength and direction of the relationship between two variables, and the resulting correlation coefficient can then be used in a hypothesis test to calculate a p -value. Generally speaking, the smaller the p-value, the more significant the correlation is, indicating that the observed effect is less likely to be due to random error. To visually communicate the significance of these results, asterisks (*) are often used as markers. Specifically, a single asterisk (*) is used when the p-value for the correlation is less than 0.05, indicating statistically significant correlation. Two asterisks (**) are used for p-values less than 0.01, emphasizing the reliability of the correlation. Three asterisks (***) are reserved for p-values less than 0.001, which usually serve as highly convincing evidence of a strong and reliable correlation between the two variables.

The Grey Relation Analysis Method

Grey Relation Analysis (GRA) is a statistical method for multifactor analysis. It determines the degree of closeness between the series of the reference data and the series of several comparison data, by comparing the geometric similarity of their curves and calculating the degree of correlation between the curves. The more similar the curves are, the greater the correlation between the corresponding sequences will be, and vice versa. The reference sequence is usually the sequence that represents the overall development trend of the system, while the comparison sequence requires analysis. Set $x_0' = \{x_0'(k) | k = 1, 2, 3, \ldots, n\}$ as the reference series, $x_i' = \{x_i'(k) | k = 1, 2, 3, \ldots, n\}$ $(i = 1, 2, 3, \ldots, m)$ as the comparison series. As the factors hold varying physical significance, the series data may not always share the same order of magnitude. This can impede comparison and make it difficult to draw accurate conclusions. To address this, it is necessary to convert all sequences to the same order of magnitude. This is typically achieved by dividing each element in the sequence by the average (as shown in Eq. (2)) or first element of the sequence (as shown in Eq. (3)). The grey correlation coefficient between the reference sequence and the comparison sequence is calculated using Eq. (4). Here, $x_i(k)$ denotes the k-th element of the i-th sequence, and $x_0(k)$ represents the k-th element of the reference sequence. The grey correlation degree of the i-th sequence r_{0i} is the average value of all grey correlation coefficients between it and the reference sequence (as shown in Eq. (5)). The rank of the i-th sequence is determined by comparing its grey correlation degree with other sequences. The resolution coefficient, ρ, should be determined based on the specific background and requirements and is in the range of (0,1). The default value of ρ is always set to be 0.5. r_{0i} denotes the gray correlation of x_0 with x_i. The closer to 1 the value of r_{0i} is, the better the correlation is.

$$x_i(k) = \frac{x_i'(k)}{\frac{1}{m}\sum_{k=1}^{m} x_i'(k)} \quad (2)$$

$$x_i(k) = \frac{x_i'(k)}{x_i'(1)} \tag{3}$$

$$\xi_i(k) = \frac{\min_i \min_k |x_0(k) - x_i(k)| + \rho \max_i \max_k |x_0(k) - x_i(k)|}{|x_0(k) - x_i(k)| + \rho \max_i \max_k |x_0(k) - x_i(k)|} \tag{4}$$

$$r_{0i} = \frac{1}{m} \sum_{k=1}^{m} \xi_i(k) \tag{5}$$

RESULTS

Time Evolution Characteristics of Terrorist Attacks

Between 2001 and 2020, the eight Gulf states experienced a total of 28,091 terrorist attacks, averaging 1,405 attacks per year. The number of deaths totaled 81,979, averaging 7,037 deaths per year, and the number of injuries totaled 140,744, averaging 4,099 injuries per year. Figure 3 illustrates the temporal evolution of terrorist attacks in all the eight Gulf states. Since the 21st century, the terrorist situation in the Gulf countries has shown significant fluctuations. The number of terrorist attacks, deaths, and injuries has exhibited a trend of growth followed by a decrease, reaching its peak in 2014. These trends are relatively consistent, with two significant turning points in 2007 and 2014. Fatalities resulting from terrorist attacks in 2020 decreased by 36.63% from the previous year to 531, marking the fourth consecutive year of decline since 2016. This decline is closely linked to an improvement in the intense conflict in Iraq.

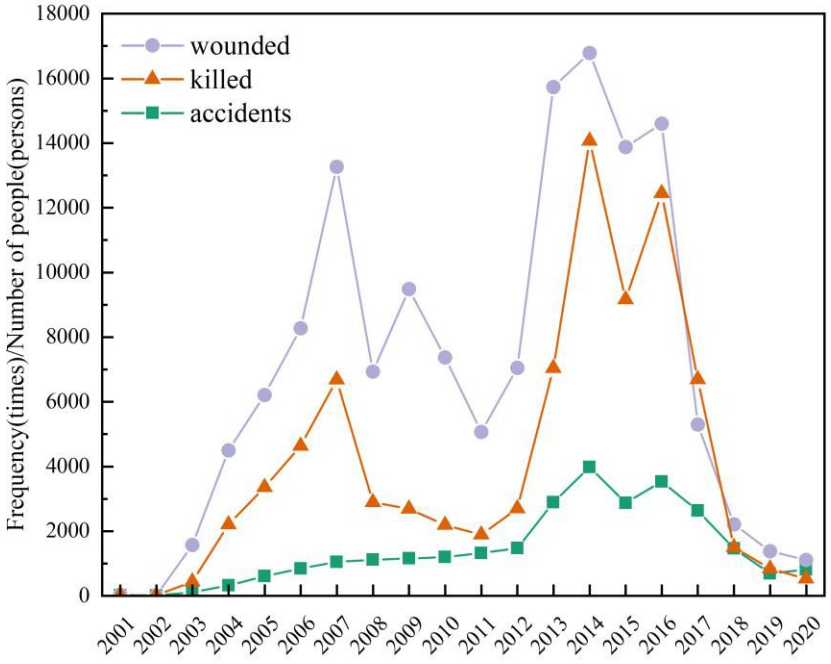

Figure 3. Interdecadal characteristics of terrorist attacks in the eight Gulf states

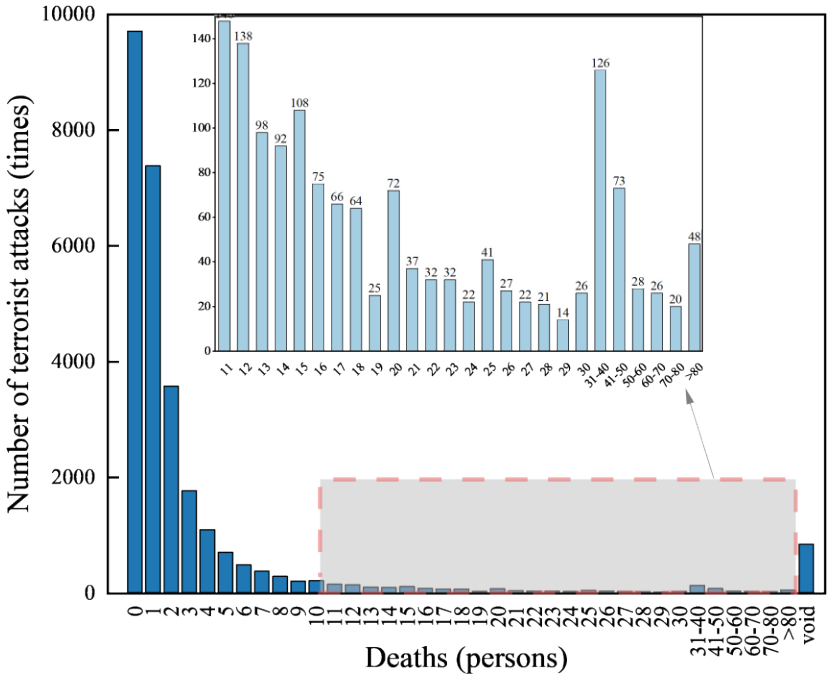
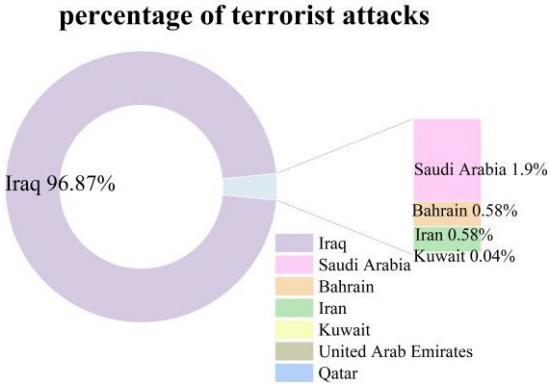
Out of the 28,091 terrorist attacks, the number of casualties from 841 terrorist attacks was unrecorded by GTD and therefore unknown. The remaining 27,250 terrorist attacks were further analyzed. Figure 4 shows the distribution of deaths in these attacks. Of all incidents, 64.39% resulted in fatalities in 17,545 cases, indicating that terrorist attacks are a considerable cause of casualties, despite the fact that the majority of terrorist attacks result in only a few fatalities.





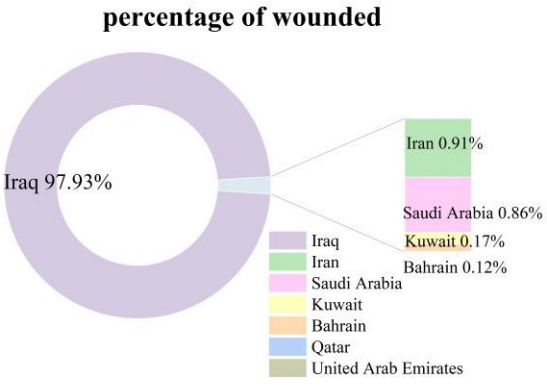


Figure 4. Characteristic analysis of casualties resulting from different terrorist attacks in the eight Gulf states

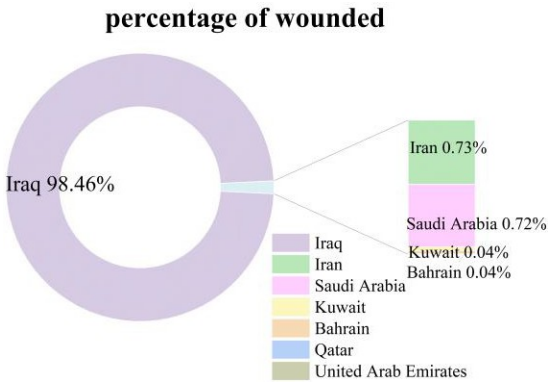
Regional Distribution Characteristics of Terrorist Attacks



This study examines the geographical distribution of terrorist attacks in the Gulf states between 2001 and 2020, using latitude and longitude data from GTD. The analysis reveals that the majority of terrorist incidents in the Gulf states during the 21st century occurred in Iraq and Iran. The number of deaths in Iraq has reached 80,719, accounting for 98.46% of the total. Additionally, 137,830 people have been injured, accounting for 97.93%. Furthermore, there have been 27,212 terrorist attacks, accounting for 96.87% (Figure 5). These statistics confirm that Iraq is a high-risk area for terrorist incidents in the Gulf region. This phenomenon may be related to the war in Iraq that began in 2003 and the establishment of the terrorist organization I SIS in 2014.

(a) Quantitative characteristics of terrorist attacks in different countries

(b) Quantitative characteristics of the injuries in terrorist attacks in different countries

(c) Quantitative characteristics of the casualties in terrorist attacks in different countries

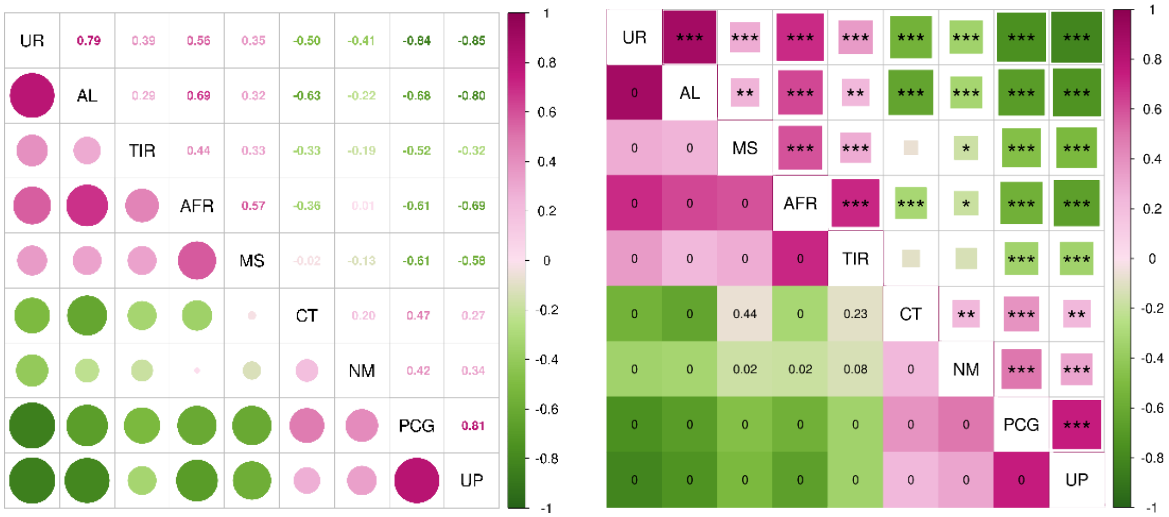


Figure 5. Regional distribution characteristics of terrorist attacks in the eight Gulf states

Correlation Analysis

Terrorism often arises from confluence of factors, such as social instability, political conflict, economic hardship and religious, racial or ethnic differences. These factors may lead to an increase in social tensions, social discontent, and extremist thinking, thus providing a breeding ground for terrorism. At the same time, the occurrence of terrorism will further aggravate social unrest and trigger a series of political, economic and livelihood problems. It can be seen that the terrorist attacks and socio-economic factors are often causal and interdependent, which is quite complex and not yet be confirmed in this field. In this paper, the causal ana lysis of terrorist attacks has been temporarily shelved in favor of a mainly correlational analysis. From the perspective of direct correlation, we have analyzed which factors might be highly correlated with terrorist attacks, and a more in-depth analysis is planned for the future. A Spearman correlation analysis of terrorist attacks in the Gulf States from 2001 to 2020 explores the relationships between the various elements listed in Table 2 above, as shown in Figure 6.

Upon careful observation of the color legend on the right side of Figure 6(a), a clear visual correlation between color and the intensity of correlation can be established. A gradual shift in color from dark to light red corresponds to a decrease in the numerical value from near 1 to 0, indicating a gradual weakening of the positive correlation. Conversely, the transition from deep green to lighter shades corresponds to a decrease in the numerical value from near -1 to 0, signifying a gradual weakening of negative correlation. The figure displays the correlation coefficients between the variables. The right triangular matrix displays the correlation coefficients among various variables, providing precise numerical values regarding their degrees of associatio n. The left triangular part employs the size of the circle as a visual aid, where a larger circle area represents stronger correlation, thus enhancing the visualization of correlation strength. Simultaneously, the circle's color aligns with the legend, emphasizing the correlation's positive and negative directions. Figure 6(b) displays the correlation analysis's significance level. The combination of p-values and asterisks (*) enables quick identification of statistically significant correlations. A value of 0 on the graph corresponds to a p-value less than 0.01, indicating high statistical significance. Similar to Figure 6(a), the colors, size, and depth of the graphs continue to indicate the strength of the correlations. In this figure, they are also integrated with the significance level, providing a more comprehensive analytical perspective.

Figure 6(a) demonstrates a positive correlation between TIR and the influencing factors of UR, AL, AFR, and MS, while a negative correlation exists between TIR and CT, NM, PCG, and UP. Figure 6(b) reveals that the p - values for the correlations between terrorist attacks and the socio-economic factors are less than 0.01, with the exception of NM. Consequently, the majority of the socio-economic factors, excluding net migration, exhibit significant relationships with terrorist attacks based on the presented da ta.

(a) Spearman correlation coefficient (b) Significance level and p-value

Figure 6. Correlation analysis between terrorist attacks and different socio-economic factors

Correlation between TIR and PCG, CT, UR

Specifically, the frequency of terrorist incidents exhibits a significant negative correlation with per capita GDP (PCG) and commercial trade as a percentage of GDP (CT), with correlation coefficients of -0.52 and -0.33, respectively. While a significant positive correlation with the unemployment rate (UR) was observed, with 0.39. It is widely acknowledged that a decrease in the number of terrorist incidents in a region is associated with increased stability and economic development, and vice versa. GDP per capita commonly serves as a key measure of a region's economic prosperity. A high GDP per capita indicates that, on average, people in the region enjoy greater economic resources and benefits, leading to improved quality of life and a more stable social environment. Conversely, lower GDP per capita generally implies economic hardship and poverty, which may lead to an increase in social tensions and discontent, subsequently elevating the risk of terrorist incidents. Therefore, it is not difficult to understand that GDP per capita (PCG) could serve as a reliable index to characterize the intensity of terrorist attacks. Similarly, the healthy development of commercial trade is usually associated with economic dynamism and international cooperation. A vibrant and thriving business environment encourages increased employment opportunities, raises income levels, and stimulates economic development. In contrast, regions with underdeveloped or restricted trade are often at risk of economic decline and social instability . High unemployment, severe poverty, and economic underdevelopment may lead to conflict and provide fertile ground for terrorism.

Correlation between TIR and UP, AL

The correlation coefficient value of -0.32 indicates a highly significant negative correlation between the frequency of terrorist attacks and the ratio of urban population to total population (UP). Additionally, there is an extremely significant positive correlation of 0.29 between the frequency of terrorist attacks and the number of hectares of arable land per capita (AL). This result implies that higher urbanization tends to lead to a lower incidence of terrorist attacks. It is well known that the UP ratio and AL per capita are important indicators of urbanization, which is usually accompanied by economic development, social progress, and improved infrastructure. On the one hand, urban areas usually offer a higher standard of living and greater employment opportunities than rural areas, potentially reducing economic pressures and social grievances that can contribute to the risk of terrorist incidents. Moreover, urban areas tend to have more social communication, promoting interaction among people and strengthening social ties and community participation. These stronger social ties help to build harmonious social relations and increase social stability, thus reducing the nurturing environment for terrorism. On the other hand, terrorist attacks can significantly impede the normal development and urbanization of cities, including a country's overall urbanization level. In conclusion, this outcome aligns with people's perceptions.

Correlation between TIR and MS

A correlation coefficient value of 0.33 indicates a significant positive correlation between the number of terrorist attacks and military strength (MS), measured as the proportion of active military members in the labor force.

According to World Bank data, the countries with the highest percentage of armed forces personnel in their labor force from 2001 to 2020 are predominantly located in Asia and Africa, including Eritrea, the Democratic People's Republic of Korea, and Jordan. It is worth noting that most of these countries are developing nations with limited economic growth. Their economic development primarily rely on agriculture, industry, or resource exploitation. They often exhibit geopolitical complexity, with border disputes or conflicts with neighboring countries. As a result, these countries tend to have stronger militaries, which does not necessarily translate into better control of terrorism. In fact, the outlook for terrorism in these countries is not optimistic. On the contrary, a stronger military sometimes leads to greater instability in the country, increasing the risk of terrorism.

Correlation between TIR and AFR

Frequency of terrorist attacks shows an extremely significant positive correlation with the adolescent fertility rate (AFR), denoted by the number of births per 1,000 females aged 15 -19, with a value of the correlation coefficient of 0.44. AFR varies across countries and regions, and is influenced by various factors, such as sociocultural attitudes, economic conditions, education level, and access to sex education and contraception. Based on 2021 World Bank data, the adolescent fertility indicator ranks African countries such as Niger, Mozambique, and Somalia at the top. Notably, these countries also face significant challenges from terrorism. On one hand, the frequent occurrence of terrorist incidents may trigger social unrest and affect the normal life and studies of adolescents, thus impacting their academic performance and future development. On the other hand, an increase in the fertility rate during adolescence may lead to greater socio-economic pressures, including education and management of troubled youth, and youth social participation. The risk of terrorist attacks may increase due to extremist religious thoughts that can arise from low levels of education, neglect of duty, and engaging in inappropriate business during adolescence.

Grey Relation Analysis

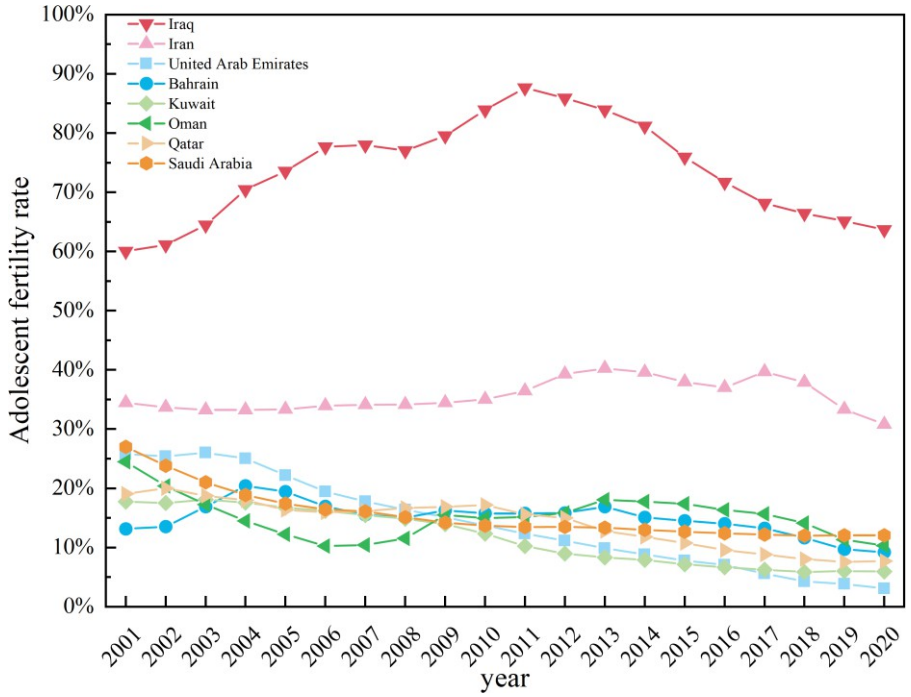
Table 3 illustrates a close and strong correlation between TIR and multiple socio-economic indicators through the application of gray correlation analysis. These findings align with the previous correlation analysis. The top three most significant factors are the adolescent fertility rate (AFR), agricultural land per capita (AL), and unemployment rate (UR), exhibiting gray correlation coefficients of 0.9013, 0.8913, and 0.8892, respectively. Notably, the relationship between terrorist attacks and the AFR is particularly strong, highlighting AFR as the most highly correlated factor.

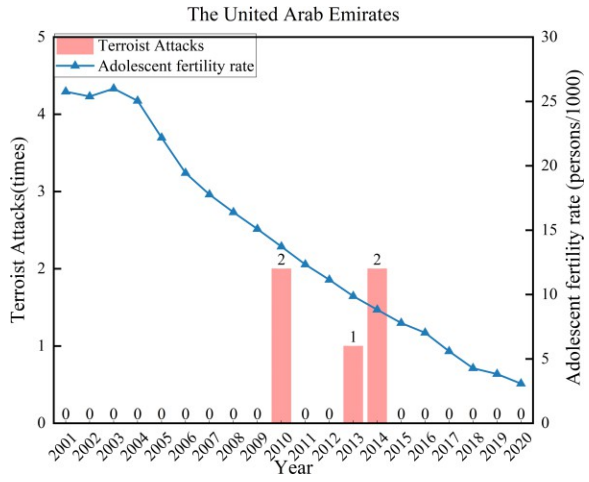
Table 3. Gray correlation analysis between TIR and different factors

Factor	Grey correlation coefficient	Rank
AFR	0.9013	1
AL	0.8913	2
UR	0.8892	3
MS	0.8876	4
CT	0.8720	5
PCG	0.8621	6
UP	0.8693	7
NM	0.8521	8

Comparing the data on adolescent fertility rates in the eight Gulf region countries (Figure 7), it is clear that Iraq has a significantly higher fertility rate than the other countries. Given the significant number of terrorist attacks that have taken place in Iraq between 2001 and 2020, there is a strong likelihood of a correlation between these attacks and the fertility of adolescents. This underscores the urgency of prioritizing educational opportunities, well-being, and human rights for adolescents in terrorist incident-prone areas. Furthermore, in Iraq, the literacy rate of young women aged 15-24 was below the world average until 2016, indicating that their right to education for this group is not fully guaranteed. Additionally, World Bank data reveals that in 2004, there were only 0.006 community health workers per 1,000 people in Iraq, equivalent to just 6 community health workers per 1,000,000 people. This statistics highlights the extreme inadequacy of community health services, which could pose a serious threat to the health and well-being of children and adolescents. From a global perspective, it is noteworthy that in

certain countries or regions, such as Gaza, Kenya, and Haiti, adolescents and their families face life-threatening crises due to political unrest, civil strife, violence, extreme poverty, and natural disasters. These crises encompass displacement, infectious diseases, and malnutrition. In contrast, the deadly threat posed by terrorist attacks on adolescents has not received sufficient attention. The paper suggests a potential association between terrorist attacks and the human rights of adolescents, which deserves further exploration.





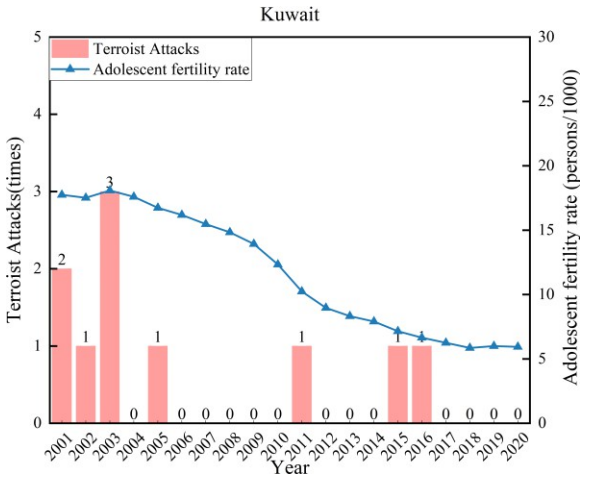


Figure 7. Comparison of adolescent fertility rates among the eight Gulf States

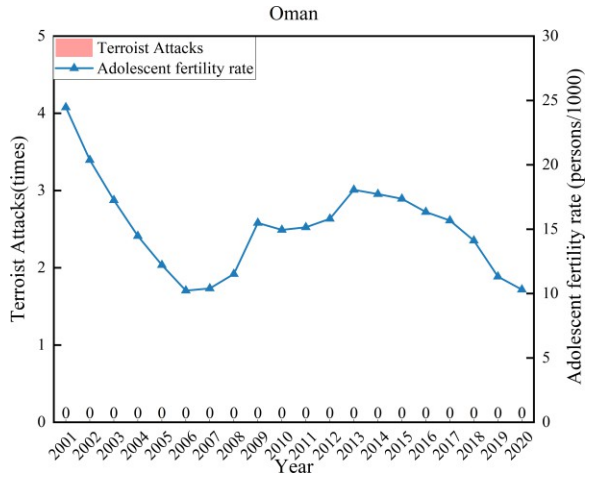
The downward trend in adolescent fertility rates over the years not only reflects the increasing emphasis on personal development and life choices but also demonstrates the deepening commitment to human rights protection. Figure 8(a)-(d) reveals that the United Arab Emirates, Kuwait, Oman and Qatar all experienced relatively few terrorist attacks between 2001 and 2020, with none exceeding 10 and an AFR of less than 30%. These countries also showed a steady downward trend. To some extent, this illustrates th e significant advancements these nations have made in upholding social stability and security amidst globalization, which assures individuals the opportunity to pursue higher-quality lives and personal growth. Within this relatively stable and secure social environment, individuals are able to make more autonomous and responsible choices in areas such as childbirth, education, and career, which is a tangible manifestation of human rights protection. Upon further examination of Figures 8(e)&(f), it becomes evident that the sustained occurrence or sudden increase in terrorist attacks, as observed in Iran and Bahrain, can potentially slow down or even reverse the downward trend in adolescent fertility rates. The situation in Saudi Arabia (Figure 8(g)) corroborates this observation.



It is particularly noteworthy that the impact of terrorist attacks on AFR may manifest indirectly through various dimensions. Following a terrorist attack, members of society may be inclined to encourage earlier marriage and childbirth among adolescents due to a sense of insecurity. Economic recession may force adolescents into the labor market earlier, thus affecting their fertility plans. Restrictions on education and cultural activities may limit adolescents' educational and social opportunities, indirectly influencing their fertility decisions. Additionally, terrorist attacks may adversely affect the reproductive health of adolescents by compromising the provision of medical services. In the case of Iraq (Figure 8(h)), the average annual number of terrorist attacks in the country is as high as 1,360.6 in 2001-2020, and the AFR has remained above 60% over the 20 year. Specifically, between 2001 and 2012, as terrorist attacks escalated, the adolescent fertility rate also rose consistently. However, from 2017 to 2020, as the situation stabilized, the fertility rate began to decline. This phenomenon underscores the significant impact of heightened terrorist activity on social instability and public panic, ultimately driving up fertility rates. Conversely, when terrorist attacks are effectively contained or social stability is restored, fertility rates may respond by decreasing. This relationship highlights the crucial role of social stability and a secure environment in promoting responsible reproductive behavior, further emphasizing the close linkage between human rights protection and social development.

LIMITATIONS AND FUTURE WORK

Firstly, this study aims to provide a correlation analysis between terrorist attacks and other socio-economic indicators, rather than causal analysis. The authors acknowledge that while causal analysis is more valuable, it is also more challenging to prove statistically whether a certain factor is the cause of terrorist attacks or a result of terrorist attacks. In addition, the mediators behind the changes in adolescent fertility, on which the article ultimately focuses, have not been thoroughly analyzed. In Figure 8, an attempt was made to illustrate the positive correlation between terrorist attacks and adolescent fertility rates through the analysis of individual countries, and qualitatively explored the underlying potential factors. However, this representation may have somewhat diminished the comparative effectiveness among countries. To enhance the depth and accuracy of the analysis, future research could delve deeper into two key directions: (1) whether differences in terrorist attack rates can serve as indicators of disparities in adolescent fertility rates among different countries, requiring comprehensive analysis and comparison of cross-national data; (2) how fluctuations in terrorist attack rates within a single country affect its domestic birth rate, which necessitates detailed national-level data support.

Secondly, as a case study, the authors only selected the Gulf states for analysis, consisting of eight countries. The authors believe that the threat of terrorism is becoming a serious international concern and requires a more comprehensive and larger-scale analysis. Moreover, the findings of this paper, which are based solely on the Gulf states, may not be applicable to other countries and regions globally. Therefore, the authors plan to expand the scope of the study by including more countries and regions to gain a better understanding of the global risk on terrorist attacks. In the near future, we may even conduct a global-scale analysis to uncover more universal and inspiring findings.

CONCLUSIONS

This paper presents a thorough analysis of terrorist attacks in Gulf states using the GTD database. The case study encompasses totally eight countries: Bahrain, Iran, Iraq, Kuwait, Qatar, Saudi Arabia, United Arab Emirates and Oman. As a preliminary exploratory study, Spearman's correlation analysis and Gray correlation analysis methods were employed to explore the correlation between terrorist attacks and potential socio-economic factors. The socio-economic factors considered in this paper include per capita GDP, unemployment rate, net migration, adolescent fertility rate, military strength, urban population, agricultural land, and commodity trade.

It was observed that:

(1) Between 2001 and 2020, the terrorism situation in the Gulf states experienced continuous fluctuation. From 2001 to 2010, the fluctuations in the terrorism situation in the Gulf states were relatively smooth. Although there were some major incidents, such as the wars in Iraq in 2003 and Lebanon in 2006, which heightened regional tensions, the overall trend was not significantly upward. From 2010 onwards, there was a fluctuating growth trend in terrorism in the Gulf states. Iraq bore the brunt of terrorist attacks. Since 2016, this trend has gradually weakened and the number of terrorist attacks decreased. However, terrorism remains a significant security risk that negatively affects economic development, overseas investments, and the well-being of the population.

(2) Terrorism in the Gulf states is a complex phenomenon resulting from multiple factors. This war-ravaged region has become a breeding ground for terrorism, further aggravating the fragile security situation in the Gulf states. The study concludes that the unemployment rate, arable land ratio, military strength and teenage fertility rate have significant positive correlations with terrorist attacks, while the urban population ratio, GDP per capita and commodity trade have significant negative correlations. These factors are interrelated and pose a significant threat to the security and stability of the Gulf and the Middle East region.

(3) Children residing in regions experiencing a high frequency of terrorist attacks often face immense difficulties in fully exercising their rights to education and. The prevalent insecurity and terrorist activities in these areas pose a profound danger to the survival and development of children and adolescents, effectively barring them from enjoying their fundamental rights to the fullest extent. Consequently, it is incumbent upon the international community and each individual nation to prioritize the survival and sustainable development of children and adolescents, implementing effective measures to safeguard their rights and welfare.

Future studies are expected to delve deeper into causal analyses of terrorist attacks and conduct comprehensive global-scale investigations. This paper proposes that the Gulf States expeditiously forge a consensus on regional security, vigorously facilitate security cooperation, and boost investments in safeguarding the welfare of children and adolescents. Additionally, the concerted effort of the entire international community is imperative to collectively tackle the humanitarian challenges posed by terrorism, attain sustainable regional and global security, and enhance the protection and development opportunities for all children and adolescents worldwide.

ABSTRACT

In disasters and crises, crisis preparation at the household level is crucial for societal resilience. However, motivating citizens to take personal responsibility and to implement preparedness measures remains challenging. This study investigates the impact of values, beliefs and norms on preparedness. Through a survey in Germany on resource-oriented crisis preparedness and participants' values, a group of more prepared and less prepared individuals was differentiated. We quantitatively analyzed the correlation between values and crisis preparedness. A quantitative analysis revealed a significant association between the value of *benevolence* and higher preparedness. Follow-up interviews (N=30) explored participants' beliefs and norms, showing minimal group differences. Although crisis preparedness is generally viewed positively, strong negativity exists towards perceived "hoarders". The study discusses implication for crisis communication and the design of nudges and persuasive systems, emphasizing intervention that can trigger benevolence to foster preparedness and appeal to the social benefits to counter the narrative of anti-social crisis preparedness.

Keywords

Crisis preparedness, values, beliefs, social norms, personal norms

INTRODUCTION

Despite advancements in understanding the causes and consequences of disasters, they continue to result in significant harms and losses. Climate change is leading to more frequent and severe natural disasters. Recently, crises such as the global Covid-19 pandemic and the invasion of Russia in Ukraine have demonstrated the importance of societal resilience and crisis preparedness. Crisis preparedness is defined as the knowledge and skills enabling anticipation, response, and recovery from disasters (UNDRR, 2016). This applies across various levels, from individual households to international organizations.

Individual households play a crucial role as even well-prepared regions may wait up to 72 hours for external assistance in disaster situations (Kohn et al., 2012). In addition, due to the increasing dependence of infrastructure, energy and internet outages can have severe negative impacts on civil society (UP KRITIS, 2014). Therefore, civil protection and disaster relief agencies often promote household crisis preparedness. They commonly recommend water and food supplies, energy sources, information access, hygiene maintenance, medical care, document copies, fire protection, and emergency kits (BBK, 2019). However, in many countries, citizens perceive that they are badly informed and unprepared for crises (Appleby-Arnold & Brockdorff, 2018) and many countries note insufficient crisis preparedness (Garschagen et al., 2019; Menski, 2016). Research suggests that families and retirees are better prepared, whereas single households, students/apprentices and people with low financial power

lag behind (Gerhold et al., 2019). Convenience appears to be more significant for preparation than risk awareness (BBK, 2013; Gerhold et al., 2019). In addition, urban residents, possibly due to the lack of space, are less prepared and more dependent on infrastructure (BBK, 2013).

Psychological factors have also been found to influence crisis preparedness behavior, particularly by affecting risk perception. Unrealistic optimism and risk compensation are widespread. In some risk cultures, there is often an overreliance on state agencies to handle crises, affecting individual preparation (Cornia et al., 2016). This indicates that prevailing beliefs about how crises occur and are managed, and prevailing social norms might play a role.

In addition, values influence behavior through norms and beliefs (Schwartz, 1992; Steg et al., 2005). As such, psychological motivation theories, such as the Values-Beliefs-Norms theory (VBN-theory), are often based on the users' values. Values are "desirable transsituational goals varying in importance, which serve as a guiding principle [...]" (Schwartz, 1992, p. 21). They are thus more overarching and stable than beliefs and have been shown to impact behavior related to sustainability, altruism and health (Honka et al., 2019; Schwartz, 2016; Steg et al., 2005). In decision-making and goal-setting values help people define and consider what is meaningful and worthwhile and by shaping moral judgments and actions (Schwartz, 1992). Values impact behavior directly and indirectly through personal norms and beliefs (Steg et al., 2005; Stern, 2000).

Finally, social norms influence behavior (Reynolds et al., 2015). Social norms are unwritten rules for specific behavior that are maintained through group approval or punishment. They manifest, for example, in an individual's perception that most people important to them should or should not do something (Ajzen & Fishbein, 1980; Kim & Seock, 2019). These norms, alongside values, have been shown to influence personal norms and, consequently, have both indirect and direct effects on concrete behavior (Kim & Seock, 2019).

However, the roles of values, beliefs, personal and social norms have so far not been explored with regard to crisis preparedness. This study contributes a first exploration by analyzing differences in these four aspects between people in Germany (N=30) who are more and less prepared for crises. After presenting the state of research concerning crisis preparedness and the impact of values, beliefs, personal and social norms on behavior, we describe the methodologies used. Then, we present the findings from a quantitative survey investigating preparedness and values, and qualitative interviews that explored beliefs and norms. Finally, we discuss the findings, before summarizing the study in the conclusion.

RELATED WORK

Crisis Preparedness

Despite the primary responsibility of state and volunteer agencies for emergency management, individual and household crisis preparedness remains crucial, especially in case of large-scale crises or infrastructure failures. Since agencies cannot serve everybody immediately, states give out recommendations for individual and household crisis preparedness. However, factors influencing the implementation of such recommendation and household crisis preparedness are currently not well-understood. Limited data on disaster preparedness exists and little research has explored the individual preparedness of vulnerable population groups (Garschagen & Sandholz, 2018), thus precise reasons for lower crisis preparedness remain unknown. Existing literature suggests factors such as household size, presence of children, square meters per person in the dwelling, educational level, employment situation, and urbanization level in inhabitants per square kilometer as relevant to preparedness levels. Furthermore, nationality may play a role due to lower experience regarding local crises, reduced awareness of informational resources, and weaker social networks potentially contributing to lower preparedness.

While families and retired individuals seem well-prepared in terms of resources, single households and those of students or apprentices often lack the recommended provisions, making them dependent on external assistance (Gerhold et al., 2019). Interestingly, despite better preparation, risk perception decreases with age (Gerhold et al., 2019), suggesting that financial resources and available living space might be important limiting factors. Other studies conclude that household size, educational level or prior crisis experiences have little impact on individual preparedness, instead, well-prepared groups might be better equipped for the sake of convenience (Garschagen et al., 2019). Urbanization also plays a role, with individuals in cities being less prepared and, consequently, more reliant on the extensive infrastructure (BBK, 2013). Particularly in urban areas, extended critical infrastructure failures, such as shortages in drinking water, can lead to severe conditions, given that only half of the surveyed population has water reserves (Garschagen et al., 2019).

Psychological Constructs and Crisis Preparedness

Alongside demographic factors and living condition, psychological factors influence crisis preparedness and risk perception. The VBN theory posits a causal chain among values, behavior-specific beliefs, personal norms, and behavior (Stern, 2000). While initially designed for environmentally conscious actions, it is believed to also be applicable to other areas of behavioral research (Steg et al., 2005).

Values, having the highest explanatory power, initiate the chain. Behavior is influenced by personal norms, which refer to individual ethical guidelines or self-imposed expectations and obligations. Affected by the general opinion within a group, personal norms can differ from it, particularly influencing altruistic behaviors and others as internalized values (Schwartz, 1977; Thøgersen & Ölander, 2002). Personal norms, in turn, are influenced by behavior-specific beliefs, fundamental thoughts about a specific behavior, affecting how it's perceived in terms of difficulty and facilitators or hindrances e.g., the conviction that there are situations threatening something important to the individual and the belief that the person can reduce this threat through actions. These beliefs, in turn, can be explained by certain values, such as "security" or "benevolence" (Steg et al., 2005; Stern, 2000). In the context of environmental protection, values reflecting concern for non-human species or the biosphere (e.g., "universalism") play a significant role. Conversely, self-centered and conservative values (e.g., "power") are negatively correlated with environmental friendliness (Steg et al., 2005). It is plausible that the value of "security" is related to individual crisis preparedness behavior, although the literature does not specify this connection.

Values "(1) are concepts or beliefs, (2) pertain to desirable end states or behaviors, (3) transcend specific situations, (4) guide selection or evaluation of behavior and events, and (5) are ordered by relative importance" (Schwartz, 1992, p. 4). Twelve internationally universal values have been identified that can be clustered into four categories (Grosz et al., 2021; building on Schwartz et al., 2012). These values serve as guiding principles for individuals, influencing their attitudes, actions, and decision-making. Individuals prioritize values to varying degrees, creating their unique value profiles. They also shape people's personal norms, attitudes, preferences, and worldview. While values are broad, enduring beliefs that guide overall behavior, personal norms are more specific, context-dependent guidelines that help shape behavior in particular situations. As such, values are antecedents to personal norms and help explain them (Steg et al., 2011). Some values have been identified to be more often prioritized together, while others are typically more opposed (see Figure 1).

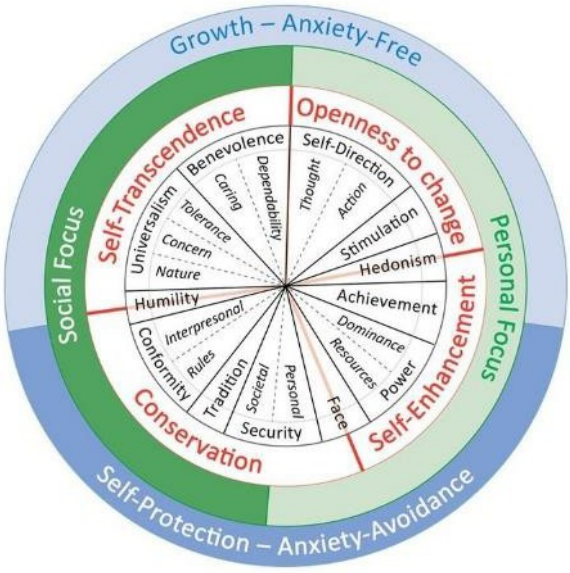

Figure 1. Value circumplex showing 12 basic values, 19 personal values, four higher-order values, and two underlying motivations. Source: Grosz et al., 2021; building on Schwartz et al., 2012. Licensed under CC-BY 4.0.

The opposition of *self-transcendence* versus *self-enhancement* reflects the tension between valuing the welfare of others and the broader society versus pursuing one's own interests and success. Self-transcendence includes values such as universalism (promoting understanding, tolerance, and protection of the welfare of all people) and benevolence (caring for others). By contrast, self-enhancement contains values such as power (seeking control over others), achievement (striving for personal success), and hedonism (pursuit of pleasure and enjoyment). The second opposition, openness to change versus conservation reflects the tension between valuing novelty, change, and exploration versus valuing tradition, stability, and preservation of the existing order. Openness to change

includes values such as self-direction (choosing one's own goals and actions), stimulation (seeking excitement and new experiences), and hedonism (pursuit of pleasure and enjoyment). Opposed to this, conservation contains values such as security (seeking safety and stability), tradition (respecting customs and traditions), and conformity (complying with social norms and expectations).

Past research has shown that environmental factors, such as time constraints, decrease the power of values, reducing pro-value behavior, e.g., the likelihood of offering help (Latané & Darley, 1976). Additionally, the impact of values on behavior can be heightened by activating values, and by a behavior being perceived as relevant to the value (Schwartz, 2016).

Cognitive distortions, such as unrealistic optimism, often lead individuals to underestimate their personal vulnerability to crises compared to peers, resulting in insufficient preparation (Weinstein, 1980). Additionally, people tend to engage in risk compensation, adjusting their preparedness behavior based on the subjectively perceived level of threat in their environment (Etkin, 1999). Therefore, visible government-led crisis management measures can reduce individuals' perceived threat, leading to decreased individual preparedness. In some risk cultures, particularly “state-oriented” and “fatalistic” risk-cultures, the populations tend to believe that crises cannot be averted, or that the responsibility for management lies with the government. This diminishes citizens’ motivation for personal preparation, leading to relatively poor preparedness and low confidence in the ability to independently cope with crisis situations (Cornia et al., 2016).

Research Gap

Values, beliefs and norms and related behavior change interventions have so far primarily been investigated with regard to environmentalism and health (Canlas et al., 2022, Nwafor et al., 2021). Only two studies looked at nudging and preparedness: One focused on a single intervention for household flood preparedness (Mol et al., 2021), finding no advantage of their social norm-nudges regarding readiness to prepare. Another has empirically tested the effect of a social and a rational-confrontational nudge on crisis preparedness, finding that only the latter, confronting with the costs and benefits of preparedness, increased the taking of crisis preparedness measures (Haunschild et al., 2023). While some studies have demonstrated that culture shapes crisis preparedness (Appleby-Arnold et al., 2021; Cornia et al., 2016), they have not engaged with underlying values, beliefs or norms.

Still, currently, no research exists on the role specifically of beliefs, norms and values for crisis preparedness. Therefore, we question the impact of each in the following research questions. First, we examine the role of different *values* by asking the question:

- **RQ1:** Do well-prepared individuals differ from less-prepared ones regarding their *value orientations*?

Personal norms play a significant role as predictors of behavior within the VBN theory (Stern, 2000). A study investigating relevant factors for flood preparedness suggests that personal norms may be significant (Mol et al., 2021), leading to RQ2:

- **RQ2:** Do well-prepared individuals differ from less-prepared ones with regard to their *personal norms* regarding crisis preparedness?

A previous study analyzing the use of warning apps has found that expected efficacy of the response significantly influences the adoption and continued use of warning apps (Fischer-Preßler et al., 2022). In addition, in most countries, disaster worry is related to the intention to take preparedness measures, whereas in Germany, perceived disaster risk is more relevant (Appleby-Arnold & Brockdorff, 2018). Another branch of research indicates that countries differ with regard to their risk culture and the resulting perceived personal responsibility (Cornia et al., 2016). Therefore, *beliefs* about the effectiveness of individual preparedness measures may influence individual crisis preparedness intentions.

- **RQ3:** Do well-prepared individuals differ from less-prepared ones with regard to their *beliefs* about crisis preparedness?

Perceived *social norms* are generally considered a strong motivator for behavior (Goldstein & Cialdini, 2007). This has also been shown to be relevant for measures related to crisis response, such as the adoption and continued use of warning apps (Fischer-Preßler et al., 2022). However, a study investigating household flood preparedness did not find this to be relevant (Mol et al., 2021), possibly due to the relative invisibility of anti-flood investments or the relatively high costs. Therefore, we explore the unclear role of social norms for less costly household preparedness measures by answering RQ4:

- **RQ4:** Do well-prepared individuals differ from less-prepared ones regarding their *perceived social norms* surrounding crisis preparedness?

METHOD

Recruitment and Sample

To recruit the sample, the study was advertised via social media platforms, including Facebook groups focusing on weather, police, and traffic updates, student *WhatsApp* instant messenger groups, the survey website *SurveyCircle* and a university email list. To ensure a diverse sample, encompassing individuals with varying levels of preparedness across demographic characteristics, participants from underrepresented groups were asked to motivate additional participants. Table 1 describes the sample. It shows that gender (with 47% females in the sample compared with 50.7% in Germany (Statista, 2023b)) and the degree of urbanization are well-represented (80% of participants living in cities compared to 78% in Germany (Worldbank, 2023). In terms of citizenship, with 23% foreigners the sample is similar to the German population (with 16% foreigners (Federal Statistical Office, 2023a). Household net income categories are based on the inflation-adjusted categorization from Gerhold et al. (2019) and are well-represented in the sample (Bundeszentrale für politische Bildung, 2020). The age median is in the group of 26-30-year-olds, presenting a section younger than the general population (*MD* = 45 years (Statista, 2023a)). The sample over-represents academics, with 60% having an academic degree compared to 18,5% in the German population (Federal Statistical Office, 2020). The distribution of household size shows fewer single- and more three-person households in the sample compared to the population (Federal Statistical Office, 2023b).

Table 1. Sample Description

Gender	Female: 13, Male: 17
Age	21-25 years: 10, 26-30 years: 8, 31-35 years: 3, 36-40 years: 1, 41-50 years: 3, 51-60 years: 2, 61-70 years: 3
Formal Educational	No degree: 2, Secondary or tertiary education: 6, Vocational training: 4, Bachelor's degree: 7, Master's degree or higher: 11
Household Size	Single: 6, Two persons: 8, Three persons: 11 (2 with children), Four persons: 2, Five persons: 1, Six persons: 1, Seven persons: 1
Household Net Income	< 1699€: 10, 1700-3000€: 7, > 3000€: 13
Urbanization	Rural (<1000 persons/km²): 6, Rural-urban (1001-2000 persons/km²): 15, Urban (>2000 persons/km²): 9
Citizenship	German: 23, European: 3, Non-European: 4

Data Collection and Analysis

Data was captured via an online questionnaire and semi-structured follow-up interviews. The survey was conducted online using the GDPR-compliant software *SoSci-Survey*. The average completion time was 20 minutes. The first of three parts gathered individual socio-demographic data (i.e., gender, age, nationality, educational qualification, employment) and data on the participant's household (i.e., size, living space, number of children, net income). For the second part, a definition of crisis preparedness was presented, and participants responded to twelve questions about their preparedness levels. These questions were based on recommendations by the Federal Office of Civil Protection and Disaster Assistance and included primarily resource-oriented preparation, that would be relatively cheap and easy to obtain, such as food, water, first aid and hygiene supplies, fire protection, energy and information sources (batteries, radio) and document backups (BBK, 2019). The third part of the questionnaire assessed values associated with crisis preparedness behavior by using the Portrait Values Questionnaire (PVQ) (Schwartz et al., 2012), adapted to crisis preparedness. For example, for the value "power", participants stated their agreement with the statement "He engages in crisis preparedness because the sense of control that resources can provide is important to him" (adjusted to participants' gender). The adapted PVQ demonstrated acceptable to excellent reliability based on assessments of internal consistency (Cronbach's α between .70 and .96).

A crisis preparedness score was computed by assigning 0 to 3 points to participants based on their responses to various preparedness measures. The assigned value of the measures was based on the risk index by (Nohl & Thiemecke, 1988) which takes the potential negative cost of the missing measure into account (see Table 2). The score was normalized to a measure between 0 and 1 by dividing the score by its maximum of achievable points.

Table 2. Assignment of Preparedness Score Values

Preparedness measures	**Points**			
	0	1	2	3
Number of days household ... has sufficient food supply is sufficient	0+	3+	7+	10+
... water supply	0+	3+	7+	10+
... has access to light/heat/cooking (energy sources)	0+	3+	7+	10+
... can access news	0+	3+	7+	10+
...can maintain hygiene standards	0+	3+	7+	10+
Time since the last first aid course	> 5 years	2-5 years	< 2 years	< 6 months
Presence of a first aid kit	No	Yes	-	-
Presence of medications	No	Yes	-	-
Knowledge of the location of important documents & readily available/digital copies	No	Knowledge	Copies	Knowledge + copies
Fire protection (fire blanket or fire extinguisher)	No	-	Yes	-
Emergency supplies (bug-out bag)	No	-	Yes	-

The median (*MD*=0.45, *SD*=0.16, spanning from .11 to .78) was used as the baseline to differentiate the groups of rather more (Group 1, N=16) and rather less prepared individuals (Group 2, N=14). Following standard practice (Schwartz & Cieciuch, 2022), the scores for the individual values were computed by averaging the related item scores. To explore the relationship between crisis preparedness behavior and personal values, Mann-Whitney-U-tests for comparing independent groups with non-normally distributed dependent variables, were performed using R statistical software. The interview (see Table 3) started with creating a comfortable environment to encourage open responses, then explored participants' understanding of crisis and preparedness, and offered a definition of crisis preparedness (UNDRR, 2016). Next, participants' beliefs, social norms and personal norms related to the topic were discussed. Interviews were conducted remotely between June 26 and July 19, 2023 and were recorded with participant consent, lasting an average of 25 minutes. The questionnaire (N=5) and interview (N=1) were pretested, leading to minor adjustments.

Table 3. Interview Guide

(1) Introduction and establishment of trustful atmosphere

(2) Topic introduction
- Do you engage in crisis preparation?
- What does the term "crisis preparation" mean to you?
- How did you come to (not) prepare yourself?

(3) Beliefs
- What advantages do you see in preparing for crises? What about disadvantages?
- What makes it difficult/easy to prepare for crisis situations?
- What motivated you to buy X/prepare for Y, or what would motivate you to buy X/prepare for Y?

(4) Social norm
- Is crisis preparedness discussed in your environment? If yes, what does it look like? Are practical strategies for dealing with it discussed?
- Do you think other people in your environment prepare for crisis situations? If yes, how?
- Who do you think would approve if you prepare for crisis situations? Who would disapprove?

(5) Personal norm
- What do you think is the right approach to crisis preparedness for you?
- Regardless of what people in your environment think or do, how do you think you should behave?
- What are the characteristics of a person who prepares for crisis situations?

(6) Closing questions
- Do you have any additional points you would like to mention? Do you have any questions?

The interviews were pseudomized, transcribed and the records deleted. The interview data were analyzed using qualitative content analysis (Mayring, 2015), inductively building a coding scheme with relevant themes that emerged from the text analysis (see Figure 2).

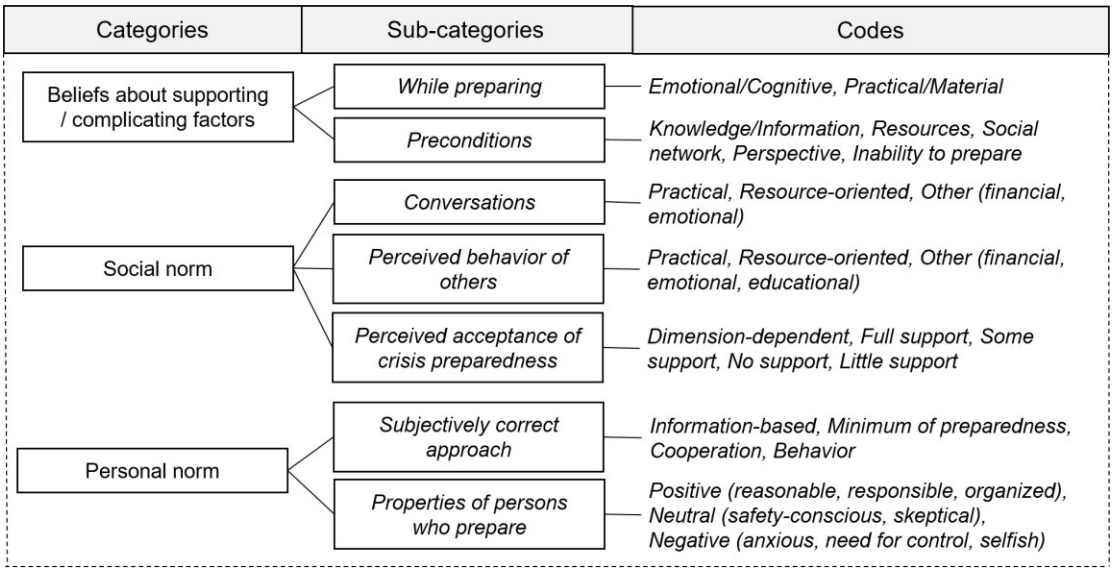

Figure 2. Coding System

RESULTS

Crisis Preparedness and Values (RQ1): Relevance of Value *Benevolence*

The prerequisites for using t-tests to address the research question were not met due to the non-metric scale level of the crisis preparedness score. Moreover, some value expressions did not fulfill the requirement of normal distribution and variance equality. Therefore, Mann-Whitney-U-tests were employed to examine possible differences in values between the differently prepared groups. Table 4 presents the means, standard deviations, and medians of values in the groups regarding crisis preparedness behavior, as well as the Mann-Whitney-U-statistic, Z-statistic, and p-values. A significant difference exists regarding the value of *benevolence*, which is higher among the individuals in the more-prepared group. An effect size of r=-.39 (Fritz et al., 2012) can be assumed, indicating a moderate correlation (Cohen, 1988).

Table 4. Comparisons between Differently Prepared Groups' Attitudes Regarding Crisis Preparedness Behavior, *p < .05

	Well-prepared (G1)			*Less-prepared (G2)*			*Mann-Whitney-U*	*Z-statistic*	*p-value*

Crisis Preparedness and Personal Norms (RQ2): Well-Prepared Group Puts More Emphasis on Minimal Preparation

The personal norm was assessed through questions about the subjectively correct approach to crisis preparedness and the characteristics of individuals engaging in crisis preparedness (see Table 5 for an overview of the results**)**.

Perceived personal norm by more-prepared individuals: Concerning the subjectively correct approach, 75% (n=12) stressed information-based measures, with an emphasis on staying informed (n=7) and preparing plans (n=4). Many made statements about the extent of preparation (81%, n=13), primarily focusing on covering the essentials (n=11). People who prepare were described positively as being reasonable, forward-thinking, calm, intelligent, and communicative (75%). Neutral characteristics covered safety-consciousness and skepticism (44%), while negative traits included anxiety, a desire for control, social weakness, and occasional perceptions of being annoying (63%).

Perceived personal norm by less-prepared individuals: An information-based strategy was also emphasized by 79% of Group 2 (n=11), involving creating plans (n=5), staying informed (n=4), and following existing recommendations (n=2). Fewer participants discussed the extent of preparation (50%, n=7), suggesting a minimalistic approach (n=5). Positive attributes mentioned by Group 2 included being organized, responsible, and reasonable (71%). Neutral characteristics comprised safety-consciousness and admiration-seeking (36%), while negative traits comprised anxiety, pessimism, egoism, and mistrust (71%).

Table 5. Personal Norms , Group 1 = more prepared (n=16), Group 2 = less prepared (n=14)

	Group 1		Group 2	
	n	**%**	**n**	**%**
Subjectively correct approach to crisis preparedness

Do nothing	*1*	*6%*	*2*	*14%*
Properties of persons who prepare				
Positive	12	75% (reasonable, forward-thinking, calm, intelligent, communicative)	10	71% (organized, responsible, reasonable)
Neutral	7	44% (safety-conscious, skeptical)	5	36% (safety-conscious, admiration-seeking)
Negative	10	63% (anxious, desiring control, socially weak, annoying)	10	71% (anxious, pessimistic, egoistic, mistrustful)

Crisis Preparedness and Beliefs (RQ3): Less Knowledge and Fewer Perceived Benefits among the Less-Prepared

Participants' beliefs were assessed though their beliefs about disadvantages (see Table 6) and advantages (see Table 7) of crisis preparedness behavior, and perceived obstacles and facilitating factors.

Beliefs about benefits and obstacles by well-prepared individuals: 63% emphasized emotional-cognitive benefits during preparation, highlighting a sense of security (n=5), competence (n=5), and an opportunity for hypothetical thinking (n=2). A majority (56%, n=9) mentioned discomfort related to engaging with the topic, such as mental strain (n=4) and fear (n=3). Half of the group (n=8, 50%) indicated practical-material benefits, including better crisis management (n=7), such as being able to react faster. Practical-material drawbacks comprised the perceived effort (n=9), wastefulness (n=5), lack of guaranteed returns (n=3), and concerns about fostering competition (n=2). 13% (n=2) attributed no benefits to crisis preparedness behavior.

As preconditions, 69% (n=11) highlighted the importance of knowledge and information, with visibility (n=3), quantity (n=3), and recommendations (n=2) playing a crucial role besides having a plan (n=2). Additionally, 44% (n=7) pointed to needing a resource surplus, including money, space, time, and physical health. Social networks (31%, n=5) and a positive perspective on crisis preparedness (19%, n=3) were also mentioned. Hindering factors

comprised lack of knowledge or information (25%, n=4), specifically a lack of orientation, resource deficiency (50%, n=8), and a negative perspective on crisis preparation (81%, n=13) expressing the demotivating aspect of the unpredictability of crises (n=6), the lack of fun and perceived effort (n=5) and not rating preparedness valuable enough (n=2). Remarkably, 63% (n=10) believed that nothing would impede crisis preparedness behavior. However, 50% mentioned barriers dependent on the extent of preparation, such as high costs (n=8) and the lack of infrastructure for certain measures (n=2).

Table 6. Beliefs about Disadvantages, Group 1 = more prepared (n=16), Group 2 = less prepared (n=14)

	Group 1		Group 2

Nothing	10	63%	8	57%
Limitations (disability, illness)	1	6%	4	29%
Lack of awareness	1	6%	-	
Perfect preparedness impossible	8	50%	3	21%
Insufficient supply infrastructure	2	13%	-	

Beliefs about benefits and obstacles by less-prepared individuals: Ten participants (71%) emphasized emotional-cognitive benefits related to crisis preparation, with a primary focus on the sense of security and independence (n=9), whereas 57% (n=8) cited emotional-cognitive drawbacks, i.e. fear (n=3) and stress (n=3). 79% (n=11) – more than in the well-prepared group – mentioned practical-material benefits, including improved crisis coping abilities (n=7) and increased flexibility in daily life (n=3). However, 93% (n=13) pointed to practical-material disadvantages, including the perceived effort (n=10), concerns about wastefulness (n=6) and fostering competition (n=3).

When it came to preconditions to preparedness, 79% (n=11) stressed the importance of knowledge and information, including its visibility (n=2) and recommendations (n=2). Around 21% (n=3) stated the value of a supportive network and practical assistance. Over 40% (n=6) mentioned a resource surplus of money, time, physical health, and available space.

Factors hindering access to behavior included lack of knowledge or information (57%, n=8), especially orientation (n=4) and lack of visibility (n=3), resource deficiency (36%, n=5), and a negative perspective on crisis preparation (50%, n=7). Notably, 57% (n=8) believed that nothing rendered crisis preparation impossible, attributing its feasibility to associated costs and effort (21%, n=3), while a third (n=4) discussed hypothetical factors like physical and psychological disabilities.

Crisis Preparedness and Social Norm (RQ4): More Discussion and Less Disapproval in the Well-Prepared Group

Social norms were assessed by inquiring about the existence and style of discourse surrounding crisis preparedness in the social environment (see Table 8).

Perceived social norm by well-prepared individuals: Over two thirds mentioned discourse on the topic (69%, n=11%), dealing with practical strategies, information sharing, discussions on financial security and emotional coping. Half of the group (n=8) believe that their social environment prepares for disasters, noting measures towards energy independence, stockpiling, financial security, and efforts to stay informed. Regarding approval for crisis preparation behavior, around a third mentioned friends (38%, n=6) and family members (31%, n=5). Almost two thirds (63%, n=10) believed that nobody would disapprove of crisis preparedness.

Contrary, a quarter (25%, n=4) states that nobody in their environment approves of crisis preparedness. 25% (n=4) acknowledged that friends might not approve, and 19% (n=3) noted potential disapproval from many in the environment. 13% (n=2) mentioned disapproval from people in the local vicinity. A significant portion of the group felt that approval (19%, n=3) and disapproval (31%, n=5) depended on the extent of preparation.

Perceived social norm by less-prepared individuals: In this group the topic is less common in discussions (50%, n=7). Discourse surrounding stockpiling during the COVID-19 pandemic (n=2) and scenarios related to infrastructure failures in the context of the invasion of Russia in Ukraine (n=2) were mentioned, as well as the merit of insurances (n=2) and patient care (n=1).

57% (n=8) assume that their personal environment is not preparing, while 43% (n=6) thought that sufficient preparations were being made. Responses included mentions of stockpiling, financial preparations, survival training, and emotional readiness. In terms of approval of crisis preparedness, 57% in this group (n=8) stated that family members would approve, in about a third (36%, n=5), friends would approve, and 21% (n=3) mentioned their local environment who might profit would be supportive. 29% mentioned that approval and understanding depended on the measures being taken, indicating a strong negative perception of "excessive" crisis preparedness.

36% (n=5) of the group – less than in the well-prepared group – expected no one in their environment to disapprove of crisis preparedness. In contrast, three statements (21%) indicated that many in the environment would not approve, twice (14%) family members were mentioned.

DISCUSSION

The quantitative results suggest that only one value is associated with crisis preparedness behavior: *benevolence*. With benevolence being defined as "preservation and enhancement of the welfare of people with whom one is in frequent personal contact" (Schwartz et al., 2000, p. 316), there might be an underlying belief that crisis preparedness contributes to the welfare of others, although this was not explicitly stated. Other values, such as *security*, which was found to be related to macro safety worry (Schwartz et al., 2000), showed no significant

correlation.

Given the importance of benevolence, questions concerning social, personal norms and beliefs could give insights into motivations. The results show that the more and less prepared individuals do not differ drastically in either of the dimensions. The sample described people who engage in crisis preparedness mainly as forward-thinking and reasonable, while a few negative associations pointed towards being egotistical or socially weak. There appeared to be a shared understanding that quite easily, crisis preparedness could become "too much", and people who prepare in this manner were labeled as "preppers" or "hoarders". Instead of emphasizing the positive social impact of crisis preparedness, e.g. by aiding emergency services, concerns about resource scarcity arose, with mentions of shortages during the COVID-19 pandemic, which was blamed on some people hoarding resources (Baddeley, 2020). Future research should investigate whether this notion persists when describing less resource-oriented crisis preparedness measures.

The qualitative content analysis indicated that the less-prepared group exhibited rather goal-oriented motivations, emphasizing a sense of security. In contrast, the well-prepared group valued the process itself, indicating competence and learning opportunities. They also demonstrated a more nuanced perspective considering preparation as a spectrum rather than a binary concept, resulting in a more practical focus on preparing a minimum supply of resources. These advantages may be due to more discourse about practical strategies in their social environment. The study found that over half of the participants perceived discussing crisis preparedness as unpleasant, associating it with fear, stress, and negative emotions. Many held the belief that it is time-consuming, and can lead to waste and competition. Further barriers to preparedness include a lack of differentiation between responsible, cooperative preparedness behavior and "hoarding". Many believe that more accessible information, recommendations, and emergency plans are needed.

From the findings, we can derive strategies for motivating people towards engaging in crisis preparedness. Firstly, given the relevance of benevolence and the negative image of "too much" preparedness, the social benefits of crisis preparedness should be stresses, especially the ways in which they positively affect one's immediate environment. A previous study used interactive nudges, which confronted users with the economic costs and benefits of (non-)preparedness and with the impact on their social environment. Positively framed statistical information, that asked users to guess costs, benefits and consequences of hazards and preparedness measures were found to be effective in increasing crisis preparedness (Haunschild et al., 2023), whereas the social nudges lead users to reconsider their behavior. In light of the identified contestation of crisis preparedness as a pro-social behavior, similar information could be used to stress the social benefits of preparedness, e.g. by confronting with the social consequences or reducing the perceived distance to hazards (Caraban et al., 2019). Research shows that interventions, such as eliciting reasonings for the relevance of a value, can lead to an increased perceived importance of that value (Russo et al., 2022). A future experiment should explore how elicitation of benevolence might affect attitudes towards crisis preparedness.

A second strategy could focus on showing the gaps and waiting times that are inherent in state-provided crisis management or in case of infrastructure failures (Reuter, 2014). This would be especially promising in countries with a state-oriented risk culture, which tend to rely overly on state institutions to manage crises (Reuter et al., 2019). While state institutions were hardly mentioned, there seems to be a common understanding that little individual preparedness is required, as predicted by risk culture theory. Future work should compare other risk cultures to see if attitudes change as the theory predicts.

Finally, in addition to offering more information on crisis preparedness and its effects, agencies should try to activate networks, encouraging individuals to discuss crisis preparedness in their immediate circles can facilitate easier adoption of the behavior. Integrating crisis preparedness into societal life is seen as a means to simplify access. Additionally, strategies from the Persuasive Systems Design model (Oinas-Kukkonen & Harjumaa, 2009), can be employed and potentially integrated into existing warning apps, offering rewards for engagement to make crisis preparedness more appealing.

The study is limited by its relatively small sample size, and future studies should seek to reproduce the connection between benevolence and crisis preparedness and possibly other values. While the median age of the sample (26-30) is younger than median age in Germany (45 years), research indicates that values (apart from conformity values, which tend to increase) remain substantially stable during adulthood (Vecchione et al., 2016). Despite efforts to stress the acceptability of all views, due to the focus of the study, participants may have perceived a desirability of crisis preparedness, introducing potential desirability bias. Additionally, the less-prepared group has lower levels in values overall, possibly influenced by the adapted questionnaire design tailored to crisis preparation behavior. As the items of the PVQ were adapted to crisis preparation behavior, this group may have been less able to identify with the values, which may explain the lower scores. A greater difference in values may have been achieved without adapting the questionnaire. Furthermore, the crisis preparedness score, relying on

official recommendations (BBK, 2019), focused on easily implementable measures. Future research may include measures that require more time, effort or financial investments, such as insurances or construction measures (Mol et al., 2021), to further differentiate people with a high intention and motivation to prepare.

CONCLUSION

This study has investigated connections between crisis preparedness and personal values, social and personal norms and beliefs. Differentiating more-prepared and less-prepared participants, the study has produced the following key findings:

- The quantitative analysis showed a significant correlation between greater preparedness and the personal value of *benevolence*.
- The qualitative thematic analysis of the interviews showed rather small differences regarding norms and beliefs between the two groups.
- A dominant social norm cannot be identified.
- A limited amount of crisis preparedness is believed to be helpful.
- A prominent theme in both groups is a negative view of "too much" preparation, leading to people being perceived as "hoarders", indicating that certain types of resource-oriented crisis preparedness are perceived as anti-social.

The study discusses strategies, such as confrontational nudges and value elicitation, for stressing the social benefits of crisis preparedness and triggering the value benevolence in this context. Recommendations for future research involve further examination of the impact of social norms and social structures, and investigating further countries characterized by different risk cultures (Reuter et al., 2019). Furthermore, the need for larger sample sizes, cluster analyses as in earlier research (Gerhold et al., 2019), and innovative approaches to promoting crisis preparedness behavior and behavior change are emphasized.

ACKNOWLEDGEMENTS

This research was funded by the German Federal Ministry of Education and Research and the Hessian Ministry of Higher Education, Research, Science and the Arts within their joint support of the National Research Center for Applied Cybersecurity ATHENE and by the LOEWE initiative (Hesse, Germany) within the emergenCITY centre. We thank Dr. Nina Gerber and Professor Verena Zimmermann for their advice and valuable feedback.

ABSTRACT

The widespread use of mobile devices has resulted in remarkable advancements in their capacity to offer and disseminate online information virtually anywhere. Users are increasingly open to installing applications that furnish valuable information to address specific situations. This paper describes joint efforts in research and development of a mobile application, called Citizen Engagement App (CEA), and related methods for engaging the public in forest fire danger awareness, data collection and presentation services. The primary objective is to provide insights into the developed methods and technologies employed. The methods are separated into two domains, namely the domain of citizen engagement approaches to educate people about forest fire prevention, and the domain of mobile application development employed for disseminating knowledge and reporting on hazardous situations in the forests. The evaluation of the mobile application took place both in the pilot demonstrations and meetings with the public to pinpoint any gaps and challenges.

Keywords

Wildfire, forest fire prevention, citizen engagement, forest fire reporting, mobile application.

INTRODUCTION

The widespread use of mobile devices has resulted in remarkable advancements in their capacity to offer and disseminate online information virtually anywhere. The users are increasingly open to installing applications that furnish valuable information to address specific situations. Even though users' willingness at data collection attendance is considered to be low (Wenz, 2023), as the use of mobile technologies for personal purposes increases, including among older groups in the population, participation in survey-based activities using these technologies is likely to increase (Jäckle, 2019). As a general rule, globally only around 4% of all forest fires have natural causes such as lightning. In all other cases, humans are responsible for the fires - be it directly or indirectly, deliberately or due to carelessness (Hirschberger, 2016). Aforementioned facts about the increasing use of mobile applications as a communication information channel and that major cause of wildfires is a human activity was the main drivers for creation of mobile application for forest fire prevention. Since the preventive actions help to decrease the forest fire causes, the sharing the information about the existing forest fires may help to put the fire under control or have better situational overview. This paper also addresses the concern of people's willingness to install and actively use the application especially during the wilderness adventures. The presented work is being developed in scope of the SILVANUS project[1].

In the next chapter, the paper provides a related work done in the domain of citizen engagement for preventing forest fires using campaigns and the use of mobile applications for forest fire reporting/monitoring. The focuses on the design, development, utilization, and acceptance of a mobile application aimed at providing the useful information on wildlife safety, the importance of wildfire prevention and sharing information about hazardous situations in the forests. The following chapters are describing the methods raising public awareness about the importance of the forest fire prevention through various channels as social media, workshops, exhibitions and especially mobile application. The next chapter focuses on mobile application design with regard on user experience, followed by the fire reporting module design and implementation of backend services. Next chapters are devoted to providing overview on the information collection and distribution framework directly used by the mobile application and the main dashboard description. The last chapters of this paper discuss the prototype application evaluation and identified challenges along with the future work addressing the challenges.

RELATED WORK

The chapter summarizes scientific works related to mobile applications and citizen engagement for fire prevention and fire reporting/warning, and also reviews the existing mobile applications in this domain. The topics covered in reviewed works include the mobile apps, analysis of emergency notification apps, integration of mobile apps into emergency communication frameworks, examination of mobile crowdsensing technologies in emergencies, and recent developments in wildfire monitoring. The mobile application EscapeWildFire benefits was described (Kamilaris, 2023) and evaluated through simulations of wildfires in Cyprus and the 2011 Amarillo, Texas wildfire to aid in real-time wildfire evacuation. The work overviewed the app's wildfire-specific design requirements. The set of the most relevant emergency notification mobile applications were reviewed and analyzed (Romano, 2016) according to the shared data types and forms of communication with citizens. One of the conclusions states that people prefer to use multi-media to write a text or fill in the forms for notifying emergencies. In the scope of PEMEA project (Pemea, 2020), twelve mobile emergency applications are integrated to the communication framework defined by ETSI (TS 103 478) standard providing citizens with fast and intuitive access to emergency services. The work (Cicek, 2023) provides a comprehensive overview of the mobile crowdsensing technologies in emergency situations as well as research and development challenges. The work concludes with a finding that mobile applications and social media prevail in hazard/risk detection, evacuation/mapping, information exchange, situational awareness and data fusion. There was a recent effort in design and develop mobile application (Teguh, 2021) to control and monitor peat fires in the Central Kalimantan (Indonesia) thus providing firefighters with information support. The requirements study (Majlingova, 2022) enlisted specific requirements for mobile application relevant to wildfire management. The following citizen requirements were identified: notification about the fire occurrence in citizens' vicinity; ability to notify the fire location to the fire and rescue service; ability to notify the forest management services on human negligence; and ability to report a suspect fire with geo-location information, photos, and a brief description. The Smoke Sense project by the US EPA (Environmental Protection Agency) utilizes a mobile app to involve citizens at different tiers to mitigate the public health effects of wildland fire smoke, drawing motivation from personal, professional, and community contexts and collecting individual reports of smoke exposure. It underscores the necessity of aligning citizen science initiatives like Smoke Sense with partner organizations to tackle intricate problem areas effectively (Hano, 2020). Although forest fire reports can also be obtained from social media through topic extraction method (Messaoudi, 2022), the

[1] SILVANUS Horizon 2020 Green Deal project https://silvanus-project.eu/

recent evolution of security and privacy getting these sources more restricted.

Apart from the scientific research, the table (Table 1) summarized the unique features of the most relevant mobile applications in wildfire monitoring and warning. The main purpose of the reviewed applications is to offer real-time updates on wildfire locations and status to keep users informed about the latest developments. The information is typically placed on the interactive maps where users can view fire incidents, evacuation routes, hotspots, and other relevant information. Another common functionality is receiving alerts and notifications about nearby wildfires, weather conditions, evacuation orders, and other critical updates. The applications commonly use satellite data for wildfire warning for global coverage or rely on fire department information sources used for local state coverage, specifically only for regions encompassing United States, Canada and Australia.

Table 1. Existing wildfire emergency applications.

	OS/Plan	Region	Summary of unique functionalities
Watch Duty	Android/iOS, Free	US	Relies on real people, including trained professionals like firefighters and dispatchers, to provide real-time information verified by humans rather than automated systems.
Fireguard Wildfire Tracker	Android, Ads	World	Global monitoring of wildfires using satellite-based activity tracking and provides near real-time updates on fire locations without requiring users to log in, but provides inaccurate/unverified alerts.
Fires Near Me Australia	Android/iOS, Free	AU	Focuses on monitoring nationwide bushfire threats in Australia and categorizes alerts into Advice, Watch, and Act levels based on the Australian Warnings System.
Wildfire Tracker	iOS, Ads/Paid	US, Canada	Provides detailed weather forecasts, air quality data, and an interactive map showing wildfire hotspots, along with push notifications and global updates.
Frontline Wildfire Tracker	Android/Free	US, Canada	Comprehensive situational awareness including event notifications and preparation checklists.
Fire Atlas	iOS, Ads/Paid		Includes additional maps from the Bureau of Land Management and the US Forest Service, with features such as offline mapping, thermal hotspots, and AccuWeather summaries.
Firespot: Wildfire app	iOS, Ads/Paid	World	Offers real-time global wildfire information with satellite and for US/Canada agency data, including perimeters, aircraft tracking, and customized alerts for subscribers.
Bushfire.io	Android/iOS, Free/Paid	AU	Provides immediate alerts, up-to-date maps, and collaboration with local authorities for verified data, along with features like emergency aircraft positions and wind forecasts.
Australian Fires	iOS, Free	AU	Aggregates data from multiple government agencies covering fire incidents across Australia, emphasizing the importance of staying informed through official channels.

CITIZEN ENGAGEMENT APPROACH

In our forest fire prevention efforts, we have implemented various strategies to engage citizens and raise awareness about the importance of wildfire prevention. One of our key initiatives involves the creation and distribution of informative posters in communities at risk of forest fires. These posters contain essential information about fire prevention measures, such as safe campfire practices, proper disposal of cigarette butts, and the importance of reporting any signs of smoke or fire promptly. By combining traditional outreach methods like posters with

modern technological solutions like the CEA application, we aim to foster a collaborative approach to forest fire prevention, involving communities in safeguarding our precious natural resources.

Overall Approach Overview

We view citizen engagement as a result of bidirectional communication, involving citizens, organizations, and authorities in wildfire management (Mojir, 2023). Media effects theory was incorporated into the definition of citizen engagement, viewing media as a means for audiences to acquire knowledge, attitudes, emotions, and behavior change (Bandura, 2001; Potter, 2012). The critical focus of the Citizen Engagement Programme (CEP) lies in determining effective communication means and channels. These tools are essential for informing citizens, aiding in wildfire preparedness, prevention, and protection efforts. Additionally, the program emphasizes active citizen participation in shaping wildfire prevention policies, supporting first responders, and engaging in post-disaster recovery activities. Figure 1 outlines simplified effects desired from citizen engagement, marked as "raising awareness," "changing attitude," and the more intricate "changing behavior" in the context of wildfire management. The figure also includes "Type of activity" aligns with these effects, including informing and educating for awareness, fostering safe practices for attitude change, and organizing assistance for behavioral change (Mojir, 2023). The desired effects are relevant in all phases of wildfire management including prevention, response and recovery.

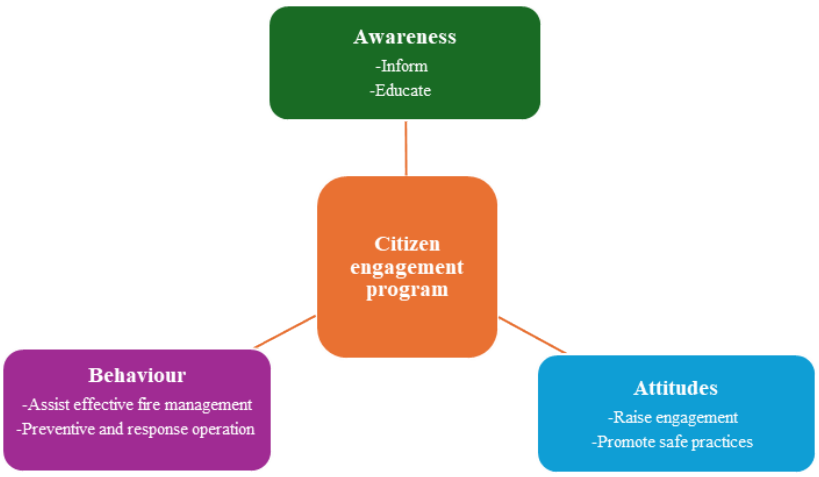

Figure 1. Simplified model of desired effects concerning citizen engagement program in wildfire management.

Examples of Content and Achievements

As part of the CEP, social media campaigns and a poster exhibition in different cities were held, involving the creation of impactful messages with visuals to prompt immediate realization or comprehension. The team, now including members with communication and graphic design expertise, manages these campaigns on social media. Additionally, work is underway to develop an online citizen engagement course based on microlearning, set to be published soon for citizens' use in various settings such as workshops, training sessions, or as a self-study course. The online course serves as a valuable tool for engaging citizens in wildfire prevention, response, and recovery. It provides educational content, empowers citizens with knowledge and skills, raises awareness, and encourages participation. A mobile application was also designed, primarily to enable citizens to assist in wildfire management processes. The mobile application will be explained in more detail. Figure 2 provides examples of published posters on social media.

Figure 2. Examples of posters designed for social media and exhibitions

CITIZEN ENGAGEMENT MOBILE APPLICATION

The primary objective of the mobile application is to provide a comprehensive guide for users moving through forested areas. The app's aim is to equip the users with essential information and guidance on how to effectively handle unexpected situations that may arise during their outdoor activities. Users may access up-to-date information about the local environment to make them sure that they can be well-prepared for expected conditions. This includes details about potential hazards and specific guidelines to mitigate risks. Whether it's dealing with common issues like sunburns and injuries or accessing region-specific information, the application strives to enhance the overall experience and safety of users exploring nature.

In addition, the application encourages users to share valuable information to the local community by reporting and sharing observations related to potentially hazardous events like forest fire or wild animals in the forest areas, which contributes to the collective safety. Through a user-friendly interface, the app seamlessly integrates essential features, such as an emergency hotline, first aid tips, and location-based services. The goal is to empower users to make informed decisions while promoting a sense of responsibility towards the environment and the local community. By combining practical guidance with community engagement, the mobile application strives to make forest exploration not only an enjoyable experience but also a safer and more sustainable one for everyone involved.

Design and Navigation in the App

The Citizen Engagement App (referenced as the App) is developed to enhance user experience and accessibility, every feature or module is designed to facilitate smoother navigation and interaction for the users.

In general, the App enables a user to navigate using bottom bar to show main or home, map and configuration panels. This navigation provides users with quick access to the modules withing the app, allowing seamless switching between the different panels. The App's central panel provides a home screen presenting a comprehensive array of features, including informative news updates, detailed guidelines covering a variety of topics relevant to forest navigation, practical tips to enhance user experiences, and engaging quizzes designed to educate and entertain users as they explore forest environments. Every feature is presented to users with a visually appealing and informative card. Each card features an image and a concise description along with intuitive navigation option. This design aims to improve user engagement and streamline access to relevant content (Figure 3).

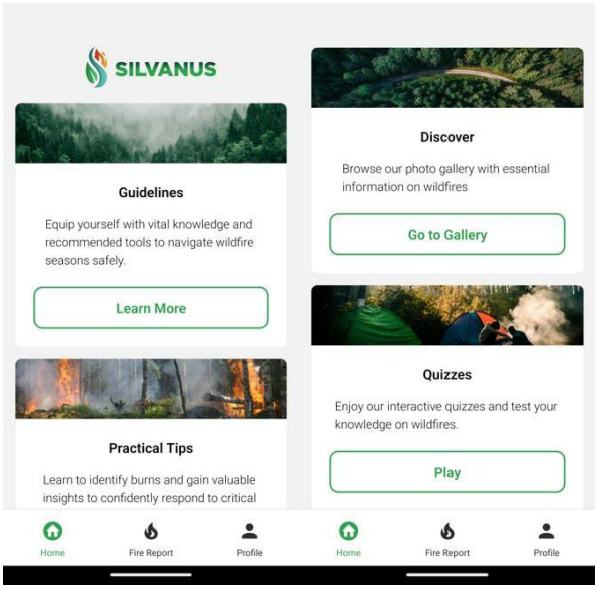

Figure 3. Screenshots of the home screen, showcasing the cards for the different modules.

Withing the configuration or profile panel there is a list of three clickable cards providing users with access to different functionalities. First, the language settings where users are presented with a dropdown menu offering a selection of languages. This feature enables users to customize the app interface and content according to their preferences. Enhancing accessibility and usability. Second, a Privacy Policy that redirects user to the documentation of the app. Third, the Q&A card provides users with access to frequently asked questions and additional information about the app and its underlying project (Figure 4).

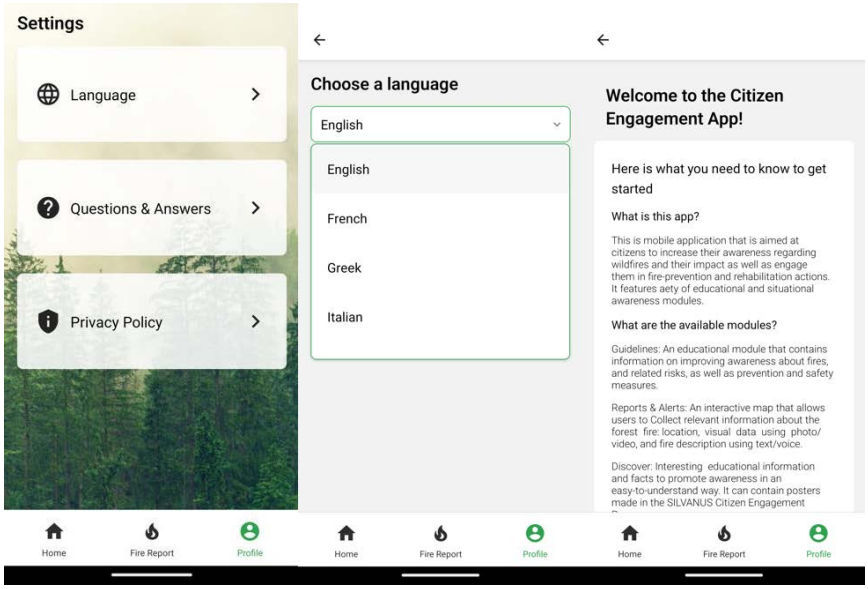

Figure 4. Profile panel. From left to right: main profile menu. Language configuration. Questions and answers information.

The map panel unwraps into the separate module used for reporting and receiving information using subscribed information channel mechanism (described in chapter Fire Reporting Module). The App's design feature is to display relevant information incorporated into the map. While focusing on the specific functionality of fire reporting, the information channels may collect information about different topics, which do not necessarily have to relate to the fire reporting.

Information and Guidance Modules

The guidelines module provides users with essential information and instructions related to wildfire prevention and safety measures. With a focus on empowering citizens residing in forested areas, this module offers

comprehensive guidance on various scenarios, including appropriate actions to take upon encountering a wildfire and post-fire instructions for safety and recovery. Upon accessing the Guidelines module, users are presented with a selection of eight topics covering a range of pertinent subjects. Navigating within each topic reveals a swipe mechanism, allowing users to seamlessly browse through informative cards that encapsulate key guidelines. Each card presents concise and actionable advice, with up to three guidelines displayed per swipe. For users seeking detailed information, a prompt button is available to access the complete list of guidelines within the selected topic (Figure 5).

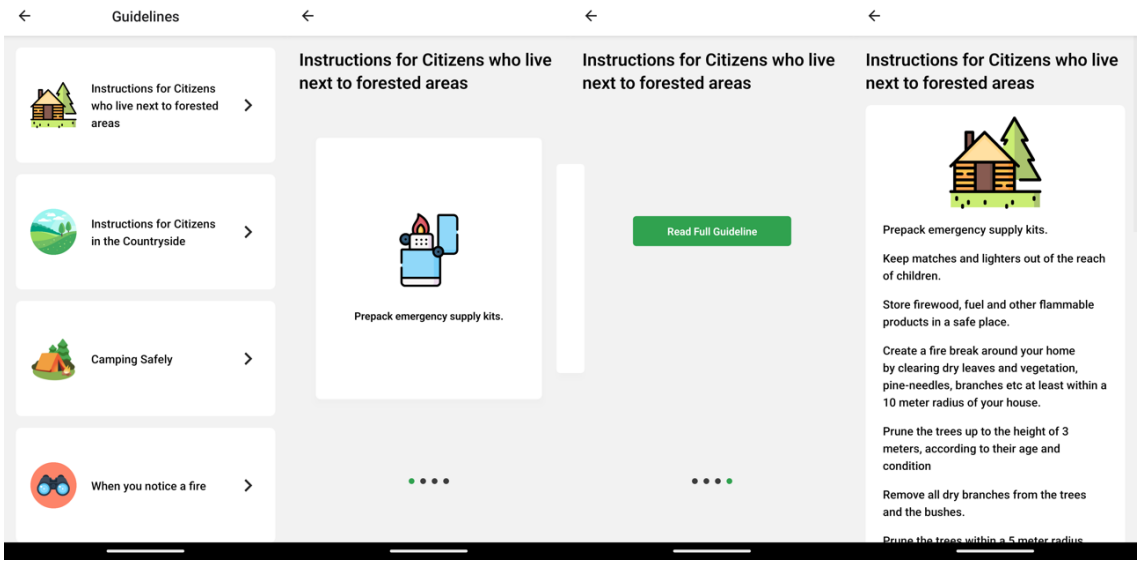

Figure 5. Screens for the guideline module. From left to right navigation of the screens.

In addition to the Guidelines module, the Citizen Engagement App features a Practical Tips section tailored to provide users with actionable insights for handling various emergency situations commonly encountered in forest environments. This module offers practical advice on topics such as first aid treatments for minor injuries, recognition of heatstroke symptoms, and understanding the causes of burns. Similar to the Guidelines module, the Practical Tips section consists of seven distinct titles, each focusing on a specific aspect of wilderness safety and emergency preparedness. Upon selecting a title, users are presented with a series of swipeable cards containing detailed tips and recommendations relevant to the chosen topic (Figure 6).

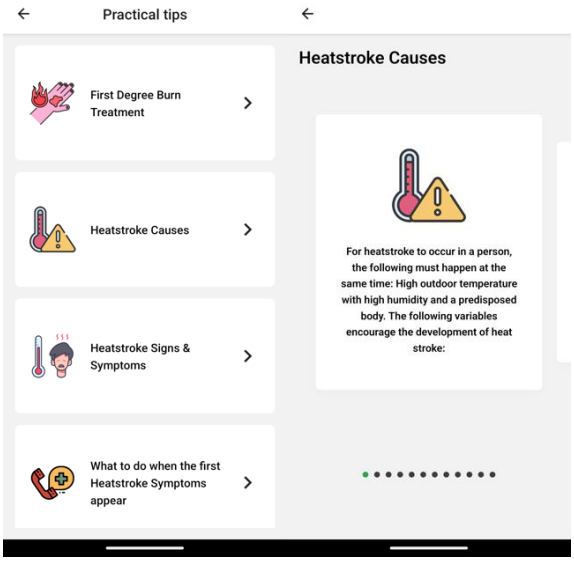

Figure 6. The screens of practical tips module. Left menu with titles. Right swipe screen.

The discover panel is designed to resemble a gallery, showcasing a range of content related to forest safety and wildfire prevention. Aiming to enrich user exploration and understanding of key topics through visual storytelling.

Upon accessing the Discover module, users are greeted with a selection of four distinct titles, each highlighting a specific theme relevant to forest safety and emergency planning. These titles include “Effects of Wildfires”, “Protect Our Home from Wildfires”, “Making a Family Emergency Plan” and “Causes of Wildfires.” Under each title, users encounter a horizontal scrolling gallery of images, providing a glimpse into the associated topic’s visual narrative. Clicking on an individual image opens it in full-screen mode, allowing users to immerse themselves in its details. From here, users can swipe horizontally to navigate through the entire collection of images within the selected title, enabling a seamless exploration experience (Figure 7).

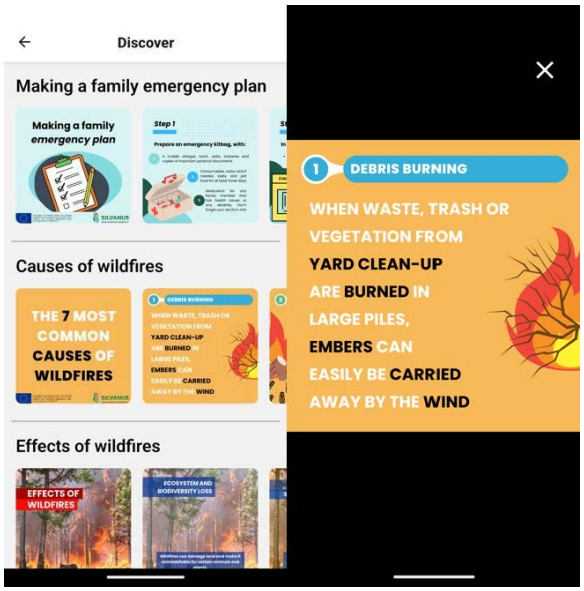

Figure 7. Screenshots of discover module. Left image gallery of photos. Right image full-screen mode.

The quizzes panel offers users an interactive and engaging way to test their knowledge on wildfire safety and emergency response procedures. With two quizzes currently available, the “Burns Quiz” and the “Heatstroke Quiz”, this module provides users with an opportunity to assess their understanding of critical topics related to wilderness safety. Upon selecting a quiz title, users are presented with a visually intuitive interface featuring a progress bar indicating the number of questions completed out of the total. Each quiz consists of multiple-choice questions designed to challenge users’ comprehension of key concepts and best practices. Upon completing the quiz, users receive a summary of their performance. If more than half of the answers were correct, users are congratulated with a message indicating their success and encouragement to continue their engagement with the app’s content. In contrast, if more than half of the answers were incorrect, users are provided with constructive feedback and encouraged to explore other modules within the app to improve their knowledge and future quiz scores. This iterative approach encourages continuous learning and reinforces key safety principles in forest environments (Figure 8).

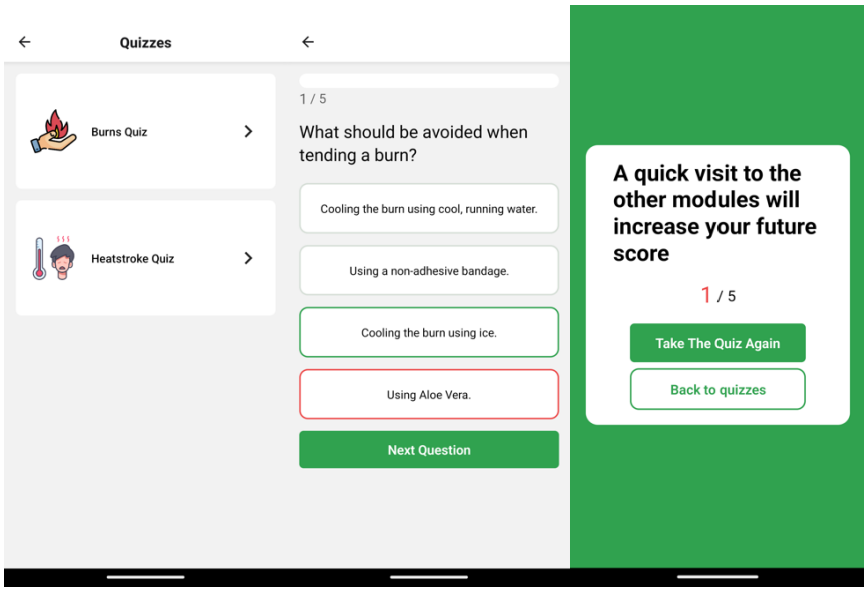

Figure 8. Quizzes module. Navigation through one quiz.

Fire Reporting Module

The Fire Reporting module is designed to provide valuable information on the main map (the first picture in Figure 9) while also facilitating the sharing of information across various information channels. The map interface shows a zoomable vector map featuring the user's current location. Positioned at the bottom right corner of the map is the fire reporting icon, which, when selected, places a fire icon at the center of the map. Through a long touch gesture, the user can update the fire icon location to accurately reflect the incident's location. Upon selecting the fire reporting icon once again, the information collection form is displayed (the second picture in Figure 9). Here, users are provided with the opportunity to select images from their smartphone's gallery or capture new photos using the device's camera. After selecting at least one thumbnail of the chosen picture and composing a brief message, users can transmit the data into information poll by clicking the submit button. The data transmission process is described in detail in the subsequent section, outlining the various parameters and mechanisms involved in the communication process.

The Channel screen (the third picture in Figure 9) serves as a hub for managing available information channels via services provided by the EmerPoll system. Within this screen, users can search among the available channels and based on their preferences, subscribe or unsubscribe to/from any channel. Subscribing to an information channel triggers the download of the corresponding poll template, which is then added to the user's active channels. Each poll template within the subscribed channels contains detailed instructions on how to construct the visual form, including visual icons and form data, as well as guidance on assembling the data packet for poll replies. Subscribed channels also influence the icon set displayed on the main map, but the behavior of the information reporting process remains the same as described for fire reporting albeit with different objectives.

The Message screen (the last picture in Figure 9) provides users with a list of messages sent or received. Here, users can review the details of each message apart of the message related location.

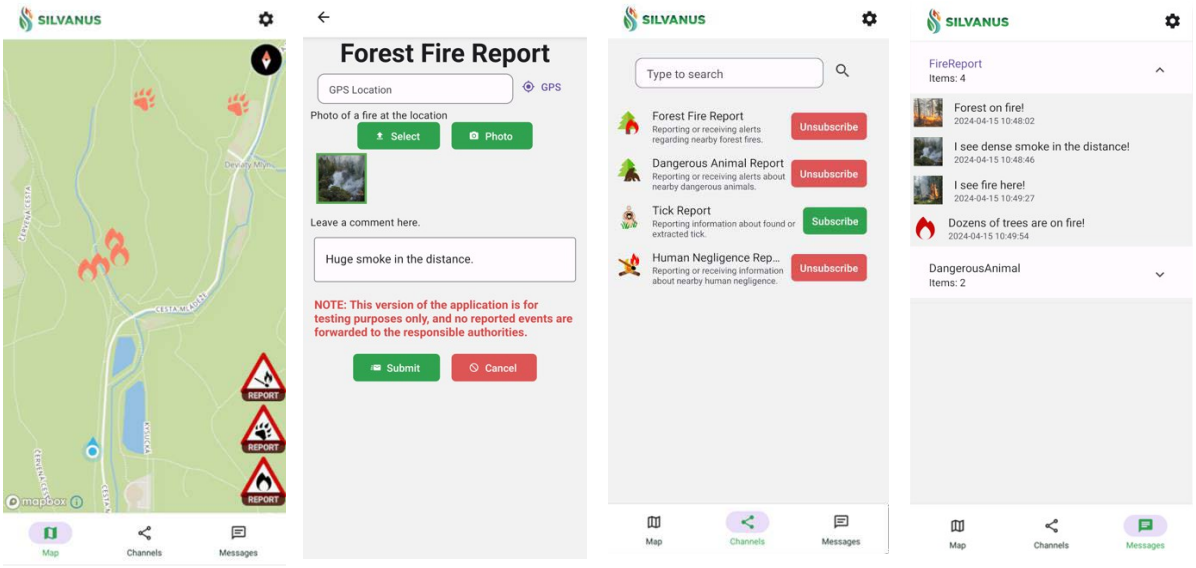

Figure 9. The screens of Fire Reporting module. From left: main map used for localizing the event, reporting form, channel management screen and message screen.

Implementation of Content and Backend Services

Implementation of mobile application based on the React Native and Expo frameworks, which allow development and deployment of mobile applications for both Android and iOS systems.

The backend services supporting the fire reporting module (depicted in Figure 10) are designed to prioritize scalability and straightforward deployment processes. Central to this infrastructure is the MQTT gateway, secured over an SSL layer facilitated by the EMQX server. This gateway serves as the primary communication channel, enabling the application to facilitate the transmission of polling messages of various channels with EmerPoll services and the user community registered to specific channels via MQTT topics. The polling message payload comprises of JSON-encoded data, primarily consisting of form data, accompanied by polling details, user information, and channel metadata. For immediate message overview, thumbnail images are included into the messages. File Storage service is employed to facilitate large binary data transfer, typically pictures, audio and video recordings captured by smartphones. This data is encoded into ‘multipart/form-data‘ format and transferred by secure HTTPS protocol. Uploaded binary data become accessible by the Nginx Web Server via links provided within the metadata of MQTT messages.

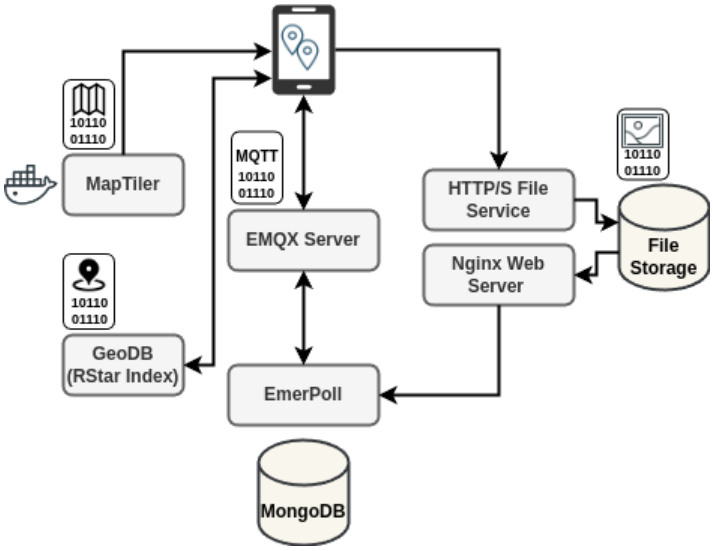

Figure 10. Fire reporting module backed services and data flow schema.

The CEA mobile application utilizes vector map tiles sourced from a containerized MapTiler server to render the Map screen. Geo-spatial information embedded within overlaid data is stored and queried using the R-star Tree

method, optionally supported by a key-value store like Leveled DB. This approach ensures efficient data management and seamless integration of spatial information within the application's interface.

INFORMATION COLLECTION AND PRESENTATION

Information Collection and Distribution Methods

Information collection method is based on the principles of Polls, Channels and Templates as described in (Balogh, 2016) and later extended by the information sharing protocols proposed in (Balogh, 2023). Actual integration with the CEA application follows the same principles that allow users to search and subscribe to information channels even other than for a wildfire warning and reporting as described in this paper. The operations such as information channel search use dedicated MQTT topic mimicking request-response communication. Information channel management actions use the MQTT topic infrastructure to facilitate the subscription process. EmerPoll utilizes the external services of the Storage Abstraction Layer (SAL), a component developed within the SILVANUS project, to facilitate the transfer of data to and from shared storage resources. SAL empowers EmerPoll by providing notifications regarding the availability of specific data, enabling seamless access for processing. This asynchronous capability allows data to be both sent and received efficiently, enhancing the overall functionality of EmerPoll.

Dashboard Data Integration Methods

Dashboard is a web-based, graphical interface created for SILVANUS platform, which is the main access point for the user to obtain and interact with outcomes of data produced by SILVANUS' various modules. Dashboard consists of layers representing the current status of chosen area of operation on the interactive map. Each layer is dedicated to individual types of data and events produced by a single User Product.

Data from EmerPoll is aggregated on the layer called Mobile Subscribers, representing emergency events reported by users in an area where occurrence of fire or smoke has been spotted. Events are visualized as a connected pair of pins representing the position of a user along with the position where the fire is taking place from the perspective of the user. Each of the singular events can be further inspected, presenting more details provided by the user. Embedded information is presented in the menu on the side, which contains exact coordinates to the location of the event, date, time, picture, description and status. Both description and picture are optional, depending on the action of the user. Example of the Mobile Subscribers layer from Dashboard is shown by Figure 11.

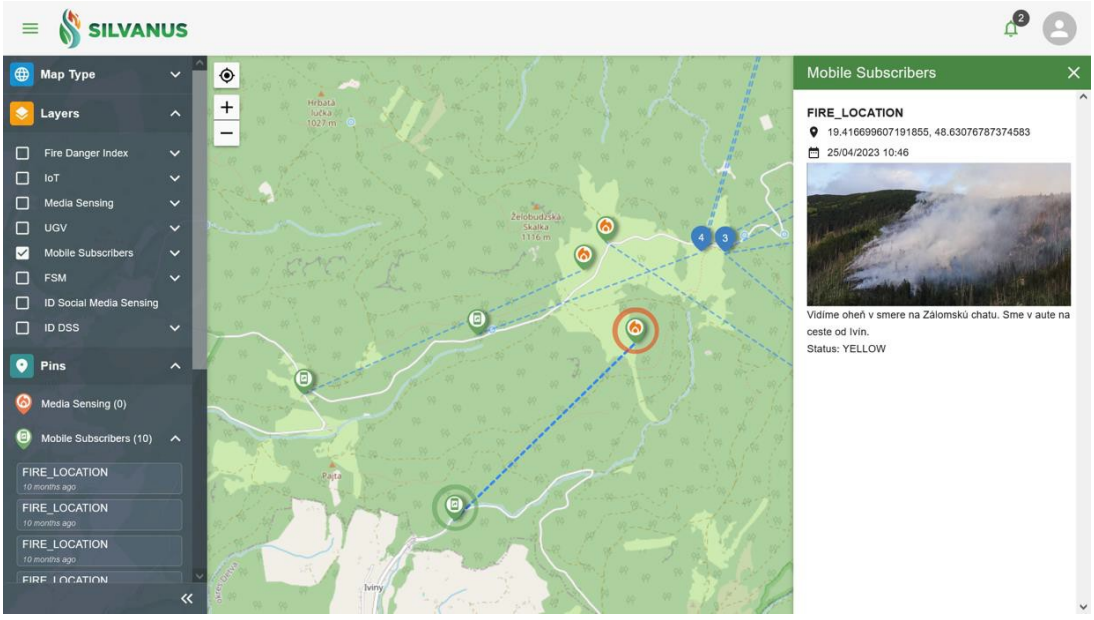

Figure 11. Mobile subscribers Dashboard layer.

The data for the Mobile Subscribers layer is available both live and archive, through the adequate message queue in the SILVANUS Storage Abstraction Layer.

Upon recognizing the danger in the area, Dashboard allows the operator to communicate directly with EmerPoll,

requesting a Poll to send a warning message to the subscribers of chosen channel.

EVALUATION AND CHALLENGES

The concept of the mobile application was first demonstrated during the Slovak pilot exercise located in Poľana region in the central Slovakia. The CEA was presented as a part of information collection framework called EmerPoll used for crowdsourced data collection and aggregation. The fire reporting data (photos and notes) were displayed on the interactive map of Dashboard Layer. The concept of pushing the wildfire warnings to smartphones was also demonstrated. The second evaluation of the technology was performed in autumn 2023 in Ostrava region located in north-east part of Czech Republic, where developed technologies was deployed in the remote command and control vehicle used to evaluate fire reporting functionality by CEA application during the fire fighters exercise. During the first evaluation phase, the coverage of mobile data connection and even slow transmission data rates was found as a limiting factor of the CEA application. To mitigate the factor of mobile data network intermittent connection along with slow data rate, the CEA adopted the off-line message acquisition using the MQTT protocol (e.g. messages are delivered as soon as the mobile data recovers) and also transmission of reported photo overview (picture thumbnails) in a single MQTT message, while full resolution picture is transferred using HTTPS protocol independently. The mobile data network coverage is panned to put as an overlay into the CEA interactive map to help users to find the places with mobile data connection in the forest area. During the second evaluation phase, the challenge with reporting the precise location was identified, where a user of mobile application may struggle to put a marker on interactive map in a correct direction. As a remedy to this situation, the virtual compass will be put into the interactive map along the distance estimation of the user from places marker for reported fire.

FUTURE WORK

The plans for future work were guided by the discussions with the potential users and first responders during the meetings and during the pilot exercises, as mentioned in the previous chapter. Specifically, the CEA is planned to be extended with the virtual compass and mobile data coverage map. The CEA application will be extended with customizable alerts that notify users of fire hazard events near a user-defined location. CEA is being prepared to acquire and display data containing evacuation routes and wildfire area temporal evolution, which will be provided by SILVANUS services. The Profile or Configuration panel's current functionalities are limited, future iterations will incorporate user authentication features, allowing users to access personalized settings and account management options. This panel serves as a centralized hub for users to configure their app preferences and access essential information, contributing to a seamless and user-centric experience within the Citizen Engagement App.

Future continuation of the developed method is foreseen in the adaptation and configuration of additional information channels, e.g. wild animal and human negligence reporting are in the preparation and testing phase. Information channel about tick reporting is being developed to help users to protect from the potentially dangerous pathogens transferred by the ticks.

CONCLUSION

This paper describes the methods for citizen engagement (Mojir, 2024) specifically incorporated with the mobile application described in the work. The content of the paper focuses solely on the citizen engagement methodologies related with the development of CEA mobile application. The current state of related existing applications focuses on warning about the forest fires and a bit neglect the prevention from the forest fires. Except the Watch Duty and Fire Atlas, the applications focus more on data sharing than on gathering relevant data from mobile users. The content of the CEA distinguishes also with the variety of useful content (practical tips and guides) for situations which may happen during outdoor activities. We also believe that providing more functionality with adaptable content will attract more people for the real use of this application. CEA application is focused on sharing the information about wildfires and other hazardous situations within a community of subscribed users with specific role of the fire and rescue authorities which supervise the crowdsourced data and share validated information (fire hazard areas and escape routes) with citizens.

ABSTRACT

Conversational agents are a technology that is used today in many different ways, for example as chatbots or voice dialog systems. While they are mostly used for applications in the business sector, research is also focusing on their use in other areas, such as medicine or disaster management. Events in recent years, such as the global Covid pandemic and advances in the field of language learning models, have led to many new approaches. Taxonomies are a good way to provide researchers and practitioners with a good overview of this growing field of research by classifying new and existing approaches. In this paper we present the current results in a methodological approach to develop a taxonomy for the classification of conversational agent approaches in disaster management. We describe the data basis of a structured literature search, the implementation of the method and the current dimensions and characteristics of the emerging taxonomy.

Keywords

conversational agent, chatbot, taxonomy, classification, disaster management

INTRODUCTION

Software applications that use natural language processing to act as an interface between human users and information and communication systems (Dale, 2016) have been gaining in importance for years. These so-called conversational agents (CAs), also known as dialog systems, are already present in the everyday lives of many people, both in the form of voice assistants such as Alexa or Siri, as well as textually in the form of chatbots (Gnewuch et al., 2017). In 2018, there were already more than 300,000 chatbots in Facebook Messenger alone (Johnson, 2018), while the development and use of individual CAs by specialized providers such as Botpress or Voiceflow is becoming increasingly easy. Advances in the field of language learning models have led to the potential of this technology becoming increasingly utilizable (vom Brocke et al., 2018), with the result that there has recently been a veritable race between large IT companies such as Microsoft, Google and Meta to implement new applications in the field of CAs (Weise et al., 2023).

While many approaches of the past focused primarily on application areas in the fields of customer services or entertainment, new approaches are becoming increasingly diversified (Brandtzaeg & Følstad, 2017; Stieglitz et al., 2022). In the field of disaster and crisis management, CAs are also becoming an increasingly important technology that can be used for general information and communication tasks (e.g. Maniou & Veglis 2020), as well as for specific scenarios such as the Covid-19 pandemic (e.g. Rodswang et al. 2020). The constantly growing number of approaches in this field of application makes it increasingly difficult for scientists and practitioners to maintain an overview and distinguish key features.

To get a better overview of a research or application area and to classify existing approaches, taxonomies are a frequently used solution. Taxonomies are artifacts used in various scientific disciplines allow sequential classification of objects based on dimensions (Marradi, 1990). Several taxonomies have already been developed to classify CAs approaches from different perspectives. Janssen et al. (2020) focus on domain-specific chatbot applications, whereas Weber et al. (2021) present a taxonomy for CAs in education. Additional contributions provide conceptualizations of certain aspects of these systems like the taxonomy for social cues in CAs of Feine et al. (2019), as well as the exploration of chatbot relationship archetypes based on the time of interaction of Nißen et al. (2022).

However, to the best of our knowledge, there is no classification of CA approaches in the emerging area of disaster management. To address this research gap, in this paper we propose a taxonomy to classify approaches on conversational agents in disaster management. The results presented here are based on the methodological approach according to Nickerson et al. (2013) for the iterative development of taxonomies. By applying this method the following research question is to be specifically investigated in this research.

RQ: *Which dimensions and characteristics of a taxonomy describe current implementations of conversational agents in disaster management?*

However, as the research is still ongoing, the method has not yet been fully applied. The data basis for this taxonomy is provided by a structured literature analysis according to vom Brocke et al. (2009). For the complete research, we want to expand the database to include applied, non-scientifically documented applications and carry out a robust evaluation. Nevertheless, even in its current state of development, the taxonomy can support scientists in classifying existing and new approaches and offer practitioners possible criteria for selecting suitable solutions for their purposes.

The paper is structured as follows: in the second section, the current state of research on CAs is discussed. The methodological approach and its instantiation are presented in the third section before the taxonomy is described in the fourth section. Limitations and desiderata are discussed in the conclusion.

ON THE STATE OF CONVERSATIONAL AGENTS

Natural language processing as the basis technology for CAs has been a relevant topic in the field of information systems research for many decades. One of the earliest related computer programs was ELIZA, developed at MIT in the 1960s (Weizenbaum, 1966). It simulated psychotherapeutic dialogues by recognizing and responding to simple patterns in user input. Despite its lack of real intelligence, ELIZA impressed with its skillful pattern recognition and is considered an early example of chatbots. Text-based chatbots are a type of CAs alongside voice-based systems such as voice assistants (e.g. Siri, Alexa) (Gnewuch et al., 2017). Another category of CAs are so called embodied agents, which are visualized characters that often use facial expressions and gestures to provide a better user experience (Brave et al., 2005). Recent developments in this space are numerous and diverse, spanning various directions. One of these innovations is conversational dashboard systems, which allow users to interact with complex data visualizations using natural language (Ruoff et al., 2021). Another are conversational co-pilots which Microsoft, for example, is currently including in its product range (Dastin, 2023), as well as Coding Assistants (Ross et al., 2023) which automate tasks, advice, as well as collaborate with users.

An important theoretical approach in research on CAs is the social response theory (Gnewuch et al., 2017; Wambsganss et al., 2021). This states that people interact with computers as they do with other people, unconsciously applying social rules such as politeness, self-disclosure and trust, based on social cues such as conversation, interactivity and social roles. An important principle of this theory is that of reciprocity, which states that people respond to computers socially by attempting to "reciprocate" or "match" the computer's interaction or behavior (Nass & Moon, 2000; Reeves & Nass, 1996).This means that designers of CAs should consciously plan the conversational style of their applications, as the social characteristics of these systems have a significant influence on their use (Chattaraman et al., 2019).

Progress in the field of CAs is currently particularly dynamic. Systems such as OpenAI's Chat GPT are experiencing impressive growth. One million users registered for the service within five days of its launch - only Meta's "Threads" could reach so many users quicker (*Infographic*, 2023). They can also be easily integrated into existing systems such as websites, social media and messaging platforms like Facebook (Johnson, 2018). The latest developments are integrations of these systems into search engines, such as Bing Chat (*The Verge*, n.d.).

Social media has been an important control center for disaster response at least since the Central European flood 2013 (Albris, 2018). There, CAs have the potential to broadcast trustworthy information from civil protection authorities to the public (Stieglitz et al., 2022). They can also help overcome language barriers and provide reliable real-time information (Ahmady & Uchida, 2020). In addition, CAs have the potential to support the coordination

of spontaneous helpers during a crisis and reduce the cognitive load on individuals (Gerstmann et al., 2019; M.-H. Tsai et al., 2019). Although research into the use of CAs in disaster management is still in its infancy and there is a lack of established design approaches, new approaches are constantly emerging and current findings indicate that the use of CAs in disaster management provide added value (Stieglitz et al., 2022). The aim of the research presented here is to take a deeper look at the developments to date to enable a classification of existing and new approaches in this rapidly growing field of research.

METHODOLOGICAL APPROACH

Taxonomy Development Following Nickerson et al. (2013)

To build our taxonomy for CAs in disaster management on a sound basis, we use the established methodology of Nickerson et al. (2013). This method prescribes a multi-stage, cyclical procedure with defined ending conditions for deriving dimensions and characteristics for a topic-specific taxonomy. The instantiation of the method in the context of our research, illustrated in Figure 1, is described below.

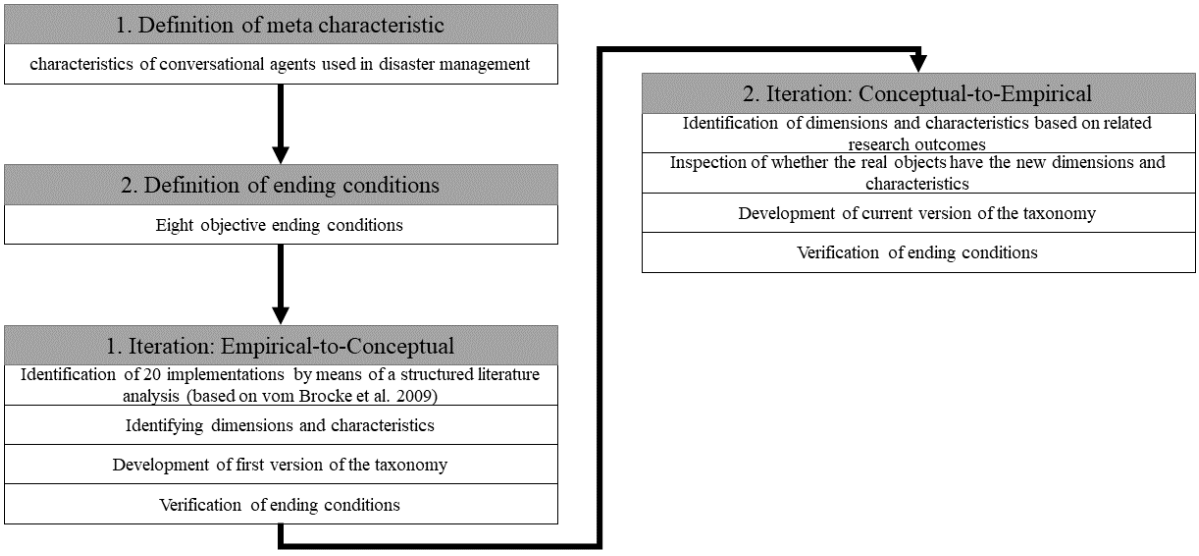

Figure 1. Procedure based on Nickerson et al. (2013)

The first step is the **definition of the meta-characteristic**. The aim here is to select a view of the objects to be examined (conversational agents in disaster management) from which all other characteristics can be derived (Nickerson et al., 2013). When defining the meta-characteristic, it is important to be clear about the objective and purpose of the taxonomy. In our case, the taxonomy is intended to be useful both for practitioners, who can use the taxonomy as a decision-making tool for the selection of suitable solutions, and for scientists from different disciplines who want to classify existing and new approaches and identify research gaps. The focus is on core features and application conditions, rather than specific technical or organizational aspects. The meta-characteristic was formulated in a correspondingly general manner: "characteristics of conversational agents used in disaster management."

The next step is to **define the ending conditions** of the iterative process for deriving new elements for the taxonomy. For this study the objective conditions (OEC) proposed by (Nickerson et al., 2013), which can be seen in Figure 2, are selected.

	Objective Ending Condition
1	All objects or a representative sample of objects have been examined
2	No object was merged with a similar object or split into multiple objects in the last iteration
3	At least one object is classified under every characteristics of every dimension
4	No new dimensions or characteristics were added in the last iteration
5	No dimensions or characteristics were merged or split in the last iteration
6	Every dimension is unique and not repeated (i.e., there is no dimension duplication)
7	Every characteristic is unique within its dimension (i.e., there is no characteristic duplication within a dimension)
8	Each cell (combination of characteristics) is unique and is not repeated (i.e., there is no cell duplication)

Figure 2. Objective ending conditions prescribed by (Nickeson et al., 2013)

In the following step the iterations for the development of characteristics and dimensions begin. These must be logical consequences of the meta-characteristic. A two-stage approach was chosen here, consisting of an initial "empirical-to-conceptual" step and a subsequent "conceptual-to-empirical" iteration. In the **first "empirical-to-conceptual" iteration** the required number of descriptions of CAs were created using a structured literature analysis, as recommended by Nickerson et al. (2013), to build the knowledge base. This is described in detail in the following section. A **second "conceptual-to-empirical" iteration** was then conducted to address dimensions related to important theoretical foundations, such as the Social Response Theory, which still need consideration. These are explored in categorizations of CAs in literature, as seen in the taxonomy presented by Janssen et al. (2020). Their taxonomy on domain-specific chatbots includes dimensions such as 'collaboration goal,' 'chatbot role,' 'relation duration,' and 'social cues' with their characteristics, which we adopt in this iteration (Janssen et al., 2020). These dimensions were used to examine the systems identified in the first cycle and assign them to the respective characteristics.

After the second iteration, the eight objective ending criteria were examined, we found that criterion OEC4 was not yet met, revealing that further iterations are necessary. As this paper is a presentation of research in progress, the procedure ends at this point. We are aware that further iterations are necessary, and an evaluation of the taxonomy will take place in future steps. The methodological instantiation described here forms the basis for the considerations on the preliminary taxonomy in the following main section.

Knowledge Base from Structured Literature Search

The first iteration of the taxonomy creation is based on a knowledge base consisting of a set of descriptions of CAs. Structured processing is recommended to set this up in a way that is comprehensible to third parties. We chose to build our knowledge base using a structured literature analyses following vom Brocke et al. (2009). The method includes a 5-step procedure: 1) definition of review scope, 2) conceptualization of topic, 3) literature search, 4) literature analysis, 5) research agenda (Brocke et al., 2009).

Starting with the **definition of review scope,** vom Brocke et al. propose a procedure based on the taxonomy of Cooper (1988) which was instantiated in Figure 3.

Characteristic	Categories			
focus	research outcome	research method	theories	applications
goal	integration	criticism	central issues	
organization	historic	conceptual	methodical	
perspective	neutral representation		espousal of position	
audience	specialized scholars	general scholars	practitioners/politicians	general public
coverage	exhaustive	exhaustive and selective	representative	central/pivotal

Figure 3. Instantiation of the Taxonomy for the "definition of review scope" according to Cooper (1988)

Based on this, the focus was placed on applications with the aim of addressing the central issues. The organization should be conceptual, whereby a neutral perspective should be adopted. Practitioners as well as specialized

researchers in the fields of disaster management and conversational systems were identified as the target group, who should be offered an exhaustive and selective coverage of the topic.

In the next phase, the **conceptualization of topic**, working definitions of the most important terms were created and an overview of the existing literature in the field of CAs in disaster management was compiled. The findings from this step were used to develop a better understanding and a relevant search string.

As part of the **literature search,** the scientific databases SpringerLink, ISCRAM, ScienceDirect, Wiley and Google Scholar were searched. Publications containing the search string in abstract, title or keywords were to be identified within the search. This is *(chatbot OR "conversational agent" OR "chat bot" OR "dialogue system") AND ("disaster" OR "crisis" OR "emergency")* and was formed from the core terms derived in the previous steps. In the Wiley and ScienceDirect databases, the search described above could be carried out via the website. For the other databases, additional steps had to be taken. The SpringerLink database had to be addressed programmatically using an Application Protocol Interface (API) to perform a full-text search. The title, abstract and keyword searches were then carried out using a Python script. The ISCRAM database did not provide the desired search functionalities either, but since it specializes in information systems in disaster control, a full-text search was also carried out on the site using Google Scholar. Finally, a title search was carried out using the search string in Google Scholar. This database also offered no possibility to search in abstract or keywords.

After the search process, in the **literature analysis,** the titles and abstracts of the results were checked according to previously defined exclusion criteria. These are (1) not in English, (2) not peer-reviewed, (3) no concrete description of a CA artifact and (4) the described artifact has not been implemented at least once. This process resulted in a total of 88 identified publications with 20 descriptions of specific CA implementations, which formed the knowledge base for the taxonomy's development. The entire literature search and the results of the individual analysis can be seen in Figure 4.

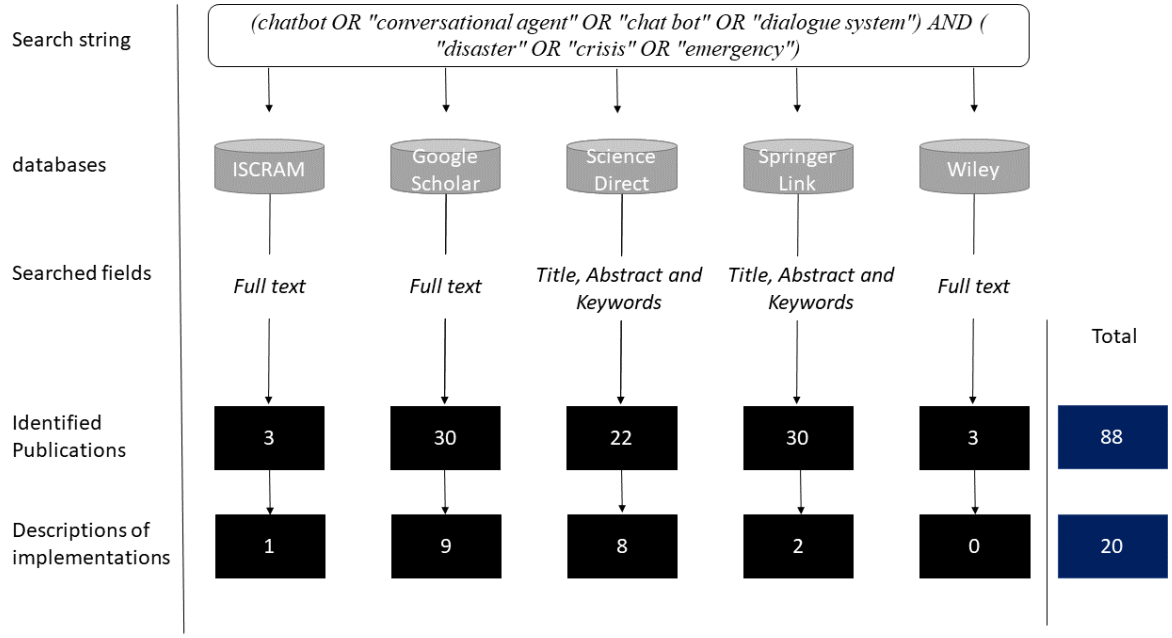

Figure 4. Literature Search Processing and Results

In this paper, the fifth step, formulation of a research agenda, is omitted as the focus on the methodology for taxonomy design renders it redundant.

A TAXONOMY FOR CONVERSATIONAL AGENTS IN DISASTER MANAGEMENT

This section describes the taxonomy in its current state of research. As part of the taxonomy development, 13 dimensions were identified. For reasons of clarity, these are divided into four categories and will be presented here. The developed taxonomy can be seen in Figure 5. Six of the included dimensions are exclusive, these are marked in the figure with an asterisk (*). The numbers in brackets after the characteristics indicate how many of the CA approaches from the knowledge base they apply to. Due to incomplete descriptions of the approaches, not all of them could be classified in every dimension.

Dimension		Characteristics			
Application Background	User*	Hospitals (2)	Disaster Management Authority (5)	Public Bodies (6)	Private Sector (2)
	Target Group*	General Population (12)	Affected (2)	Specific groups of the general population (4)	Disaster Management Officer (2)
	Type of Disaster*	Flood (4)	Pandemic (12)	Unspecific (4)	
Communication Goals and Language Processing	Intended Use	Coordination (6)	Information (13)	Education (1)	Decision Support (3)
	Conversational Goal*	Task-oriented (9)		Chatter (11)	
	Language Comprehension	Rule-based (7)		Natural (15)	
Interaction	Input Interaction	Text-based (16)	Voice-based (3)	Buttons (5)	Multimedia (2)
	Output Interaction	Text-based (16)	Voice-based (4)	Multimedia (6)	Facial Expression(1)
	Integration	Messenger Platform (10)	Native (8)	Smart Home Device (1)	
		Telephone (1)		Augmented Reality Device (1)	
	Human in the Loop	Forwarding to a Hotline (2)	Request to Adapt the Content (1)	No Described Functionality (17)	
Social Aspects	Role Model	Facilitator (9)	Peer (2)	Expert (9)	
	Relationship Length*	Short-term Relationship (12)		Long-term Relationship (8)	
	Social Cues*	Present (9)		Not Present (7)	

Figure 5. Taxonomy for Conversational Agents in Disaster Management

Category: Application Background

This category is intended to summarize all dimensions that deal with the primary actors and the overall situation in which the CA is used.

The **user** dimension describes the people and organizations that operate and administer the system. *Hospitals* are an example of this, but CAs are also used in the *private sector* (Jang & Lee, 2023; Sarbay et al., 2023). In contrast, the system designed for *disaster management authorities* by Tsai et al. attempts to provide a simple interface to retrieve up-to-date information on the current situation (M.-H. Tsai et al., 2019). A final characteristic is users in *public bodies*, such as government agencies or universities (Balderas et al., 2023).

The **target group** dimension describes which user group should be reached by the system. This can be the *general population*, whereas other systems try to address *disaster management officers* (Chan & Tsai, 2019; Nomura et al., 2020). The user group *Specific groups of the general population* can be illustrated by the "Emergency Reporter" system, which was created with the participation of indigenous groups to give them an opportunity to interact with the disaster management authorities (C.-H. Tsai et al., 2023). *Affected people* are also identified as a target group by systems (Syed et al., 2020).

The **disaster type** dimension describes the type of crisis in question, with a distinction being made between various types. A first example is the *flood*, but many CAs have also been identified that deal with *pandemics*, especially the Covid-19 pandemic (Sermet & Demir, 2018; Yoneoka et al., 2020). However, there are also systems that can be used *unspecifically* in several different types of crises. One example of this is DisBot, which uses knowledge accessed via social media to support citizens and first responders in disaster scenarios, improving community resilience and decision-making (Boné et al., 2020).

Category: Communication Goals and Language Processing

Strategic intentions of the system and the planned results of the interaction are relevant factors of CAs.

The **Intended Use** dimension refers to the purpose for which the CA was developed and which specific tasks or functions it should fulfill. The *Information* characteristic emphasizes the role of the CA as a source of information. The agent can for example provide real-time updates on hazardous situations, evacuation instructions and other relevant information to keep the public informed (Sermet & Demir, 2018). Used for *coordination*, a CA can ensure efficient communication and resource allocation during a disaster situation (Konstantoudakis et al., 2023). *Decision support* is another application in which the CA was developed to support decision-makers in disaster management with relevant data and semi-automated processes (Lai et al., 2020). Finally, a CA can be used in the field of *education* to prepare for disaster situations. By providing training materials, the agent helps to raise awareness and prepare for potential disasters (Syed et al., 2020).

The dimension of the **Conversational Goal** refers to the overarching goals or intentions that are pursued during the interaction with the user. A distinction is made here between CAs that act in a *task-oriented* manner and collaborate with the user (Tsai et al., 2023), and those that are *chatter*, as is the case with a simple question-answer scheme, for example (Goh et al., 2006; Konstantoudakis et al., 2023).

The **Language Comprehension** dimension of CAs describes how they process the user's utterances. *Natural language understanding* enables a CA to interpret the natural language of the user. This method enables versatile and human-like communication, as the agent can react to different expressions and formulations (Syed et al., 2020). In contrast, *rule-based language understanding* is based on predefined rules or scripts that the CAt uses to understand and respond to user utterances (C.-H. Tsai et al., 2023).

Category: Interaction

Interaction with a CA can be designed in very different ways. Dimensions in this category describe various aspects of the exchange of information between CAs and users.

The **Input Interaction** dimension describes how users can make inputs. Common input interactions take place via *text* or *voice* (Chan & Tsai, 2019; Nomura et al., 2020). An example of interaction with *buttons* is the chatbot presented by Maniou and Veglis for news dissemination in crises, which allows navigation using various button menus (Maniou & Veglis, 2020). Other systems can process *multimedia* input, for example a chatbot to collect information from volunteers and citizens, with the submission of images being one use case (Konstantoudakis et al., 2023).

The **Output Interaction** dimension specifies how output is transmitted to the user. Three types represent the output of *text*, *voice* or *multimedia* (Lai et al., 2020; Rodsawang et al., 2020; Yoneoka et al., 2020). A final type is the output of *facial expressions*, such as the intelligent embodied CA called AINI as a front-end interface for a crisis communication network portal (Goh et al., 2006).

The **Integration** dimension plays a crucial role in the embedding and deployment of CA systems, as it considers the different platforms and environments. These systems can be integrated in a variety of ways to ensure an optimal user experience. Examples of integration possibilities include implementation in *messenger platforms* to enable seamless interaction via messaging services (Konstantoudakis et al., 2023). Alternatively, a CA can be natively integrated into specific applications or operating systems to ensure deeper integration. Use via phone calls enables broader accessibility, while integration into smart home systems enables interaction in the context of the home environment (Lai et al., 2020; Sermet & Demir, 2018). In addition, integration into augmented reality platforms offers an immersive and enhanced level of interaction for users (Sermet & Demir, 2018).

The **Human in the Loop** dimension describes the possibility and mechanisms for human operators to intervene in the process. The *forwarding to a hotline* represents an identified mechanism that can be found in a voice Bot, for example. This partially automated the medical history processes for a hospital during the Covid-19 pandemic. As soon as it detected symptoms that indicated a disease, it forwarded the patient to a human operator (Lai et al., 2020). The *content customization prompt* was identified in an employee training application. The flow of conversation focuses on material created by a supervisor and can be interrupted if it is unclear. In such cases, a message is automatically sent to the supervisor, who is given the opportunity to revise the learning material (Syed et al., 2020). However, most approaches provide *no specific functionality*.

Category: Social Aspects

As described above, social response theory plays an important role in the design of CA. Dimensions of this category describe which general features CAs support in order to imitate human-like behavior.

The dimension **Role Model** classifies the existing systems based on the roles they take on towards the user. A CA in the role of a *facilitator* acts as a link between different parties to transmit information or facilitate communication (C.-H. Tsai et al., 2023). In the role of a *peer,* the CA interacts with the user on an equal footing without assuming a superior position. The interaction takes place in a cooperative and supportive manner, with the agent acting as a partner (Jiang et al., 2022). A conversational agent in the role of an *expert* imparts specialized knowledge and provides in-depth information on a specific topic (Goh et al., 2006)

The **Relationship Length** dimension concerns the duration and development of the interaction between the user and the CA, with different systems taking different approaches to the design of this relationship. An example of *short-term relationships* is a chatbot for medical history taking in a hospital presented by (Rodsawang et al., 2020). In contrast, Jiang et al. provide an example of a conversational agent that establishes a *long-term relationship.* They describe the use of the REPLIKA service during the Covid-19 pandemic which is intended to provide users with a supportive and empathetic conversation partner (Jiang et al., 2022).

Another dimension is the CA's ability to recognize, interpret and respond appropriately to **Social Cues**. These include facial expressions, gestures and tone of voice, which play a key role in creating an authentic and human-like interaction. An example of *present* social signals in this context is the output of facial expressions into a chatbot that can respond to user emotions (Goh et al., 2006). In contrast, these social signals are *not present* in other CAs (M.-H. Tsai et al., 2019).

CONCLUSION

In this paper, the research in progress and first results towards a taxonomy for conversational agents in disaster management was presented. The taxonomy was developed on the basis of an established methodology using an extensive, systematically compiled knowledge base. After two methodological iterations, a taxonomy consisting of 13 dimensions and 42 characteristics was created. The derived dimensions address both core features of the CAs and organizational aspects such as purpose and user groups, as well as domain-specific characteristics. This general orientation makes it possible to classify all domain-specific approaches and serve different purposes. The taxonomy can be used to help practitioners differentiate between suitable solutions for their purposes and to get an overview of what features they can or cannot expect from current IT systems. The examples given in the explanation of the dimensions can also provide inspiration for the use of CAs in disaster management. On the other hand, the taxonomy can also support scientists in the classification of research artifacts in the form of software demonstrators and application concepts. In addition, the taxonomy also represents an analysis of the current state of the art and shows which aspects of CAs for disaster management have so far been addressed to a greater or lesser extent by research. Although the analysis of the state of the art is not the focus of the paper, some trends can already be identified based on the frequency of the dimensions addressed. Most of the conversational agents examined serve to inform users and are generally designed for pandemics offering text-based interaction. The target group is usually the general population and subgroups of this population, with disaster managers being a secondary target. An interesting observation is that, in contrast to applications in the commercial sector only a few exceptions rely on human-in-the-loop functionalities. Even though research has shown that implementing human-in-the-loop functionalities in CAs can benefit users, task workers, and system performance (Reitmeier et al., 2020).

Since the research is still in progress not all steps in the underlying methodological approach of Nickerson et al (2013) have been executed yet. An important future step is the evaluation of the results. Nickerson et al. suggest having potential users evaluate the usefulness of the artifact. In the present scenario, disaster managers should be consulted to determine the extent to which the presented taxonomy aids them in choosing the appropriate CA for their specific use case. Similarly, the subjective termination criteria could not be considered and not all objective ending conditions could be met after the last iteration (Nickerson et al., 2013), so that further iterations will be necessary in future steps. The underlying knowledge base could be expanded for this purpose. With the selected search string, only CAs that were built specifically for disaster management applications can be identified. An extension of the search string could include other, domain-unspecific applications based on their potential use in disaster situations. The inclusion of solutions in practical use that have not yet been scientifically documented is also conceivable. In these ways, we want to further develop the taxonomy, which already offers decision-making and orientation aids for practitioners and scientists in its current state, into a valid and well-founded tool in the future.

ABSTRACT

Floods are prevalent disasters in the United States, posing escalating risks due to climate change-induced factors like rising sea levels and erratic rainfall patterns. Despite governmental efforts, flood risk communication rema ins inadequate, hindering preparedness and response capacity. While governmental agencies predominantly employ traditional, one-sided information dissemination approaches, social media platforms pose as crucial early warning indicators and sources of real-time information. This study conducts the first part of our intended comparative analysis of social media messages between governmental agencies and communities. We perfo rm a case study on a flooding event in Michigan from May 17-20, 2020. Utilizing advanced topic modeling, we examine Twitter/X message content and sentiment from community-based posts. Insights aim to inform more effective flood communication strategies, bridging the gap between official information and community needs during events. Future work will compare social media messages' content and sentiment from governmental agencies relative to those from the community.

Keywords

Crisis informatics, flooding, natural language processing (NLP), social media, Twitter/X

INTRODUCTION AND BACKGROUND

Floods are one of the most common weather-related natural disasters in the United States (NOAA National Severe Storms Laboratory, 2024). Indeed, seventy-five percent of all Presidential Disaster Declarations in the United States can be attributed to flooding (National Weather Service, 2018). As climate change continues to contribute to rising sea levels and unstable rainfalls, the risk of floods is increasing (Tabari, 2020). In fact, the U.S. National Flood Insurance Program experienced a 660% increase in dollars paid out for flood insurance claims from 2000 to 2020 compared to the claims from 1980 to 2000 (Federal Emergency Management Agency, 2021). Beyond flood damage to physical systems, floods have been documented to substantially impact communities' physical, mental, and financial health, causing long-term changes to quality of life that can persist for years after the flood event (Van

Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

Ootegem & Verhofstadt, 2016). For example, studies have shown increased instances in anxiety, depression, and post-traumatic stress disorder in people who have experienced a flood compared to a control group (Van Ootegem & Verhofstadt, 2016). Further, those affected by floods have been reported to experience long- or short-term injuries, respiratory and gastrointestinal illness due to exposure to pathogens via contaminated drinking water, unsafe conditions for food preparation, or lack of access to hygienic practices, and, in some cases, carbon monoxide poisoning (Burger & Gochfeld, 2014; Mulder et al., 2019; Sampson et al., 2019; Van Ootegem & Verhofstadt, 2016; Waite et al., 2014). Moreover, these effects are not experienced independently of one another; a systematic review of factors related to one's vulnerability before, during, and after a flood event determined that the effects of floods can be compounded by other risk factors, such as the frequency and severity of floods experienced or health, socioeconomic, and educational status (Lowe et al., 2013; Sampson et al., 2019). In particular, urban flooding has been shown to occur disproportionately due to racial and spatial segregation (Hughes et al., 2021). Midwest states, including cities on the Great Lakes, are particularly prone to urban flooding, which tends to occur in cities with high percentages of impervious surfaces and outdated or aged infrastructure, such as combined stormwater/sewer systems (National Academies of Sciences, 2019).

The magnitude and widespread effects of floods, as well as their increasing risk of occurrence, has motivated a number of studies examining the information available to those experiencing a flood before, during, and after the flood event. The primary means through which communities receive information about a flood is via flood risk messages from a governmental agency, such as public health, weather service, or emergency management agencies on a federal, state, or local level. However, studies investigating the effectiveness of flood risk messages from these sources have found that they are inadequate for improving individual self-efficacy, adaptive capacity, and flood preparedness (Forsyth et al., 2023; Haer et al., 2016; Scott & Errett, 2018). For example, a study examining the information available on social media via government during the 2016 Louisiana floods found that, while most messages had information about recovery resources and updates about the status of the disaster and response, few contained 'actionable requests,' or requests that were substantial and relevant enough to those experiencing the flood that they increased self-efficacy (Cooper et al., 2022; Mostafiz et al., 2022; Scott & Errett, 2018). Further, while some agencies release 'Get Ready' checklists as a tool for preparedness before a flood, they do not adequately cover the long-term impacts on mental health and overall well-being that may be experienced (Forsyth et al., 2023). Current flood risk communication practices are still primarily based on a knowledge- or information-deficit model which perpetuates one-sided communication from a governmental agency to the community (Maidl & Buchecker, 2015). These models are based on the assumption that the public does not understand the risk and that simply providing more information will result in 'better' decision-making (Maidl & Buchecker, 2015; O'Sullivan et al., 2012).

An increasingly recognized additional source of flood risk information are the messages, communicated via social media, by the community who is affected by the flood. Indeed, in an effort to improve flood mitigation and management practices, several studies have demonstrated the effectiveness of community-based social media messages as early warning indicators of floods (Carlos Villagrán De León et al., 2013; Cools et al., 2016). For example, a study analyzing the content of 60,000 tweets over a 5-day flood period found evidence of early and local detection of multiple-flood events (Shoyama et al., 2021). A method for identifying flood events globally using social media messages to build a real-time and historic database has been created (de Bruijn et al., 2019). A recent study developed a method for real-time sentiment analysis of social media messages to provide up-to-date information on community needs during a flood (Bryan-Smith et al., 2023); another designed a multilingual multimodal neural network to classify tweets containing information related to a flood with high precision ((de Bruijn et al., 2020). While these studies use a variety of approaches to analyze the content and sentiment of social media messages, machine learning methods such as natural language processing (NLP) can considerably speed up the process. Topic modeling is an NLP technique that generates structured text data from unstructured text data inputs, and in doing so, allows for the discovery of latent topics in the text. Analyzing social media messages for content and sentiment using NLP or topic modeling has been well-established in the literature. In the disaster space, for example, topic modeling has been used to identify the sentiments and thoughts of populations during flood events (Choirul Rahmadan et al., 2020), hurricanes (Mihunov et al., 2022; Zhou et al., 2023), and earthquakes (Vo & Collier, 2013).

Few studies have completed a combined analysis of the social media messages from governmental agencies and community networks during a flood event. However, given the observed gaps in flood risk communication from governmental agencies, there is an opportunity to learn about the community's needs and concerns from the content

and sentiment of community-based social media messages in comparison to government-based social media messages during flood events. A better understanding of these needs can be used to build more effective communication practices and reconcile the gap between what is provided versus what is needed by communities before, during, and after a flood. To that end, this preliminary study conducts a comparative analysis of the content and sentiment of tweets from governmental agencies versus community residents for the state of Michigan during a flood event from May 17 - 20, 2020 using topic modeling. We aim to answer the following research questions: (1) What insights can be gained from a comparative study of these social media messages in the context and sentiments of flood response and communication strategies?, and (2) Do the frequency of specific topics, message content, and sentiments of social media messages during the flood event differ between governmental (i.e., state and federal) agencies and community residents?

RESEARCH DESIGN AND METHODS

Case Study

To investigate our research questions thoroughly, we performed a case study analyzing a flooding event that occurred in Michigan during the year 2020. Midland County, Michigan is located in close proximity to Saginaw Bay, which connects to the Great Lake Huron. On May 17, 2020, record rainfall in Midland County began due to a low pressure system and frontal boundary from the Great Lakes (National Weather Service, 2020). Consequently, the Saginaw and Tittabawasee Rivers flooded. Heavy rains, totaling 5 to 8 inches, in the Tri-Cities region (i.e., Bay County, Midland County, and Saginaw County) resulted in catastrophic failures of the Edenville and Sanford dams in Midland County. This prompted the issuance of Flash Flood Emergencies, signaling life-threatening flooding and the evacuation of 10,000 Midland residents. Significant flooding also occurred along several lake shores, affecting several other counties in southeast Michigan. The rainfall fell within thirty-six hours and the event was considered over on May 20, 2020. This flood event was the worst that had occurred in the region since 1986, prompting discussion by those throughout the state on social media.

Data Collection and Filtering

Twitter data were collected for the state of Michigan from between May 15, 2020 at 20:00:09 and May 23, 2020 at 19:59:57 using a Twitter/X streaming API built in the Network Dynamics Lab (Wang & Taylor, 2015). In the realm of disaster studies, flooding is a prime example of what is known as a short-notice disaster (Chiu & Zheng, 2006). This means agencies typically have only 24 to 72 hours to send out important risk communication messages, such as evacuation notices (Wolshon et al., 2001). Furthermore, upon our initial analysis, we observed a consistent decline in the frequency of tweets concerning our case study within three days following the conclusion of the event. Therefore, the date and time range of May 15, 2020 to May 23, 2020 were chosen to encompass the average timeframe for a short-notice disaster (i.e., 48 hours prior) prior to the beginning of the flood event and three days after the incident. To compare the content and sentiment of tweets between governmental agencies and the public, the Twitter data were filtered for twelve specific state and federal agency handles (Table 1). This list was determined by including the social media platforms for relevant Executive Branch departments in the state (State of Michigan, 2024), as well as common federal agencies employed for disastrous events such as floods. Tweets from these handles were treated as the messages from governmental agencies and all other remaining tweets from the data collection were considered to be from the public or community based.

Table 1. List of state and federal governmental agencies for comparative analysis.

Agency Name	Twitter Handle
Environmental Protection Agency (EPA)	@EPA
Federal Emergency Management Agency (FEMA)	@fema

Topic Modeling

Next, to analyze the Twitter/X dataset collected, BERT (Bidirectional Encoder Representations from Transformers), an advanced NLP model introduced by Google in 2018 (Devlin et al., 2018), was used. BERT utilizes bidirectional encoding to generate contextualized word embeddings, revolutionizing various NLP tasks. For this project, we specifically employed BERTopics, an extension of BERT, that leverages its contextualized embeddings to perform topic modeling by aggregating document-level representations derived from BERT embeddings and subsequently clustering similar documents based on their semantic content. This method enables fine-grained topic differentiation and accurate thematic analysis, and has been used successfully to assess Twitter/X datasets for a range of environmental topics (Kastrati et al., 2023; Pampapura Madali et al., 2022).

We carried out hyperparameter tuning to optimize the performance of our topic modeling approach. During this process, we tuned the parameters of three key models: UMAP (Uniform Manifold Approximation and Projection) for dimensionality reduction, HDBSCAN (Hierarchical Density-Based Spatial Clustering of Applications with Noise) for clustering, and BERTopic for topic modeling. Specifically, we adjusted parameters such as the number of neighbors and components for UMAP, the minimum cluster size and minimum samples for HDBSCAN, and minimum topic size for BERTopic. For a comprehensive list of the tuned parameters, please refer to the Supplementary Information at the end of the paper (SI 1).

To understand the meaning of each topic, we manually interpreted them and then labeled them based on their keywords to best capture their core meaning. The topic modeling tool assigns a c-TF-IDF (class-based term frequency-inverse document frequency) score to each word in the topic, indicating its relevance to the topic. These scores are ranked by importance, with the highest-scoring words most closely mirroring the central theme of the topic. While more topics can contain up to ten words, those with the highest c-TF-IDF score better reflect the overall meaning of the topic.

ANALYSIS

Results: Entire Dataset

We extracted 124,362 tweets from May 15 to May 23. The topic modeling clustered the tweets into 133 topics. The four most tweeted topics from the entire dataset were about "Food" (Topic 0, 4,583 tweets), "Thankfulness" (Topic 1, 3,411), "Jobs" (Topic 2, 2,537), and "Music" (Topic 3, 2,402) (Figure 1).

Figure 1. Top most tweeted topics from May 15 to May 23 in Michigan.

The topic most related to flooding events in Midland was Topic 15, which had 892 tweets in the cluster. The five most important words in Topic 15 were "Midland", "Dam", "Flooding", "Water", and "River" (Figure 2). Figure 2 also demonstrates the decline in score c-TF-IDF for each additional word included in the topic. The frequency of tweets categorized as belonging to Topic 15 varied over the search period. To start, there were virtually no tweets about the flood from between May 16 and May 19, followed by a rapid increase and peak posting on May 20, and then a decline between May 20 and May 23; however, during this period, the Tweet frequency remained higher than before the event (Figure 3).

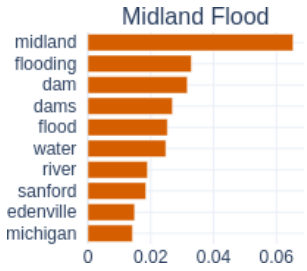

Figure 2. The top ten words associated with Topic 15, "Midland Flood".

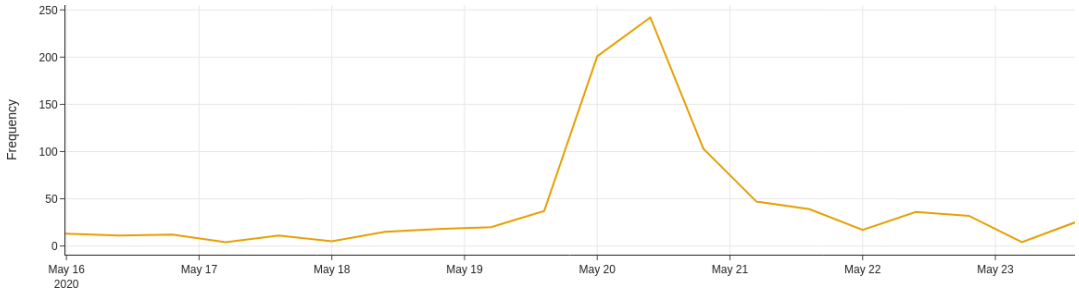

Figure 3. Frequency of Tweets associated with Topic 15 from May 16 to May 23, 2020.

The sentiment analysis results showed that for Topic 15 the most conveyed emotions were fear (347 tweets) and sadness (176) (Figure 4).

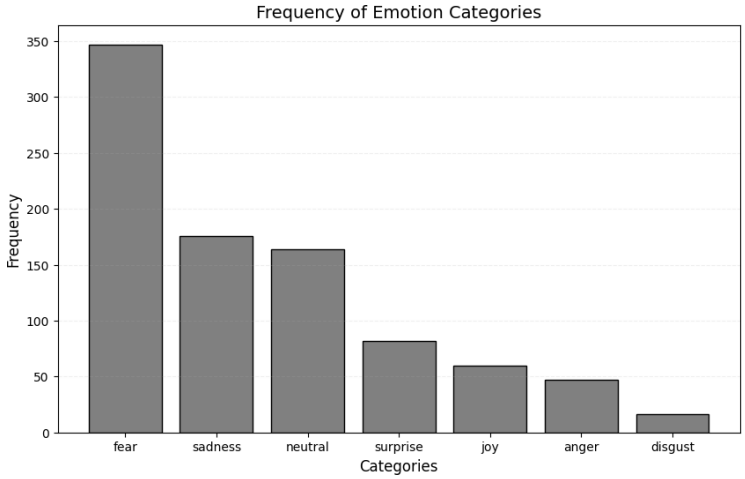

Figure 4. Sentiment Analysis of Topic 15 Tweets.

A hotspot analysis indicates that there is geographical variation in the location of tweets regarding the flooding events. Unsurprisingly, the location with the highest density of tweets was in and around Midland (Figure 5). There were also a large number of tweets occurring in other major Michigan cities such as Detroit and Lansing.

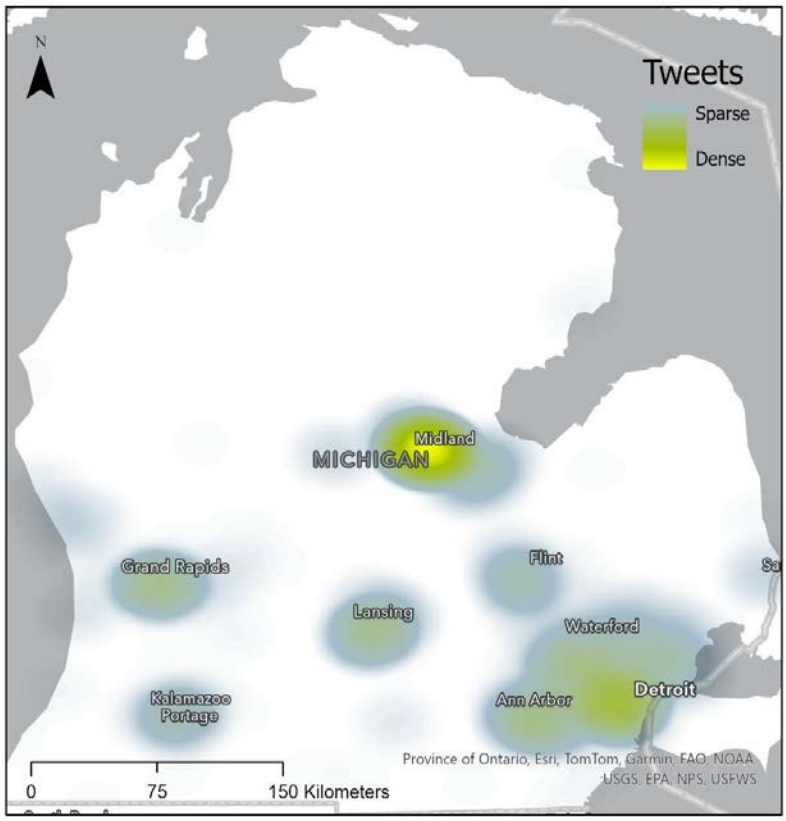

Figure. 5 Heatmap of tweets in the state of Michigan concerning the May 2020 flooding incident.

Results: Initial Comparison of Community vs. Government Tweets

Upon analyzing the dataset and dividing it into community and government tweets concerning the flooding event, we encountered a disproportionately small sample size of government tweets (13 out of 892 tweets; 1.4%) compared to the extensive volume generated by community members. All agency tweets were by either NWSDetoit (6 tweets) or NWSGaylord (5 tweets). Of these tweets, only three were directly related to Midland County, and a further three related to the associated flooding occuring in the village of Sanford, while all other tweets focused on a Gladwin County flooding event that occurred further north. This discovery perpetuates the ongoing notion of inadequate communication from key stakeholders at the local, state, and federal levels and the communities they serve, particularly on platforms as influential and interactive as social media, and identifies an opportunity to reach a broader audience through utilizing social media as a communication medium.

As our research remains ongoing, we intend to conduct another case study focusing on a different flooding event. Our aim is to either achieve a more robust sample size for both groups or pivot the study's focus to further comprehensively analyze the entire dataset, thereby uncovering novel insights in the forthcoming weeks. We anticipate presenting our findings at this conference upon acceptance and final submission of this work in progress paper.

DISCUSSION AND CONCLUSIONS

The particular insights gained from our study in the context and sentiments of flood response and communication strategies was the discovery that tweets surrounding the flood predominantly conveyed fear. Additionally, the frequency of tweets for Topic 15 (i.e., the topic most relevant to the incident itself) began rising mid-day on May 19, rapidly increasing on the 20th and peaking mid-day on the 21st. Overall, the highest volume of tweets for Topic 15 occurred between May 19 and May 22 with discussion continuing, to a lesser extent, on May 23. Rainfall began on May 17 and ended approximately thirty-six hours later. The temporal trends of tweet volume starting on May 19 shows, in near real-time, the community discussion and reactions to the impacts of the rainfall, including catastrophic flooding and dam breakages. Such insights are invaluable for stakeholders involved in risk communication, aiding in the development of initiatives and strategies to effectively disseminate information that promotes community safety during such disasters. This includes understanding not only the content to convey but also the timing when people are most likely to engage with and absorb such messages amidst the peak of discussion about the event.

Although this study effectively utilized the BERT model to identify communication inefficiencies, certain limitations must be acknowledged. Firstly, as is common in social media research, there exists variability in the collected tweets, including differences in the frequency of tweets and how engaged users are. Notably, the volume of community-scale tweets significantly outweighed those from governmental sources. It is possible that governmental agencies were communicating about the flood on another social media platform other than Twitter. Given the volume of community Tweets during the flood event, the lack of tweets from governmental sources indicate that there may be a missed opportunity to communicate important information about the flood via this platform. Consequently, the lack of a balanced sample size may restrict the generalizability of the conclusions to other flooding events. Additionally, the filtering process (i.e., the selected state and government entities) implemented during data collection may have influenced the results obtained, potentially impacting the comprehensiveness of the findings. For example, we have not captured any tweets that may have originated from national agencies because we filtered for tweets from the state of Michigan only (i.e., EPA and FEMA).

In future research, it is imperative to explore additional social media networks for government-based tweets. For instance, investigative reporters or news journalists that work on the local, state, and federal level and their networks can be included in future works to improve the dataset for flood risk communication from government stakeholders. Additionally, expanding the analysis to encompass tweets from local agencies can be advantageous. We initially concentrated on state and federal entities, and finding more local agencies would provide a more comprehensive understanding of flood-related communication patterns and potentially increase our dataset. To this end, future investigations should delve deeper into other forms of classification in the content of flood-related tweets, following the approach outlined by (Scott & Errett, 2018). For instance, examining tweets within specific topics, such as Topic 15, could shed light on the discussion of resource requirements, incidents of downed power lines, and other relevant themes. Lastly, previous studies have found different predominant emotion from tweets surrounding other natural hazard events such anger associated with hurricanes (Berbère et al., 2023). This disparity may show that different

natural hazard event types may evoke different emotion responses, or that public emotion may change throughout the timing of the event. As these studies only looked at the dominance of emotion and not temporal patterns, future analysis of such data should map the temporal distribution of emotion to best understand public perceptions. For example, fearful tweets may occur primarily before the event, whilst angry tweets may occur more frequently in the aftermath.

In conclusion, our work highlights how pressing challenges in flood risk communication persist, emphasizing the need for innovative approaches. While a more comparative analysis is forthcoming, the lack of government-based tweets generated again still show significant inefficiencies from these stakeholders to communicate with citizens. By analyzing social media messages, illustrated during a flooding event in Michigan, the study emphasizes the potential of social media platforms in enhancing real-time information dissemination and community engagement. These findings call for a paradigm shift towards more collaborative and responsive flood communication strategies to better address community needs and bridge the gap between official agencies and the public during flood events.

ACKNOWLEDGEMENTS

This project is supported by the Eric and Wendy Schmidt AI in Science Postdoctoral Fellowship, a Schmidt Futures program. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors. We would also like to extend a special thank you to the Network Dynamics Lab at the Georgia Institute of Technology, for providing their archived Twitter/X postings for us to utilize in this research.

ABSTRACT

This paper introduces an innovative educational initiative focused on producing a community radio program to enhance students' understanding of wildfires. It creates an open dialogue platform for students to share ideas and concerns about wildfire preparedness, promoting an inclusive and participatory learning environment. A key component of this educational approach is establishing a 'readiness' framework to equip students with the necessary competencies to converse thoughtfully and effectively about the multifaceted narratives, dilemmas, and tensions inherent in dealing with significant wildfires. The project also emphasizes the importance of risk communication, aiming to improve students' abilities to convey information about wildfire risks clearly and accurately, catering to diverse audience needs. This approach is vital for enabling students to make informed decisions and take appropriate actions before, during, and after wildfire events, thus integrating scientific understanding and practical communication skills to foster proactive community engagement.

Keywords

Radio, youth engagement, preparedness, wildfires.

INTRODUCTION

Wildfire management is a complex and multifaceted challenge that requires a comprehensive approach to address effectively. The importance of changing attitudes, improving capacity, investing in community participation, and modifying stakeholder engagement procedures and policies is underscored by numerous studies, indicating that traditional methods of wildfire management are no longer sufficient in the face of increasing wildfire frequency and intensity due to climate change and other factors. Tedim et al. (2016) conceptualizes fire as a biophysical phenomenon and a fundamentally social process intricately tied to the human-natural systems in which it occurs. This perspective is echoed and expanded upon by Thompson et al. (2015) and Schultz and Moseley (2019), who call for systemic changes in wildfire management. They argue that addressing the current challenges of wildfires transcends the mere application of a set of theoretically sound procedures. Instead, it demands a localized understanding of wildfires, tailoring strategies to make territories less prone to wildfires and communities less vulnerable yet more resilient. This approach aligns with the goals of economic valorization, sustainable development, and the safeguarding of territorial resources.

Thompson specifically advocates for integrating risk management principles into decision-making processes, whereas Schultz and Moseley (2019) focus on the importance of collaborative governance to effectively tackle the complex challenges of wildfire management. Their research collectively underlines the necessity for a comprehensive strategy beyond traditional firefighting tactics. Such a strategy emphasizes a proactive

management stance, focusing on anticipating, assessing, and mitigating wildfire risks, underscoring the importance of a holistic plan that incorporates scientific understanding and community involvement to enhance resilience and safety.

From the assumption that improving societal readiness for wildfires requires a holistic approach to risk communication and attitude modification, it is clear that comprehensive methods are needed to successfully address the complex issues related to wildfire threats. This viewpoint emphasizes how crucial it is to incorporate many approaches and involve various stakeholders to foster a more resilient and knowledgeable community. In order to be effective, risk communication must go beyond the conventional one-way information transmission approaches and adopt interactive, participatory techniques that foster understanding and conversation. It is essential to leverage a range of technology and communication channels to reach different audiences. This will ensure that information about the risks posed by wildfires and how to prepare for them is clear, practical, and easily accessible.

The research presented here advocates a multidimensional strategy focused on three key pillars: a) the value of youth engagement and participation, b) establishing school-community learning collaborations, and c) emphasizing intergenerational capacity-building methods. Collectively, these pillars aim to enhance community resilience, encourage collaborative governance, and ensure a holistic and inclusive approach to wildfire risk communication and management.

YOUTH ENGAGEMENT AND PARTICIPATION

Promoting youth engagement and active involvement in society has become increasingly important in the past few decades (DFID-CSO, 2010). Participatory research programs have demonstrated their efficacy as interventions in promoting individual and community development. These initiatives operate under the premise that the current generation has valuable knowledge and should express their opinions firsthand, drawing from their own experiences (Kim, 2019, among others). According to the systematic review conducted by Anyon et al. (2018), youth participatory research programs have yielded significant outcomes in various domains, including social, interpersonal, cognitive, academic, and professional achievements, as well as leadership and personal agency.

Therefore, engaging youth in wildfire preparedness and environmental stewardship initiatives plays a vital role in building a resilient future, providing them with the necessary knowledge to grasp the complexities of wildfire risks and environmental conservation. Giving youth the tools to participate in prevention efforts and respond adeptly and effectively in emergencies instils a sense of responsibility and agency.

Moreover, engaging youth from an early age promotes a proactive mindset towards disaster risk management, emphasizing the importance of anticipation, planning, and prevention over a reactive stance (Pfefferbaum et al., 2018). This approach is crucial in preparing communities to respond to wildfires efficiently and engage actively in risk mitigation through thoughtful land management, community planning, and policy advocacy. The active participation of youth in these initiatives nurtures a culture of resilience, wherein the values, knowledge, and skills acquired are passed down and expanded upon, influencing peers, families, and future generations. Such a generational transfer solidifies a collective approach towards resilience, transforming how communities f ace wildfires and environmental challenges and ensuring a sustainable and secure future for all.

SCHOOL-COMMUNITY LEARNING PARTNERSHIPS

Through the utilization of educational institutions as primary hubs for community participation and resource sharing, these collaborations enable a comprehensive and inclusive educational experience that goes beyond the physical boundaries of the classroom, reaching families, local organizations, and various community members (Monroe et al., 2015; DePetris & Eames, 2017). This collaborative model enhances the learning ecosystem by spreading knowledge and skills about wildfire preparedness throughout the community (Paveglio & Edgeley, 2020). This fosters a shared feeling of responsibility and encourages collective action to reduce the dangers of wildfires.

These partnerships offer a distinctive platform for engaging and experiential learning activities that integrate theoretical knowledge with practical applications.

INTERGENERATIONAL APPROACHES IN CAPACITY BUILDING

The significance of intergenerational approaches in capacity building for wildfire preparedness cannot be overstated (Prior & Eriksen, 2013). These initiatives promote community resilience against wildfires by promoting communication and collaboration across multiple age groups, thereby using each generation's unique

capabilities and views. Elders in the community often possess a wealth of knowledge about local landscapes, traditional fire management practices, and historical patterns of wildfire activity. By sharing this expertise, they provide younger generations valuable insights that can supplement and amplify current scientific understanding and technical progress in wildfire management.

Moreover, involving youth in intergenerational learning initiatives empowers them to become proactive agents of change (Trujillo-Torres et al., 2023). Young people bring fresh perspectives, energy, and a natural aptitude for technology and innovation, which can be instrumental in developing new solutions for wildfire detection, monitoring, and communication.

INTERVENTION

We developed a school-based intervention, Forest FM, based on the foundational pillars described above. The following section will present the aims, procedures, and results.

Aims

In 2017, Portugal experienced devastating wildfires that ravaged over 539,000 hectares of land and claimed the lives of more than 100 individuals. These catastrophic events were partly attributed to the effects of climate change, leaving profound economic and environmental scars on the affected regions. It also highlighted the population's vulnerability in rural areas and underscored the need for measures to ensure assistance and increase community preparedness for the risks associated with climate change.

ForestFM is an educational initiative that emerged in response to the crisis of devastating wildfires, with a primary aim to educate and engage young people about the dangers of wildfires and the critical importance of preparedness. Central to the project's approach is establishing a community radio program by students, serving as a powerful platform to disseminate invaluable insights drawn from the experiences of local elders. Through this initiative, teenagers acquire knowledge about wildfire risks and actively preserve and honour traditional wisdom while gaining essential skills to access and effectively communicate vital information.

The implementation of ForestFM reflects a comprehensive approach to wildfire preparedness, integrating the principles of youth engagement, school-community collaboration, and intergenerational knowledge sharing. The project's immersive workshop on radio production, spanning multiple sessions, serves as a testament to this approach. In the initial training block, students are introduced to radio as a medium, alongside discussions on wildfire content and formats. This phase establishes a foundational understa nding and lays the groundwork for appreciating the significance of youth involvement in wildfire preparedness.

Subsequently, the workshop progresses to a deeper exploration of radio production techniques, emphasizing the use of sound and language to convey messages effectively. Significantly, students are sensitized to the importance of listening to and incorporating local knowledge and community perspectives into their content. This aspect underscores the value of school-community partnerships in fostering a more inclusive and informed approach to wildfire communication and preparedness.

In the final phase of the workshop, students actively apply their newfound knowledge and skills to produce radio content explicitly focused on wildfire preparedness. This culmination reflects the collaborative efforts of youth, educators, and local community members, embodying the intergenerational exchange of knowledge and the collective commitment to wildfire resilience.

Procedures

The study included students from three high schools in central Portugal's high-risk wildfire zones. The methodology focused on an intervention in which students created radio content. The study aims to assess the impact of the intervention on students' knowledge, awareness, and information -seeking behaviours related to wildfires by conducting surveys before and after the workshop. This comprehensive methodology allowed for a complete analysis of the intervention's effects and offered helpful information for designing future wildfire education programs aimed at teenagers in high-risk regions.

The first survey aimed to understand local adolescents' collective knowledge and awareness levels by targeting a more significant cohort of students across the three schools (N=234). This method yielded insights that extended beyond the workshop attendees. The subsequent survey was only given to the workshop participants (N= 49), allowing for a more targeted examination of how the intervention affected their awareness and attitudes concerning wildfires.

Both surveys had a specific area to evaluate where participants obtained information about wildfires. Participants evaluated a set of statements of information-seeking behaviour using a 5-point scale ranging from 1 (total disagreement) to 5 (complete agreement). However, for the purpose of this paper, we specifically focus on the effects of the intervention on social conversation related to wildfires. This includes examining the frequency of discussions with family and friends as well as self-perception of wildfires knowledge

Results

In this section, we present the findings from a pre-post survey designed to assess changes in participants' engagement in social conversations about wildfires with family and friends and their self-perception of knowledge on the subject. Our analysis focuses on three key questions: the frequency of discussions regarding wildfire preparedness within their networks, the depth and quality of these conversations, and the participants' self-assessed understanding of wildfires before and after engaging with the radio program. These aspects are crucial for evaluating the program's impact on fostering a culture of preparedness and awareness through informed dialogue and self-reflection. By examining these indicators, we aim to shed light on the effectiveness of the radio program in enhancing not just awareness but meaningful communication and self-perceived knowledge about wildfires among community members.

Table 1. Levels of Agreement on Frequency of Wildfire Discussions with Family and Friends on Self-perception of Preparedness (%)

	Strongly Disagree		**Somewhat Disagree**		**Neutral**		**Somewhat Agree**		**Strongly Agree**	
	Pre	**Post**	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Post**	**Pre**	**Post**
I frequently talk about wildfires with my family members	21.8	4,1	24.8	16.3	32.1	40.8	18.4	32,7	3.0	6.1
I usually talk about wildfires with my friends	28.6	2.0	23.9	34,7	25.8	26.1	17.1	24.5	4.3	12.2
I have sufficient knowledge of what to do in the face of wildfires	2,6	0.0	15.5	4.1	25.3	40.8	17.2	49.0	9.4	6.1

Table1 presents findings from a pre-post survey designed to assess changes in behaviours and perceptions related to wildfire discussions and self-assessed knowledge following an educational intervention. Here are some key points developed further from the table:

1. **Increased Conversations about Wildfires**: There is a notable shift in the frequency of discussions participants have about wildfires with their family and friends. Before the intervention, a smaller percentage of respondents reported frequently discussing wildfires with their family (3.0% strongly agree) and friends (4.3% strongly agree). Post-intervention, these numbers increased to 6.1% for family discussions and 12.2% for discussions with friends, indicating the intervention's effectiveness in encouraging more conversations about wildfire preparedness.
2. **Change in Discussion Dynamics**: The pre-survey data showed that a significant portion of participants were either neutral or disagreed with the statement about frequently discussing wildfires with family and friends. Post-intervention, there is a shift towards agreement, especially in the "somewhat agree" category for family discussions, which almost doubled from 18.4% to 32.7%. This suggests a positive change in participants' willingness or opportunity to engage in conversations about wildfires.
3. **Self-Assessed Knowledge Improvement**: The most striking change is observed in the participants' self-assessment of their knowledge regarding what to do in the face of wildfires. Initially, only 9.4%

strongly agreed with having sufficient knowledge, but post-intervention, there was a significant increase in the "somewhat agree" category from 17.2% to 49.0%. This reflects a substantial improvement in confidence among participants about their understanding of wildfire preparedness. However, the "strongly agree" category decreased slightly, suggesting room for further enhancement in perceived knowledge depth.

4. **Decrease in Neutral Responses**: Post-intervention, there is a noticeable decrease in neutral responses across all questions, most significantly in the self-assessed knowledge about wildfires, dropping from 25.3% to 40.8%. This reduction suggests that the intervention helped clarify participants' uncertainties or ambiguities regarding wildfires, pushing them towards a more decisive stance on their knowledge and discussion frequency.
5. **Reduction in Disagreement**: There is a general decrease in the percentages of "strongly disagree" and "somewhat disagree" responses from pre- to post, particularly in conversations about wildfires with family. This trend suggests that reservations or reluctance to engage in these discussions have been mitigated, possibly due to increased knowledge and awareness.

CONCLUSION

A comprehensive strategy for wildfire management necessitates understanding the fire as a biophysical and social process, as Tedim et al. (2016) suggest, and a proactive and inclusive approach to learning and adaptation. This strategy should emphasize youth engagement, intergenerational capacity building, and school-community partnerships as central pillars. By integrating these concepts, communities can foster a culture of continuous learning and adaptation to the dynamic nature of wildfire threats.

Regular evaluation of community participation efforts, risk communication campaigns, and preparedness operations becomes crucial in identifying areas for improvement. Learning from past wildfires and adjusting strategies based on new information and changing conditions are essential to enhance societal preparedness. Moreover, involving young people and creating opportunities for intergenerational learning can lead to more innovative solutions and a deeper understanding of wildfire risks.

School-community partnerships can play a pivotal role in this context, bridging knowledge and action. Through educational programs focusing on wildfire preparedness, risk communication, and resilience building, these partnerships can empower communities to be better prepared for, respond to, and recover from wildfires. Such a comprehensive strategy, grounded in community involvement and intergenerational collaboration, enhances resilience to wildfires and helps safeguard communities and conserve ecosystems against the backdrop of evolving climatic conditions and increasing wildfire threats.

The educational initiative Forest FM aspires to create a more informed and resilient generation of students through its focus on open dialogue, readiness framework, and the strategic incorporation of risk communication. By developing their understanding of and ability to communicate about wildfires, the project supports the broader goal of enhancing community preparedness and resilience in the face of natural disasters.

The data from the Forest FM project, which involved the creation of radio content focused on wildfires, reveal a significant increase in discussions about wildfires among participants with their families and friends, as well as an improvement in their self-assessed understanding of how to respond to these events. The positive shift in responses post-intervention highlights the effectiveness of targeted educational initiatives in cultivating a more informed and proactive community regarding wildfire awareness and preparedness. This project equipped individuals with the knowledge and skills to address wildfire concerns and contributed to a broader cultural shift towards environmental sustainability and resilience.

The effort highlights the need for education to develop a well-informed and adaptable society to face wildfire concerns by promoting community-wide involvement in preparedness measures. Schools play a crucial role in developing resilient, knowledgeable, and cohesive communities by integrating these programs into their curricula. This all-encompassing educational method promotes a broad cultural shift towards environmental sustainability and resilience, preparing communities to be more resilient and proactiv e in dealing with environmental challenges in the future.

ACKNOWLEDGMENTS

ForestFM (PCIF/AGT/0087/2019) is a project funded by the Portuguese Foundation for Science and Technology (FCT) and seeks to promote the engagement of young people in promoting attitudes and behaviors favorable to wildfire prevention.

ABSTRACT

Tasks such as semantic search and clustering on crisis-related social media texts enhance our comprehension of crisis discourse, aiding decision-making and targeted interventions. Pre-trained language models have advanced performance in crisis informatics, but their contextual embeddings lack semantic meaningfulness. Although the CrisisTransformers family includes a sentence encoder to address the semanticity issue, it remains monolingual, processing only English texts. Furthermore, employing separate models for different languages leads to embeddings in distinct vector spaces, introducing challenges when comparing semantic similarities between multi-lingual texts. Therefore, we propose multi-lingual sentence encoders (CT-XLMR-SE and CT-mBERT-SE) that embed crisis-related social media texts for over 50 languages, such that texts with similar meanings are in close proximity within the same vector space, irrespective of language diversity. Results in sentence encoding and sentence matching tasks are promising, suggesting these models could serve as robust baselines when embedding multi-lingual crisis-related social media texts. The models are publicly available at: https://huggingface.co/crisistransformers.

INTRODUCTION

In times of crisis, social media platforms such as Facebook and Twitter are critical channels for information sharing and communication (Imran, Castillo, Diaz, et al. 2015; Simon et al. 2015; Lamsal, Harwood, et al. 2022a). These platforms help promptly disseminate essential information, whether it is related to wildfires, earthquakes, hurricanes, floods, epidemics, etc (Starbird and Palen 2010; Thomson et al. 2012; Alam, Ofli, Imran, and Aupetit 2018; Pourebrahim et al. 2019; Lamsal, Read, et al. 2023a). They serve as central information hubs for both the general population and emergency responders, providing updates on unfolding situations (Sarcevic et al. 2012). Social media also assists in allowing individuals to seek and offer assistance while coordinating relief efforts (Purohit et al. 2014). The extensive amount of user-generated content on these platforms is a valuable historical and real-time data source. However, the challenges of analyzing and understanding crisis-related social media texts arise from their sheer volume (Stieglitz et al. 2018) and linguistic complexities. As the number of conversations exponentially increases during a crisis, automated analysis becomes necessary to comprehend the situation at the ground level. Such conversations contain situational information (Hughes and Palen 2009; Vieweg et al. 2010; Vieweg 2012) about the affected population, damages, injuries, casualties, rescue and volunteering efforts, etc. (Imran, Mitra, et al. 2016), shared by populations, whether directly or indirectly impacted (Imran, Castillo, Diaz, et al. 2015; Lamsal, Harwood, et al. 2022a).

*corresponding author

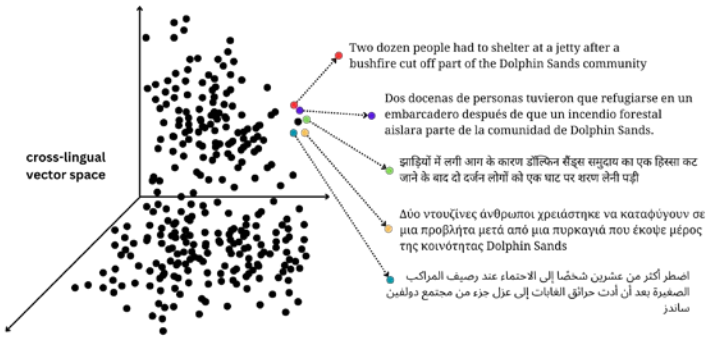

Figure 1. An illustration of a cross-lingual vector space for crisis-related social media texts.

The majority of analyses in processing crisis-related social media texts involve tasks like text classification (Ashktorab et al. 2014; Caragea et al. 2011; Imran, Elbassuoni, et al. 2013a; Li et al. 2018), semantic search (Dutt et al. 2019), and clustering (Ashktorab et al. 2014; Curiskis et al. 2020; Lamsal, Harwood, et al. 2022a). The advancement in these areas plays a key role in enhancing our comprehension of crisis discourse to facilitate informed decision-making processes and assist in the development of targeted interventions and communication strategies. This holds true not only during the course of an unfolding crisis but also retrospectively, drawing insights from historical events. The knowledge extracted from previous crises significantly contributes to the formulation of effective and efficient response strategies for similar future crisis scenarios, thus strengthen preparedness and response capabilities for future challenges.

Transformer-based (Vaswani et al. 2017) pre-trained language models like BERT (Devlin et al. 2018) and RoBERTa (Liu et al. 2019) have significantly advanced performance in numerous NLP tasks across domains including crisis informatics. Moreover, the recently introduced CrisisTransformers (Lamsal, Read, et al. 2023b), an ensemble of pre-trained models trained on a corpus of over 15 billion word tokens from more than 30 crisis events, has further improved the state-of-the-art. However, the contextual embeddings provided by these pre-trained models lack semantic meaningfulness[1] and perform worse than averaging GloVe embeddings (Reimers and Gurevych 2019). For semantic search and clustering tasks, it is crucial to have sentence embeddings with semantic richness. While the CrisisTransformers family does offer a sentence encoder for the task, improving upon the Sentence Transformers (Reimers and Gurevych 2019), it remains monolingual, processing only English-language social media texts. Any geographical region can have a diverse linguistic population, whether it's a county, city, state, or country. Social media platforms, therefore, can be flooded with posts in various languages during the same crisis event. Analyzing solely the texts in a specific language increases the risk of overlooking essential information available in texts shared in other languages. Also, employing separate models for different languages leads to embeddings in distinct vector spaces. This discrepancy poses a challenge when comparing the semantic similarities between sentences in various languages.

Adopting a single embedding space is critical to addressing these challenges and enhancing the effectiveness of crisis informatics. Such an encoder would facilitate mapping texts from different languages with similar meanings to close proximity within the same vector space, as illustrated in Figure 1. This approach ensures that semantically related content in diverse languages can be effectively processed, enabling a more comprehensive and nuanced understanding of crisis-related information irrespective of linguistic diversity. Therefore, we address this need by introducing the first-ever multi-lingual sentence encoders for embedding crisis-related social media texts. In general, this study contributes the following to the existing crisis informatics literature:

- We introduce two multi-lingual sentence encoders (CT-XLMR-SE[2] and CT-mBERT-SE[3]) that embed crisis-related social media texts with semantic richness for 52 languages: Albanian, Arabic, Armenian, Bulgarian, Catalan, Chinese (Simplified), Chinese (Traditional), Croatian, Czech, Danish, Dutch, Estonian, Finnish, French, French (Canada), Galician, Georgian, German, Greek, Gujarati, Hebrew, Hindi, Hungarian, Indonesian, Italian, Japanese, Korean, Kurdish (Sorani), Latvian, Lithuanian, Macedonian, Malay, Marathi, Mongolian, Myanmar (Burmese), Norwegian, Persian, Polish, Portuguese, Portuguese (Brazil), Romanian, Russian, Serbian, Slovak, Slovenian, Spanish, Swedish, Thai, Turkish, Ukrainian, Urdu, and Vietnamese.

[1] Semantically similar sentences are embedded together in a vector space, and those embeddings can be compared using similarity measures such as cosine similarity.

[2] https://huggingface.co/crisistransformers/CT-XLMR-SE

[3] https://huggingface.co/crisistransformers/CT-mBERT-SE

- We publicly release the sentence encoders, making them easily accessible for integration with the Transformers library (Wolf et al. 2020). We anticipate that these sentence encoders will serve as robust baselines for tasks that involve embedding multi-lingual crisis-related social media texts.

RELATED WORK

Semantically rich embeddings position similar sentences closely together in a vector space. Learning such embeddings is an extensively explored area, briefly discussed in this section. (Kiros et al. 2015) trained an encoder-decoder model to reconstruct the neighbouring sentences of an encoded sequence. This training aimed to map sentences with similar semantic properties to comparable vector representations. (Conneau, Kiela, et al. 2017) introduced a siamese Bidirectional Long Short-Term Memory (BiLSTM) network, incorporating max-pooling on the Stanford Natural Language Inference (SNLI) dataset. This approach surpassed previous unsupervised methods (Kiros et al. 2015; Hill et al. 2016). (Cer et al. 2018) extended unsupervised learning by training a transformer network on the SNLI dataset. Furthermore, (Yang, Yuan, et al. 2018) proposed an unsupervised learning method for sentence-level semantic similarity based on conversational data.

With the introduction of BERT in 2018, the unsupervised training component was replaced with pre-trained models in designing sentence encoders. (Reimers and Gurevych 2019) fine-tuned BERT using siamese and triplet networks on the SNLI and Multi-Genre Natural Language Inference (MultiNLI) datasets. The fine-tuning involved a softmax classifier with "contradiction", "entailment", and "neutral" labels. Similarly, (Gao et al. 2021) proposed SimCSE, a contrastive approach to fine-tune pre-trained models using natural language inference datasets, utilizing "contradiction" pairs as hard negatives. Building on this, (Reimers and Gurevych 2019) fine-tuned multiple pre-trained models using over 1 billion sentence pairs and released the second version of their models. Following the approach of utilizing "contradiction" pairs as hard negatives, as proposed in (Gao et al. 2021), (Lamsal, Read, et al. 2023b) replaced pre-trained models such as BERT and RoBERTa, which were trained on texts from broad and general domains with crisis-specific pre-trained models. Their domain-specific models, publicly released as CrisisTransformers, were trained on an extensive corpus containing over 15 billion word tokens from 30+ crisis events, including disease outbreaks, natural disasters, protests and activism, conflicts, civil war, etc. Performance improvement of >17% was reported compared to Sentence Transformers (Reimers and Gurevych 2019) in sentence encoding tasks for crisis-related social media texts. However, their sentence encoder is monolingual, processing only English language texts.

Multiple approaches have been proposed in the literature to train multi-lingual sentence embeddings. (Artetxe and Schwenk 2019) trained an encoder-decoder network on parallel corpora with a translation task and used output from the encoder as the sentence embedding. While this approach is effective in identifying exact translations across various languages, its performance diminishes when evaluating the similarity of sentences that are not exact translations. (Yang, Cer, et al. 2019) learnt multi-lingual sentence embeddings using a multi-task setup on the SNLI dataset and millions of question-answer pairs. They used a translation ranking task to align cross-lingual vector spaces. However, this approach is susceptible to catastrophic interference and has significant computational overhead. In addressing these issues, (Reimers and Gurevych 2020) proposed a training approach (Sentence Transformers) to map a translated sentence to the same location in the vector space as the original sentence. In this way, a multi-lingual model (student model) can be trained on translation pairs to mimic a mono-lingual model (teacher model) and learn a common vector space for multiple languages. In this study, we consider Sentence Transformer's top-performing model *all-mpnet-base-v2* as a baseline.

MATERIALS AND METHODS

Training Architecture

We utilized CrisisTransformers' sentence encoder (Lamsal, Read, et al. 2023b) as a teacher model and extended it to develop multi-lingual models with a student-teacher training architecture (Reimers and Gurevych 2020). The training network is illustrated in Figure 2. We considered XLM-R (Conneau, Khandelwal, et al. 2019) and mBERT (Devlin et al. 2018) as student models. XLM-R is the multi-lingual version of RoBERTa, trained on 2.5TB of CommonCrawl data containing 100 languages. Similarly, mBERT is the multi-lingual version of BERT, trained on Wikipedia data for 104 languages.

Training: For a dataset $D = ((en_1,t_1), (en_2,t_2), ..., (en_n,t_n))$, where en_i are English sentences and t_i are respective translated sentences (can be any language), we trained a network with student model S and teacher model CT while minimizing the following training objective for a given mini-batch B:

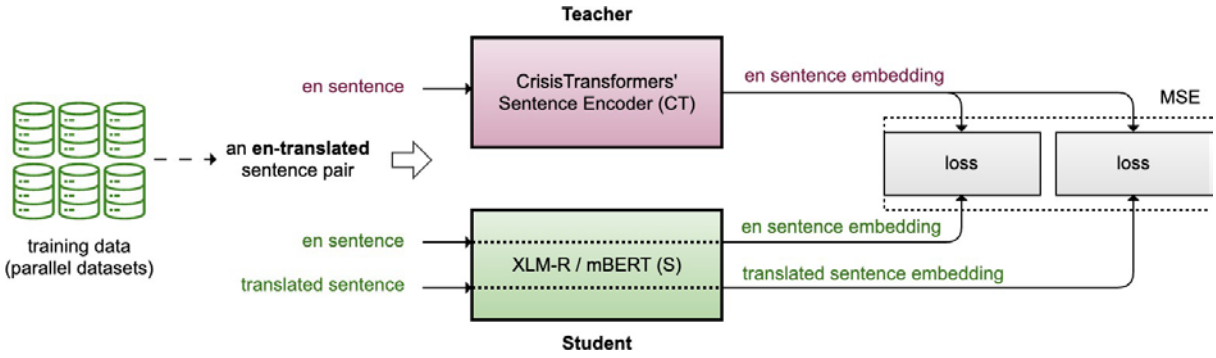

Figure 2. The student-teacher training architecture.

$$\frac{1}{|B|}\sum_{j\in B}\left[(\mathrm{CT}(en_j)-\mathrm{S}(en_j))^2+(\mathrm{CT}(en_j)-\mathrm{S}(t_j))^2\right] \quad (1)$$

With the above training objective, trained on dataset D we aim to obtain S such that $\mathrm{S}(en_i) \approx \mathrm{CT}(en_i)$ and $\mathrm{S}(t_i) \approx \mathrm{CT}(en_i)$. S will be our multi-lingual model. We train XLM-R and mBERT in separate networks with common teacher CT , and their final checkpoints are named CT-XLMR-SE and CT-mBERT-SE (where *SE* stands for *sentence encoder*). The training was done on an NVIDIA A100 GPU (80GB) for a maximum of 20 epochs, and 20k steps were used to warm up the learning rate with AdamW as an optimizer. Mixed precision training was done to improve the training time. We implemented the following training setting: maximum sequence length: 128, batch size: 64, maximum sentence per training file: 500k, and learning rate: 2e-5. The training of both networks in parallel finished in approximately 30 days.

Training Data

The training data D comprised multiple publicly available parallel datasets merged together. For each language, the maximum number of sentence pairs considered for training from any single dataset was 500k. Some samples in certain datasets had a single entry, either a sentence in English or any other language; in such cases, those samples were ignored. In total, the training data included over 128 million sentence pairs. The released versions of all the datasets already had the texts pre-processed. Some example pairs from the training data are provided in Table 1. The following parallel datasets were considered in this study:

- **Europarl** (Koehn 2005): Sentences extracted from the proceedings of the European Parliament.
- **GlobalVoices** (Tiedemann 2012): News stories collected from the website globalvoices.org.
- **JW300** (Agic and Vulic 2019): Publications crawled from the website jw.org.
- **MUSE** (Conneau, Lample, et al. 2017): Ground-truth bilingual dictionaries.
- **News-Commentary** (Barrault et al. 2019): News commentaries collected from the website Project Syndicate, provided by WMT for shared tasks.
- **OpenSubtitles** (Lison and Tiedemann 2016): Large-scale collection of movie and TV subtitles.
- **Tatoeba**[4]: Large-scale collection of sentences and their translations.
- **TED2020** (Reimers and Gurevych 2020): Translated subtitles of over 4,000 TED talks.
- **WikiMatrix** (Schwenk et al. 2019): Parallel sentences from Wikipedia's contents.
- **WikiTitles** (Reimers and Gurevych 2020): Cross-lingual Wikipedia titles extracted from Wikipedia dumps.

1917 also saw the last issuance of 2 kroner coins.	[Portuguese] 1917 tambe´m viu a última emissa˜o de moedas de 2 kroner.
Resumption of the session.	[Spanish] Reanudacio´n del per´ıodo de sesiones.
And then we can ask questions, real questions, questions like, what's the best life insurance policy to get? – real questions that people have in their everyday lives.	[German] Und dann können wir Fragen stellen, echte Fragen, Fragen wie: Welche ist die beste Lebensversicherung? – echte Fragen, die die Leute im ta¨glichen Leben haben.
Then they surrendered and so did the 4 other ships, one after another.	[Dutch] Toen gaven ze zich over, evenals de vier andere schepen, de een na de ander.
Declaration of Fundamental Rights and Freedoms adopted by the Parliament.	[French] De´claration des droits et liberte´s fondamentales adopte´ par le Parlement.
Most economists failed to foresee the economic dynamics that actually led to the crisis, because they failed to pay enough attention to the rapid increase in US total debt.	[Italian] La maggior parte degli economisti non riusc`ı a prevedere le dinamiche economiche che condussero davvero alla crisi, perche´ non presto` sufficiente attenzione al rapido incremento del debito complessivo americano.

Evaluations

Sentence Encoding Tasks

We implemented the sentence encoding task described in (Lamsal, Read, et al. 2023b) to evaluate the embeddings generated by students compared to those by the teacher. This assessment measures how closely the students have replicated the teacher's vector space. For a crisis-related labelled dataset, we calculated the weighted average cosine similarity among tweets within individual classes as below:

$$D_{\text{avg}} = \sum_{k=1}^{K} \hat{w_k} \cdot \frac{1}{|\{i : y_i = c_k\}|} \sum_{i:y=c_k} \text{similarity}(\mathbf{e}_i, \mathbf{e}_j) \quad (2)$$

where, K is the number of classes in a dataset, $\hat{w}_k$ is the normalized class weight, similarity$(\mathbf{e}_i, \mathbf{e}_j)$ computes the cosine similarity between embeddings $\mathbf{e}_i$ and $\mathbf{e}_j$, where $\mathbf{e}_j$ is a crisis-text from same class as $\mathbf{e}_i$.

Datasets: For this task, we utilized 18 publicly available human-labelled crisis-related texts datasets, all of which are in English. The following datasets were considered: CrisisMMD (Alam, Ofli, and Imran 2018), CrisisLex (Olteanu et al. 2014), AIDR (Imran, Castillo, Lucas, et al. 2014), ISCRAM2013 (Imran, Elbassuoni, et al. 2013a), SWDM2013 (Imran, Elbassuoni, et al. 2013b), CrisisNLP (Imran, Mitra, et al. 2016), COVID-19 stance (Poddar et al. 2022), SAD Stressor (Mauriello et al. 2021), SAD Stress (Mauriello et al. 2021), SAD COVID (Mauriello et al. 2021), LocBERT (Lamsal, Harwood, et al. 2022b), HMC (a) (Biddle et al. 2020), Vaccination opinions (Cotfas et al. 2021), HMC (b) (Biddle et al. 2020), PHM (Karisani and Agichtein 2018), COVID-19 patients and COVID-19 contacts (Klein et al. 2021), and ANTiVax (Hayawi et al. 2022).

Sentence Matching Tasks

Next, we assessed the multi-lingual aspect of the student models. We considered the test sets provided in TED2020 (Reimers and Gurevych 2020) to evaluate our student models. Each test set comprised 1,000 sentence pairs. For every test set and each student, we performed sentence matching tasks as follows:

Let E be the set of English sentences and T be the set of translated sentences. We have n sentence pairs, where $E = \{en_1, en_2, ..., en_n\}$ and $T = \{t_1, t_2, ..., t_n\}$. For each i (where $1 \leq i \leq n$), we compute the embeddings $S(en_i)$ and $S(t_i)$ for the English and translated sentences, respectively.

English to translated language evaluation: For each i, assess if t_i has the highest cosine similarity with en_i compared to all other translated sentences in the set T:

$$\text{en-t-match}_i = \begin{cases} 1 & \text{similarity}(S(en_i), S(t_i)) \geq \text{similarity}(S(en_i), S(t_j)) \text{ for all } t_j \neq t_i \\ 0 & \text{else} \end{cases} \quad (3)$$

Table 2. Results (weighted average cosine similarity) from sentence encoding tasks.

Average	0.6374	0.7485	0.7255	0.7280

Table 3. Performance of vanilla XLM-R and mBERT on sentence encoding tasks.

	XLM-R	mBERT
Average	0.0032	0.3581

Translated language to English evaluation: For each i, assess if en_i has the highest cosine similarity with t_i compared to all other English sentences in the set E:

$$\text{t-en-match}_i = \begin{cases} 1 & \text{similarity}(S(t_i), S(en_i)) \geq \text{similarity}(S(t_i), S(en_j)) \text{ for all } en_j \neq en_i \\ 0 & \text{else} \end{cases} \quad (4)$$

In Equations 3 and 4, "1" denotes a correct match, and "0" an incorrect match. The accuracy for each language is calculated by dividing the total number of correct matches by the number of sentence pairs in the test set.

Sentence Embeddings

For generating sentence embeddings, we performed mean pooling on the token embeddings of an input sentence while considering the attention mask. The following pre-processing steps were performed to each input sequence: (i) replacing URLs with the HTTPURL token, (ii) substituting mentions with the @MENTION token, (iii) decoding HTML entities, (iv) eliminating newline characters and unnecessary whitespaces, (v) fixing text encoding issues for consistency, and (vi) replacing emojis with their corresponding textual representations. A tweet was considered one input sequence with the maximum sequence length set to 128.

RESULTS AND DISCUSSIONS

As discussed earlier, we implemented the student-teacher architecture and used a collection of parallel datasets, totalling over 128 million sentence pairs, as training data to train multi-lingual sentence encoders based on XLM-R and mBERT. The final checkpoints of the sentence encoders (CT-XLMR-SE and CT-mBERT-SE) were evaluated to assess: (i) how well they have learned the teacher's vector space and (ii) their multi-lingual capacity. The results from sentence encoding tasks are provided in Table 2 and Table 3, and those from sentence matching tasks are summarized in Table 4.

Table 4. Results (accuracy) from sentence matching tasks. For each language, the best average score is highlighted and equal scores across models are underlined. `en-t`: English to translated language and `t-en` is translated language to English.

Table 2 presents results from sentence encoding tasks on real-world crisis-related human-labelled social media texts. The evaluated models include SBERT (Sentence Transformer's top-performing model: all-mpnet-base-v2), CT (CrisisTransformers), CT-XLMR-SE, and CT-mBERT-SE. All of these models utilized mean pooling over the token embeddings of an input sequence, considering the attention mask. Across all 18 datasets, our multi-lingual models consistently outperformed SBERT, whose D_{avg} = 0.6374. CT-XLMR-SE with D_{avg} = 0.7255 exhibited a 13.79% improvement over SBERT, and CT-mBERT-SE with D_{avg} = 0.7280 showed a 14.17% improvement. We also present the performance of vanilla XLM-R and mBERT on sentence encoding tasks in Table 3. The results show that sentence embeddings generated by these models lack semantic richness, aligning with findings in the existing literature that transformer-based pre-trained models, out-of-the-box, do not produce semantically meaningful sentence embeddings (Reimers and Gurevych 2019; Lamsal, Read, et al. 2023b).

Table 4 provides a detailed overview of the performance of the student models across 52 languages for sentence matching tasks on the TED2020 test sets. The evaluation metrics include accuracy scores for English to translated language task (en-t) and translated language to English task (t-en) and the average for each language. Out of 52 languages, CT-XLMR-SE performed best in 32 languages on average accuracy, while CT-mBERT-SE excelled in 18 languages. In 2 languages, both models performed equally. The results show variation among models in their performance across languages. Portuguese (Brazil), Spanish, Macedonian, Dutch, Portuguese, German, Serbian, and Slovak exhibit better results with CT-XLMR-SE. However, for languages such as Swedish, Romanian, and Croatian, CT-mBERT-SE surpasses CT-XLMR-SE. For Galician and Ukrainian, both models performed equally. CT-XLMR-SE achieves accuracy above 0.95 across 27 languages, while CT-mBERT-SE achieves this across 28 languages. Seven languages fall within the [0.8, 0.9) accuracy bracket for CT-XLMR-SE, and five languages for CT-mBERT-SE. The only outlier is CT-mBERT-SE, which achieved a score of 0.3055 for Kurdish (Sorani), placing it as the only language below the [0.8, 0.9) bracket. In contrast, CT-XLMR-SE achieved a score of 0.8890 for the same language. Overall, European languages tend to attain higher scores compared to languages from other regions. This trend could be attributed to the availability of more training data for European languages in the parallel datasets considered by this study.

The mean squared error (MSE) loss used in the training is based on the deviation of student's embeddings from teacher's embeddings. Since the student is approximating the embedding space of the teacher, it does not surpass the teacher in tasks involving English texts. The teacher's specialized training on English texts gives it a more nuanced understanding of the language, allowing it to perform well in English tasks. However, the strength of the student model lies in its ability to process multiple languages. Sentence Transformers also offer multi-lingual versions of several of their pre-trained embedding models utilizing the same student-teacher embeddings deviation-based loss. Both our student models surpass Sentence Transformers' top-performing model, *all-mpnet-base-v2*, in English sentence encoding tasks while maintaining multi-lingual capacity. As the second part of the training objective, i.e. $(\mathrm{CT}\ (en_j) - \mathrm{S}(t_j))$, involves aligning the student's non-English embeddings with the teacher's English embeddings, the student produces similar embeddings for translated pairs of sentences, which is evident with results and examples provided in Tables 4, 5 and 6. Table 5 lists an originally posted tweet and its translated (with Google Translate) versions, and Table 6 provides cosine similarities amongst them. Given that our student models replicate the embedding space of CrisisTransformers and surpass Sentence Transformers by > 13%, it is reasonable to expect that they perform well compared to Sentence Transformers' multi-lingual models. However, further study is required to quantify how well these models perform on real-world non-English crisis-related social media texts.

Multilingual embedding models are critical within crisis informatics. Areas where the proposed student models can be applied include semantic search, clustering, and topic modeling. Semantic search powered by multilingual embedding models enables the identification of semantically related content, such as matching help requests with relevant offers (Dutt et al. 2019), thus facilitating efficient allocation of resources during crises. For instance, if a first responding agency needs to filter through a large amount of social media messages, semantic search can quickly help identify messages indicating urgent needs, such as evacuation requests from a building collapse. By comparing the embeddings of search phrases with those of incoming social media streams in multiple languages, relevant messages can be efficiently retrieved and prioritized. For example, a similarity search with embeddings of any sentences in Table 5 with a similarity threshold of 0.9 would return remaining sentences as they are literal translations of each other. Moreover, multilingual embeddings are instrumental in clustering social media messages, offering benefits throughout the disaster management cycle. Clustering helps in organizing similar messages together, aiding in the identification of emerging trends, hotspot areas, or critical needs. This assists decision-makers in allocating resources and planning response strategies effectively. Also, neural topic models (Grootendorst 2022) can use the cross-lingual sentence embeddings to perform topic modeling without language restrictions. These models can uncover underlying themes and topics within crisis-related social media data, providing insights into

evolving situations and public concerns across diverse linguistic contexts.

CONCLUSION

In this study, we introduced two multi-lingual sentence encoders (CT-XLMR-SE and CT-mBERT-SE) designed for embedding crisis-related social media texts. Both models were trained as students in student-teacher networks, with CrisisTransformers' (mono-lingual) sentence encoder serving as the common teacher. The training process utilized a large-scale dataset comprising 10 different parallel datasets, totalling over 128 million sentence pairs (e.g., en–es, en–de, en–fr, etc.) across 52 languages. The proposed models underwent evaluation through sentence encoding tasks to assess how well they approximated the teacher's vector space and sentence matching tasks to evaluate their multi-lingual capabilities. Results from both tasks demonstrate that the models generalize well to the languages introduced during training and mimic CrisisTransformers' sentence encoder's embedding space. XLM-R and mBERT, upon which the proposed multi-lingual sentence encoders are based, were originally trained on extensive text corpora containing 100 and 104 languages, respectively. We performed additional training to align these models with CrisisTransformers' sentence encoder's vector space, concentrating on 52 specific languages.

Advancing the area: Our objective is to expand language coverage, including low-resource languages. There is increasing interest in distillation techniques to create small yet effective models from large pre-trained ones. This presents an exciting opportunity to distill knowledge from large models for generating state-of-the-art dense embeddings suitable for real-time processing of crisis-related social media texts. Additionally, we aim to integrate CrisisTransformers with distilled knowledge from large language models to enhance the quality of embeddings. Moreover, the crisis informatics domain lacks translation pairs to train a similar student-teacher architecture, suggesting a potential area for future exploration. Could crisis-specific translation pairs potentially outperform crisis-specific or general-purpose pre-trained models that are subsequently fine-tuned on parallel data from the general domain? This requires further investigation.

ACKNOWLEDGEMENTS

This study is supported by the Melbourne Research Scholarship from the University of Melbourne, Australia. This research was undertaken using the LIEF HPC-GPGPU Facility hosted at the University of Melbourne, which was established with the assistance of LIEF Grant LE170100200.

ABSTRACT

The growth of social media usage this last decade has made available a massive and valuable volume of multimedia data. However, the lack of large multimodal annotated datasets, along with the inherent noise and the diversity of multimodal relations in this type of data presents challenges for machine learning methods. Unlike classic multimodal data, social media data comes with a large diversity of relations between image and text making the interaction between the two modalities more difficult. Previous research concentrated on fusion strategies with separate encoders for each modality. This paper introduces CMB (Caption-based Multimodal BERT), a method of classifying crisis-related social media posts by utilizing information from both images and texts. CMB translates the image modality into a text-compatible space, facilitating intermodal interaction. Furthermore, CMB presents training opportunities to enhance the model's robustness to missing modalities. Experimental results show that CMB is competitive with well-established, costly, and manually crafted multimodal models.

Keywords

Deep Learning, multimodal data, text/image fusion, Crisis data

INTRODUCTION

Proliferation of social media and advancements in internet technology have significantly changed the nature of online content, especially on platforms such as X (previously Twitter[1]), where user-generated data has immense value to a wide range of domains, including public health, economics, and politics (Wu & Mebane Jr, 2022). In times of crisis (natural disasters), this data can be used to gain situational awareness and assist humanitarian organizations in their preparedness, mitigation, response, and recovery efforts. However, the large volume of data present on social media requires the development and implementation of automated systems to effectively categorize and identify informative posts by analyzing information present across modalities.

Many works in this scope focused on processing unimodal data including images (Nguyen et al., 2017) or texts (Kumar et al., 2011). To leverage both modalities, many papers have proposed general-purpose self-supervised

*corresponding author

1We will be using Twitter and tweets as a reference for X and X posts

vision-language models (Y.-C. Chen et al., 2020; Kim et al., 2021; Tan & Bansal, 2019). Nevertheless, these large pre-trained (multimodal) models are primarily designed for homogeneous data, such as images and their captions. They therefore do not take into account the heterogeneous informational content that may exist between an image and its associated text, as is the case in social media (Vempala & Preo¸tiuc-Pietro, 2019), making transfer learning suboptimal (Liang et al., 2022). In this context of multimodal social media tasks, prior works have concentrated their efforts on fusion strategies. The prevailing practice involves using two unimodal encoders, one for each modality, followed by fusing the unimodal embeddings. Many fusion strategies were proposed (Ofli et al., 2020) for instance used the concatenation of the two embeddings, while (Abavisani et al., 2020) introduced a cross-attention mechanism to achieve a more effective fusion. In contrast, (Liang et al., 2022) explored early interaction strategies to enable interactions on low-level features.

However, the lack of large annotated datasets coupled with the variety of the inter-modality relations between image and text presents additional challenges for learning task-oriented fusion. Moreover, previous studies (Fan et al., 2023; Wang et al., 2020) have shown that different modalities tend to overfit and converge at different rates when using two encoders. This indicates that optimizing the same objective for various modalities results in inconsistent learning efficiency. In this paper, we investigate the effectiveness of captions in vision-language tasks for crisis tweets. It is hypothesized that the embedding integration of both texts and images into a common semantic space and the use of a single trainable encoder may thus facilitate the challenging learning problem. For this, we propose to use a caption-based method, which consists of translating a modality (e.g. image) towards another modality (e.g. text). We, therefore, present the CMB method ***C****aption-based* ***M****ultimodal* ***B****ERT*, that leverages captioning models to translate image into text and concatenate resulting captions with the tweet's text before inputting the combined data into a text encoder.

To thoroughly evaluate this approach, we conduct experiments with a variety of captioning models that have been pre-trained on different datasets. We also propose a training strategy that allows to use our method in unimodal settings without significant performance loss. Our experiments focus on crisis context, in particular on the well-studied multimodal CrisisMMD dataset (Alam et al., 2018). The examples in Figures 4 and 5 illustrate the challenges of this dataset in terms of the relationship between modalities (complementarity, heterogeneity or partial redundancy (Vempala & Preo¸tiuc-Pietro, 2019)). Our contributions are as follows:

- We present CMB, a method to homogenize the input space of image/text data to enable better information processing by BERT-like architecture.
- We compare three captioning models and show that this method can achieve highly competitive results for crisis-related tweets.
- We propose a training strategy to use our models in unimodal settings without significant loss of performance.
- Lastly, we present a qualitative analysis of the success and failure of our method.

RELATED WORKS

IMAGE-TEXT MULTIMODAL LEARNING

The image-text machine learning research area encompasses a variety of application domains, such as image captioning (Cho et al., 2022; Mokady et al., 2021), visual question answering (Antol et al., 2015) and visual reasoning (Zellers et al., 2019). Recently, several pre-trained models have been developed to address these tasks : LXMERT (Tan & Bansal, 2019) employs two unimodal streams and a cross-attention encoder to combine information from multiple modalities, while UNITER (Y.-C. Chen et al., 2020) uses a single stream transformer to enable inter-modality attention from the early layers of the model. In contrast, VILT (Kim et al., 2021) allows interaction between text and image at the fine-grained feature level without requiring prior convolution or region detection.

Multimodal learning has been applied to a range of social media projects, including emergency response (Abavisani et al., 2020; Liang et al., 2022; Long & McCreadie, 2022), emotional recognition (Yang et al., 2020), fake news detection (Tuan & Minh, 2021) and political science (Wu & Mebane Jr, 2022). There are two main approaches to multimodal social media post classification: early fusion and late fusion. In early fusion, the interaction between modalities is allowed from the early layers of the model, as shown by the Multimodal Information Injection Plug-in units introduced in (Liang et al., 2022), which preserve the strong intra-modal processing ability of large pre-trained unimodal models. In late fusion, separate encoders are used for each modality, such as DenseNet (Huang et al., 2017) or ResNet (He et al., 2016) for images and BERT (Devlin et al., 2018) or RoBERTa (Liu et al., 2019) for texts.

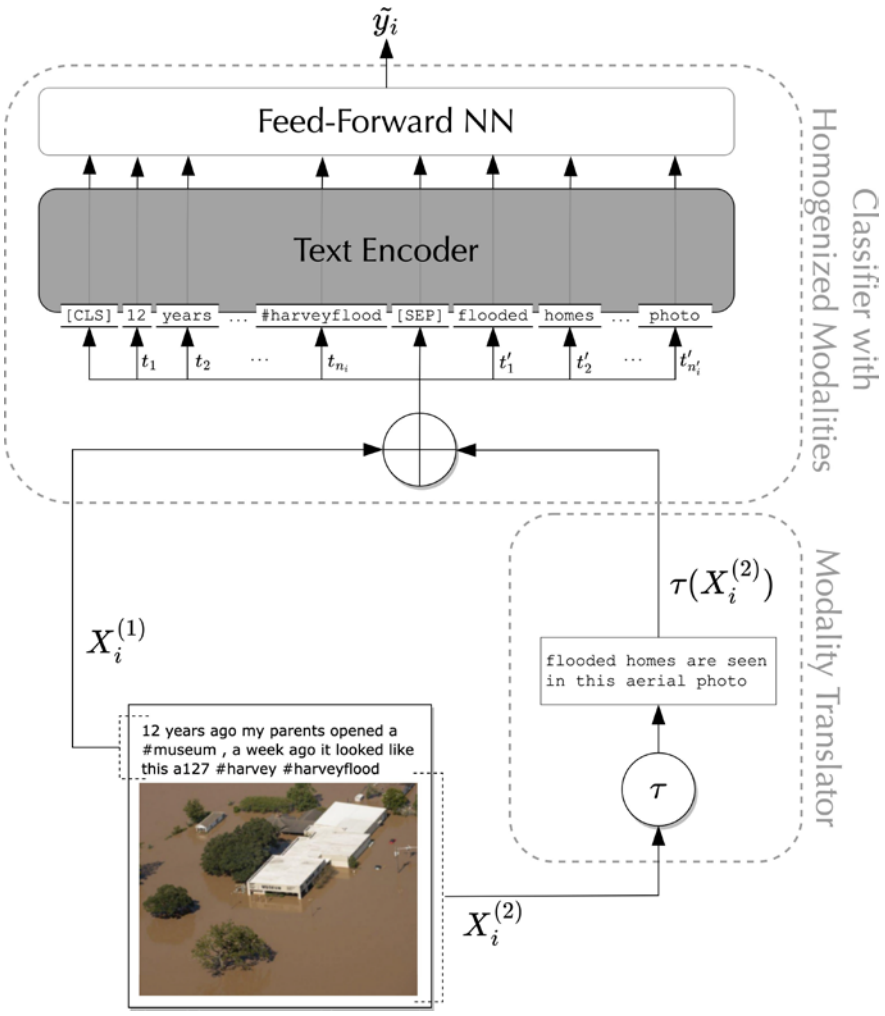

Figure 1. Overview of the CMB method structured in two main parts: a non-learnable process represented by the modality translator (image captioning model) and the homogenized modalities classifier as trainable module.

Interaction between modalities occurs at the high feature level through techniques such as feature concatenation (Long & McCreadie, 2022) or cross-attention (Abavisani et al., 2020).

In this study, however, we explore the effectiveness of image captions, employing pre-trained captioning model to capture the image information. The acquired information is then integrated into a text embedding space to facilitate fusion.

MACHINE LEARNING FOR EMERGENCY RESPONSE

Using social media information in emergency response is increasingly considered essential for the management of natural disaster crises. Many prior works have focused on unimodal signals: (Kumar et al., 2011) proposes a system to analyze and monitor (text) tweets to help humanitarian organizations better manage crises, (Nguyen et al., 2017) uses images posted on Twitter to determine the level of damage caused by disasters (Little, mild or severe). In a multimodal setting, (Abavisani et al., 2020) applies late fusion with two unimodal encoders to filter informative image-text tweets, while (Liang et al., 2022) employs early fusion to enhance low-level inter-modal feature interactions. Unlike previous approaches, we argue that the inherent complexity within social media data can be challenging due to the verity of relations between modalities, (Vempala & Preo¸tiuc-Pietro, 2019). To overcome this challenge (Sosea et al., 2021) introduced DisRel, a dataset for learning to distinguish the relationships between images and texts according to their nature (*complementary*, *similar* or *unrelated*). Their work demonstrated that incorporating such tasks can enhance the performance of models trained on CrisisMMD.

In this work, we propose an alternative method leveraging captioning techniques for image-to-text translation, in order to map the image representation space into text facilitating fusion within a shared representation space.

IMAGE CAPTIONING FOR FUSION

In previous works, captions have been used to represent images for multimodal interaction, such as Multimodal Named Entity Recognition (MNER) (S. Chen et al., 2020). It has been argued that models trained for semantic understanding, like image captioning models, may provide better image representations. The use of captions as image representations allows for the incorporation of textual descriptions of the image content, providing additional context and useful information to understand and interpret the image. Moreover, (Wu & Mebane Jr, 2022) uses captions as a translated version of image in addition to the tweet's image and text to improve performance in classifying multimodal tweets. Contrary to (Wu & Mebane Jr, 2022), the method CMB proposed in this paper uses - through captions - modality translation as a substitute and not as a complement to the image to improve inter-modality interactions while keeping the modal simple to train and use in real-world scenarios (with limited resources). Moreover, we argue that the use of one encoder helps to overcome the problem of different convergence rates of each modality encoder and lead to more efficient learning.

METHODOLOGY

PROBLEM STATEMENT

Let D be a multimodal dataset with N instances, denoted by $D = \{(X_i, y_i)\}_{i=1}^{N}$. Each $X_i \in X$ represents a multimodal data point with M modalities, represented as $X_i = \{X_i^{(p)}\}_{p=1}^{M}$. Associated with each instance is a label $y_i \in C$, where C is the set of possible labels. The multimodal classification task aims at learning a classifier $h : X \rightarrow C$ that combines information from different modalities to make accurate predictions. In the following, we consider only bimodal instances ($M = 2$) where the two modalities are different in nature, typically textual and visual modalities. Thus, $X_i^{(1)} = (t_1, \ldots, t_{n_i})$ is a sequence of tokens while $X_i^{(2)} \in R^{C \times H \times W}$ is an image (where C, H, and W are the number of channels, the height, and the width of the image respectively.

MODEL OVERVIEW

Since modalities of different natures (typically text and image) are hard to combine in multimodal fusion strategies, we propose a two-step categorization approach that leverages modality translation to homogenize the inputs (Figure 1). The first step, *Modality Translator* consists in translating one modality into a space compatible with the space of the other modality using a translator function $\tau(.)$. In our particular context of text-image tweets processing, the image modality $X_i^{(2)}$ is translated into a text (sequence of tokens) by means of an image captioning process $\tau(X_i^{(2)}) = (t'_1, \ldots, t'_{n'_i})$. The second step *Classifier with Homogenized Modalities* takes as input the concatenation of the homogenized modalities $X_i^{(1)} \oplus \tau(X_i^{(2)})$ to train both a text encoder and the final classification layer. Let us notice that the approach allows to process both multimodal ($X_i^{(1)} \oplus \tau(X_i^{(2)})$) or unimodal data ($X_i^{(1)}$ only or $\tau(X_i^{(2)})$ only).

MODALITY TRANSLATORS

In our multimodal approach, the captioning model is viewed as a modality translator. For our investigation, we use three publicly available captioning models, which vary depending on the encoders and the training data they use.

- **CLIP Prefix for Image Captioning** (Mokady et al., 2021). A captioning model using the CLIP (Radford et al., 2021) (Contrastive Language-Image Pre-training) multimodal encoder, which is trained on a large dataset sourced from the Web. It extracts image features using the CLIP encoder and employs them as a prefix for text generation by a language model. Trained with either the MSCOCO dataset (Lin et al., 2014) or the Conceptual Caption dataset (Sharma et al., 2018), the authors argue that the rich semantic features of the CLIP encoder, coupled with a pre-trained language model (GPT2 (Radford et al., 2019)), provide a comprehensive understanding of both visual and textual data, resulting in high quality captions. In the following, these captioning models are referred to as *CLIP_cc* (trained with Conceptual Captions) and *CLIP_coco* (trained with MSCOCO).
- **Fine-grained Image Captioning with CLIP Reward**. In (Cho et al., 2022) the authors use CLIP (Radford et al., 2021) in two ways, first as an image encoder, and then CLIP text and CLIP image are used to compute a multimodal similarity that then serves as a reward function for each generated caption to obtain descriptive and distinctive captions. This captioning model is referred to as *CLIP_reward* in the following.

Table 1. Training and evaluation settings.

Train \ Eval	*Text*	*Image*	*Caption*	*Text + Image*	*Text ⊕ Caption*
Text	T_T	-	-	-	-
Image	-	I_I	-	-	-
Caption	-	-	C_C	-	-
Text + Image	-	-	-	TI_TI	-
Text ⊕ Caption	TC_T	-	TC_C	-	TC_TC

- **Transformer based Captioning**.(Vaswani et al., 2017) uses the Transformer architecture and first process the image using Mask-RCNN (He et al., 2017), the features are then fed to the Transformer in order to generate the caption. This captioning model is referred to as *Trans cap* in the rest of the article.

The CMB approach we propose in this paper allows to independently integrate any of the four captioning models presented above. In the following experiments, we will focus on measuring the contribution of the captions generated by each model in our proposed multimodal framework.

MULTIMODAL CLASSIFIER WITH HOMOGENIZED MODALITIES

Transformer based models (Devlin et al., 2018; Liu et al., 2019; Radford et al., 2019; Vaswani et al., 2017) has achieved state of the art result in large set of natural language processing tasks, by leveraging various self-supervised pre-training techniques. Therefore, without loss of generality, we use BERT (Devlin et al., 2018) as text encoder to extract embeddings from the input $(X_i^{(1)} \oplus \tau(X_i^{(2)}))$, which are then used to perform the classification task using a feed forward neural network layer.

EXPERIMENTAL SETUP

DATASET AND TASKS

The **CrisisMMD** (Alam et al., 2018) benchmark aims to identify crisis events that require emergency response using social media posts as a basis. The dataset for this benchmark consists of tweets (image-text pairs) obtained through searching for specific hashtags on Twitter and labeled for three tasks Informativeness, Humanitarian, and Damage severity assessment. In this work, we only consider the first two multimodal tasks:

- **Informativeness**: a binary classification task identifying whether or not a given tweet (text or image) is informative for humanitarian aid purposes, i.e., useful for providing assistance to people in need.
- **Humanitarian**: Identifying whether a given tweet (text or image) belongs to one of the following seven categories : *infrastructure and utility damage*; *vehicle damage*; *rescue, volunteering, or donation efforts*; *injured or dead people*; *missing or found people*; *other relevant information*; *not humanitarian related*.

This dataset provides a total of 16,058 tweet texts and 18,082 tweet images labelled for these two tasks, resulting into 8,079 multimodal instances for the Humanitarian task and 12,168 instances for the Informativeness task. Unfortunately, the CrisisMMD dataset does not offer one label for each *tweet*, but one label for each *modality* of a tweet. Therefore, it is not directly suited for the (multimodal) classification task we are considering in this work. Thus, we adopt the practice proposed in (Ofli et al., 2020) by using only instances with similar labels on the two modalities (text and image). Although this process excludes a non-negligible number of tweets, it is nevertheless based on the fairly reasonable assumption that a label that matches on both modalities can be used as a label for the entire tweet.

BASELINES

We compare our approach to both uni- and multimodal baselines in the field of image-text classification. Recently, the trend is to use multiple architectures in this research area. To provide a comprehensive evaluation of our approach, we implemented two popular multimodal architectures: the feature concatenation (Long & McCreadie, 2022) and the cross-attention (Abavisani et al., 2020) methods. Additionally, we included the unimodal methods BERT (Devlin

Table 2. Comparisons on CrisisMMD in terms of classification accuracy, Macro F1-score and weighted F1-score.

et al., 2018) (text only) and DenseNet (Huang et al., 2017) (image only) for comparison. Furthermore, we conduct a comparison between our approach and two other methods: CLIP (Radford et al., 2021) and CLIP-Concat. In the latter, we concatenate features from CLIP image encoder and BERT to accomplish the multimodal classification task. We aim to evaluate the effectiveness of CMB against these well-established methods to illustrate its usefulness in the crisis domain.

IMPLEMENTATION DETAILS

In this work we consider the four modality translators described above. Specifically, for each captioning model, we produced five captions for every image using the authors' provided demo for CLIP-based captioning models (CLIP_cc, CLIP coco and CLIP reward) and the demo from a GitHub repository2 for the Trans_cap model. We keep the most similar caption - from the five generated by each model - to the image in terms of clip similarity score (Cho et al., 2022).

We used the BERT base model from (Wolf et al., 2020) as a text encoder with token type embeddings different for captions ($\tau(X_i^{(2)})$) and texts ($X_i^{(1)}$). To classify, we computed the mean pooling on embeddings provided by BERT and used a classification layer consisting of a ReLU activation function and a dropout layer between two feed-forward layers. The models were trained on a Nvidia Tesla V100 GPU for 3 to 5 epochs with $batch\ size = 128$ and $learning\ rate = 5e^{-5}$. We made our code available on GitHub3.

UNIMODAL AND MULTIMODAL SETTINGS

To evaluate the robustness of our methodology across diverse scenarios, we conduct an array of experiments involving the training and evaluation of various iterations of our model, each employing distinct modalities such as Text, Image, or Caption. Table 1 uses specific notations to delineate these different experimental setups.

The first three rows of the table focus on unimodal approaches (T_T, I_I, and C_C settings), wherein a single modality is exclusively used for both training and evaluation. For text categorization (T_T, C_C), we employ BERT (Devlin et al., 2018), while for image categorization (I_I), DenseNet (Huang et al., 2017) is utilized.

The fourth row shows multimodal approaches (TI_TI setting), involving the simultaneous use of Text and Image during both training and evaluation. This incorporates a basic feature concatenation strategy, along with the previously mentioned cross-attention architecture (Abavisani et al., 2020) which uses attention mechanisms to merge representations from the two unimodal architectures (BERT and DenseNet).

Finally, the last line corresponds to our multimodal method based on modality translation, whose architecture is generic enough to adapt to multiple settings. We investigate its ability to learn efficient hybrid models for categorizing both multimodal and unimodal data by training it on both text and caption and then evaluate it on different data configurations: Text only (TC_T), Caption only (TC_C) and Text $\oplus$ Caption (TC_TC).

We utilize the same dataset across various configurations. In the TC configurations, both text and caption are used as input during training or testing phases. In the T configuration, only text is used as input to the model, with captions being ignored. Conversely, in the C configuration, only captions are used as input, while text is disregarded. This data split remains consistent across all configurations, encompassing training, validation, and testing phases.

To expand our experiments, we propose a mixed training strategy in which the model is trained on a mixture of data that contains text-only instances ($X_i^{(1)}$) and on instances with Text $\oplus$ Caption ($X_i^{(1)} \oplus \tau(X_i^{(2)})$). The details of our experiments are presented in the following sections.

CMB-Trans_cap	0.8920±0.0039	0.8749±0.0045	0.8907±0.0039	112
MARMOT CLIP_cc	0.9220±0.0022	0.9105±0.0024	0.9215±0.0021	309
CMB-CLIP_cc	0.9203±0.0036	0.9081±0.0043	0.9196±0.0037	112

EXPERIMENTAL RESULTS

This section presents the results of our experiments on the proposed method using different captioning models compared with unimodal and multimodal baselines. Additionally, we evaluate the robustness of CMB on unimodal data settings.

CAPTIONING MODELS COMPARISON

Table 2 displays the results of our experiments on the two multimodal tasks of the CrisisMMD dataset (Informativeness and Humanitarian). The first two rows report unimodal classifiers results, while the next two rows present the performances of multimodal baselines. The last four rows show the performances of our approach using each of the four captioning models described before. Firstly, the results obtained confirm that multimodal methods outperform unimodal ones. Additionally, our method is very competitive with other multimodal baselines, regardless of the modality translator used.

Specially, the performance gap between the different captioning models can be significant, as demonstrated by the 3% performance gap on the informativeness task between the method based on Trans_cap and the best-performing method. Importantly, the CLIP_cc captioning model allows the CMB method to outperform the proposed strong baseline of 1-3% in terms of weighted F1-score on both CrisisMMD tasks. Moreover, employing the identical data splits, our experiments yield competitive results with state-of-the-art (Liang et al., 2022) findings as well as results reported on the MVSA dataset. In the tasks of informativeness and humanitarian, we scored 91.96 and 94.84 W-F1, respectively, while their scores were 91.3 and 93.6.

Furthermore, we can observe the gap between the CLIP_cc and CLIP_coco models despite using the same architecture: we hypothesize that the Conceptual Caption dataset (Sharma et al., 2018) has more coverage and similarity with Twitter images, containing figurative representations with different levels of iconicity such as photographs, drawings, charts, or even non-figurative pieces of digital art for instance. Finally, the clear gap between the CLIP-based models and the simple Transformer model confirms the findings of (Bielawski et al., 2022), indicating that CLIP generalizes better on human-centric tasks (defined by the authors as involving knowledge of cultural, social, aesthetic and/or affective components of the world). In our case, this fits particularly our need on social media, where humans post for other humans.

In order to expand our investigations, we compared our approach with MARMOT (Wu & Mebane Jr, 2022) : a model incorporating images, captions, and textual elements for tweets classification. Employing two distinct captioning models, namely Trans_cap and CLIP_cc, the experiments outcomes are shown in Table 3. Despite the diminished parameter count (approximately one-third) in our method relative to MARMOT, it exhibited competitive performance in both scenarios. Noteworthy disparities were observed, particularly in the Trans_cap scenario, whereas the performance differentials were closely aligned when utilizing CLIP_cc captions. This underlines the influence of employing high-quality captions in this configuration. In the continuation of this paper, we use the best captioning model, namely CLIP cc.

UNIMODAL AND MULTIMODAL RESULTS

As discussed previously, the CMB method contains two parts : a modality translator and a trainable module (text encoder + classifier). The input of the trainable part is exclusively text-based, enabling the use of both unimodal ($X_i^{(1)}$ or $\tau(X_i^{(2)})$) and multimodal ($X_i^{(1)} \oplus \tau(X_i^{(2)})$) data as input. This section investigates the unimodal and multimodal capabilities of the model by conducting an experiment with three main configurations, TC_T, TC_C and TC_TC. Results of the experiments are reported in Figure 2. Performances of CMB (for the different

4We used significance level = 0.05

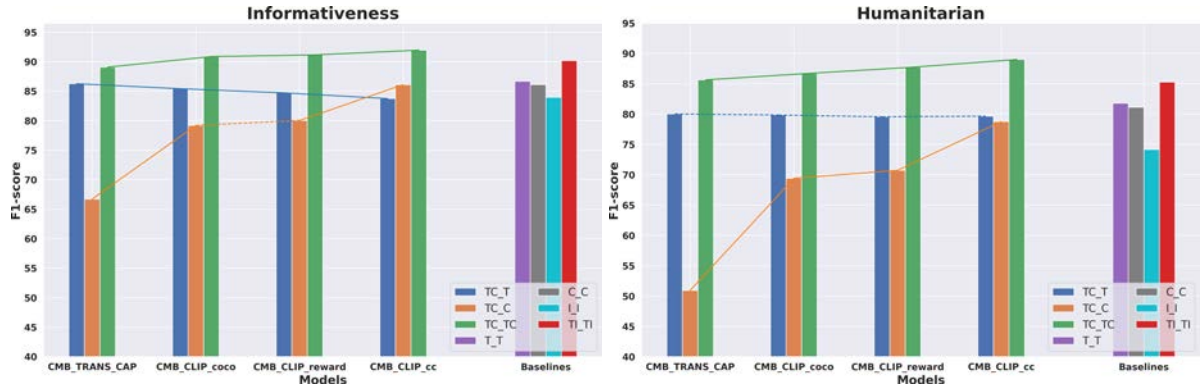

Figure 2. Comparison of modality translators on Unimodal and Multimodal settings (see Table 1). Y-axis shows mean Weighted F1-score results over 10 runs. The X-axis represents the different modality translators used in this experiment. Dotted lines are used for non-significant differences.4

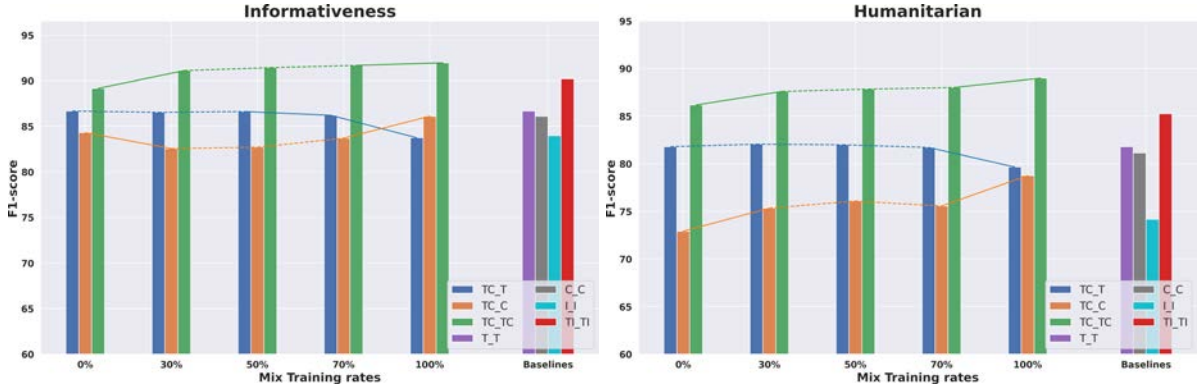

Figure 3. Mix training results. In the X-axis, $X\%$ represents the proportion of multimodal instances ($X_i^{(1)} \oplus \tau(X_i^{(2)})$) in training data, the remaining $100 - X\%$ data are text only ($X_i^{(1)}$). Dotted lines are used for non-significant differences.

captioning models) is compared across the three main configurations as well as to BERT (Devlin et al., 2018) (as T_T configuration), CMB_CLIP_cc (C_C), DenseNet (Huang et al., 2017) (I_I) and the features concatenation model (TI_TI). As mentioned in the previous section, the results clearly illustrate the improved performance when using the two modalities sources for classification. Additionally, these experiments reveal a relationship between the captions-only (TC_C) and multimodal (TC_TC) performances, indicating that the model performance depends on the caption quality. The figures also show that captions-only models can outperform the (I_I) DenseNet model. However, the model in the TC_T setting exhibits poor performance compared to BERT (in T_T configuration) with a 2-3% loss. These results suggest a form of *caption dependency* of the models. To address this issue, we discuss a mix training method in the next section.

MIX TRAINING RESULTS

Twitter posts can be either unimodal or multimodal, but in practice, keywords are used as filters to retrieve tweets with the Twitter API, making some tweets containing only text (without image). Rather than using two different models depending on the nature of each tweet (unimodal or multimodal), we suggest that the CMB model can be used to process both unimodal and multimodal tweets. This hybridization requires an appropriate training strategy, called the *mix training* approach. In this study, we propose an experiment to test our method in TC_T and T_T settings. The goal of this mix training approach is to train a hybrid model that can handle both multimodal (*text+caption*) and unimodal (*text-only*) tweets. To this end, we consider training samples with various *text-only*/*text+caption* balances and observe the ability of the derived models to classify *text-only*, or *text+caption* tweets. In this experiment, the captioning model used is CLIP_cc. The proportions of *text+caption* tweets in the training sample is increased from 0% to 100%, with the remaining examples being *text-only* tweets. The results of the mix-training strategy, as presented in Figure 3, provide interesting insights into the performance of the hybrid model in different scenarios.

Figure 4. Examples of caption using success cases when baseline BERT and Cross-attention failed

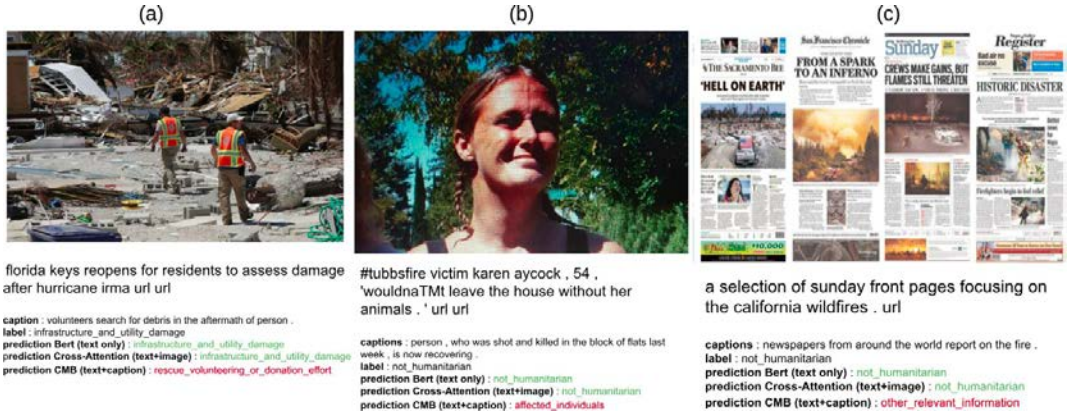

Figure 5. Examples of caption leading to failure cases when baseline BERT and Cross-attention succeed.

When evaluated on text-only tweets (TC_T), the model's performance (F1-score) experiences a slight decrease of approximately 2-3% as the proportion of text+caption tweets in the training sample increases from 50% to 100%. This indicates that the introduction of captions has affected the performance of the model on text-only settings, specially when having more than 70% *text+caption* examples. Additionally, it's evident that the performance in caption-only evaluation (indicated by the orange bar in TC_C) improves as the proportion of *text+caption* examples increases. However, there is one unexplained anomaly observed during the informativeness experiment when transitioning from 0% to 30% of *text+caption* examples.

On the other hand, in the multimodal setting (TC_TC), the same change in the training sample, with an increase in the proportion of text+caption tweets from 50% to 100%, results in an improvement of about 0.5-1% in the model's performance. This suggests that the hybrid model benefits from exposure to a higher proportion of multimodal data during training, leading to better performance in the multimodal tweet classification task. The proposed hybrid model demonstrates its competitiveness with BERT (T_T) when trained on a sample with 50% text+caption tweets, achieving an impressive F1-score of 81.98%. Despite a small loss of performance in the TC_TC setting compared to the text-only scenario, the hybrid model remains clearly superior to the TI_TI baseline, showcasing its capability to effectively handle both unimodal and multimodal tweets. Furthermore, the analysis reveals that the best compromise on caption rates, is achieved at 50%. This suggests that a balanced mixture of text-only and text+caption tweets in the training sample is optimal for achieving peak performance in the hybrid model. Finally, this experiment indicates that the mix training strategy makes the learned models more robust and usable for classifying both unimodal and multimodal tweets in real time.

QUALITATIVE ANALYSIS

Finally, we provide several examples to illustrate the success and failure cases of our proposed method. Figure 4 shows three examples in which the cross-attention baseline and BERT failed, but our method made the correct prediction on the Humanitarian task. In particular, Figure 4(a) is an example of the success of using a caption, as the synthetic image is difficult to be processed by a conventional image model pre-trained on ImageNet (Deng et al., 2009). In figure 4(b) the successful generation of the words "blocks the road" may have contributed to the prediction of the correct label, highlighting the model's ability to capture discriminative information. Finally, Figure 4 (c) is a multimodal example in which the text alone fails to predict the label; in this case, the caption captures information that is merged with the text to achieve the right prediction.

In Figure 5, we present three examples where the caption model produced inaccurate results. The image in Figure 5(a) illustrates the potential of captions to be misleading and result in incorrect predictions; the model captured some information from the image in a poorly structured sentence, resulting in an incorrect prediction. The image in Figure 5(b) demonstrates a failure due to an inaccurate caption generated by the captioning model, highlighting the sensitivity of our approach to the modality translator. Finally, the image in Figure 5(c) shows a situation in which both the label and the prediction fall into a gray area, where either could be considered a valid label. These examples provide insight into the successes and failures of our proposed method, specifying potential areas for improvement.

CONCLUSION

In conclusion, our multimodal classification method based on a modality translation process was found to be competitive with strong baselines and state-of-the-art results on the CrisisMMD dataset. Our analysis confirms that multimodal approaches generally outperform unimodal ones and that the performance gap between different captioning models can be significant. We also found that the caption quality is important for the overall performance of the model, and we proposed a mixed training method to create a hybrid model that can handle both unimodal and multimodal sources. However, our method has several limitations that should be addressed in future work, including the sensitivity on caption quality and the focus on the crisis domain. Overall, CMB is a promising approach for multimodal classification and highlights the importance of considering multiple modalities in tasks involving social media data.

ABSTRACT

Real-time information extracted from social media platforms can be highly valuable during emergencies. For example, reports and direct witnesses can help build situational awareness in the early phases of an emergency, with the potential to save lives. However, suitable techniques for selecting relevant data are needed to gather this information from large-scale social media streams and utilize it effectively. Given the multimedia nature of these streams, selection techniques should simultaneously understand textual and image information, as previous studies highlighted. Leveraging recent advances in language and vision models, we propose and evaluate a method working with a homogeneous, text-only representation for the different modalities of social media posts. Experiments on established and novel datasets, including video data, show that the proposed method achieves state-of-the-art performances while providing a highly general and plug-and-play approach to multimodal data filtering.

Keywords

social media, multimodal data filtering, LLMs

INTRODUCTION

Nowadays, the widespread availability of portable devices and mobile connections has made information production and sharing ubiquitous, making social media a valuable source of information for various purposes, from staying informed to gathering a general overview of a phenomenon. Social media can enhance situational awareness during crisis events by highlighting critical situations, damage to things or people, urgent needs, and other information useful for managing response operations, potentially saving lives. This information often comes in the form of multimedia, such as images and videos. However, the large volume of items posted during crisis events requires proper resources and technologies to rapidly isolate and utilize this information, since their amount is exceptionally high in the first hours following the onset of an emergency.

Several past works investigated the usefulness of social media data for obtaining actionable information during an emergency. The use of social media for collecting up-to-date descriptions during emergencies has been widely advocated over the last decade (Stollberg and De Groeve, 2012), often utilizing a "human as a sensor" paradigm (Avvenuti et al., 2016). Many studies aim to classify social media content according to different categorizations of interest, leveraging various forms of data, including text and multimedia content such as images and videos, to obtain a timely description of ongoing events. Classifying which content is relevant for a given categorization is perceived as a principal barrier to exploiting social media data (Stieglitz et al., 2018).

*corresponding authors

In the present study, we aim to contribute to the task of understanding the informativeness of social media content. Specifically, we look at how augmenting multimodal social media posts with text descriptions derived from Large Language Models (LLMs) might improve their informativeness. We derive textual descriptions from photographic scenes using automatic text generation and combine this additional information with the original text of the posts. Our methodology is tested against two relevant scenarios: a well-known multimodal Twitter dataset (Alam et al., 2018b) and a manually labeled dataset of videos acquired from Reddit. We compare our approach with existing studies and conduct an explainability analysis to understand the nature of the additional information introduced.

The remainder of this work is structured as follows. We summarize literature relevant to our research in the *Related Work* section. Our proposed approach for classifying social media posts is detailed in the *Method* section. In the homonymous sections, we provide the details of the *Datasets* utilized, the *Experiments* performed, and the *Results* obtained by the empirical evaluation of the method. The findings are then examined in the *Discussion* section. Finally, *Conclusions* are drawn in the last section, together with future directions.

RELATED WORK

The prevalent approaches for classifying disaster-related social media posts are grounded in supervised learning. One of the classic works in literature (Sakaki et al., 2013) proposes an algorithm for monitoring tweets to detect earthquake events, focusing on the timeliness of the detection. Over time, approaches based on deep neural networks gained attention (Wiegmann et al., 2020), and production-level platforms for the automatic extraction of relevant posts have been proposed (Imran et al., 2014; Havas et al., 2017). The ability of supervised methods to generalize, especially among different types of events, is one of the critical obstacles, highlighting the need for general-purpose approaches, such as few-shot models (Wiegmann et al., 2020; Kruspe et al., 2020). This challenge also holds for works related to classifying image data or image and text data together (Imran et al., 2020). Recent technological advances have widely upgraded the discerning of both textual and image data. In the context of emergency management, Convolutional Neural Networks (CNNs) have been employed for content classification and damage assessment. The relevance of images during crisis events has been highlighted and exploited by many studies (Peters and De Albuquerque, 2015; Alam et al., 2018a; Bono et al., 2022; Nguyen et al., 2017).

Multimodal fusion techniques aim to enhance classification performance by combining information from both visual and textual modalities (Ramachandram and Taylor, 2017). In recent years, these approaches have been broadly evaluated in emergency scenarios (Abavisani et al., 2020). The integration of modalities can be categorized into two primary strategies. The first and most prevalent involves using distinct backbone networks for each modality, with multimodal fusion occurring either at the classification score level (Wang et al., 2021) or through the combination of high-level features from each network (Kiela et al., 2018; Mozannar et al., 2018), using techniques like addition, outer product, cross-gating, and tensor fusion. The primary limitation of this strategy is the minimal interaction between the different modalities. The second strategy focuses on merging the mid-level features of each modality for a more detailed inter-modal interaction (Huang et al., 2020). Notably, recent multimodal BERT models incorporate transformer layers over these mid-level features, enhancing a fine-grained interplay between text and image features through the attention mechanism (Li et al., 2019). Finally, Liang et al., 2022 propose a method for adapting pre-trained unimodal models like DenseNet and BERT to process image-text pairs for multimodal recognition by integrating cross-modal features without altering the original network structures.

Our study takes a distinct approach from previous ones. Rather than customizing an architecture for combining multimodal data, we convert image information into text with a recent large multimodal model. We then use text-only representations to train a transformer-based classifier. Furthermore, our method is tested with both image and video content, applying it to practical scenarios and including a type of media not frequently considered in similar studies.

METHOD

In the present work, we investigate whether automatically derived textual content, such as captions and descriptions obtained from LLMs, can support multimedia classification and improve the ability to distinguish informative content published on social media. We utilize Large Language and Vision Assistant (LLaVA) (H. Liu et al., 2023), a state-of-the-art large multimodal model, for generating image-related descriptions, and Robustly Optimized BERT Approach (RoBERTa) (Y. Liu et al., 2019) for training the classifier on the resulting representation. We focus on a binary classification setup, aiming at differentiating "*informative*" and "*not informative*" content, according to a context-dependent definition of informativeness. The generated text is concatenated to the original text of the post, thus obtaining a homogeneous, augmented textual representation. A RoBERTa classifier is then trained over this representation. The architecture of the proposed method is illustrated in Figure 1.

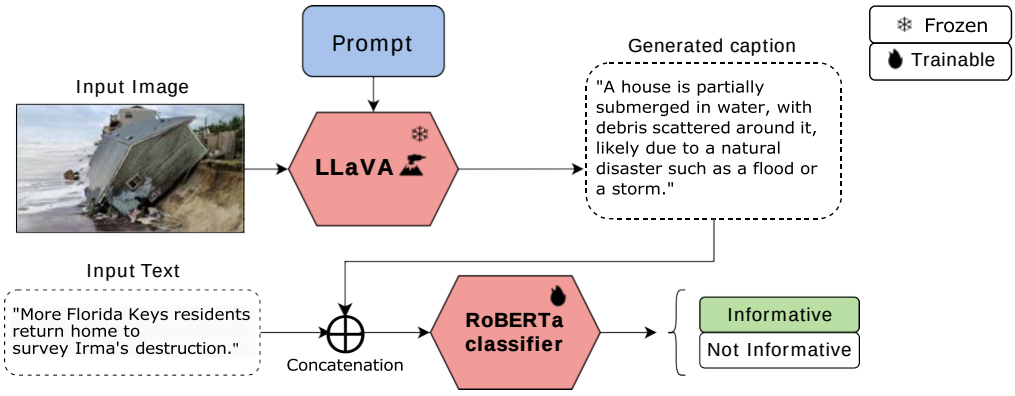

Figure 1. **Architecture of the proposed integration and classification method**

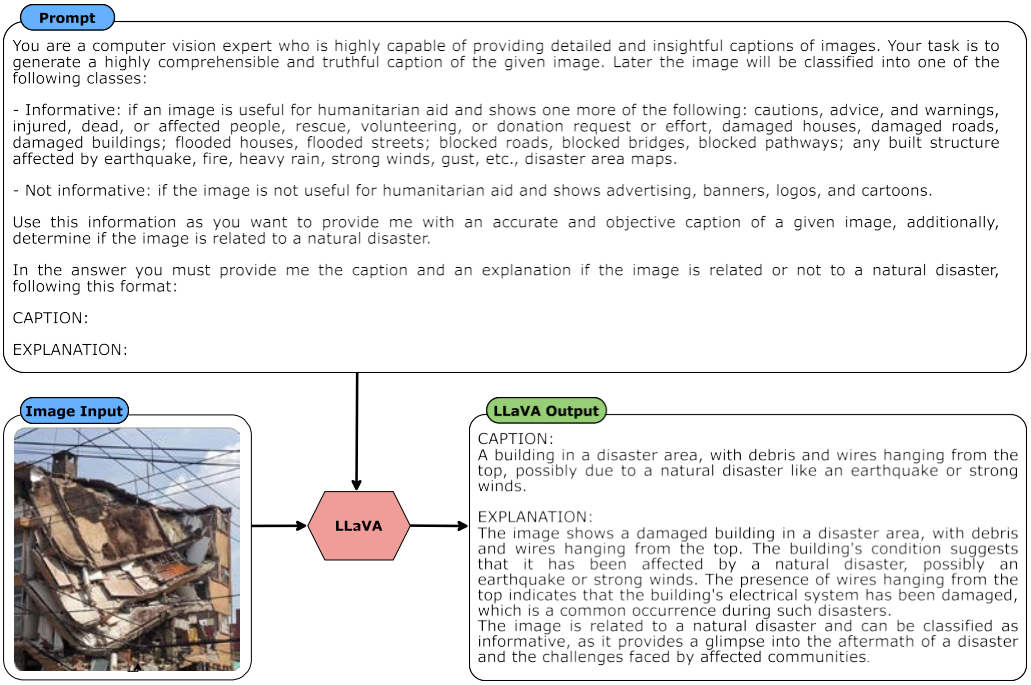

Figure 2. **Information augmentation for the**

As discussed in the previous section, fusion models usually require ormation from text and images, as these data modalities have inherently different hallenges in model design and optimization. When employing image-only models, visual features, mainly disconnected from the semantic features of textual data. use of a text-only classifier, avoiding the need for more complex fusion methods t performance.

LLaVA is a large, general-purpose multimodal model combining visual and a vision encoder and the Vicuna chat assistant (Zheng et al., 2023). The model information from images according to a preferred semantic level, such as an imag or task-dependent reasoning. A fundamental feature of the approach is its ability textual ones, allowing for control over the semantic level and format of the generated prompt engineering.

In the considered setup, multiple text generation tasks are requested, such as visual-onl The idea is to exploit the language model, through suitable prompts, for different kinds of which could in turn improve the downstream classification task. An example is reported in 2 detailed in the Experiments section. Each component of the generated information, derived frames attached to posts, can be regarded as supplementary text, extending the original pos

Table 1. **Characteristics of the datasets**

	Number of posts	Number of images	*Informative* images (%)
CrisisMMD	11,400	12,708	66.63
Reddit	838	35,551	6.39

Each type of resulting textual representation is then separately fed to a transformer-based model for training and evaluation.

DATASETS

We conducted tests on two distinct datasets to benchmark the effectiveness of the proposed method. The first one, CrisisMMD, is a well-established multimodal dataset collected from Twitter during natural emergencies (Alam et al., 2018b). The second is a novel dataset consisting of video content collected from Reddit over one week at the onset of the 2023 conflict between Israel and Hamas.

CrisisMMD The dataset was collected using event-specific keywords and hashtags during seven natural disasters that occurred in 2017: Hurricane Irma, Hurricane Harvey, Hurricane Maria, the Mexico earthquake, the California wildfires, the Iraq-Iran earthquakes, and the Sri Lanka floods. The dataset has been annotated for three tasks. In the current study, we specifically focus on the *informativeness* task, which aims at recognizing whether a social media post is informative or uninformative for humanitarian aid purposes (see the definition of *informativeness* in Ofli et al., 2020).

In CrisisMMD, text and image pairs, which are annotated separately, could carry different labels. To properly compare the proposed method with previous works (Liang et al., 2022; Ofli et al., 2020), we align with the benchmark guidelines by focusing exclusively on the portion of the dataset where text and images share the same label for the informativeness task. The resulting dataset composition is reported in Table 1.

Reddit Videos To evaluate our method on a recent event, we collected Reddit posts with video attachments during the initial days of the 2023 conflict between Israel and Hamas. We used the Reddit API via the *praw*[1] library, using "*gaza OR israel OR hamas OR palestin**" as a case-insensitive search query, gathering 49,788 posts from October 13th to 19th, 2023. To account for the different nature of this dataset, we adapted the definition of *informativeness* as follows. The post is considered *informative* if it reports or shows direct proof of damage to people, such as injured, dead, or affected persons, or damage to man-made things, such as buildings, infrastructures, or vehicles, including the damaging act itself. Non-primary sources and indirect reporting, including newscasts, interviews performed either in a studio or in the field, reaction videos, edited videos, and non-photographic videos, are considered *not informative*.

Among the collected posts, 2,644 had a video attachment. Of these posts, 1,959 had a text length of at least ten words. This minimum word count was chosen arbitrarily to focus on posts with substantial descriptions. We filter out duplicated videos via video hashing[2].

Videos are then classified as *informative* based on the definition mentioned above, with two annotators using Label Studio[3]. We only keep videos where both annotators agreed on the label. Analogously to the data selection performed in the previous dataset, the annotators performed a second pass to exclude a limited number of videos for which the labels and the original posts' text did not agree. Then, we extracted all the keyframes from the videos and eliminated duplicated frames using image hashing[4]. Each frame was assigned the label and text from its original post, although we recognize that this method might not be perfectly accurate. The final dataset composition is reported in Table 1. This dataset, which includes some level of noise and is related to a human-made emergency, is meant to test the method's effectiveness under challenging conditions[5].

EXPERIMENTS

LLM Setup

Regarding the text augmentation, we used LLaVA 13B version 1.5 for the CrisisMMD task and LLaVA 7B version 1.5 for the Reddit task because of budget limitations. These models were trained in September 2023 on various datasets, including a set of GPT-generated multimodal instruction-following data. The architecture adopted for the text classifier is RoBERTa base6, pre-trained on 58M tweets and fine-tuned for sentiment analysis with the TweetEval benchmark.

For the text augmentation on the CrisisMMD dataset, the LLaVA *Temperature* parameter, which controls the randomness of the output, was set to 0.7, while the *Maximum Number of Generated Tokens* was set to 1024. The *Nucleus Sampling* parameter, also known as *Top P*, which determines diversity by only considering a subset of the most probable next words, was set to 0.7. In the case of text augmentation on the Reddit dataset, the settings used were analogous to those for the CrisisMMD dataset, except for the *Temperature* parameter, which was adjusted to 0.2. This is done due to the nature of the dataset, which frequently features video frames with significant motion and complexity. By lowering the *Temperature* setting, the model's range of generative options is somewhat limited, which supposedly helps to generate consistent descriptions of the video frames.

Classifier Setup

LLaVa weights are kept frozen and used only for text generation. The weights of the text classifier are instead fine-tuned while training for the informativeness classification task. We use Adam as optimizer, using a mini-batch size of 64, and weighted cross-entropy as a loss function, with weights accounting for class imbalance. We employ a Cyclical Learning Rate policy (Smith, 2017) for mini-batch Gradient Descent. Cyclical Learning Rate adjusts the learning rate by cyclically changing it between a minimum value of $1e^{-5}$ and a maximum value of $1e^{-4}$. To mitigate overfitting, we use an early-stopping condition on the validation cross-entropy loss, with patience of 5 epochs. Both LLaVa generation and RoBERTa training were performed on an A40 GPU. We did not specifically tune any hyper-parameter; hence, there is likely room for improvements in future studies.

Models are assessed using three metrics: classification accuracy, macro-averaged F1-score (M-F1), and weighted F1-score (W-F1), with weights determined by the number of samples for each class. It is important to note that during emergency events the distribution of samples across categories is usually imbalanced. This motivated the choice of macro-averaged and weighted F1-score to properly synthesize false positives and false negatives.

CrisisMMD

To compare our method against previous works (Liang et al., 2022), we keep the same training, validation, and test data splits provided by the dataset creators (Alam et al., 2018b). Table 2 shows the total number of tweets and attached images for each category, along with their distribution among training, validation, and test sets. The variation in the number of tweets and images in the training set is due to some tweets having multiple image attachments. These tweets are assigned exclusively to the training set.

Table 2. **Labels and data splits for the CrisisMMD informativeness task**

	Train (70%)		**Valid (15%)**		**Test (15%)**		**Total**	
	Text	**Image**	**Text**	**Image**	**Text**	**Image**	**Text**	**Image**
Informative	5,546	6,345	1,056	1,056	1,030	1,030	7,632	8,431
Not informative	2,747	3,256	517	517	504	504	3,768	4,277
Total	8,293	9,601	1,573	1,573	1,534	1,534	11,400	12,708

We used LLaVA to generate textual descriptions for images using prompt engineering techniques. We instructed the model to act as a computer vision expert and outlined the specific tasks. These tasks included generating a descriptive caption and an explanation for a given image, with information related to the specific classification task. Additionally, we specified the format for the two required outputs: a "*CAPTION*" providing a concise and factual image description and an "*EXPLANATION*" justifying if and why a given image could be *informative* in the current scenario. The prompt utilized is reported in Figure 2.

6https://huggingface.co/cardiffnlp/twitter-roberta-base-sentiment

Table 3. **Labels and data splits for the Reddit informativeness task**

	Train & Valid (70% - 15%)		Test (15%)		Total	
	Text	**Frame**	**Text**	**Frame**	**Text**	**Frame**
Informative	61	2,066	11	208	72	2,274
Not informative	651	28,490	115	4,787	766	33,277
Total	712	30,556	126	4,995	838	35,551

We processed the generated texts to craft six distinct inputs for the classifier, namely: the tweet text concatenated with the caption; the tweet text concatenated with the explanation; The tweet text concatenated with both the caption and the explanation; the caption concatenated with the explanation, without the tweet text; the caption alone; the explanation alone.

We compared our approach with traditional networks trained on a single modality (unimodal image and text, Ofli et al., 2020), as well as existing state-of-the-art image-text multimodal classification methods. Studies such as Abavisani et al., 2020 primarily employ a multimodal fusion of global features from each unimodal backbone. Others, like Huang et al., 2020, employ pre-trained multimodal BERT models adapted for image-text classification and inter-modal interaction via the attention mechanisms. We also compare to standard multimodal recognition techniques: score fusion (averaging unimodal classification scores) and feature concatenation (merging global features from each unimodal source). The study from Liang et al., 2022, which proposes a method for integrating information from other modalities into the unimodal models, was considered as a reference for the reported performances of the cited models.

Reddit Videos

Similarly to the CrisisMMD task, we used LLaVA to obtain information about the video frames. We instructed the model to act as a computer vision expert analyzing video frames. The requested output consisted of three text elements: a "*CAPTION*" providing a brief, factual description of the image; an "*EXPLANATION*" offering a justification aligned with the informativeness task; and a "*REASONING*" section, which elucidates the model's "reasoning" concerning the content of the image and its connection to the classification task described. The prompt utilized is reported in Figure 3.

We processed the generated texts to craft six distinct inputs for the classifier, namely: the post text concatenated with the caption; the post text concatenated with the explanation; the post text concatenated with the reasoning; the post text concatenated with both the caption and the explanation; the caption alone; the explanation alone. Finally, the dataset was partitioned into training, validation, and test sets, accounting for 70%, 15%, and 15% of the posts, respectively. We ensured, by leveraging video identifiers, that all frames from the same video appeared only in one partition. When partitioning, we ensured the preservation of class balance among the partitions by stratifying based on class labels. Table 3 displays the total posts and video frames for each category, including their distribution over splits.

To evaluate the robustness and generalization ability of the proposed method on the Reddit dataset, we replicated the same experiment over five random samples. We conducted the same experiment across five distinct pairs of training and validation sets, each generated through random partitioning of non-test data. We ensured that frames from the same video appeared only in one fold, and stratified the sampling on class labels. To evaluate the classifier's performance also at the video level, a video is classified as *informative* if at least 50% of its frames are predicted as *informative*.

RESULTS

CrisisMMD

In Table 4, we report the performance results achieved by different methods, including the proposed one, on the informativeness task.

In Figure 4, we present the test set confusion matrices for the multimodal model developed by Ofli et al., 2020 and for the three best-performing models proposed in this work. Confusion matrices from other studies are not included, as they were not provided in the respective papers.

[†]Reported performances are taken from Liang et al., 2022

In Table 5, we report the performance results achieved by the proposed method on the Reddit informativeness task. The table reports the performance metrics computed both at the frame and video levels.

DISCUSSION

CrisisMMD

We can draw the following observations from Table 4. First, the unimodal models generally perform worse than the multimodal approaches. Second, we can see that the late unimodal fusion models (Cross-attention, CentralNet, GMU, CBP, CBGP), as well as the large pre-trained multimodal BERT models (MMBT, VisualBERT, PixelBERT, and ViLT) share similar performances.

The proposed approach, when injecting LLM-generated information, achieves state-of-the-art performances. We observe that the models that consider the original texts of the tweets generally perform better than the ones using only LLM-generated information. Although expected, this highlights the relevance of the tweets' contents for discerning relevance. In addition, we observe that the model combining the original text and captions performs better than combining the original text with other LLM-generated information. This fact may be due to the brief, factual information provided by the captions, which are possibly more helpful to the classifier. In contrast, explanations tend to be more detailed, including descriptions, comments, and evaluations. These additional details could lead the classifier astray, making it possibly more complicated to interpret the overall text accurately.

The confusion matrices presented in Figure 4 show that the proposed model combining tweet text and captions significantly outperforms the other three models in correctly identifying true positives and minimizing false negatives. Although this configuration generates a few more false positives than the model that combines text and explanations, a higher number of false negatives would be far more problematic during an emergency than a slight increase in false positives. The performance looks slightly worse when text is paired with explanations than when it

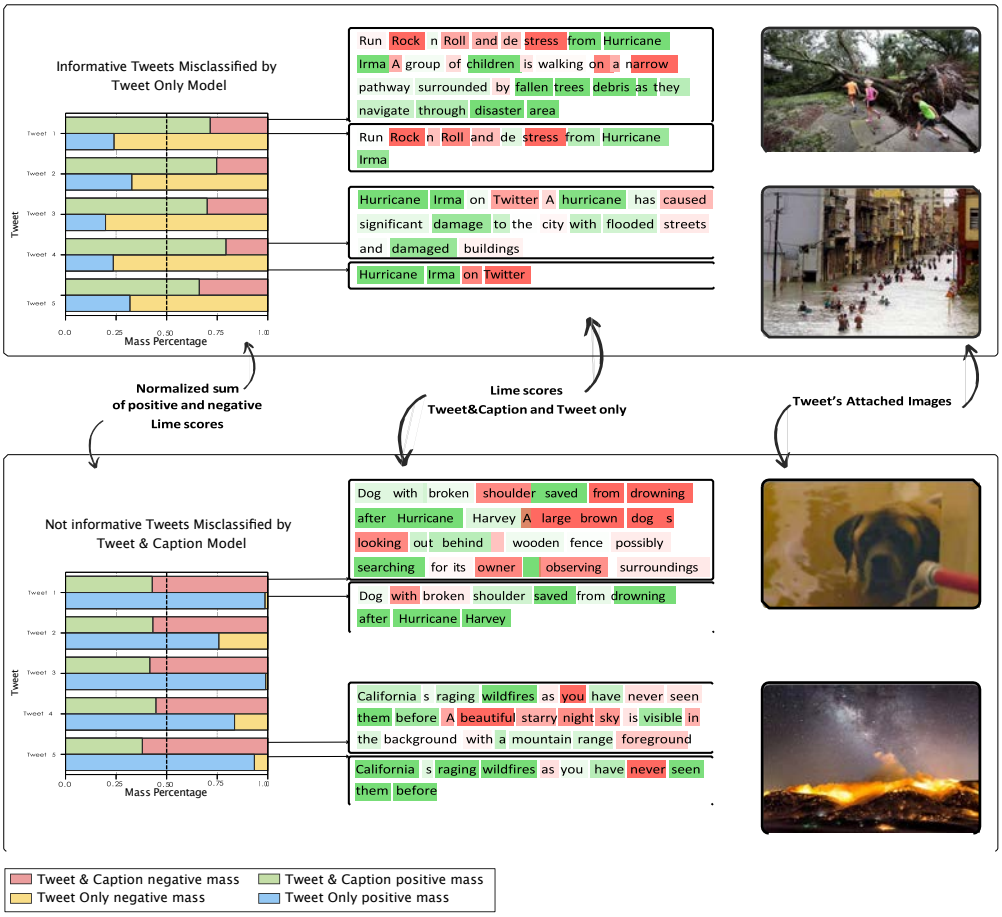

Figure 5. **Information Amplification Analysis in CrisisMMD: On the left, normalized LIME scores are displayed for selected tweets; in the middle, word-level LIME scores are highlighted (green for positive, red for negative); on the right, the images linked to each tweet are reported. *Positive* and *negative* mass percentages refer to the normalized sum of LIME scores within each tweet**

is paired with captions. When text, captions, and explanations are combined, the performance falls between the two preceding scenarios, possibly due to the beneficial effect of captions. This supports the hypothesis that explanations make the task more difficult in this scenario.

To understand the effect of the information amplification performed by the LLM-generated text, we performed an explainability analysis via Local Interpretable Model-Agnostic Explanation (LIME, Ribeiro et al., 2016). LIME perturbates the input instances and uses the model's predictions on these instances to fit an interpretable model in the proximity of the selected instance; this second model reveals which features are influential for the specific instance and how much they contribute to the global model's prediction.

Figure 5 illustrates how the LLM augmentation can help the classification task. On the left, each pair of bars represents an *informative* Twitter post from the CrisisMMD dataset, with the different areas representing the normalized sums of positive and negative LIME scores for two configurations, *"Tweet & Caption"* (first row) and *"Tweet only"* (second row).

In the upper section, we observe that positive scores are boosted after augmenting the text with LLM-generated captions, recovering false negative cases. However, the information injection also has a counterproductive effect in some cases, as seen in the bottom section. Here, examples of *informative* tweets are misclassified by the *Tweet & Caption* model due to features with negative scores becoming prevalent. Although the balance between misclassifications remains favorable compared to not using information amplification, as shown in Table 4, this observation highlights the challenges in managing the impact of the additional information introduced.

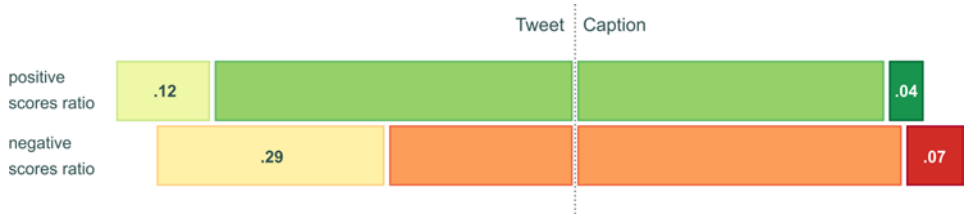

Figure 6. **Normalized LIME score ratios in CrisisMMD test set; Tweet-only lemmata on the left; Caption-only lemmata on the right; lemmata shared by both sections in the middle**

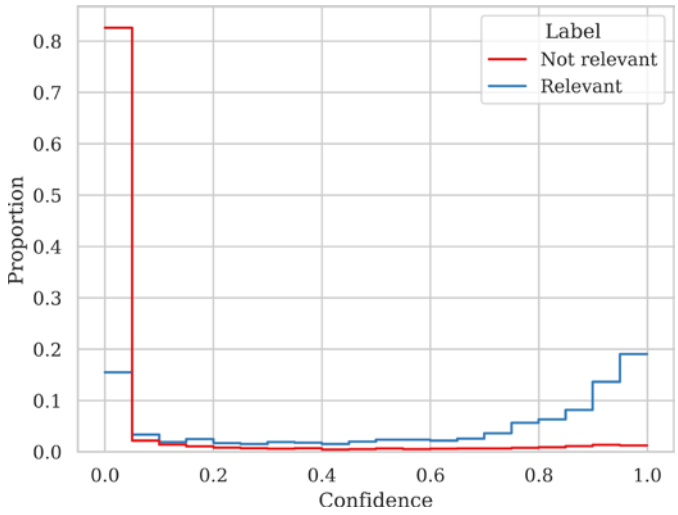

Figure 7. **Test set frame confidence distribution, normalized per class (Reddit Task)**

Figure 6 provides a visual representation of the overall effect of the information introduced by the LLM. The figure refers to the *Tweet & Caption* model and highlights the contribution of each of the two sources – original tweet and caption – to the classification outcome by aggregating and normalizing the LIME scores related to lemmata[7], after excluding English stopwords. In the figure, positive and negative scores are aggregated as rows, while a vertical line partitions tweet-dependent and caption-dependent scores. The three colors highlight the characteristics of the lemmata: the two lighter blocks on the left account for the weight of lemmata seen only in tweets, while the two darker blocks on the right account for the weight of lemmata seen only in captions.

As a general observation, it can be seen that most of the scores originate from lemmata shared between the two sources. The effect of new terms introduced by the LLM is limited, roughly one-fourth of the percentage of scores for tweet-only lemmata. This observation suggests that the tweet's text could consistently describe the images' contents. Overall, the original tweet text accounts for 57% of the positive scores and 52% of the negative scores.

Reddit Videos

The proposed approach shows a good separability of the classes already at the frame level, as the distributions in Figure 7 show. Roughly 16% of the *informative* frames are classified as *not informative* with more than 95% confidence. Upon manual inspection of a sample of these frames, the reasons behind the misclassifications were not completely clear, since some relevant frames were present in this subset, together with generic, blank, and indistinct frames isolated from videos labeled as *"informative"*. This observation also suggests that a more fine-grained approach to labeling, such as considering video segments instead of whole videos, could be beneficial for the task, albeit more burdensome as an annotation task. On the other hand, this does not impair the performance of the video classifier, since only individual frames are affected by the misclassification.

Moreover, it should be noted that the reported performance results, based on common-sense thresholds — 0.5 confidence at the frame level and 0.5 proportion of positive frames at the video level — prove to be conservative

[7] "*A form of a word that appears as an entry in a dictionary and is used to represent all the other possible forms*" according to the Cambridge Dictionary

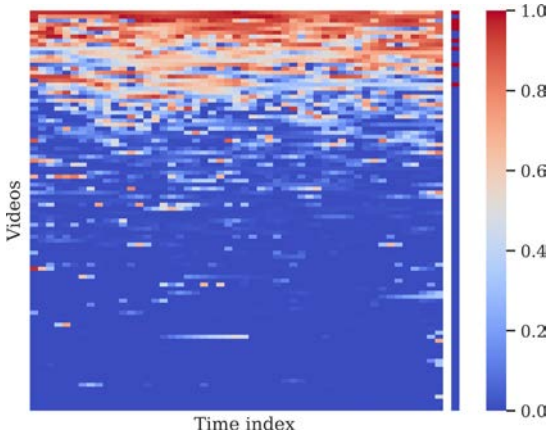

Figure 8. **Confidence for "*informative*" class for each test set video, over normalized time index. True label on the right (Reddit Task)**

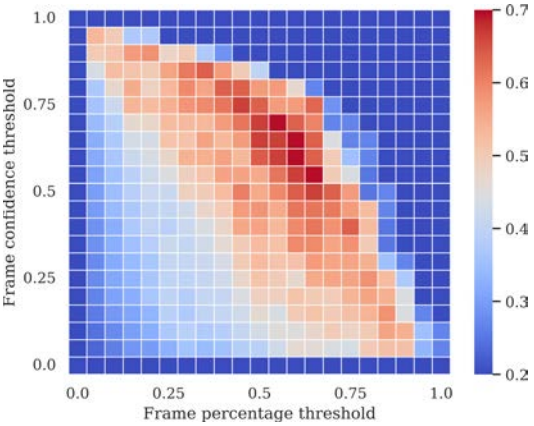

Figure 9. **Response of the test set F1-score for the "*informative*" class varying classification thresholds (Reddit Task)**

estimates of the performance. Figure 9 reports a grid exploration of the thresholds, showing that an increase in the video-level threshold could lead to better performances. We have chosen to evaluate our approach using a common-sense threshold to assess its performance as a general-purpose method. It should also be noted that the *"Caption Only"* model performs better at the video level, even if the F1 score at the frame level is worse. This is due to a higher false positive rate in the majority class (*"Not Informative"*), leading to a better final result since frames predicted as positive are still a minority when considered at the video level.

An understanding of the frame-level labels for the test set videos can be obtained from Figure 8. The figure illustrates how the confidence of being an *informative* frame is distributed along the videos, with red indicating higher confidence. The video durations are normalized for convenience. It can be observed that higher confidence regions, while still present in many of the *not informative* videos (blue region in the bottom part of the graph), are scattered across the video length; these false positives are mostly absorbed by the threshold at the video level. The fact that the *"Caption Only"* performs reasonably well without relying on the original text could also be related to the fact that, often, the text of the Reddit submission in the scenario analyzed is not merely descriptive but contains additional considerations, such as stances and advocacy.

CONCLUSIONS AND FUTURE WORK

We proposed a method for categorizing multimodal posts by extracting text-only representations from multimedia attachments and merging this information with the text of social media posts. One of the advantages of this approach is that it is general-purpose and we showed that it achieves state-of-the-art performances on the informativeness task without the need of fine tuning for a specific case. Further room for improvement is left by performing hyper-parameter tuning on the classifier on the specific case, although this was not the goal of the present study.

Amalgamating text and image information in social media data is crucial, as they often present complementary or conflicting information. Since current multimodal classification methods assume common labels for different modalities, future works should investigate multimodal learning algorithms capable of handling heterogeneous input (e.g., text and image pairs with conflicting labels).

One of the main hindrances to adopting LLMs is their computational cost, which is linked to energy utilization and environmental consequences. We plan to examine the trade-offs offered by alternative smaller models and efficiency-oriented methods such as network quantization, considering the combined effect of performance, execution times, and computational requirements to support a wider choice of use cases.

Finally, we plan to extend the evaluation of the proposed approach to few-shot and continual learning scenarios, since the intrinsically dynamic nature of emergency events poses significant challenges to adopting relevance-oriented classifiers. Moreover, since historical emergency-related data can be limited depending on the kind of emergency, learning informativeness on the fly could be the only viable option in some scenarios.

ABSTRACT

Critical Infrastructure Facilities (CIFs), such as healthcare and transportation facilities, are vital for the functioning of a community, especially during large-scale emergencies. In this paper, we explore a potential application of Large Language Models (LLMs) to monitor the status of CIFs affected by natural disasters through information disseminated in social media networks. To this end, we analyze social media data from two disaster events in two different countries to identify reported impacts to CIFs as well as their impact severity and operational status. We employ state-of-the-art open-source LLMs to perform computational tasks including retrieval, classification, and inference, all in a zero-shot setting. Through extensive experimentation, we report the results of these tasks using standard evaluation metrics and reveal insights into the strengths and weaknesses of LLMs. We note that although LLMs perform well in classification tasks, they encounter challenges with inference tasks, especially when the context/prompt is complex and lengthy. Additionally, we outline various potential directions for future exploration that can be beneficial during the initial adoption phase of LLMs for disaster response tasks.

Large language models, disaster management, social media, information classification, information retrieval

INTRODUCTION

Critical infrastructures, including essential facilities and services vital for societal functioning, span sectors like energy, transport, healthcare, and telecommunications (Labaka et al., 2016; Pescaroli & Kelman, 2017). Ensuring the continuous functioning and accessibility of critical infrastructures is essential in assisting vulnerable populations during disasters and disruptions to these critical infrastructures can result in increased human and economic losses (Auerswald et al., 2005). However, during major disasters, authorities are overwhelmed and thus face challenges in maintaining an updated status of these facilities, and as a consequence, the general public is kept uninformed about the latest status of these facilities.

This paper bridges the gap by exploring an unconventional data source—social media—to monitor Critical Infrastructure Facilities (CIFs) in a given area of interest (AOI). Social media platforms, especially microblogging sites such as X (formerly Twitter), are important data sources for real-time disaster updates. People post information about early warnings, cautions, damages, and their needs almost instantaneously (Olteanu et al., 2015; Qu et al., 2011). Past studies show the use of social media information for several disaster response tasks including damage and needs assessment, among others (Castillo, 2016; Imran et al., 2015).

While social media holds valuable information, it frequently becomes overloaded with noise—comprising casual chatter filled with slangs, abbreviations, and grammatically unconventional sentences. Past studies suggest employing supervised classification techniques to discern social media messages relevant to disaster response (Imran et al., 2015). However, these techniques require human-labeled data for each unique classification task or even when adapting a model trained on past disaster data to a new emergency. For example, Alam et al. (2021) manually labeled around 77K tweets to train deep neural network models such as BERT, RoBERTa, for detecting situational awareness messages. Similarly, Zahra et al. (2020) shows an extensive feature engineering process to train classifiers for eyewitness message detection. These methods are tailored for specific classification tasks, and should a new task/class be needed, retraining of the models would be required. To tackle this challenge, our work explores the use of Large Language Models (LLMs) to perform traditional computational tasks, an effort toward eliminating the requirement for explicit model training.

To monitor CIFs in a specified AOI, our proposed approach starts by acquiring all critical facilities in the area from Open Street Maps (OSM) through automatic APIs. Social media data collected about an ongoing disaster is processed through an LLM to generate embeddings and stored in a vector database.[1] Embedding of a message encapsulates its semantics and thus yields better search results. Therefore, for each CIF obtained from OSM, we query the vector database, where raw embeddings are stored, to retrieve messages pertinent to the specified CIF. The retrieved messages are then analyzed by LLMs to identify *(i)* the impacts reported in each message, *(ii)* the severity of the reported impacts, and *(iii)* the operational status of the CIF. We perform all the tasks in a zero-shot setting and evaluate each step of the proposed methodology using standard evaluation metrics.

Through extensive experimentation, we show both the strengths and limitations of LLMs in handling various computational tasks associated with the processing of social media messages. Notably, we showcase diverse configurations of our CIF retrieval query and the corresponding advantages they offer. For instance, our CIF query consisting of a fixed general term (e.g., "disaster impacts") yields better outcomes compared with a detailed listing of impacts. Furthermore, we note better classification performance of LLMs for individual messages when compared to the classification and inference from a set of messages. Overall, we demonstrate that LLMs, even in the zero-shot setting, hold great potential to replace traditional supervised models. However, there are certain weaknesses as well. Notably, LLMs may struggle with context understanding and misinterpret nuanced or ambiguous language commonly found in social media. Additionally, their performance can be influenced by factors like data biases and the nuances of prompt engineering. Acknowledging these limitations is crucial to refining the application of LLMs in processing social media messages effectively.

The rest of the paper is structured as follows. The following section reviews Related Work. In the Methodology section, we provide details of our proposed approach. Results are presented in the Results section and further deliberated upon in the Discussion section. The paper concludes in the final section.

RELATED WORK

Critical infrastructures are at the heart of economic and social welfare in all countries. Therefore, understanding their risk and resilience to various hazards and disasters have been crucially studied in literature (Yusta et al., 2011). For example, Fekete et al. (2015) explored the use of Geographic Information Systems (GIS) and Remote Sensing (RS) whereas Jovanovic´ et al. (2018) presented an indicator-based approach to assess resilience of critical infrastructures to disasters. To this end, Baloye and Palamuleni (2016) proposed a critical infrastructure-driven spatial database for proactive disaster management. Taking a step further, Qiang (2019) provided a comprehensive assessment of flood exposure of all major critical infrastructures in the United States.

In the last decade, with the advancement of social networks, researchers started to explore the use of real-time social media data during disasters to assess risk and resilience of critical infrastructures. For instance, Mittelsta¨dt et al. (2015) integrated social media data with mobile in-situ data to monitor the disaster impact on critical infrastructure. Later Fan and Mostafavi (2019) developed a graph-based method for detecting credible situation information related to infrastructure disruptions during natural disasters. In another study, Roy et al. (2020) presented a multilabel classification approach to identify hurricane-induced infrastructure disruptions through a sentiment analysis of social media data. They utilized several supervised machine learning models to classify disruptions in social media messages. Alternatively, Heglund et al. (2021) demonstrated the utility of social media data for critical infrastructure resilience based on statistical analysis and forecasting methods. While plethora of these methods utilize conventional pipelines of message filtration, trend detection, and other case-specific algorithms, our methodology leverages more generalized inferential capabilities of the large language models (LLMs).

[1]The list of CIFs, data, and embeddings are available upon request.

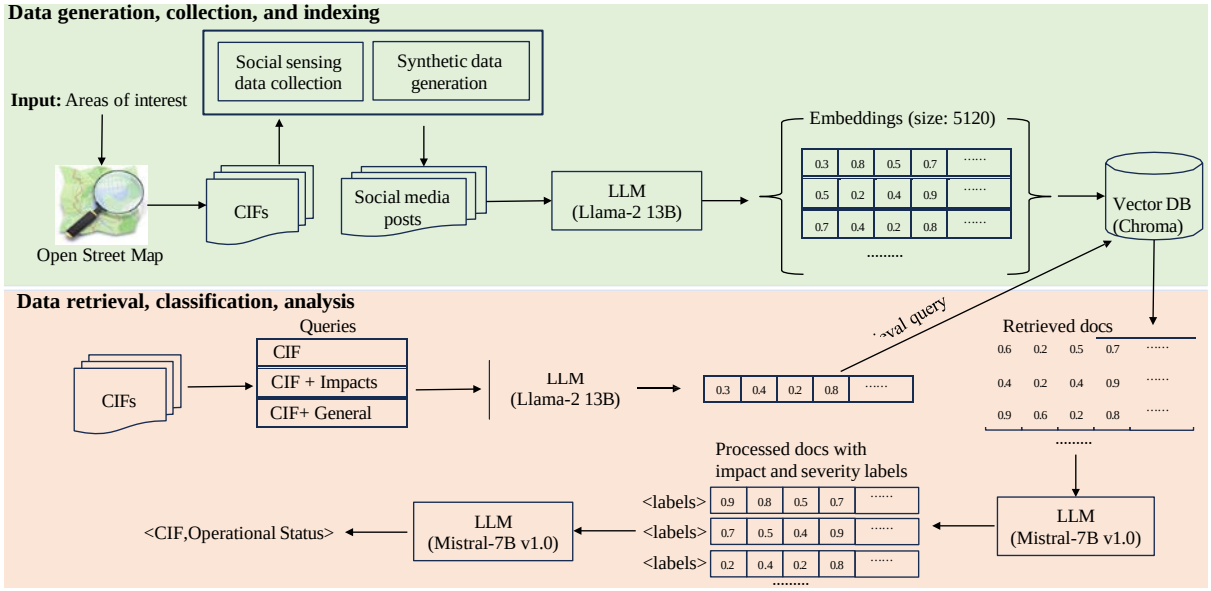

Figure 1. High-level methodology detailing two pipelines: *(i)* data generation, collection, and indexing, *(ii)* data retrieval, classification, and analysis

With the emergence of pre-trained LLMs such as GPT3.5 (Brown et al., 2020), GPT4 (OpenAI et al., 2023), Llama2 (Touvron et al., 2023), Mistral 7B (Jiang et al., 2023), more versatile capabilities have become available for research. For instance, Colverd et al. (2023) has recently studied the use of LLMs for generating flood disaster impact reports via a system initiated by a search query phrase, which is then utilized to gather textual data about the disaster from the web. Another recent use of LLM is geotagging of tweets where few-shot learning is utilized for identification of various location descriptors in tweets such as door number addresses, road segments, and road intersections (Hu et al., 2023).

Inspired by this trend, we capitalize on an LLM for real-time monitoring of critical infrastructure facilities (CIFs) during disasters by classifying their situations in three crucial aspects including the type of impact, its severity, and the operational status. Additionally, to compensate for lack of a publicly available dataset with situational information about CIFs, we again revert to an LLM for its generative capabilities to create synthetic data to test our CIF monitoring pipeline.

METHODOLOGY

Overview

The primary objective of this work is to perform real-time monitoring of various Critical Infrastructure Facilities (CIFs) amidst large-scale disaster scenarios. Specifically, we aim to obtain three types of updates for each CIF in the given area of interest, including *(i)* identifying the disaster impact (e.g., damaged, burned) to the CIF, *(ii)* assessing the severity of the impact (e.g., moderate, severe) and *(iii)* determining the operational status of the facility (e.g., closed, partially closed, or open). We employ social sensing data from social media platforms, harnessing its capability to potentially deliver immediate updates, potentially from eyewitnesses or people possessing any relevant information.

Figure 1 depicts the high-level methodology comprising two pipelines: *(i)* data collection and indexing, and *(ii)* data retrieval and processing. The data collection and indexing pipeline performs tasks related to data acquisition, synthetic data generation, embedding generation, and indexing. The pipeline for data retrieval and processing focuses on retrieving pertinent data from the embedding database. Subsequently, the retrieved data are analyzed through LLMs to identify the impact, severity, and operational status of CIFs. Next, we provide detailed descriptions of the important processes of the methodology.

Obtaining CIFs

We utilize Nominatim APIs2 from Open Street Map (OSM) (OpenStreetMap contributors, 2017) to retrieve information about CIFs within a specified geographical area of interest (AOI). In this work, we focus on two regions

2https://nominatim.openstreetmap.org/

prone to natural disasters: Christchurch, New Zealand, susceptible to earthquakes, and Broward County, Florida, USA, susceptible to hurricanes. We note that for both AOIs we also have Twitter data previously collected from these locations during past disasters. To extract CIF data for these AOIs, we construct queries that include the AOI name and the type of infrastructure, including hospitals, fire stations, rail stations, educational facilities, bridges, roads, and tunnels. Example queries include "Christchurch hospitals," "Christchurch fire stations," etc. Employing this approach, we gathered 58 CIFs from Christchurch and 82 CIFs from Broward County, along with associated metadata such as names, addresses, and geographic coordinates.

Data Curation: Real and Synthetic

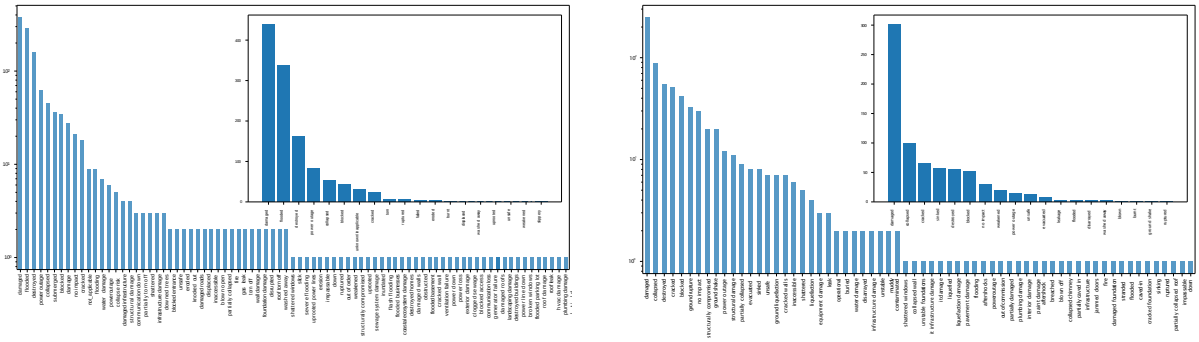
Social media data about CIFs is central to our study. However, to the best of our knowledge, there is no publicly available social media data containing tagged CIFs and their associated impacts, severity, and operational statuses. To address this gap, we leverage generative AI to create synthetic data (i.e., tweets) that include real-world CIFs from our selected AOIs. In particular, we utilize the open-source Llama-2 13B model (Touvron et al., 2023) to generate tweets reporting diverse impact scenarios on CIFs retrieved from OSM. Moreover, for each generated tweet, we ask the model to provide the reported impact along with its corresponding severity labels. The specific prompt employed for tweet generation for Broward County is as follows:

> *Generate 15 diverse tweets describing the impact of a Category-5 hurricane on [CIF NAME & ADDRESS]. The disaster triggered sub-events such as tornado, storm surge, burst of rain, strong winds, resulting in varied impacts like flooded, collapsed, submerged, damaged, destroyed, cracked, etc.*
>
> *Ensure linguistic diversity in each tweet, providing unique insights into the impact and its severity. In some tweets, include the infrastructure's address. Aim for tweet lengths between 100 to 250 characters, and avoid using emojis. Tag each tweet with the type of impact (e.g., damaged, destroyed) and its severity (e.g., low, mild, severe). These tags will be used for training classifiers.*
>
> *Always include 2 tags at the 'end' of the generated tweet with the following template: (Tags: ***** , *****)*

For instance, the response returned by the LLM for CIF *"Aventura Hospital and Medical Center & 20900, Biscayne Boulevard, Aventura, Miami-Dade County, Florida, 33180, United States"* looks as follows (showing first three tweets for brevity):

> *Aventura Hospital's emergency room is flooded after a burst of rain caused by the Category 5 hurricane. Patients and staff are being evacuated to safer areas. (Tags: Flooded, Mild)*
>
> *Strong winds from the hurricane have caused significant damage to Aventura Hospital's roof and windows, leaving many areas closed off to patients and staff. (Tags: Damaged, Severe)*
>
> *The storm surge from the hurricane has submerged the lower levels of Aventura Hospital, forcing patients and staff to be evacuated to higher floors. (Tags: Submerged, Severe)*

A similar prompt is used for Christchurch where the first paragraph is adapted for an earthquake scenario as follows:



> *Generate 15 diverse tweets describing the impact of a severe earthquake on Christchruch's [CIF NAME & ADDRESS]. The disaster triggered sub-events such as ground shake, landslide, liquefaction, ground rupture, aftershock, resulting in varied impacts like collapsed, cracked, damaged, destroyed, etc.*

Subsequently, we utilize the same LLM employed for tweet generation to assign an operational status label to each generated tweet. The model is restricted to select one of four operational statuses: "open," "closed," "partially open," "partially closed," and "unknown" if no operational status is explicitly mentioned in the tweet. The prompt to obtain the operational status is as follows:

> *Your task is to analyze the provided tweet and determine the operational status of the mentioned infrastructure. The operational status could include descriptors such as open, closed, partially open, partially closed, or unknown.*
>
> *Tweet: [TWEET]*
>
> *Operational status:*

A sample response from the above prompt for the tweet *"The computer lab at Christchurch Girls' High School has been closed due to a collapsed ceiling. Students are using temporary facilities until further notice. #ChristchurchEarthquake"* is as follows:

> *Operational status: closed*

(a) Broward County (b) Christchurch

Figure 2. Distribution of impact labels in the synthetic data for (a) Broward County and (b) Christchurch. The outer charts with light blue bars correspond to the LLM-generated raw tags whereas the overlaid smaller charts with dark blue bars show the manually pruned ground-truth tags.

In total, we generated 728 tweets for Christchurch for 58 CIFs and 1,205 tweets for Broward County against 82 CIFs. Although instructed, the model does not always generate 15 tweets for each CIF. Tweets with incorrect tags/labels were manually corrected. As we did not control the prompt to enforce a closed-set of impact types, the resulting list of impact tags is open-ended (N=83), which also allowed for more diversity in the generated tweets. Figure 2 shows the distribution of the resulting tags for each AOI. We noticed multiple similar impact labels (e.g., flooded, flooding, inundated, etc.) in the model responses, which we merged into a unified list of tags, as illustrated in Table 1. The sub-figures in Figure 2 depict the distribution of the refined tag list. Note that, unlike impact tags, we utilized a closed-set of tags for classification of severity (i.e., severe, moderate, mild, and unknown) and operational status (i.e., open, closed, partially open, partially closed, and unknown).

Later, for each CIF, we dispersed its generated tweets across four six-hour time intervals (spanning a 24-hour time frame) by considering their impact order (e.g., "destroyed" followed by "damaged" or "cracked" and so on). The impact ordering ensures a coherent progression of the impact to a CIF. This step is crucial for simulating a real-world setting in our subsequent experiments. Moreover, given that several past studies highlight the prevalence of noise and the limited relevant information in real-world tweets (Grace, 2021; Kumar et al., 2017), we aim to ensure the realism of our dataset. To achieve this, we introduce noise into our generated data with a signal-to-noise ratio of 2% (signal) to 98% (noise). For this purpose, we incorporated tweets collected during past disasters for both AOIs. Specifically, for Christchurch, we used tweets collected after a magnitude-7.1 earthquake struck New Zealand on September 2nd, 2016. For Broward County, we utilized tweets collected after Hurricane Ian hit Florida in September 2022. In total, we prepared 36,286 and 60,062 tweets (including both synthetic and real) for Christchurch and Broward County, respectively. To ensure that CIFs also appear in non-impact tweets, we injected CIF names into 8% of the noisy tweets in each time interval.

Finally, to assign an overall status for a CIF within each time interval, we deduce its operational status. To achieve this, we chronologically order tweets for a CIF and use the operational status of the last tweet as an overall status. If the operational status of the last tweet is "unknown", we use the last valid status.

Generating and Indexing Tweet Embeddings

Next, we employ Llama-2 13B (Touvron et al., 2023) to compute embeddings for all the tweets, including synthetic and real. Each tweet is converted into a 5120-dimensional embedding vector which is the default embedding size of Llama-2 13B. This embedding is then indexed into ChromaDB[3], a well-known open-source vector database. These embeddings serve as the basis for semantic search, enabling the retrieval of tweets specifically mentioning certain CIFs.

Retrieval of CIF Tweets

The first step in determining the impact and operational status of a CIF involves retrieving tweets referencing a specific CIF. To achieve this, we explore three types of retrieval queries: *(i)* a query comprising only the CIF name, *(ii)* a query involving both the CIF name and a set of impact terms such as damaged, cracked, burned, destroyed, submerged, and *(iii)* a query combining the CIF name with the term "disaster impacts." For each query, we first

3https://www.trychroma.com/

Table 1. Raw impact labels and their mapping to final impact taxonomy for LLM-based classification

Consolidated labels	Raw model labels
damaged	aftershock damage, damage, damaged, broken windows, damaged infrastructure, damaged roads, damaged roofs, damaged walls, electrical damage, coastal ecosystem damage, foundation damage, landscaping damage, exterior damage, hvac damage, infrastructure damage, roof damage, plumbing damage, sewage system damage, structural damage, wall damage, water damage, equipment damage, damaged foundation, interior damage, IT damage, liquefaction damage, partially damaged, pavement damage, plumbing damage, IT infrastructure damage, equipment damage, paint damage
flooded	flooded basement, flooded businesses, flooded parking lot, flooding, severe flooding, flash flooding, submerged, inundated
destroyed	destroyed, destroyed buildings, destroyed homes, rubble
weakened	weakened, structurally compromised
cracked	cracked, shattered, shattered windows, debris, cracked wall, cracked walls
blocked	blocked access, blocked entrance, impassable, obstructed, clogged sewage, inaccessible, partially blocked, landslide, jammed doors
torn	partially torn off, roof torn off
power outage	power line down, power loss, power outage, power down, communication down, communication loss, down, knocked out, disrupted, downed trees, offline
ruptured	blown open, gas leak, roof leak
collapsed	partially collapsed, collapsed, crushed, collapse risk, collapsed wall, collapsed chimney, partially collapsed roof
failed	generator failure, ventilation failure, out of order
uprooted	uprooted, uprooted power lines
eroded	eroded, erosion
washed away	washed away, muddy
slippery	slippery, slick
displaced	displaced
blown	blown, blown off
burnt	burnt, burning, fire
unsafe	unsafe, unstable, structurally compromised, uninhabitable, contaminated
leakage	leak, gas leak, gasleak
sinked	ground liquefaction, liquefaction, buried, sinked, sinking, caved-in, ground rupture, liquefied
unknown/inapplicable	not applicable, not humanitarian, no impact, unknown

obtain its embeddings from the Llama-2 13B model and subsequently retrieve the top-K (ranging from 5 to 50 with a step size of 5) tweets by querying ChromaDB using cosine similarity.

Top-K results for each query are then used to compute Average Precision (AP) using Equation (1).

$$\text{AP@}K = \frac{1}{\text{GTP@}K} \sum_{\substack{k=5n \\ 1 \le n \le N}} \text{P@}k \times \text{rel@}k, \text{ for } K = 5N \text{ and } N = \{1, \ldots, 10\} \tag{1}$$

where

$$\text{P@}k = \frac{\text{Number of relevant documents retrieved @}k}{k}$$

$$\text{rel@}k = \begin{cases} 1, & \text{if } k^{th} \text{ document is relevant} \\ 0, & \text{otherwise} \end{cases}$$

$$\text{GTP@}K = \min(K, \text{Total number of relevant documents})$$

In Equation (1), we normalize the total sum by the number of 'retrievable' ground-truth documents or *signals* (i.e., Ground Truth Positive or GTP). Finally, to determine the overall retrieval performance of a given query, we

compute mean Average Precision (i.e., mAP) in a time interval $t \in$ {0h-6h, 6h-12h, 12h-18h, 18h-24h, 0-24h} using Equation (2).

$$\text{mAP@}K^t = \frac{1}{M}\sum_{i=1}^{M} \text{AP@}K_i^t \text{, for } K = 5N \text{ and } N = \{1, \ldots, 10\} \quad (2)$$

Tweet Classification for Impact, Severity, and Operational Status

We employ the Mistral 7B v1.0 model (Jiang et al., 2023) for classifying the retrieved tweets that are identified as relevant by the CIF queries. These tweets are likely to encompass information about impacts experienced by critical facilities. To perform the impact and severity classification of each tweet, we use the following prompt template:

> *Your task is to analyze the provided tweet and determine the impacts of the disaster on the mentioned infrastructure. Please include only impact descriptors from the list such as blocked, blown, buried, burnt, collapsed, cracked, damaged, destroyed, displaced, disrupted, eroded, failed, flooded, ground liquefaction, ground shake, leakage, muddy, power outage, ruptured, slippery, torn, unsafe, uprooted, washed away, weakened or not applicable, and severity such as severe, mild, moderate, unknown.*
>
> *Tweet: [TWEET]*
>
> *Infrastructure impact:*
> *Infrastructure severity:*

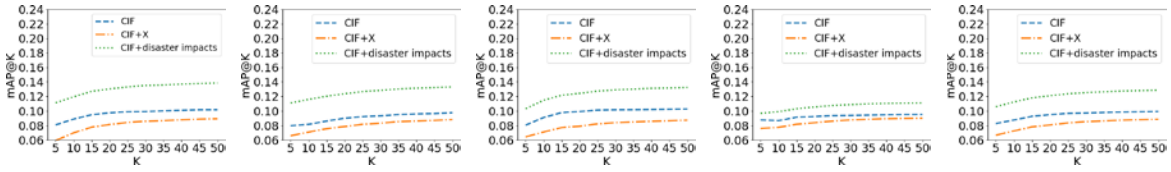
The response returned by the model to an example tweet such as *"The Christchurch Public Hospital's radiology equipment is malfunctioning due to the earthquake, making it difficult to diagnose patients. #ChristchurchEarthquake"* looks as follows:

> *Infrastructure impact: damaged*
> *Infrastructure severity: moderate*

Finally, tweets that are tagged with an impact type are further analyzed to infer the operational status of CIFs. For this purpose, we use the Mistral 7B v1.0 model with the following prompt:

> *Your task is to analyze the provided tweet and determine the operational status of the mentioned infrastructure. The operational status could include descriptors such as open, closed, partially open, partially closed, or unknown.*
>
> *Tweet: [TWEET]*
> *Operational status:*

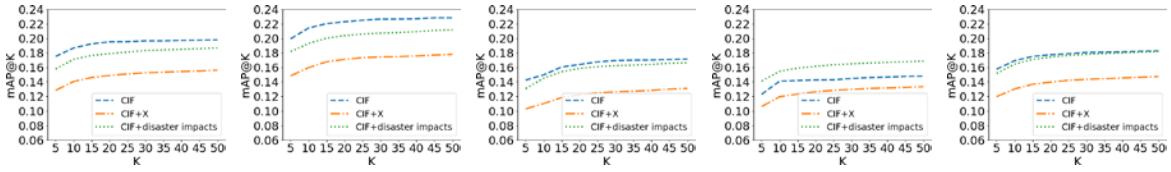
The response returned by Mistral 7B v1.0 model to an example tweet such as *"Ground shake from Christchurch earthquake caused significant damageto Wigram Fire Station's foundation, rendering it unstable. #ChristchurchEarthquake"* looks as follows:



> *Operational status: closed*

To evaluate the performance of impact, severity, and operational status classification, we compare the labels predicted by the Mistral 7B model with the ground-truth labels obtained from the Llama-2 model and report results using standard evaluation metrics such as precision, recall, and F1-score.

Obtaining Overall Operational Status of CIFs



The last step in the tweet classification and analysis pipeline involves extracting the overall operational status of tweets retrieved through a CIF query. The set of tweets resulting from a CIF query may encompass information about the queried CIF, but these tweets may vary in terms of containing impact-related details. Therefore, to determine the overall operational status of a CIF at a specific time, we only consider tweets containing impacts (relying on the impact labels obtained in the previous step). To achieve this, we employ the Mistral 7B v1.0 model with the following prompt to retrieve the overall status.

> *Your task is to analyze the tweets given below and deduce the operational status of a facility, named [CIF]. Since these tweets are retrieved based on the facility name, it's possible that some tweets may not pertain to the given facility. Focus solely on the tweets pertinent to [CIF] and derive the most recent operational status for the facility. Your operational status label must be one of these: open, closed, partially open, partially closed, or unknown.*
>
> *Tweet: [TWEET 1]*
> *Tweet: [TWEET 2]*
> *Tweet: [TWEET 3]*
> *...*
>
> *operational_status:*

Figure 4. Performance comparison of retrieval queries for Christchurch

RESULTS

In this section we present our results for the retrieval and classification tasks described in the Methodology section.

Retrieval of CIF Tweets

For each AOI, we considered three types of queries to fetch relevant tweets pertaining to each CIF:

(i) *CIF* — a query comprising only the CIF name

(ii) *CIF + X* — a query involving both the CIF name and a set of impact terms such as damaged, cracked, burned, destroyed, submerged, etc. (denoted as X for brevity)

(iii) *CIF + disaster impacts* — a query combining the CIF name with the term "disaster impacts"

Specifically, for Broward County *X* comprises *flooded, submerged, damaged, destroyed, weakened, cracked, blocked, torn, power outage, ruptured, collapsed, failed, uprooted, eroded, burnt, washed away, slippery, displaced, disrupted* whereas for Christchurch it consists of *flooded, destroyed, leak, blocked, cracked, ground liquefaction, power outage, ruptured, buried, collapsed, ground shake, unsafe, muddy*.

We also experimented with K to assess its effect on the retrieval performance. That is, we ran queries for top-K where we changed K from 5 to 50 with a step size of 5. We then computed the overall mAP@K in each time interval using Equation (2) to evaluate the overall performance of each query type. Figures 3 and 4 show the performance plots for all query types across different K values and time intervals for Broward County and Christchurch, respectively. The plots initially show an increasing trend in performance with increasing K but the performance improvement generally slows down after $K = 30$. For Broward County, *"CIF + disaster impacts"* queries outperform the other queries by a big margin whereas for Christchurch *"CIF"* queries hold a slight edge over the other queries in the six-hour time intervals but perform only on par with *"CIF + disaster impacts"* in the 0h-24h time interval.

Tables 2 and 3 summarize the mAP@K scores for $K = 50$ for Broward County and Christchurch, respectively. Again we observe that the scores for the *"CIF + disaster impacts"* queries are highest in all time intervals for Broward County whereas *"CIF"* and *"CIF + disaster impacts"* queries perform on par for Christchurch. However, it is important to note that, for both AOIs, *"CIF + disaster impacts"* queries retrieve the highest number of relevant tweets among all query types in 0h-24h time interval, i.e., 534 out of 1205 relevant tweets in Broward County and 402 out of 728 relevant tweets in Christchurch. Therefore, we conclude that *"CIF + disaster impacts"* query type yields the best overall retrieval performance, and hence, we use it as the default query type in the proposed pipeline.

We note that the resulting mAP scores are generally low and the effective hit rate (i.e., ratio of relevant retrieved tweets to total number of retrieved tweets) is only slightly above 3% for both AOIs. To investigate this further, we color coded and plotted the distribution of relevant and irrelevant tweets in Figure 5. We additionally sub-divided irrelevant tweets belonging to either noise or other CIF that we generated. From Figure 5, we observe that although a large portion of the distribution for each CIF contains irrelevant tweets, a significant portion of irrelevant tweets is

Table 2. Retrieval performance (mAP@50) of the Broward County queries

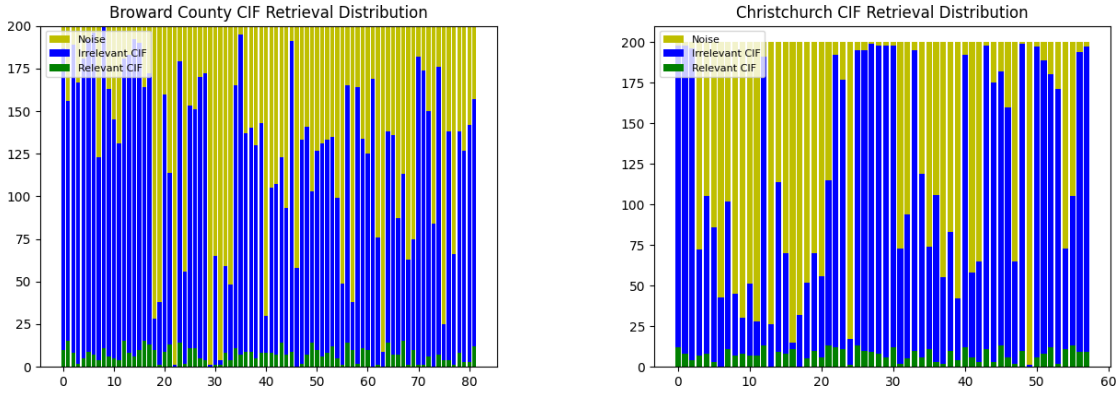
	Time Intervals					
Queries	0h–6h	6h–12h	12h–18h	18h–24h	0h–24h	Y
CIF	0.102	0.098	0.103	0.095	0.099	303
CIF + X	0.089	0.088	0.087	0.090	0.089	484
CIF + "disaster impacts"	**0.139**	**0.133**	**0.133**	**0.111**	**0.129**	**534**

X = flooded, submerged, damaged, destroyed, weakened, cracked, blocked, torn, power outage, ruptured, collapsed, failed, uprooted, eroded, burnt, washed away, slippery, displaced, disrupted
Y = Number of relevant tweets retrieved out of 1205 in 0-24h time interval

Table 3. Retrieval performance (mAP@50) of the Christchurch queries

	Time Intervals					
Queries	0h–6h	6h–12h	12h–18h	18h–24h	0h–24h	Y
CIF	**0.198**	**0.229**	**0.172**	**0.148**	**0.183**	288
CIF + X	0.156	0.178	0.131	0.134	0.148	326
CIF + "disaster impacts"	0.187	0.212	0.167	0.169	0.182	**402**

X = flooded, destroyed, leak, blocked, cracked, ground liquefaction, power outage, ruptured, buried, collapsed, ground shake, unsafe, muddy
Y = Number of relevant tweets retrieved out of 728 in 0-24h time interval



occupied by tweets describing impacts to other CIFs and share some semantic similarity with the relevant tweet. For each query on average roughly 60% of the retrieved results belong to a certain CIF (not necessarily the correct one) and the remaining contains pure noise. Although achieving a higher hit rate is always desirable, we defer further improvements for the retrieval process to our future work.

Tweet Classification for Impact, Severity, and Operational Status

Here we compare the ground-truth impact, severity, and operational status labels obtained from the Llama-2 13B model in the dataset generation stage with the labels inferred by the Mistral 7B v1.0 model in the data analysis and classification stage. Because we do not expect the classification models to depend on a specific CIF or time interval, we evaluate the classification performance over all tweets across all CIFs and time intervals using standard evaluation metrics such as Precision, Recall, and F1-score. Table 4 summarizes the results of tweet-level impact, severity, and operational status classification for both AOIs. The results indicate that the proposed LLM-based classification models achieve reasonable performance for the task at hand. In general, the models achieve better precision than recall in all three tasks. However, the differences between precision and recall are bigger in the operational status classification task, which leads to the lowest F1-scores among all the tasks.

To take a closer look at the impact classification performance on the synthetic data, we provided confusion matrices in Figure 6. For Broward County, the most prominent impact classes such as *damaged* and *flooded* are correctly classified most of the time, but it is notable that around one third of the *flooded* tweets are classified as *damaged* (N=112). This is understandable because *damaged* class has a broader meaning and coverage that overlaps with many other impact types including *flooded*. Similarly, *blocked* (N=20), *destroyed* (N=56), and *power outage* (N=58) tweets are usually classified as *damaged*. However, the opposite is not correct, and in line with this expectation, we see much fewer *damaged* tweets getting labeled as *flooded* (N=2), *blocked* (N=13), *destroyed* (N=2), and *power outage* (N=1). We also observe that two thirds of the *unknown/inapplicable* tweets (N=20) are confused as *damaged*, which is not very desirable and needs closer investigation. For Christchurch, we observe similar trends where, as the most prominent impact class, *damaged* tweets are correctly classified most of the time (N=302), but many other impact tweets such as *blocked* (N=17), *collapsed* (N=51), *cracked* (N=55), *destroyed* (N=15), and *weakened* (N=15) are also tagged as *damaged*. Moreover, majority of the *unknown/inapplicable* tweets (N=23) are confused as *damaged* tweets. Altogether these observations suggest that it is challenging to get the Mistral 7B v1.0 model (or any other LLM for that matter) distinguish between fine-grained impact types.

We then also analyze the impact classification performance on the output of the retrieval system which contains noisy data due to imperfect nature of the retrieval process. Here we assume that ground-truth labels for the noise tweets belong to *unknown/inapplicable* class for all classification tasks. Table 5 summarizes the scores for impact,

(a) Broward County **(b) Christchurch**

Figure 5. Signal-to-noise distribution of retrieved tweets for each CIF in (a) Broward County and (b) Christchurch

Table 4. Performance scores for impact, severity, and operational status classification on the synthetic data

	Impact			Severity			Operational Status		
AOI	Precision	Recall	F1-score	Precision	Recall	F1-score	Precision	Recall	F1-score
Broward County	0.660	0.563	0.565	0.668	0.512	0.566	0.805	0.349	0.445
Christchurch	0.603	0.570	0.569	0.550	0.458	0.490	0.655	0.280	0.342

severity, and operational status classification on the retrieved tweets. These scores are higher thanks to the model's ability to correctly identify the (incorrectly retrieved) noise tweets as "unknown/inapplicable."

Figure 7 visualizes confusion matrices for further analysis of the classification results of the retrieved tweets. For both AOIs, the confusion matrices are dominated by the correctly identified noise tweets as *unknown/inapplicable* (i.e., N=4987 for Broward County and N=1178 for Christchurch). Besides, for Broward County, majority of the tweets are correctly classified as *damaged* (N=1536), *destroyed* (N=1336), *flooded* (N=1781), *blocked* (N=381), and *power outage* (N=365). However, many ground-truth *damaged* tweets were also labeled incorrectly as *torn* (N=467) or *power outage* (N=273) and many *flooded* tweets as *damaged* (N=308) or *power outage* (N=285). Whereas for Christchurch, while *damaged* (N=252), *destroyed* (N=90), *collapsed* (N=108), and *blocked* (N=47) tweets are classified correctly in general, we see that most *cracked* tweets were confused as *damaged* (N=84) and *damaged* tweets as *collapsed* (N=34). We also see that impacts such as *burnt, ruptured, uprooted, sink,* and *weakened* are oftentimes misclassified. Another interesting observation is that so many tweets are classified (incorrectly more than half of the time) as *power outage* in Broward County whereas almost no tweet gets classified as *power outage* in Christchurch.

Overall Operational Status Classification of CIFs

Tweets retrieved with the impact labels were processed using Mistral 7B v1.0 to infer the overall operational status of a target CIF. The results are provided in Table 6. While exhibiting a reasonable precision, the model struggled with the recall. This could be due to the retrieval process, which incorporates messages from other CIFs and noise. Even though we mitigated the noise by focusing solely on impact-related messages, messages about other pertinent CIFs still pose a challenge for the model.

DISCUSSION

Besides illustrating the opportunities LLMs have to offer for real-time monitoring of CIFs by analyzing social media data during disasters, this study also reveals various challenges to be tackled along the way. For instance, an important challenge is how to instruct LLMs to generate a realistic timeline of short messages (i.e., tweets) about CIFs during disasters that are coherent and consistent both spatially and temporally. Another important challenge is how to guide LLMs to eliminate irrelevant messages successfully in the retrieval process. Yet another important challenge is how to prompt LLMs in a zero-shot setting to discern fine-grained details about disaster impact types and severity affecting CIFs as well as to infer the operational status of CIFs from a set of impact and severity reports.

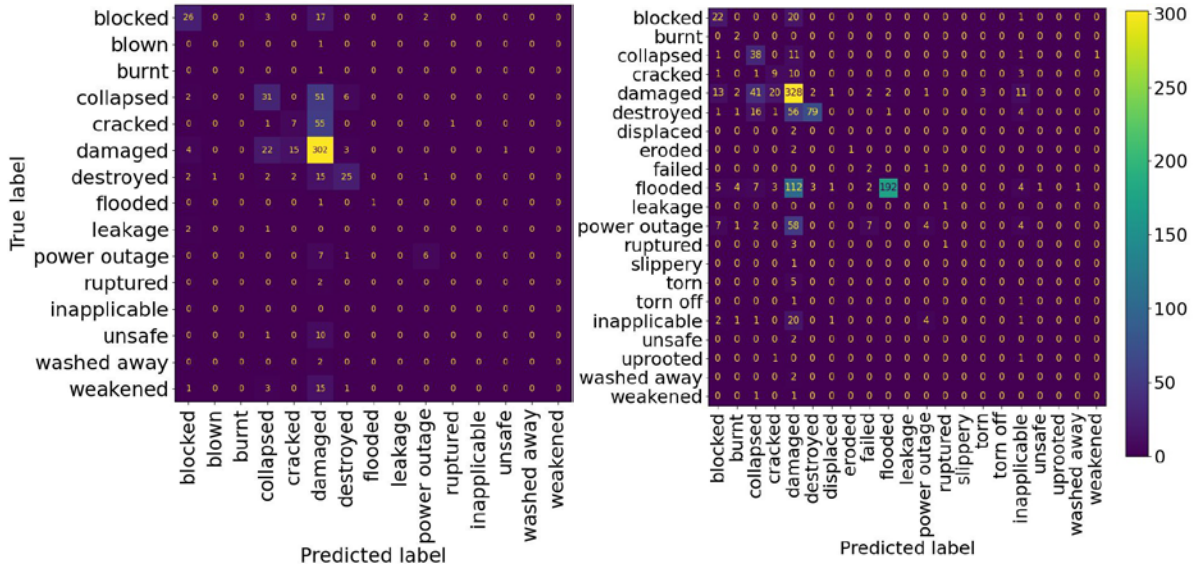


Figure 6. Confusion matrices for all signal impact classification (left) Broward County and (right) Christchurch

Table 5. Performance scores for impact, severity, and operational status classification on the retrieved tweets

	Impact			Severity			Operational Status		
AOI	Precision	Recall	F1-score	Precision	Recall	F1-score	Precision	Recall	F1-score
Broward County	0.821	0.747	0.769	0.687	0.6445	0.6442	0.517	0.352	0.399
Christchurch	0.841	0.805	0.777	0.817	0.794	0.797	0.919	0.779	0.809

On the data side, we opted for open-ended generation of impact types. This allowed us to generate a quite diverse set of fine-grained impact types (N=83), a property sought by stakeholders to make key decisions. However, this strategy also resulted in a long-tail distribution of impact types where the generic *damaged* became the most prominent impact type by a large margin while more than two thirds of the impact types appeared only once or twice in the entire dataset (see Figure 2). An alternative strategy could be to impose more control over the distribution and ask LLM to generate tweets for a specific impact type at a time (potentially at the expense of reduced diversity).

On the retrieval side, our current approach experienced difficulty in eliminating the irrelevant content for some CIFs more than others (see Figure 5). This could be attributed partly confusing nature of similar CIF or partial/shortened CIF names and partly to weaknesses of the retrieval method employed. In future studies, we plan to explore more sophisticated retrieval techniques.

On the classification side, we observed weaknesses of LLMs in distinguishing granular details about disaster impact types as analyzed through confusion matrices in Figures 6 and 7. There is also the fact that there are multiple correct answers many times and formulating the problem as a single-label classification becomes problematic as illustrated by the examples below:

> *Case 1: The Category 5 hurricane has caused significant damage to the South Area Alternative School's electrical system, leaving the building without power. The school's future is uncertain.*
>
> *Llama-2 13B (ground truth): Power outage*
> *Mistral 7B v1.0 (classified): Damaged*
>
> *Case 2: The hurricane has caused a tree to fall on top of a building near Broward Health Imperial Point, causing significant damage and blocking access to the hospital.*
>
> *Llama-2 13B (ground truth): Damaged*
> *Mistral 7B v1.0 (classified): Blocked*
>
> *Case 3: The University of Florida Field Laboratory's interior is flooded, causing significant damage to research equipment and infrastructure. The facility is closed indefinitely.*
>
> *Llama-2 13B (ground truth): Flooded*
> *Mistral 7B v1.0 (classified): Damaged*

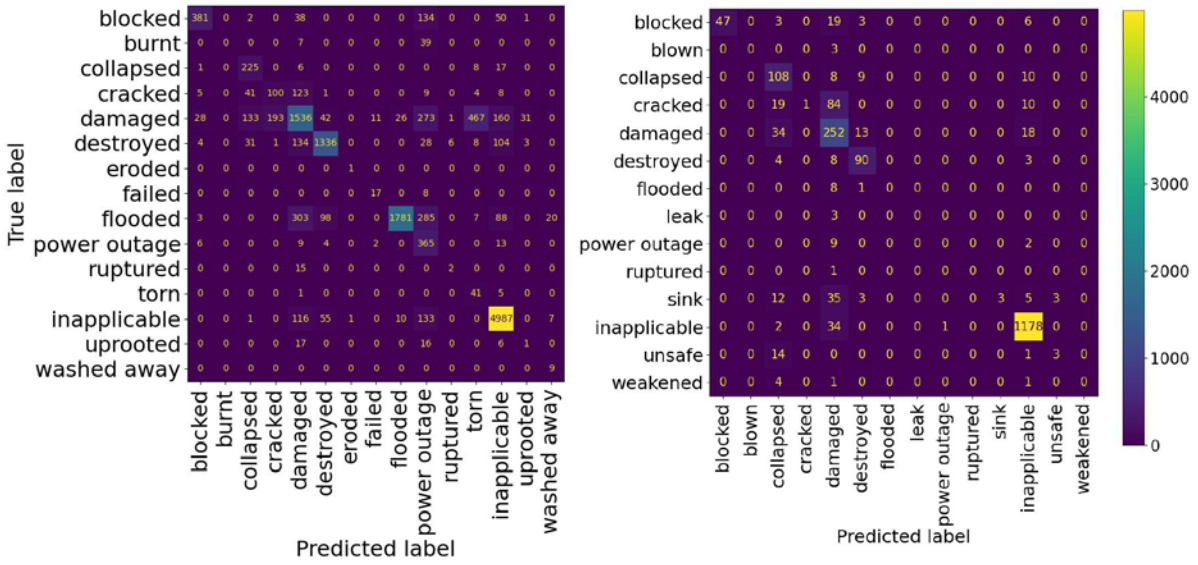

Figure 7. Confusion matrices for impact classification of retrieved tweets (left) Broward County and (right) Christchurch

Table 6. Performance scores for overall operational status classification on the retrieved results

	Overall Operational Status		
AOI	Precision	Recall	F1-score
Broward County	0.522	0.305	0.216
Christchurch	0.470	0.248	0.197

Case 4: Honey Hill Fire Station's front entrance crushed by fallen tree. Emergency responders working to clear debris and reach those trapped.

Llama-2 13B (ground truth): Collapsed
Mistral 7B v1.0 (classified): Blocked

In all cases, both ground-truth and classified labels seem reasonable with subtle differences stemming from how each LLM interprets the overall situation.

Among all the tasks performed by LLMs, the most challenging proved to be inferring the overall operational status of a CIF. Given that the retrieval process may include messages that are semantically akin to a CIF query, potentially encompassing both, messages about other CIFs and noise, the model tends to face confusion when deducing the overall operational status. We remark that enhancing the retrieval process will significantly improve the performance of the inference task.

LIMITATIONS AND FUTURE WORK

In this section, we describe the biases and limitations of this study. Our main source of bias comes from the dataset utilized in this study. Due to the unavailability of real-world curated datasets describing impacts to CIFs, we utilized Llama-2 13B to generate the relevant tweets as well as the matching labels. In Figure 2, we note that the distributions of impacts generated by Llama-2 13B mainly cover broader impacts such as *damaged, destroyed, flooded and collapsed*. Although Llama-2 13B also generated fine-grained impacts such as *shattered windows, ruptured pipe, HVAC damage and muddy road etc*, such distribution might not be representative of the distribution of impacts in real-world disaster. Likewise, the class/label imbalance in the dataset also limits us from fully accessing the capabilities of Mistral 7B v1.0 for the classification of various low-frequency classes. Moreover, the progression of impacts to CIFs in 24-hour time window was done by manually assigning the precedence of impacts to a CIF by the authors. This in part is also a bias that could have affected the prediction of the overall operational status performed in this study.

Among the limitations, the most predominant ones are the language usage, the choice of LLM models and the nature of disasters selected for this study. Unlike real-world tweets, the synthetic tweets generated by Llama-2 13B

were free from any typos, slang or grammatical errors. This study, therefore, does not fully assess the sensitivity of LLM-based classification to such inconsistencies. Moreover, we limited the type of disasters as well the choice of AOI used in this study to only two. This significantly limits the vocabulary of impacts as well as the nature of the content of the tweets in the generated dataset. The choice of AOI used, i.e., Christchurch and Broward County, also resulted in the generation and classification of only English medium tweets.

Likewise, this study is also limited to one particular LLM for the data generation i.e., Llama-2 13B and another LLM for the classification task i.e., Mistral 7B v1.0. Therefore, further analysis of the quality of data generation and classification of crisis-relevant tweets by other LLMs is deferred to our future work.

CONCLUSION

In this study, we investigated the application of Large Language Models to monitor the operational status of critical facilities in an area during large-scale disasters. We utilized social sensing data (both synthetic and real-world) from X (formerly Twitter) for two distinct locations and performed their analysis using LLMs for various computational tasks, including retrieval, classification, and inference. The outcomes are presented using standard evaluation metrics and further discussed to highlight the strengths and weaknesses of LLMs. In summary, we emphasize that the use of LLMs in the zero-shot setting, as compared to supervised models requiring training data, demonstrates reasonable performance. However, challenges arise for LLMs when dealing with complex contextual information provided through lengthy prompts. Additionally, we outline various future directions that we anticipate to be beneficial for the community to build upon.

ABSTRACT

Social media and online platforms play an important role in assessing the impact of a natural disaster, especially in the immediate aftermath of the event. The information from social media demonstrated the potential to accelerate the response to a crisis. Locating social media images is critically important to help the victims immediately, mobilize community support, and provide enhanced situational awareness. However, finding the location of relevant social media images still challenges humans and computational processes.

This study introduces a social media image classifier aimed at enhancing crowdsourced geolocation. The model is trained using data annotated by experts in disaster risk management. Its main goal is to reduce the difficulty of geolocating images by detecting those that are "easy" to geolocate. We combined the classifier with an ad-hoc crowdsourcing platform and tested it with pictures posted during a crisis. The experimental results indicate that the proposed approach speeds up the geolocation process of social media images while increasing the level of location precision

Keywords

Social media, geolocation, disaster management

INTRODUCTION

Data from social media demonstrates the ability to facilitate quicker response in crisis situations. In 2020, the Joint Research Center European Commission activated a social media analysis to understand the Beirut explosion. Their work proposes a framework to strengthen the use of social media for crisis management that could complement the current Copernicus Mapping service in the initial phases of the crisis. Further developments aim at the automated

*corresponding author

detection of relevant media, their localization and classification providing an initial impact assessment starting from a few moments after the disaster 1. Despite usefullness of social media data in previous example, employing data from social media to evaluate the damage introduces significant challenges. For privacy concerns, major social media platforms remove the meta information about locations by default. Out of millions of posts on Twitter, one of the most used platforms by researchers, only up to 3% are geolocated by users (Huang and Carley, 2020). Furthermore, identifying the location of relevant photos with evidence of damage to organize the first response efficiently presents a challenge. While several techniques have been proposed to automatically geolocate social media content, including images (e.g., Murgese et al., 2022) and text (e.g., Scalia et al., 2022), their predictions need to be more precise to enable their use by practitioners in the field. Combining automatic geolocation with crowdsourcing offers a valuable solution to this problem, with the former providing a preliminary location estimate and the latter being used to enhance the level of precision of that location. The geolocation is then pinpointed on a map to visualize the affected areas. The actual goal of extracting location from social media images is to create a disaster map that could help the first responders locate the events seen on posted images.

Thanks to the combination of Crowdsourcing and Artificial Intelligence methods, this research aims to reduce the overall time of geolocating social media images posted from regions impacted by a crisis and increase the geolocation precision. To pursue the objective, we decrease the difficulty of geolocating images by selecting easy-to-geolocate images. The study leverages past research activities on social media images for the disaster risk management domain to support emergency response as a framework (Rufolo et al., 2021), a platform (Lorini, Panizio, and Castillo, 2022), and a disaster map (Lorini, Rufolo, and Castillo, 2022).

The remainder of the paper is organized as follows: First, we discuss related work and research gaps. Second, we describe our dataset and experiment method based on the research gaps and present the methods we followed to shorten the research gaps and detail the experiments that demonstrate the validity of our approach. Then, we report the experimental results with social media data from four disaster events. Finally, last section concludes this work and provides future research directions.

RELATED WORK

Geolocation prediction on social media involves linking an entity, like images or posts, to a specific location with a high level of accuracy. This process can pinpoint locations ranging from a street level to city or country-wide areas. In recent years, the scientific community has shown a growing interest in using social media geolocation for disaster management research. Various studies have adopted methods using images, text, and combined approaches to improve the accuracy of geolocation identification.

In an image-based approach,(Murgese et al., 2022) proposed a solution to estimate images' locations by implementing Focal Modulation Networks for predicting the geolocation. The authors used geolocated images from Flickr2 and Mapillary3 to evaluate the proposed approach. Mapillary is an open-source map that provides street-level scenes. The focus of the study was the Barcelona City, Spain. Around 70% of Mapillary data, which had street-level imagery similar to Google Street View, was successfully pinpointed at neighborhood level. However, the proposed approach did not use social media data, and the precision of geolocation prediction was limited to the neighborhood level.

A multimodal (combining visual and textual features) approach was introduced by (Tahmasebzadeh et al., 2023). In the work, the author predicted the geolocation of news photos. To implement the approach, the authors also introduced a new dataset called Multimodal Geolocation Estimation of News Photos (MMG-NewsPhoto). The work demonstrated that the multimodal approach outperformed the unimodal.

Related works on text-based geolocation use several approaches, for instance, Named Entity Recognition and Location Indicative Words, to infer the geolocation candidate (Utomo et al., 2018). For example,(Middleton et al., 2018), implemented the Named Entity Recognition algorithm to predict geolocation from social media data. In the experiment, they used Twitter4 and Flickr as the experimental dataset. The works were evaluated qualitatively and quantitatively. However, the experimental result demonstrated low results with a high radius from the location.

Another technique called Location Indicative Words, adopted by (Han et al., 2012), used a dataset of cities in the experiment. They developed and evaluated the approach on the English dataset. The experimental result demonstrated that the feature selection improved information gain and outperformed state-of-the-art geolocation prediction methods by 10.6% in terms of accuracy. Also, the result showed the mean and median of prediction error distance by 45 km and 209 km. Despite the innovative technique, the precision deviation was still high.

1https://publications.jrc.ec.europa.eu/repository/handle/JRC124081
2https://www.flickr.com/
3https://www.mapillary.com
4https://twitter.com

In a recent study,(Scalia et al., 2022) proposed a context-aware approach to geolocate emergency-related social media posts. The system implemented post metadata and post network of relationships. The experimental results showed that around 35% of images geolocation inferences were within a 500-meter radius from the ground-truth location. About 62% of images were predicted within 12 km. However, the results still had a high radius from the actual location.

Text-based geolocation prediction research often includes text from social media posts. The other alternative is by extracting the text from an image and using the extracted text to retrieve the location. (Firmansyah et al., 2023) proposed an automated text-extraction pipeline to predict the geolocation of an image. The work used the text in a social media image as input for a text-based geolocation prediction algorithm. The experiment incorporated 1,752 images curated from four different disasters in the world (Croatia Earthquake, Catania Floods, Central Europe Floods, and Haiti Earthquake). The experimental results demonstrated that the number of original images that could be successfully geolocated within the bounding boxes (affected area) varies between 9% and 11% of the original dataset, depending on the geolocation algorithm used. However, the work was still in the preliminary phases and had a country-level precision.

In a hybrid technique, (Ravi Shankar et al., 2019) introduced a platform called Crowd4EMS. This platform collects, analyzes, and geolocates social media information by combining crowdsourcing and automatic methods. They used data related to the Amatrice Earthquake in 2016 to evaluate the platform, coming from Flickr, Twitter, and Youtube. The work demonstrated that the suggested approach could better support the crowdsourcing communities in providing high-precision geolocation in the context of disaster response. However, the work also shows that crowdsourcing the geolocation of social media images is a complex and time-consuming task, which produces unpredictable delays that could prevent the information from being available in the immediate aftermath of the event.

In addressing the challenge of combining expert analytical capabilities with the scalability of crowdsourced efforts, the study introduces "GroundTruth," an online system designed to augment expert tasks with crowd participation. This system employs three distinct shared representations—a diagram, grid, and heatmap—to facilitate real-time collaboration between experts and crowds in the complex task of image geolocation, a critical process utilized by professional journalists and human rights investigators. Through a mixed-methods evaluation involving 11 experts and 567 crowd workers, the findings demonstrate GroundTruth's effectiveness in aiding image geolocation tasks, while also highlighting the interaction challenges and successful strategies between experts and non-experts. The research contributes valuable insights into the design of shared representations for enhancing visual search and sensemaking tasks, extending its implications beyond image geolocation to broader applications (Venkatagiri et al., 2019).

RESEARCH QUESTIONS

This paper proposes that the timing and accuracy of the overall geolocation process of social media posts using crowdsourcing and automatic methods can be improved by prioritizing those images deemed easy to geolocate. In this way, easy-to-geolocate images are presented earlier to the crowd, preventing delays from difficult or even impossible-to-geolocate social media posts. This process requires the implementation of an image classifier to detect the level of difficulty associated with the process of geolocating an image.

This work answers the following research questions (RQs):

- **Can the proposed classifier automatically predict the difficulty of geolocating an image?** (RQ1)
- **Does favoring images easy-to-classify improve the overall geolocation process?** (RQ2)

DATASET, METHODOLOGY, AND EXPERIMENT

This section provides an overview of the dataset and methods utilized in the experiment, followed by a comprehensive explanation of the experimental design. To answer the proposed research questions, we devised three major tasks: In the first task, images extracted from a reference dataset are presented to a crowd of domain experts that labels each image with a grade representing the difficulty level of geolocalization. To answer the RQ1 stated above, the second task aims at training a deep learning model for classification using the data annotated in the first task. Finally, the third task consists of a domain adaptation experiment where the same crowd of experts is asked to geolocate previously unseen images annotated by the model, thus answering the second research question (RQ2).

Table 1. Summary of the image geolocating results considering just the total number of geolocatable records

Records	Catania floods		EU floods		Haiti earthquake		Croatia earthquake		All datasets	
	N	%	N	%	N	%	N	%	N	%
Geolocatable	113	100	271	100	1,462	100	627	100	2,473	100
Geolocated	70	61.9	214	79	961	65.7	549	87.6	1,794	72.5
Timeout	43	38.1	57	21	501	34.3	78	12.4	679	27.5

Dataset

As a reference dataset for this research, we used the images geolocated by GIS (Geographic Information System) experts for the study EMSV070 - Reference Datasets for SM (Social Media) Image Geolocation in DRM (Disaster Risk Management) requested within the Copernicus Emergency Management Services framework. The dataset contains geolocated images and text collected during four different disasters: (1) Croatia Earthquake, 2020 (30.7%); (2) EU Floods, 2021 (3.9%); (3) Central European floods, 2021 (11.9%); and (4) Haiti Earthquake, 2010 (53.5%) (see Table 1).

Preferably, the damage in the image (flooded point, damaged building, etc.) was selected for geolocation. There are 5,430 records in the four datasets together. Of these, almost 13% (693) were repeated (non-analyzed), and about 87% (4,737) were analyzed. The details of 4,737 records were 2,264 non-geolocatable and 2,473 geolocatable. Out of 2,473 geolocatable records, we opted for 1,794 records, while 679 records were excluded because they timed out during image access.

Within the analyzed records, the non-geolocatable images were identified and discarded by GIS experts. Reasons for being considered as non-geolocatable are:

1. The URL of the image does not work, or the URLs of both the image and tweet do not work.
2. The information visible on the image does not allow its geolocation since it is a mosaic of images or a painting, or the image has bad quality (e.g., it is blurry, dark, etc.), or the image does not have visible, recognizable elements to be geolocated unless external information helps in its geolocation.
3. The image could be geolocated only at the city level.
4. The image does not correspond to any of the disaster events under study.
5. The image corresponds to regions outside of the study areas.

The geolocation was performed by GIS experts considering the following:

1. The information provided by the images themselves.
2. The text contained in the tweets.
3. The images and/or videos contained in the tweets.

Google Street View, Mapillary, Google Earth Pro, and Google Maps were used for localizing the places, recognizing the visible elements in the images, and/or for the subsequent image geolocation. Additionally, the already recognized images during the execution of the task were also considered for the geolocation of new images. Mainly, the geolocation was performed by:

1. Focusing, when possible, on the geographic information specified in the text of the tweets.
2. Selecting in the image some location relevant to the disaster event under study (flooded area or damage due to an earthquake), which was expected to be easily geolocated with the help of Google Street View or Mapillary, etc.
3. Selecting some feature/s in the image that help locate the photo the viewers used.
4. Providing the [Latitude] and [Longitude] for the selected location.

Consequently, in our work, we used images that were geolocated by the experts at least at the level of city and in 90% of cases with a precision of 10 to 100 meters. Figure 1 depicts the geolocation accuracy distribution of four different disasters.

Accuracy (m)	Catania Floods		EU Floods		Haiti Earthquake		Croatia Earthquake		All datasets	
	N	%	N	%	N	%	N	%	N	%
<10	65	92.9	173	80.8	647	67.3	532	96.9	1,417	79
<100	1	1.4	25	11.7	213	22.2	17	3.1	256	14.3
<1000	4	5.7	16	7.5	101	10.5	0	0	121	6.7
>1000	0	0	0	0	0	0	0	0	0	0
Total	70	100	214	100	961	100	549	100	1,794	100

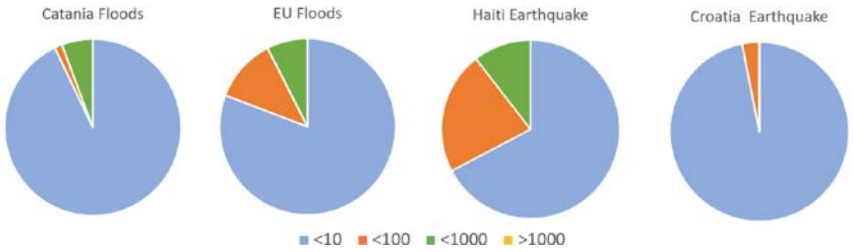

Figure 1. Distribution of the accuracy values(%) assigned to the images geolocated in each of the four datasets

We asked experts in the domain of Disaster Response, specifically the European network VOST Portugal (VOSTPT) to classify the images of the reference dataset, each based on the difficulty of geolocating them. VOSTPT is a community of citizens from different countries accross Europe that has an objective to create a more prepared, more informed, and more resilient society to natural disasters and other events 5. To label the images, four different levels were used: (1) Easy, (2) Medium, (3) Difficult, or (4) Impossible to geolocate (see Figure 2). Each image is labeled at least by five different raters.

Figure 2. The example of geolocation difficulty level for image

The crowdsourcing of the images was carried out via the Pybossa framework (Gonza´lez et al., 2020). Specifically, the execution of this task uses an instance of Pybossa hosted at the Citizen Science Center Zurich, a joint initiative created by the University of Zurich and ETH Zurich6. The application is called the Citizen Science Project Builder (CSPB).

5https://vosteurope.org/
6https://citizenscience.ch/en/

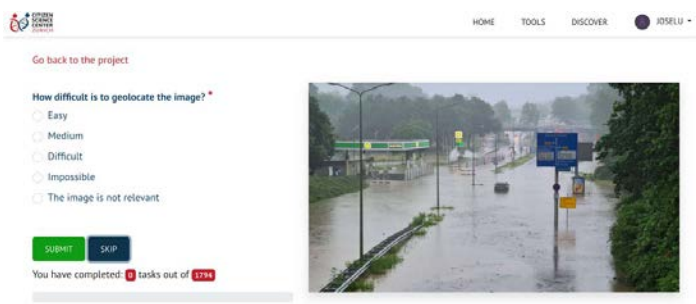

Figure 3. Screenshot of the Citizen Science Project Builder used to crowdsource the labeling of images depending on the level of difficulty to find its location

Figure 3 shows the user interface implemented for crowdsourcing the geolocation difficulty level of each picture in the dataset. The crowd is asked to determine the level of difficulty to geolocate the image on the right. The user interface also enables users to answer two different conditions stating whether it is impossible to geolocate or the image is not relevant. If the users were not sure about their choice, they could also skip the task.

As for the dataset for the second task, i.e., training our deep learning model, Majority Voting and Dawid-Skene (Dawid & Skene, 1979) consensus mechanisms were adopted to aggregate the annotations collected in the first task. We detail both mechanisms in the experimental results section.

Training a CNN to Predict the Level of Difficulty in Geolocating a Given Photo

Our second task is to create a classifier to classify the difficulty level to geolocate a given photo automatically. To this end, we implemented a Convolutional Neural Network (CNN) and the methodology for training the CNN consisted of the following steps:

First, we imported images from the annotated training dataset. We loaded images and distributed them among the classes "Easy" and "Difficult". In the beginning, we decided to use all the labels existing in the annotations, but after some preliminary analysis, we decided to reduce the complexity of the classification. Hence, we removed the Medium samples from the dataset and merged Difficult and Impossible into Difficult to make the task a binary classification between Easy (Easy) and Difficult (Difficult or Impossible). The reason for this choice was to focus on accurately identifying True Positive values (the Easy class).

We then deduplicated the data using hashing algorithms[7] that are particularly good at finding exact duplicates, as well as CNNs, which are also good at finding near duplicates. We then used some standard data analysis to check the distribution of images. Figure 4 shows the distribution of the images after the deduplication. The classes were well-balanced.

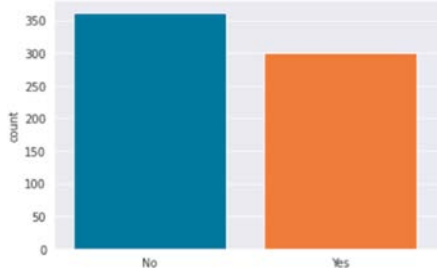

Figure 4. The almost-balanced distribution of images after deduplication

We split the dataset with a training, validation, and test ratio of 70% (448 images), 20% (150), and 10% (61), respectively. The data preparation phase included data augmentation and pre-processing. The data augmentation increased the diversity of our training set by applying random (but realistic) image rotation and image flipping (horizontally). Figure 5 shows an example of data augmentation.

[7]https://pypi.org/project/imagededup/

Figure 5. Image augmentation examples. The augmentation flips and rotates the images at certain degrees.

This step basically multiplies the number of images used in our training. Every image was augmented by being flipped and rotated. After freezing the all layers, the first 25 epochs to train the neural network. The next 25 epochs were used to fine-tune the neural network. The number of epochs was inspired by a similar experiment on leveraging a pre-trained model using social media images for natural disaster (Firmansyah et al., 2022; Ofli et al., 2020) and considering several factors such as dataset size, overfitting prevention, and learning rate.

EfficientNet 8 is among the most accomplished models that reach state-of-the-art accuracy on both ImageNet 9 and common image classification transfer learning tasks. The model was performing better than other models and could be chosen as the best option (Alam et al., 2020). In our experiment, we chose the EfficientNet-B6 due to its good balance between computational demand and model performance and because it uses an image size (528x528 resolution) similar to the ones found on social networks. Aware of the fact that training a deep learning model from scratch with a relatively small dataset might lead to suboptimal results, we implemented transfer learning. It involved starting with a pre-existing model trained on a large dataset and adapting it to our task. This practice reduces the data needed, reduces training time, and improves the model's performance on smaller datasets.

To customize the pre-trained model for our specific task, we performed fine-tuning on the last 66 layers of the EfficientNet-B6 in a two-steps process: first freezing all layers and training only the top layers, and then unfreezing the last 66 layers (out of 666). A relatively large learning rate (1e-2) was used for the first step, while the second step fit the model using a smaller learning rate. Fine-tuning involves adapting the weights of a pre-trained model to new data, allowing us to leverage both the general feature extraction learned during pre-training and the specific patterns found in our disaster imagery.

In conclusion, the experiment sought to leverage the power of EfficientNet-B6 and the robustness of noisy student pre-training by fine-tuning the model to our specific classification. Noisy student is a semi-supervised learning method where a model trained on labeled data (teacher model) produces pseudo-labels for unlabeled data. The pseudo-labels are then combined with noisy data and labeled data to train another model called the student model (Xie et al., 2020). Figure 6 shows a comparison of accuracy while testing different weights. It compared two EfficientNet-B6 models with two different weight (ImageNet and Noisy Student). The EfficientNet-B6 model used a training dataset of 448 images as explained above.

The base classifiers were trained with the objective of decreasing the cross-entropy loss. Cross-entropy measures how well a classifier approximates the probabilities of its predictions. The code generated to create and evaluate the classifier is accessible as open-source10.

We ran two experiments with two datasets originating from Majority Voting (MV) and Dawid-Skene (DS) consensus algorithms and compared the performances of the two models. The model trained with the DS dataset presented better results than the one with Majority Voting, as we expected since DS weighs the raters' answers based on their error rates computed by the same algorithm. That is, the annotations of the raters who perform better (i.e., make fewer errors) have more influence on the consensus calculation. Thus, we expect to have a more reliable consensus with DS. Figure 7 demonstrates the comparison of the training accuracies with MV and DS datasets and their evolution after being fine-tuned (the fine tuning started at the vertical green line).

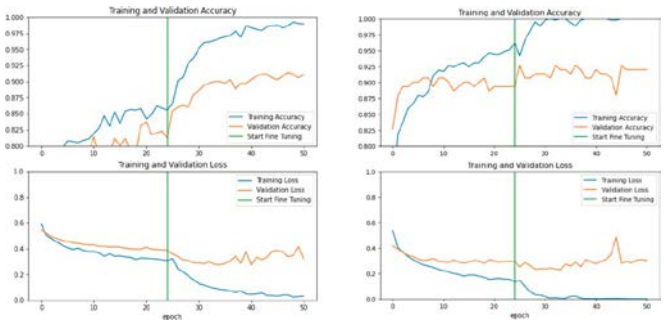

Figure 7. The comparison of model training performances between Majority Voting (left) and Dawid-Skene (right) consensus training datasets.

This preliminary result shows that classifiers could estimate the difficulty of geolocating a social media image. This step is critical to filter out images that are impossible to geolocate and to optimize the ratio of images geolocated per person right after a disaster happens when the time is crucial. Thanks to this methodology, easy images could be scheduled with higher priority than those difficult to geolocate, saving invaluable time for disaster management. We assess the validity of our hypothesis in the following section. Figure 8 shows examples of classifications correctly inferred by the model.

Domain Adaptation Classification Experiment

A central hypothesis in this research is that the photos which are automatically classified as Easy to geolocate should be geolocated with higher precision and faster by humans than the images classified as Difficult. The tool selected for the crowd annotation experiment is Citizen Science Project Builder 11 adopting the user interface design implemented within the E2MC EU project that facilitates manual geolocation (Ravi Shankar et al., 2019).

To answer our RQ2, we set up a domain adaptation classification experiment (Gopalan et al., 2015) where the model described in the previous section classifies unseen photos and human experts geolocate them and provide the precision of the location. Figure 9 and Figure 10 show screenshots from the Citizen Science Project Builder tool with the user interface for geolocating social media images. The interface combines the following: (1) initial estimation of the position of the image extracted from the analysis of the associated text to the photo, which allows participants to start refining the position rather than geolocating an image from scratch; (2) incorporation of Google Map and Google Street View which allow matching the image from social media, with images from Google Street View. When the user locates the photo on Google Street View and clicks the Submit button, the geolocation (longitude and latitude) is submitted automatically within a precision of a few meters. The user interface allows to annotate the precision of the geolocation with three different levels, i.e. the precision the user was able to achieve in the geolocation process.

Figure 11 shows the three levels of precision: i) High precision means the user found the exact location by matching it with the referenced dataset's latitude and longitude. ii) Medium precision means the user knows the image was taken close to a position, such as a street, road, path, or similar, but it could not be matched the referenced one. iii) Low precision means the image is geolocated only at the city level.

Figure 10. Screenshot geolocation using Google Street View (Photo from Croatia earthquake)

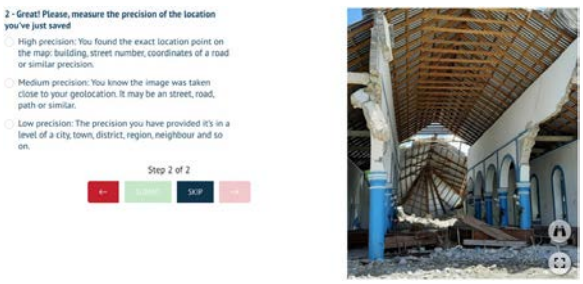

Figure 11. Screenshot CS Project Builder, final step geolocation precision levels.

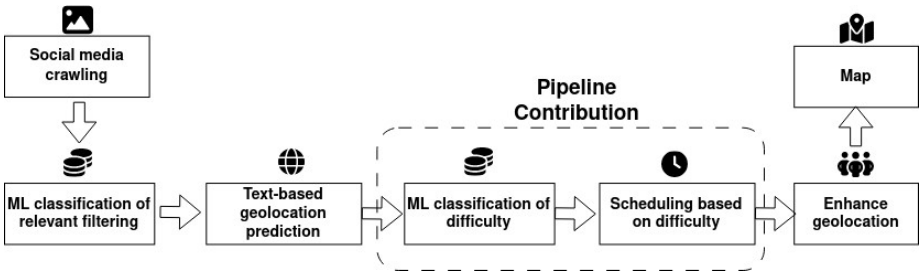

Figure 12. The pipeline of social media images geolocation

Proposed Pipeline

The most common approach to get the geolocation is by extracting location information tagged to the social media post using GPS. Our approach is completely different from that context for two reasons. First, our approach minimized the crowd effort by automatically estimating the geolocation difficulty using machine learning. Second, the approach incorporated crowd to accelerate and improve the image geolocation step.

To make use of the geolocation enhancement for the social media data proposed in this paper, we provide a novel pipeline which extends previous work from Crowd4EMS (Ravi Shankar et al., 2019) and SMDRM (Lorini, Panizio, & Castillo, 2022) by adding two additional processes. Figure 12 shows the overview of a proposed pipeline which is composed of six processes. The dashed line indicates the two additional processes integrated into the pipeline:

- **Social media crawling** fetches informative posts from social media by selecting appropriate keywords which depend on the type of disaster. The initial step is to get the social media post by formulating the appropriate search query (Alam et al., 2018; Lorini, Panizio, & Castillo, 2022).
- **ML classification of relevant filtering process** filters the irrelevant images and keeps the relevant images crawled from the previous process. For example, images containing cartoons, banners, news logos, and edited images are considered irrelevant (Alam et al., 2018).
- **Text-based geolocation prediction** uses social media posts to predict the initial geolocation of images. The main goal of the process is to provide initial geolocation information based on social media posts. The text-based geolocation prediction is used to prevent the crowds to find an image location from scratch, when possible.
- **ML classification of difficulty** predicts the difficulty level to geolocate an image into predetermined categories (i.e. easy, medium, difficult, etc). The process is critical because the institution's resources could put attention to the easier-to-geolocate and more relevant images first instead of to all images. For example, images that are impossible to geolocate should not be sent to the crowd. The process of classification difficulty is done by implementing automated machine learning (ML) described previously in Section Training a CNN to predict level of difficulty in geolocating a photo.
- **Scheduling based on difficulty** chooses images in a desired order of difficulty level to be sent to the crowd. In certain situations like disasters, the time constraint may be more strict. When time is considered an essential dimension for geolocating an image, the first responders organization should prioritize images that need to be sent to the crowd earlier (e.g., Easy before Difficult images as labeled by the automated machine learning).
- **Enhance geolocation** incorporates crowd to improve the geolocation precision.
- **Map** visualizes the geolocation enhancement on a map.

EXPERIMENTAL RESULTS

This section provides the experimental results from the three different tasks presented in Section Dataset, methodology and experiment. The aim of this section is to answer the two research questions.

As the pilot study, we first worked with 1,794 photos annotated by the VOSTPT community using the interface presented in Figure 3, with the redundancy of at least five annotations per image. In total, 8,970 classifications were performed by the VOSTPT community were each image was classified by the level of geolocation difficulty, i.e. Easy, Medium, Difficult and Impossible. With the annotation dataset in hand, we initially evaluated the inter-rater

agreement. Fleiss' Kappa12 is a common statistical measure to assess the reliability of agreement between raters in the context of categorical ratings, like our case. We computed the Fleiss' Kappa for the VOSTPT dataset using the Python library Crowdnalysis (Cerquides & Mu¨la^yim, 2022). The value was 0.288 which indicates a Fair agreement on the kappa scale among the VOSTPT community for this dataset. The low value of fleiss kappa suggests that the task of assigning a geolocation difficulty level to a social media image is a complex task and the annotation result might be noisy. Also, there was a probability that the annotator would answer the level of difficulty randomly. Considering that issue in the experiment, we decided to choose Dawid-Skene (DS) model instead of majority voting (MV) since DS also models individual annotator behavior. We further explain this choice below.

To generate the dataset for the next step, i.e., the training of the CNN, we needed to find a consensus between the five annotators for each image. The Crowdnalysis library, besides the standard Majority Voting, provides advanced probabilistic methods of consensus (Cerquides et al., 2021) such as the seminal Dawid-Skene model (Dawid & Skene, 1979) (DS). The DS method allows modelling individual annotator behaviour, thus with enough data, it yields more reliable consensus results which can prove crucial in disaster management scenarios, as mentioned earlier.

Table 2. The percentage of warnings in consensuses with Dawid-Skene (DS) and Majority Voting (MV) models.

	Easy	Medium	Difficult	Impossible	Not Relevant
DS	**4.4%**	**5.2%**	**9.7%**	**0.7%**	0.43%
MV	57.2%	58.8%	10%	2.7%	**0%**

Table 2 shows the percentage of warnings for each consensus result. The warning was a condition where there was only a < 0.1 difference between the probabilities of the top and second-best estimated consensus classes for the photo. The boldface values indicate the lower values between models trained with DS and MV consensus datasets.

Table 3 shows the confusion matrix result of evaluating the model trained with the DS dataset. The model exhibits 0.87 accuracy, 0.88 precision, and 0.88 recall. Assessing the difficulty of geolocating an image is challenging even for humans, as demonstrated by the Kappa value above. However, the evaluation of the proposed model shows that it is possible to automatically predict the difficulty of geolocating an image. This result answered the first Research Question (RQ1).

Table 3. Confusion Matrix of the CNN model with binary classification

	Predicted	
Actual	Difficult	Easy
Difficult	29	4
Easy	4	24

After demonstrating the feasibility of predicting the difficulty of geolocating an image from social media, the next question to address is whether images classified as easy contribute to the enhancement of the overall geolocation process. The main focus is to investigate whether images labeled as easy result in increased precision and reduced time for geolocation during the crowdsourcing process. Figure 13 shows that most of the images predicted as easy are gelocated with high precision (horizontal axis = 2) and within 300 seconds. On the other hand, Figure 14 shows that images predicted as difficult are geolocated with low precision (horizontal axis = 0). Overall, prioritizing easy-to-geolocate images accelerates the geolocation time and enhances precision. The detail of the results is explained below.

We then asked experts to geolocate 39 images. Those images were classified using previously trained model. From that automated classification,about 22 images were predicted as Easy. Figure 13 shows that most of the images classified as Easy are geolocated with high precision (within a few meters). Most of the images geolocated with high precision were geolocated in less than 4 minutes. If we assume an average of 3 minutes per photo, a person could potentially geolocate 20 images per hour. Consequently, in a group of 10 volunteers, we could geolocate 200 images per hour with high precision. On the other hand, 17 images were predicted as Difficult. Figure 14 shows the precision and time spent on geolocating images classified as Difficult to geolocate. We could see how most of them are geolocated with low precision within the city level.

Although this is a preliminary result based on a limited number of images, it clearly shows that prioritizing images easy-to-classify during the crowdsourcing process could potentially augment the overall geolocation process, by increasing the precision and reducing the time needed to geolocate the images.

CONCLUSIONS AND FUTURE WORK

Finding the location of social media images related to a disaster is a key process to make the data actionable, i.e., data that can be used to enable better-informed decisions. Geolocation of social media images is a task usually performed by humanitarian communities such as Stand By Task Force, GISCorp, or VOSTPT. It is a well-known fact that crowdsourcing the geolocation of social media images is always a difficult task which slows down the process of assessing the impact of a natural or man-made disaster in the immediate aftermath of the event. This preliminary research activity demonstrated that it is indeed possible to automatically predict the difficulty of geolocating an image, thus allowing to filter out impossible-to-geolocate images and giving priority to images that can be geolocated within a few minutes with high precision. Consequently, the proposed approach would enable a more efficient and timely analysis of social media data which is critical in a disaster.

Finally, regarding future work, first, the proposed approach needs to be evaluated in a real-time crisis response to demonstrate the potential of using social media data to assess the impact of disaster within 24 hours. Second, we will increase the number of geolocated images to answer the research questions in a robust manner.

ABSTRACT

Problem: Despite the potential of artificial intelligence for rapid social media analysis, practical implementation remains limited. **Approach:** We conducted a scoping review using iteratively developed search terms in two electronic databases. We then conducted a descriptive and thematic analysis to capture the key concepts, findings and methods in the literature. **Results:** After reviewing 130 papers, 27 papers were identified that met our inclusion criteria. Four key themes emerged, including tool development, tool performance comparison, gaining insights from social media data, and usefulness for decision makers. **Conclusions:** While acknowledging the importance of integrating social media into crisis and disaster management, there is a lack of empirical evidence on data reliability and preparation for decision makers. More empirical studies on social media analytics, specifically focusing on usefulness for crisis and disaster management, are recommended.

Keywords

scoping review, social media, crisis and disaster management, sudden onset disaster, evidence

INTRODUCTION

Effective disaster relief and management requires a comprehensive understanding of the disaster situation (Fan et al., 2020). As the frequency and intensity of crises and disasters increases, decision makers' knowledge of the situation is becoming ever more important to enhance the effectiveness of response and recovery efforts. Decision makers in the context of crises and disasters are individuals or entities responsible for making critical decisions related to emergency response, recovery, and management. In the digital age, social media (SM) has evolved beyond its role as a platform for personal exchange to become a valuable source of information that can reflect the collective intelligence of the public (Lang et al., 2020). Gaining insights into people's perceptions, reactions and behavior on SM can contribute significantly to crisis and disaster management (Z. Wang & Ye, 2017). Acknowledging the collective intelligence of the public as reflected in social media is a key aspect. This connects with broader discussions on Open Source Intelligence techniques, citizen engagement, and the potential for harnessing distributed knowledge during crisis situations (Pastor-Galindo et al., 2020). However, the sheer volume and variety of information on SM makes manual processing in real time almost impossible (Avvenuti et al., 2015). To overcome this challenge, various artificial intelligence techniques have emerged that offer the possibility of efficiently classifying, analysing and visualizing SM data. This aligns with broader research on the application of AI in disaster response, including natural language processing, machine learning, and data visualization (Abid et al.,

*corresponding author

2021; Fan et al., 2020). The passive collection of information, i.e. without active participation in the conversation or demand for information, allows topics and problems relevant to the population (Ghermandi & Sinclair, 2019). Passive information gathering aims to use existing data sources without disrupting user activity. While numerous studies have examined the technical implementation of these techniques, the integration of SM insights into the overall picture of the situation remains limited in practice due to the complexity of existing algorithms and the lack of comprehensive software solutions. Due to the high number of scientific publications in the field of SM analysis in crises and disasters, there is an increasing need for overviews. However, existing reviews focus unidimensionally on thematic or methodological orientations of the evidence, so that the temporal dimension and usefulness for decision makers are not explicitly considered (Acikara et al., 2023; Luna & Pennock, 2018). This review aims to fill this gap by capturing the available evidence, including the temporal dimension, and providing an overview of the use of passive information gathering from SM for crisis and disaster management in sudden onset disasters. The following research questions guide this review paper:

RQ1.1 How does the number of publications about social media analyses related to the support of decision makers during sudden onset disasters vary over time?

RQ1.2 On what data are the publications on social media analytics related to supporting decision makers during sudden-onset disasters based, taking into account the evolution over time?

RQ2 What methods are used to obtain information from social media to enhance the situation picture for decision makers in sudden onset disasters?

METHODS

A scoping review was used to capture the key concepts, main sources and types of evidence available in the literature on the passive extraction (observing without active communication) of information from SM in sudden onset disasters for decision makers in crisis management teams and consequently to complement the situational picture. Sudden-onset disasters are events that occur suddenly and unexpectedly, usually with little or no warning, and have an immediate and severe impact on communities and infrastructure, i. e. earthquakes and floods. The focus is intended to provide an overview of direct practical implications and options for disaster management decision-makers in time-critical contexts. The review was based on the methodological guidance for scoping reviews according to the Joanna Briggs Institute (JBI) (von Elm et al., 2019) and conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR guidelines) (Moher, 2009). The overarching research project *#sosmap* focuses on the state of the art regarding the passive derivation of information from SM on the psychosocial needs and resources of the population in any crisis and disaster situation. This work-in-progress paper presents a subset of the results in relation to the knowledge gained from SM for decision makers in sudden onset disaster. As scoping reviews aim to provide an overview of the available evidence, regardless of methodological quality or risk of bias, no critical appraisal was undertaken.

Search Strategy

In several iterations, we have developed a search query that covers a range of terms defined by three key topics: (a) SM, (b) decision making and (c) crises and disasters. Two databases were searched from the beginning: IEEE Xplore (until 20.07.2023) and Web of Science (WoS) (until 09.08.2023). When selecting the databases, WoS was chosen because of its in-depth coverage (1945 to the present). IEEE was included due to its technical focus. The review focuses exclusively on primary literature, including published research results in specialized journals, databases, and conference contributions. There is no time limit set, and only English-language literature is considered as no german-language literature was available. The focus on sudden onset disasters was realized by manual title and abstract screening. Table 1 lists the search terms using the syntax for WoS, consisting of the linked topic complexes: extraction of information from SM for decision making in crises and disasters.

Table 1. Key Search Terms

Search terms
(”social media” OR ”user-generated data”) (Title) AND (analy* OR monitor* OR ”social listening”) (Topic) AND (crisis OR crises OR disaster* OR emergenc* OR catastrophe* OR ”extreme event*”) (Topic) AND (”situation* assessment” OR ”situation* aware-ness” OR ”decision mak*”) (Topic) NOT (covid-19 OR marketing) (All Fields)

Study Selection

Scientific publications addressing the three key topics were reviewed, with a focus on passive data collection and

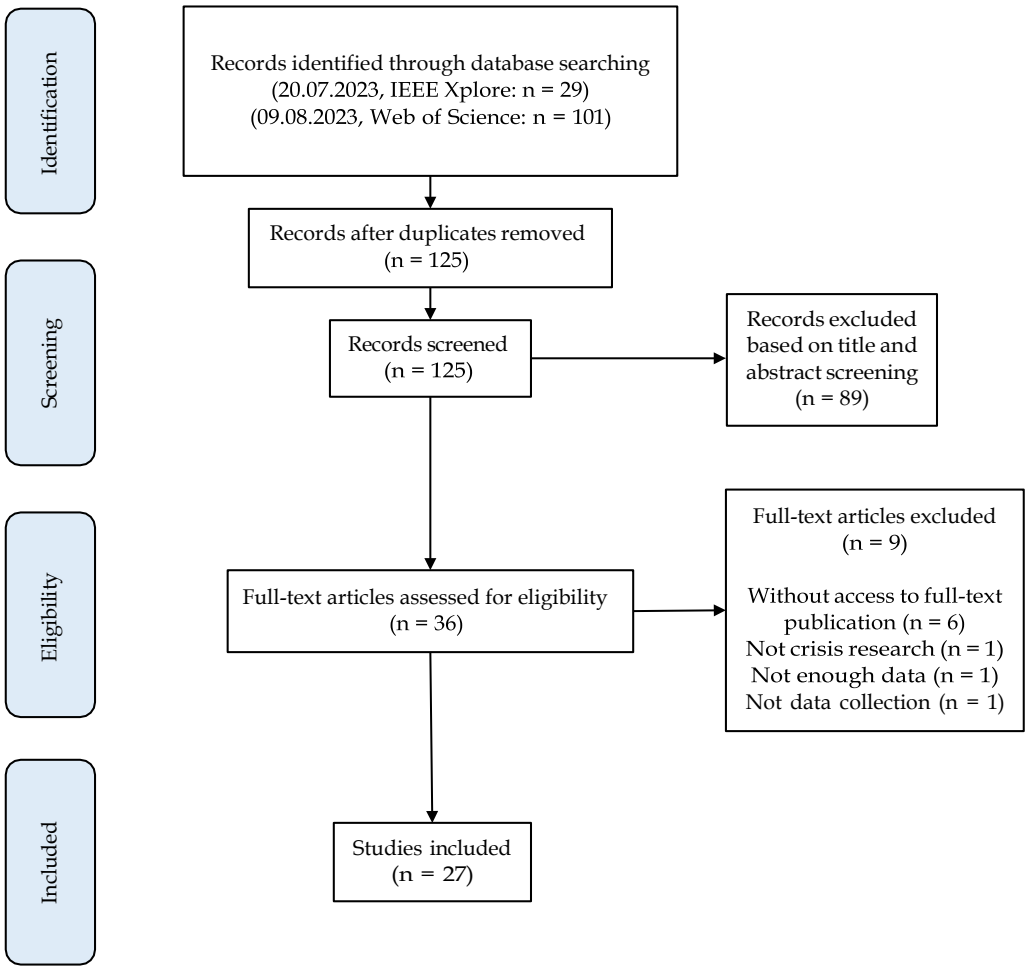

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) Flowchart

analysis via manual, automated, or combined methods. The data sets had to be directly related to sudden onset disasters and support crisis management or complement the situation assessment. Initially, 125 articles were identified, with duplicates removed. Many articles were deemed irrelevant during title and abstract screening, particularly those focusing on active social media engagement or crisis communication. The manual selection of the articles comprised two stages. First, a title and abstract screening was performed to select papers that addressed all three key topics. After the first screening, 36 articles were read in full text. In a second round of full-text screening, data sets were excluded if there was no full-text access and their thematic focus was not sufficiently on all three key topics. A total of 27 studies were identified that were relevant to the research topic. To minimize subjective influences, a second person carried out the two steps on 10 % of the total number of articles. The inclusion and exclusion decisions were identical in 100 % of cases. Figure 1 illustrates the article selection process. The full search protocol is available on request from the authors.

Data Extraction

Details of the included studies can be found in Table 2. Here, for each reference included, the disaster analyzed or the data set analyzed, the social media platforms included for data collection, the data analysis methods used and a concise summary of the findings are compiled. Our in-depth analysis of the included literature included an inductive thematic analysis according to Kuckartz to identify, analyze and present recurring focus areas in the articles (Kuckartz, 2018). The derived focus areas are:

A Development/presentation of tool/framework,

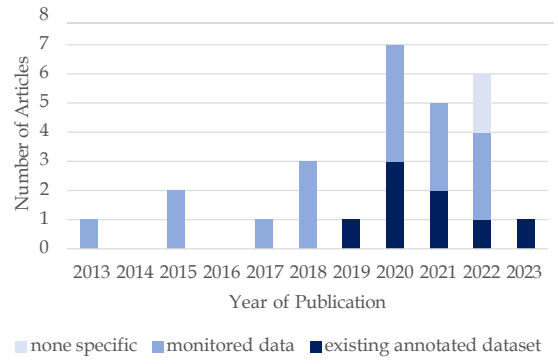
B Performance comparison of tools,

C Gaining knowledge from SM (data insights) and

D usefulness for decision makers.

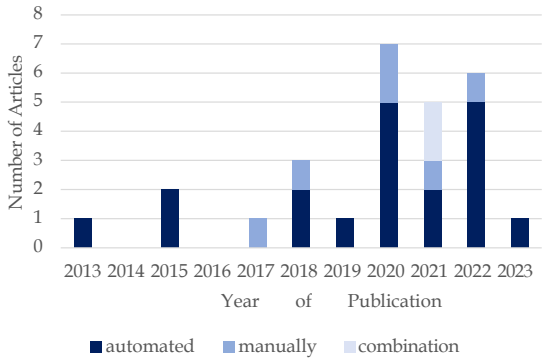
The presentation of the descriptive summaries takes into account the time dimension.

RESULTS



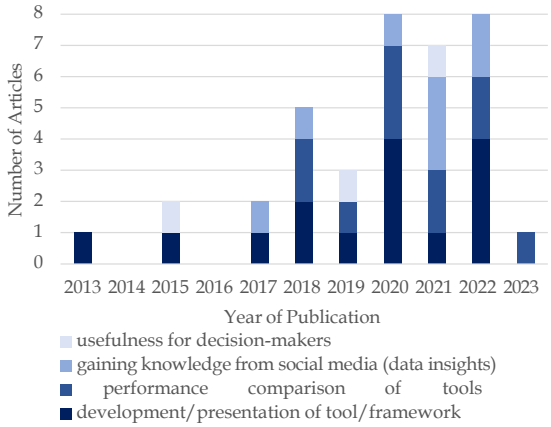
As part of the inclusion and exclusion process, only articles with a publication date after 2013 were integrated. The importance of integrating SM into crisis and disaster management is clearly emphasized by all papers reviewed and beyond. However, very few papers focus on what decision makers really need and adapt the analysis accordingly. Many assumptions are made about what information and presentation methods would be helpful.

Data-specific Consideration



The findings reveal that 63 % of studies relied on monitored data, with annotated datasets comprising 30 %. Notably, the prevalence of existing datasets emerged since 2019. Key datasets included Crisis Benchmark Dataset, CrisisNLP, CrisisLex, MediaEval, European Flood 2013 dataset, Harvard Dataverse, and Hurricane Harvey Twitter dataset, with CrisisNLP being the most used. There's a shift towards utilizing existing and annotated datasets, suggesting a common training basis for models. Figure 2a depicts the trend in data source usage over time. The differentiation was made between already publicly available, annotated datasets of social media data ("existing annotated datasets") and data collected by the authors themselves ("monitored data"). Regarding data formats, 48 % of integrated studies (n_{total} = 27 articles) exclusively used text-based data, while 22 % focused solely on image-based data. Since 2020, there's been a rise in combining text and image data (30 %). The analysis of disaster types showed that 70 % of the studies (n = 19 articles) focused on natural disasters, of which 31.6 % (n = 6 articles) considered several types of natural disasters. Only one study focused on man-made disasters, while 11 % did not focus on a specific crisis and 15 % analyzed several types of disasters. Twitter was the most studied platform (63 %), with Sina Weibo in 7 % of studies. Additionally, 30 % of the studies examined various sources of social media data, including but not limited to Facebook, Instagram, and YouTube. Over time, it can be seen that the consideration of several platforms in one study shows an increasing trend and the singular use of data from Twitter shows a decreasing trend. Since 2020, there's been a decline in studies using Twitter as a data source (-1.6 studies per year).

Method- and Content-specific Consideration



Our analysis revealed that approximately 59 % of articles were case studies. Regarding methodology, 70 % used automated analysis, 22 % manual classification, and only 7 % combined both (Figure 2b). Notable integration of manual and automated analysis is exemplified by Virtual Operations Support Teams (VOST) as highlighted

(a) Data-specific Consideration (Single Assignment)

(b) Method-specific Consideration (Single Assignment)

(c) Content-specific Consideration (Multiple Assignment)

Figure 2. Stacked Bar Charts of the Considered Articles Integrated into the Review

by Fathi and Fiedrich 2022. Article foci included tool/framework development (15 articles), tool performance comparison (11 articles), insights from SM (9 articles), and usefulness for decision makers (5 articles). Figure 2c illustrates the distribution of article foci over time. Named Entity Recognition (NER) was the most commonly used algorithm (6 articles), followed by Convolutional Neural Networks (CNN) and Visual Geometry Group (VGG) architectures (5 articles each). However, the temporal distribution of algorithm usage did not provide further insight into preferences over time.

DISCUSSION OF THE RESULTS

Existing reviews lack a temporal dimension linked specifically to SM in sudden-onset disasters. Therefore, we addressed these gaps by focusing on publications about SM analyses supporting decision makers during sudden onset disasters over time.

RQ1 The analysis reveals a substantial number of studies (63 %) focusing on passive information extraction from SM, primarily from Twitter, with a decreasing trend observed, especially since 2020, possibly due to API changes. Due to the complete switch from Twitter to X and clear restrictions in the API terms and conditions, there could be a further decline and an increased focus on existing data sets in the future. While text-based data remains prevalent, there is a growing trend, particularly since 2020, towards combined analyses of various data formats. Surprisingly, only one study integrated man-made disasters, with a predominant emphasis on natural disasters. Since 2019, there has been an increasing reliance on existing datasets, facilitating more comparative analyses across different crises.

RQ2 The surge in dataset usage is accompanied by a heightened emphasis on comparing different artificial intelligence (AI) techniques, particularly since 2018. However, there is limited consideration of manual classification in comparative or combined methodologies. While concepts like VOST appear promising (Fathi & Fiedrich, 2022), their validation involving decision makers is lacking. Instead, the focus tends to be on understanding crisis situations rather than collaborating with decision makers.

However, our review has limitations. Snowballing was not employed to identify additional literature, potentially restricting the scope. Additionally, screening was not conducted by both examiners for all titles, abstracts, and full texts, possibly leading to omissions. Furthermore, qualitative content analysis for data extraction was performed by both examiners only about 40 % of the time, introducing potential bias. Lastly, our focus solely on sudden-onset disasters may limit the generalizability of our findings.

However, our findings reveal similarities with existing reviews and studies. For example, Karimiziarani (2023) and Kondraganti (2021) emphasize the potential of integrating multimodal data sources, including SM, to improve disaster response efforts. They highlight the importance of ethical considerations and privacy concerns in SM analytics research, advocating for further research to ensure responsible SM data use.

CONCLUSION AND FUTURE OUTLOOK

In this scoping review, we aim to provide a overview of the current state of research regarding passive information extraction from social media (SM) in sudden onset disasters for decision makers. By considering the temporal dimension, we seek to identify the current trends in scientific inquiry.

Looking ahead, it is imperative to shift towards addressing the needs of decision makers during crises and disasters, facilitating the translation of research into practical applications. While numerous articles detail the technical implementation of information extraction from SM, there is a dearth of evaluations targeting the intended user group. Future efforts should prioritize comparative presentations of algorithms and evaluation indicators, such as accuracy and performance, with a clear delineation of their intended use.

This work-in-progress paper offers a glimpse into the ongoing evidence presentation within the research project #sosmap. The forthcoming analysis will delve deeper into an expanded database, implementing an enhanced search strategy focused on deriving psychosocial needs/resources, sentiment, and other factors in various crises.

Table 2. Overview of Selected Article Characteristics

No./ Focus	*Reference*	*Disaster/ dataset*	*Platforms*	*Data analysis methods*	*Summarized results*
1/ B	Alam et al., 2023	Crisis Benchmark Dataset	Twitter	automated (ResNet18, ResNet50, ResNet101, AlexNet, VGG16, DenseNet, SqueezeNet, InceptionNet, MobileNet, EfficientNet)	Optimization of the algorithms is possible through training using consolidated data sets. Based on performance and computational effort, EfficientNet is the best option for real-time applications.
2/ B	Asif et al., 2021	CrisisMMD (CrisisNLP)	multiple	automated (YOLOv4, YOLOv3, VGG16)	With an accuracy of 96 %, YOLOv4 shows better results than YOLOv3 for categorizing images.
3/ A	Avvenuti et al., 2015	Earthquake, Italy, 2012; Flood, Italy, 2014	Twitter	automated (WEKA, NLP, MLR)	Strong earthquakes can be identified by monitoring SM. The algorithm used showed an accuracy of 83.5 % for English tweets and 90.1 % for Italian tweets. In data processing, term clouds contribute to improved situational awareness.

Continued on next page

Table 2 – continued from previous page

No./ Focus	Reference	Disaster/ dataset	Platforms	Data analysis methods	Summarized results
4/ B, C	Dong et al., 2021	Hurricane Sandy, 2012; Hurricane Matthew, 2016; Hurricane Harvey, 2017; Hurricane Michael 2018; Hurricane Dorian, 2019	Twitter	combination of automated + manually (manual classification, LR, NB, DT, SVM, KNN, RF, Adaboost, MNN)	SM is seen as an important platform for gathering information about disasters. It was also found that there is a difference between people's basic needs in natural disasters. The performance of the model adapted to the optimal settings is significantly better than the existing and lexicon-based machine learning models. Moreover, Na¨ıve Bayes is the best performing model in terms of classification accuracy, confusion matrix and ROC-AUC graph in our study.
5/ A, B	Fan et al., 2020	Hurricane Harvey, United States, 2017	Twitter	automated (NER, BERT classifier)	The integration of NER and Google Map Geocoding API enables advanced georeferencing. The fine-tuned BERT-based classifier performs best in classifying tweets into different humanitarian categories. Credible identification of situational information can be implemented through a graph-based clustering approach. In addition, the suggested pipeline can be used to map the development and geographical distribution of disaster events.
6/ C, D	Fathi and Fiedrich, 2022	Floods, Germany, 2021	multiple	combination of automated + manually (ScatterBlogs + VOST)	Information collected by VOST increases situational awareness. The resulting actionable information can contribute to the crisis team's decision-making. Contributions with a potential impact on the health and safety of those affected and image contributions are prioritized higher than others.
7/ C, D	Fromm et al., 2021	Storm Dragi, Germany, 2019; Storm Eberhard, Germany, 2019	Twitter	manually (categorization)	Respondents rate the usefulness of traffic information and eyewitness accounts from private individuals the highest. However, the indication of location and an indicator of relevance and trustworthiness is important. Adaptable filter options are proposed in order to do justice to the disparity between individual assessments of different types of tweets.

Table 2 – continued from previous page

No./ Focus	Reference	Disaster/ dataset	Platforms	Data analysis methods	Summarized results
8/ A, B	Jixian et al., 2022	none specific	multiple	automated (BiLSTM-Attention-CNN-XGBOOST ensemble model for NN and others)	The BiLSTM-Attention-CNN-XGBOOST model proposed in this paper achieves better accuracy than NB MODEL, Ngrams-TFIDF model, charCNN, wordCNN, LSTM model and RCNN model, regardless of whether it is Chinese or English data from WeiBo, Twitter, Wechat or Facebook platforms.
9/ C, D	Kankanamge et al., 2020	Floods, Australia, 2010-2011	Twitter	automated (capture-understand-present framework, DT, WEKA, IDW)	The use of Twitter is a promising approach, not specifically to gather new situational information, but rather to capture citizens' knowledge. Tweets could be used to identify variations in disaster severity over time. The spatial analysis of tweets confirms the applicability of geographically located messages to delineate severely affected disaster areas.
10/ A, B, D	Lazreg et al., 2019	CrisisLex, CrisisNLP	Twitter	automated (NER, NN, CNTM and others)	The proposed framework for obtaining information from SM provides exactly the information required in 70.09 % of cases.
11/ A, B, C	Z. Li et al., 2017	Floods, United States, 2015	multiple	combination of automated + manually (text matching + manual checking and selection + ArcPy, ArcGIS geoprocessing tools)	There was an 83.4 % match between the map developed based on SM data and official flood maps from the USGS (United States Geological Survey). People share more on SM when they are closer to the event and when the extent of flooding increases during the flood event. Twitter activity reflects the extent of flooding in the relevant geographic area with no obvious time lag.
12/ A, B	X. Li et al., 2018	google image data; Typhoon Ruby/H-agupit, Philippines, 2014; Earthquake, Nepal, 2015; Earthquake, Ecuador, 2016; Hurricane Matthew, 2016	multiple	automated (VGG19, CNN, DDM, GCAM)	The developed Damage Assessment Value in combination with the Damage Detection Map can help assess the severity of damage and identify and prioritize useful information. In addition, the developed tool provides visual explanations for the suggestions made.

Table 2 – continued from previous page

No./ Focus	Reference	Disaster/ dataset	Platforms	Data analysis methods	Summarized results
13/ B	Lopez-Fuentes et al., 2020	MediaEval 2018	Twitter	automated (double-ended NN and others)	By reducing the number of composite models to 30, the number of networks can be reduced. This makes the solution faster and easier, while at the same time improving the results.
14/ A, B	Mao et al., 2018	power outage (keywords), United States, 2016	Twitter	automated (BiLSTM model coupled with a CRF top layer, and others)	The developed algorithm shows a classification accuracy of 86 % in identifying genuine blackout tweets. In addition, about 20 times more tweets can be georeferenced than are already geotagged. Capturing the number of geo-referenced SM data related to the power outage allows to derive the number of people without power.
15/ A, B	Ning et al., 2020	Floods, United States, 2017; Floods and Florence hurricane, United States, 2018	Twitter	automated (VGG16 with integrated YOLOv3 object detector and a face recognition model)	In general, the developed RIASM system has the potential to be integrated into conventional flood mapping systems to close knowledge gaps and provide additional evidence of the extent of a disaster (total accuracy of flooding photo detection was 93 %).
16/ B	Pereira et al., 2020	European Flood 2013 dataset, MediaEval 2017 (YFCC100m), MediaEval 2018	multiple	automated (DenseNet, EfficentNet, AGDenseNet)	All three models compared showed very similar results. It was found that the number of images available for model training influences the quality of the results. When assessing the water depth, the best results were achieved with the DenseNet model.
17/ A, B	Pohl et al., 2013	Flood, United States, 2011; Bombing, Norway, 2011; Riots, United Kingdom, 2011; Hurricane Irene, United States, 2011	multiple	automated (SOM, AC, 2PG, and 2PGT)	Social multimedia in combination with clustering can be used as part of crisis and disaster management to identify partial events. This allows SM to be integrated into crisis and disaster management without the need for time-consuming manual monitoring. AC and SOM can be used in particular for a quick overview, 2PG and 2PGT for a more user-friendly visualization.

Table 2 – continued from previous page

No./ Focus	Reference	Disaster/ dataset	Platforms	Data analysis methods	Summarized results
18/ B	Styve et al., 2022	CrisisLex (CrisisLexT6), Harvard Dataverse (Flood Tweet IDs)	Twitter	automated (LR, RF, CNN, ULMFiT, NER)	90 % of tweets were categorized as relevant by at least one classifier, however only 20-40 % were categorized as relevant by all classifiers. This shows that there are differences in the way individual tweets are classified and implies that the same tweets are not necessarily classified as relevant by each classifier, raising questions about the reliability of their predictions.
19/ A, B	Sufi and Khalil, 2022	none specific	Twitter	automated (NER, CNN, Getis-Ord Gi*, AR)	The purposed method can pinpoint a disaster location with 0.93 precision, 0.88 recall, 0.90 F1-Score, and 0.97 accuracy.
20/ C	Tavra et al., 2021	Forest fire, Croatia, 2017	multiple	manually (filtering, analysis and georeferencing)	The advantage of using multiple types of crowdsourcing data is that all age groups of citizens are covered and technical limitations can be overcome, such as a poor mobile connection. Data from the Crowdmap platform showed a low quantity but high spatial and temporal quality.
21/ D	Thom et al., 2015	Floods, Germany, 2013	Twitter	automated (ScatterBlogs)	decision makers confirm that analytical tools are helpful to manage the volume of data, identify eyewitness accounts and engage with citizens more broadly. However, it is important that analytical tools build on existing systems, language and identifiers. Classification, automatic event recognition, real-time capability, data protection and geo-referencing are considered particularly important. The aim should be to gather information from unmonitored areas as well as public opinion on response measures.
22/ C	Z. Wang and Ye, 2018	Hurricane Sandy, United States, 2012	Twitter	combination of automated + manually (annotation, LQ and Markov transition probability matrix)	The chosen approach of combinatorial evaluation of space, time, place and topic makes it possible to derive the focus of the population during the course of the disaster. In the period before and during the disaster, the main topics were infrastructure/utilities and weather/environment. During and after the disaster, donations/environments were discussed in particular.

Table 2 – continued from previous page

No./ Focus	Reference	Disaster/ dataset	Platforms	Data analysis methods	Summarized results
23/ A, B	R.-Q. Wang et al., 2020	Hurricane harvey twitter dataset	Twitter	combination of automated + manually (NeuroNER, CV, CNN, ResNet v2)	The manual data check of automated classification shows significant advantages for credibility and reliability. By extracting information that official media may ignore, an orthogonal dimension can be opened up. In particular, information on street-level locations in SM can play a passive hotline that can support decision makers in the distribution of emergency response teams.
24/ A, B, C	Wu et al., 2022	Typhoon Lekima, China, 2019	Sina Weibo	automated (LDA, SnowNLP, OPTICS)	By linking multiple sources with SM data, deeper insights can be gained. In addition, negative sentiment extracted through sentiment analysis from microblogs can roughly show the spatial distribution of injuries and victims. The accuracy of extracting information about the actual victims at district level reached 31.8 % in the analysis conducted 72 hours after the typhoon hit.
25/ A, B	Yang et al., 2022	Flooding, China, 2020	Sina Weibo	automated (HanLP, NER)	One cannot get more disaster information by only paying attention to the posts with uploaded location tags, as there are few or no SM in some severely affected areas. The social network can be effectively combined with remote sensing image data and can help to gain more disaster information, such as assessing the disaster situation in different areas and analyzing the spatial distribution of people paying attention to flooded areas. By effectively combining data from multiple sources, the advantages of different data sources can be better utilized, contributing to a comprehensive description of disaster progression.

26/ A, B, C	Zhang et al., 2020	Hurricane Harvey, United States, 2017	Twitter	combination of automated + manually (SocialDISC: WSD, BiLSTM, SLPA)	SM analysis should (a) filter out irrelevant data, (b) sort information based on sub-events, needs, or user-defined categorizations, (c) reflect societal reactions to the impact of the disaster, (d) provide concise and easy-to-read results, and (e) ensure timely data processing. Analyzing the impact of Hurricane Harvey revealed that the disruption of housing and goods had the greatest impact on people's lives. In particular, tweets about relief and rescue were the most frequent among the nine categories and showed the most positive emotional signals. Information on societal impact, differences between expectations and realities, can be used in conjunction with other data as a reference for evaluating mitigation and preparedness plans for future disasters. Societal impact information derived from SM posts has the potential to improve disaster-specific models and assessment tools, contributing to increased community resilience.
27/ A, B	Zou et al., 2021	CrisisMMD and RE-SOURCE #9 (Cri-sisNLP)	Twitter	automated (adjusted VGG16, FastText model, Multimodal Fusion)	The presented multimodal approach consisting of deep learning method, FastText framework and data fusion model shows a better performance than the unimodal approach with 87.6 % and shows a better accuracy than the existing multimodal approach.

ABSTRACT

Utilizing social media and crowdsourcing (SMCS) in crisis management is crucial for improving communication and citizen engagement. However, practitioners working in crisis management organizations often face challenges when translating the outcomes of scientific research into actionable knowledge. To aid disaster management organizations, a comprehensive set of resources including practical tools, guidelines, and use examples are necessary. This will help response organizations to integrate the different components of SMCS coherently and consistently in their organizations and to promote disaster resilience for different users. An integrative Framework, developed by the authors as part of the EU-funded Horizon 2020 project, LINKS – *strengthening links between technologies and society for European disaster resilience* , serves such resources. This paper presents how this Framework came into being and describes its main components. It then provides a case study from the Netherlands, focusing on the scenario of industrial, chemical hazards, to illustrate how the Framework was actually used.

Keywords

Social media, crowdsourcing, crisis management, disaster resilience, integrated framework.

INTRODUCTION

Beginning in the early 2000s, professional first responders, citizens, and local community members started to use social media platforms during crises to obtain information and assistance. Since that time, the use of social media platforms have been studied, and many empirical studies gave evidence to th e benefits for improved crisis management and crisis communication (Vieweg et al., 2010; Meier, 2012; Burgess et al., 2013; Hughes & Tapia, 2015). Indeed the integration of social media and crowdsourcing (SMCS) in crisis management has become increasingly important in recent years (Imran et al., 2018; Reuter & Kaufhold, 2018; Lovari, 2020; Haupt, 2021; Mavrodieva & Shaw, 2021; Harrison et al., 2024). This is due to its potentials for enhancing citizen engagement and improving communication during disaster situations.

Researchers have found that the use of social media in crisis management can greatly enhance disaster resilience. The usage of social media platforms can help with the quick collection and sharing of crucial information, tapping into the *collective intelligence* (Bruns et al., 2012, Palen et al., 2009; Palen & Hughes, 2018). Social media can also provide a platform for citizens to share information, mobilize resources, and coordinate activities (Reuter & Kaufhold, 2018; Reuter et al., 2018), and facilitate collaboration and coordination between disaster management organizations and citizens – to which we refer with the term crowdsourcing. The platform Ready2Help, developed and utilized by the Netherlands Red Cross provides a perfect example (Schmidt et al., 2 018; Boersma et al., 2019. This initiative utilizes an app to activate members from an extensive network of nearly 100,000 volunteers during emergencies.

However, practitioners working in the field of crisis and disaster often have a hard time translating the outcomes of scientific research into actionable knowledge. This paper focuses on how SMCS can be adopted by first responder organizations and argues for organizational change toward disaster resilience in a Dutch case study related to industrial (chemical) hazard scenarios. The main objective is to help disaster management organizations to improve crisis communication and citizen engagement. To this aim, this paper proposes an integrative Framework for implementing SMCS into crisis management, which can address the challenges that come with the use of social media in disaster situations. By bringing together different components required for successful SMCS utilization, the Framework can help disaster management organizations to navigate the complex landscape of social media communication and address challenges such as information accessibility, credibility and relevance, and misinformation. Furthermore, it can help ensure that all populations, including vulnerable ones, have equal access to timely and accurate information during disasters.

In the remaining part of this paper we would like to propose an *integrative Framework* that could support (research into) organizational, institutional change towards disaster resilience by enhancing knowledge for improved communication and citizen engagement. We will present a case study from the Netherlands to show how the Framework can be utilized. The case focusses on three organizations and their stakeholders: the public organization *Safety Region*[1] *of South Limburg*, responsible for managing emergencies and communicating risks to the community; *Sitech Services*, a technical service provider that offers advice and support to companies on emergency services at the *Chemelot site*, an industrial multi-user site and research campus that houses sixty-four industrial – mainly chemical - plants and about one hundred and fifty organizations, with over eight thousand employees.

SOCIAL MEDIA AND CROWDSOURCING: OPPORTUNITES AND CONSTRAINTS

Social media play an important role in disaster community resilience by enabling crisis communication, encouraging citizen involvement, and giving access to key information. It may give useful real-time data and information from many sources, boosting perception of the situation on the ground and helping disaster management organizations to respond more effectively (Apuke et al., 2018). Social media assist emergency response groups in communicating with the public, allowing for real-time updates, early warning systems, and the transmission of crucial information during a crisis. It can also help them to provide valuable data and information to other emergency management agencies to make informed decisions.

Social media has become an essential tool in crisis management for disaster management organizations and stakeholders, helping to engage with citizens, improve communication, increase public awareness, and ultimately save lives. SMCS has a great potential in engaging citizens in disaster management activities and to provide insights into integrating citizen-generated content for a more accurate response. Effective communication

[1] In the Netherlands, a Safety Region (Dutch: Veiligheidsregio) is a public body whose task is to facilitate regional cooperation in dealing with crises, disasters.

strategies that consider diverse needs and perspectives are necessary, particularly for vulnerable populations. SMCS also demonstrated importance in successful crisis response and recovery by facilitating *social connections*, which is especially important since social media may be used to organize response activities, mobilize resources, and offer real-time information to impacted people (Bukar et al., 2022).

These and many more studies have provided evidence that using social media in crisis management may significantly improve disaster resilience, crisis communication, and response efforts. *However*, incorporating social media communication strategies into crisis management has to overcome a number of obstacles.

First of all, there is a *practical* constraint as most response organizations lack the recourse and the organizational routines to integrate SMCS into their day-to-day (operational and strategic) practices (Boersma et al., 2016; Nielsen et al., 2023). If SMCS tools are not carefully integrated in crisis management plans, protocols and organizational routines, its effective and efficient use during crises cannot be ensured. In practice, the implementation of SMCS in organizations remains a struggle.

Secondly, while studies have shown the usefulness of SMCS for engaging citizens in crisis management and communication, they also revealed the *exclusion* of disadvantaged groups from essential information because of issues with information accessibility, such as the digital divide and language barriers. This exclusion can lead to a lack of timely and accurate information reaching those who need it the most, perhaps exacerbating the effect of a crisis (Lovari et al., 2020; Pérez-Escolar & Canet, 2023).

Thirdly, the rapid diffusion of information on social media platforms can lead to the *spread of disinformation*, which we have in particular seen during the COVID-19 pandemic, and which can have serious consequences during times of crisis (Fernandez and Alani, 2018; Burel et al., 2021). Misinformation travels quickly and widely, undermining public faith in official information sources and creating p ublic doubt. This has the potential to aggravate the problem and make reputation management more difficult (Roshan et al., 2016). Therefore, crisis communication plans need to be designed to identify and address misinformation, while also ensuring that accurate and relevant information is disseminated promptly and in an inclusive way.

A way forward to overcome such challenges is to develop and use an integrative Framework that can help stakeholders working in disaster management organization to utilize existing insights and focus on what's important when considering the application of SMCS in disasters. Furthermore, it can help in strategic thinking especially in the planning phases, and guides disaster management stakeholders through existing knowledge based on the objectives and needs of their organization.

METHODOLOGY

The data collected for this paper has been part of a project, called LINKS "Strengthening links between technologies and society for European disaster resilience", funded under the H2020 Research and Innovation Program, Disaster Resilient Societies (DRS). LINKS aimed to address the challenges of SCMC for crisis management and communication (Clark et al., 2024). An important outcome of the LINKS project is an integrative Framework that can serve as a knowledge resource for disaster management organizations a nd other relevant stakeholders to guide them in applying SMCS in disaster risk management. The guidance through the Framework is organized under two thematic areas: 1) engaging with citizens and 2) improving crisis and risk communication. The Framework has a user guidance, which provides simple access to the tools in the Framework through a dedicated website. A visualization of the Framework is presented in Figure 1, and detailed information is provided at the LINKS website: https://links-project.eu/links-Framework/.

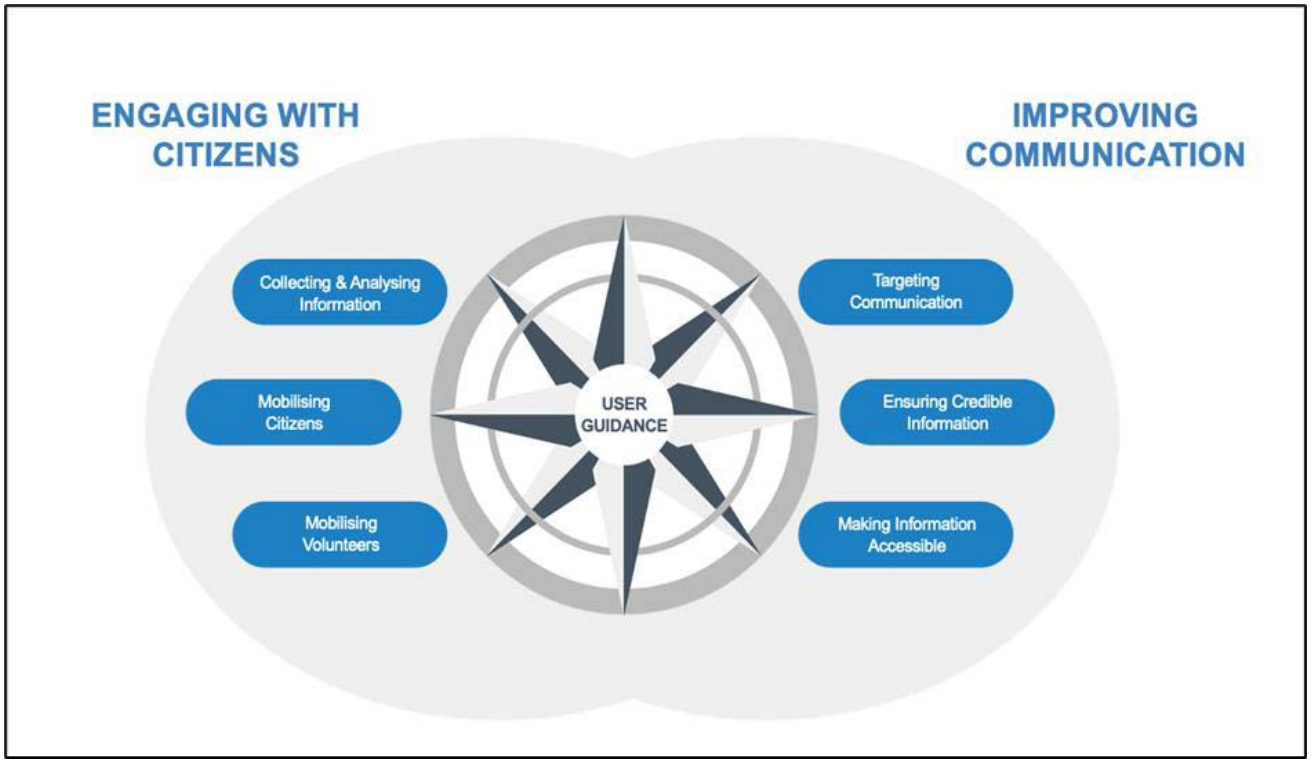

Figure 1. LINKS Framework adopted from Fonio et al., 2022

The Framework has been developed via an iterative process and based on a *participatory research approach* (Barreteau et al., 2013; Boersma et al., 2022) and on *action-research* (McNiff, 2013). The participatory dimension of our approach refers to the *co-creation* process that we adopted: in all phases of the research and the development of the Framework both academics and practitioners were involved from over 20 organizations. Usually it is hard to include citizens and community members in crisis management (Ferguson et al., 2018) but the Framework has been developed closely together with community representatives, labelled community *ambassadors*, whose role is explained in detail below. While the first few workshops were not organized in coordination with community representatives, over the course of several workshops the feedback from previous workshops and contacts in the field (both government and citizen contacts) have been used to better organize our workshops so they would be more appropriate for the audience and the needs. Currently this network is still used, in particular for communicating risk. On the long term this network has a big potential for active communication during a crisis.

In other words, the approach was action-oriented as the Framework was used as a tool to *intervene* in crisis management organizations to create organizational routines for the utilization of SMCS. The Framework was developed though different stages to do justice to both the participatory and the action -oriented dimension of the research.

In the first phase, we conducted 67 semi-structured interviews and an online survey with 284 responses across Europe to gain insights into the experiences, effective practices, and requirements of disaster management organizations and stakeholders regarding the use of SMCS for disaster management purposes. It was a vital part of our *participatory approach*. Specific themes were examined, such as decision-making protocols, sensitivity to vulnerability, reliable information, education, and technical aspects related to SMCS tools and processes used by disaster management organizations. The results were used to develop a first version of the Framework. Via five case studies related to specific hazards – drought, flooding, terrorist attacks, earthquakes and industrial incidents - we identified needs and gaps. The cases were contextualized in four European countries: the Netherlands, Denmark, Germany and Italy.

The second phase of the research was *action-oriented*: the Framework was implemented at case-level through workshops with practitioners (and other relevant stakeholders) to enhance crisis management (both response and preparation) and communication. Practitioners were asked to adopt SMCS in their crisis and communication plans using specific products embedded in the Framework, and also assisted with the development and updates of the products. Some of the most important issues we had to overcome organizing the workshops were:

- It was challenging to organize a workshop for shopkeepers, the general response was that they did not have the time to attend. We needed to adjust our workshop format for this group .
- We struggled to organize the workshop for civilians from the village Limbricht, which is located approximately 7.5 km away from the Chemelot site, citizens stated that they did not perceive any real danger for their town. We ended up organizing this workshop late in the evening on a non-holiday day.
- For those in the Lindenheuvel, directly neighboring the Chemelot site, the civilians had already been suspected to multiple research studies. Organizing the workshop in the Lindenheuvel required some mediation between other active (project) groups in the neighborhoods. This was done in order to prevent overloading the citizens any further.
- There were citizens who did not like hearing that they could contribute to preparedness as they felt that this was the responsibility of the formal authorities and the disaster management organizations. We heard reactions such as: "It is your job to keep us safe! Why does the responsibility have to land on our shoulders?". We were required to carefully navigate communicating safety in a way that did not feel leave the impression we were displacing responsibility.

Each workshop had its own focus group and included members of schools, hospitals, small businesses, shopkeepers. We also organized workshops with civilians in areas close to the Chemelot site (the neighborhoods of Lindenheuvel and Urmond) and one further away from the site (the neighborhood of Limbricht).

The workshops consisted of an informative component provided by professionals from the safety region of South - Limburg and from Sitech Services, a technical service provider. With information on the various roles of the disaster management organizations involved in the region during a chemical disaster, the upscaling of disaster scenarios and the actions that are taken by the disaster management organizations responsible during the various disaster phases.

Aside from an informative part the workshops also included an informal focus group discussion . The primary goal of the workshops was to ensure that citizens were made aware of the risks and that they know what to do in the event of a chemical incident. But perhaps most importantly, during the workshops we emphasized the importance of creating a plan and to practice this plan.

Participatory Action Research in the Dutch Case

During the initial stages of the project, we conducted qualitative and quantitative research into the communication practices of disaster management organizations active in the Safety Region of South-Limburg. In doing so we identified SMCS gaps in the communication practices of several disaster management organizations in the region. As an example, we found that the Safety Region utilizes the SMCS tool Obi4Wan. Obi4Wan is a very useful tool for data analysis and for monitoring social media activity. The inf ormation gathered through Obi4Wan is collected to make informed decisions during crises and for education and training purposes within the organization. The Safety Region of South Limburg uses its social media platforms to post about safety related information before and during crises. This information is often quite general, as this information is intended for a very large audience. The Safety Region of South Limburg does not have a tool which they can use to directly target specific communities or groups with risk and crisis communication. Nor is there a direct line of communication between the Safety Region and the community.

The participants in the meetings argued that organizing them around a certain *target group* or stakeholder (see Figure 2) would have the best effect if the participants could relate to a specific topic. In order to shape such target groups we reached out to the various organizations that belonged to a specific group or profession and left it up to the organizations to decide whom they chose to send as representative in what we called *community-based workshops*. To give an idea, for schools directors of several schools, members of school management, representatives of the school district (board) and representatives of the school's BHV team (bedrijfshulpverleening; the emergency response team of the school) represented educational professiona ls working in the near proximity of Chemelot. They brought in vital information about how schools (the school board, teachers and children) appreciated the industrial risks but also they could bring in information about the social fabric of the school's community that is useful for crisis management organizations.

The community-based workshops included: a discussion about the (formal) responsibilities of the disaster management organizations and governmental parties involved in preserving the safety of those at risk in the event of a chemical incident; an overview of the various actions disaster management organizations and governmental parties conduct in the preparation for and management of chemical incidents; a walkthrough of the safety protocols (what civilians are expected to do); a discussion on how civilians can improve their preparation and how disaster management organizations such as the Safety Region and Sitech can improve their communication in order to more directly target the needs of these groups in the communicative form that works best for them.

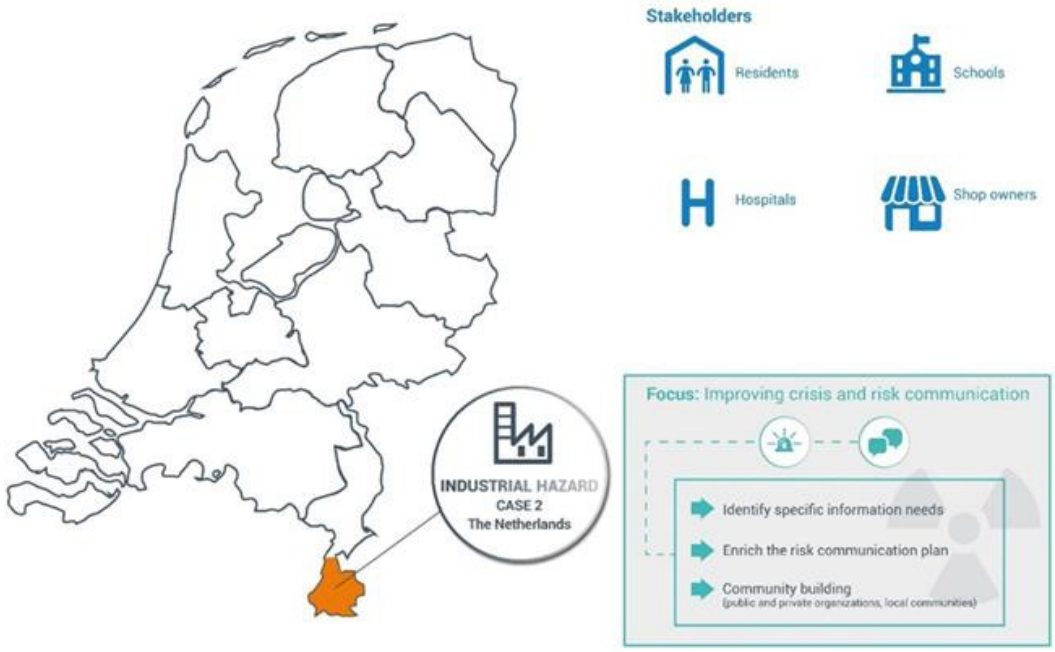

Figure 2. Case Area (from Clark et al., 2022)

Shaping an Ambassadors Network

The first community-based workshop was held in the municipality of Sittard-Geleen, neighboring the industrial site Chemelot, with the target group of *healthcare organizations*. This community-based workshop had eighteen participants, of which seven were healthcare professionals and eleven non -healthcare related professionals with a vested interest. This workshop included directors and healthcare professionals from various hospitals, healthcare practices and care homes from the surrounding municipalities. This workshop was primarily aimed at improving the risk awareness of the healthcare professionals, of making them aware that (chemical) accidents can happen and that proper preparation is therefore crucial, especially when there are so many moving parts. For example, staff on the road (on the way to clients or on the road with ambulances), staff at the homes of clients (care personnel), and staff at hospitals operating on patients (in the ICU).

The second targeted group was *schools* in from the various municipalities neighboring Chemelot (Beek, Stein, Sittard-Geleen). The workshop targeted school directors, school management, and school district representatives. The workshop had a total of thirty attendees, twenty-two were directors and upper management who represented the schools and board of education from the various municipalities. Of the remaining participants, five were organizers from the research team, and three were experts on risk and crisis communication (from the Fire Brigade, Sitech, Chemelot, the local government). This workshop had a similar goal of communicating the risks of a chemical incident, assessing the needs of the participants, providing an overview of the responsibilities of various parties and discussing the importance of creating a disaster plan. School directors, school management, and school district representatives appreciated the open discussion format of the community -based workshop, this provided the opportunity to exchange ideas, concerns and hurdles with us but also with one another.

The involvement of active representatives in the community-based workshops resulted in a network of *ambassadors* that helped us to *co-create* both the content and the implementation of the Framework and contributed to the understanding of the gaps in crisis communication and citizen engagement. The ambassadors can be seen as key figures who acted as 'boundary spanners' (Neal et al., 2022). Because the ambassadors were member of specific target groups *and* engaged in the risk awareness they were able to mobilize different stakeholders, such as healthcare institutions, schools (primary and secondary), and shop owners. The workshops brought together representatives of stakeholder groups that were identified a s priority target groups in the initial phase: health institutions, shop owners, and educational institutions. The meetings provided insight into the information needs of various stakeholders, investing in a sustainable community of professionals and resid ents, and supporting entrepreneurs, companies, and institutions in their preparations for a potential chemical incident.

RESULTS

Throughout the various workshops, we learnt about the vast number of online groups such as neighborhood WhatsApp groups or sport club WhatsApp groups. A single targeted safety message in one of these groups has the potential of being read by hundreds of individuals. The ambassadors advised us on how we can best target the groups or communities they help represent. They could give valuable input to the crisis management professionals present at the workshops on the type of preferred communication format (digital, print, word of mouth), langua ge and information is preferred. In addition, the ambassadors help share safety information about the chemical industry through their networks and help expand our existing network.

During the workshops the participants indicated that building and maintaining relationships with stakeholders is crucial, not only during emergencies (response phase) but also in 'normal' circumstances (preparation phase). This seems to be an obvious result, but it was striking how difficult it was for the different stakeholder to find each other despite the good intentions. Social media platforms were seen as a promising tool for making new connections, but at the same time their rapid changing popularity makes it difficult for the users to fully utilize their potential and to integrate them in the first responders' crisis communication strategies.

The community-based workshops' participants agreed that understanding *how* information is shared and received by citizens and professionals is key and depends on the characteristics of a specific platform . Not knowing how to use them and how to make sense of the data creates confusion. For example, various publicly accessible social media sources are used by the Safety Region Limburg South to gauge information needs and sentiments, but there are doubts about how representative these sources are of how the inhabitants of the municipalities actually feel about hazards and risks. Communication between citizens increasingly occurs in non-public spaces, such as neighborhood apps or family groups, which can make it challenging to assess information needs and sentiment towards organizations.

The discussions revealed that adequate and precise crisis communication is challenging in case of a chemical spill. For example, recalling people back inside or instructing them to stay indoors during a chemical incident was identified as an area that needs more attention. The workshop participants emphasized the need for better communication systems and guidelines within healthcare organizations to ensure that critical information is disseminated effectively.

Finally, we found a need among the first responders to clarify the concept of *crowdsourcing*, as they struggle with finding the right tools to mobilize citizens. The lack of internal guidelines, organizational routines but also laws and regulations regarding social media and crowdsourcing during crises and disasters were seen as serious constraints.

Zooming in: Community-Based Workshops with Healthcare and Educational Professionals

The community-based workshops we organized with and for *healthcare professionals* identified several key conclusions regarding the preparedness of healthcare organizations for chemical incidents. Participants highlighted the need for more emphasis on self-reliance and preparedness of healthcare organizations and their staff, indicating a gap in current practices. They also expressed surprise that they were supposed to practice and prepare for chemical incidents, and they indicated the need for greater awareness and room for training to ensure that healthcare professionals are adequately prepared for such events.

The healthcare professionals appreciated being able to communicate their reservations and needs directly during the workshop. They pointed out that they would like more direct and targeted communication between disaster management organizations and the communication teams of the respective hospitals and healthcare practices. For example, questions raised by the workshop's participants were: "If we need to close the doors and windows, are we allowed to let our staff inside?", "If we turn of the ventilation or IC units won't function anymore.", "A lot of our care home workers are often on the road with the bike or car, how do we preserve their safety?" and – a returning question - "How do we make sure people stay indoors during an incident?"

They hoped for more targeted information during crises but also assistance in creating disaster plans for their own organizations. The workshop participants emphasized the need for incident training exercises for healthcare organizations and suggested that existing structures, such as hospital ventilation and organizational guidelines, should be re-evaluated and adapted for chemical incidents. These findings suggest that ongoing preparedness efforts are needed to ensure the safety of healthcare professionals and patients in the event of a chemical incident and that a comprehensive approach is required to address the identified gaps in current practices.

The community-basedworkshops with *educational professionals* identified several key conclusions related to the preparedness of educational systems for chemical incidents, highlighting the need for accessible and functional

windows, doors, grilles, and ventilation systems that can be quickly and easily closed off in the event of an incident. The workshop also recommended that schools have a pre-prepared (digital) message for parents, teachers, and children, as well as a meter card for chemical incidents and a well-coordinated communication plan. Additionally, the workshop emphasized the need for schools to establish a clearance program and practice different scenarios to ensure they are well-prepared to respond to any potentia l incidents.

Some of the school directors advised the crisis management professionals to practice exercises with their schools and others requested assistance with their disaster plans. The schools commented that they would appreciate more direct communication with the Safety Region in particular, they felt it would also be beneficial if there was a way to improve the communication between the schools themselves. It can be confusing for parents with children that go to different schools when not every school reacts the same way to incidents. For example, certain schools letting the children go while other schools keep the children inside for safety reasons. Examples of the kind of questions and issues for discussions during these meetings were: "What do we do if there are parents at the door, but we are required to keep students indoors for their safety?" and "We had an incident a while back where students from a neighboring district were allowed to go home, but we kept the students indoors. What do we tell the angry parents?"

The community-based workshops (guided by the implementation of the Framework) proved to be effective in contributing to the development of effective tools and resources for enhancing preparedness and response capabilities in the event of a chemical incident. By sharing practical perspectives, they contributed to the development of a more comprehensive and inclusive framework for engaging citizens in various crisis contexts.

DISCUSSION AND CONCLUSION

In this paper, we argued for the need to develop a coherent set of tools and guidelines – an integrated Framework - to successfully implement, utilize and further develop social media and crowdsourcing in crisis and disaster management. SMCS tools were seen as promising, but only if they serve the needs of local communities and under the condition that they could be easily integrated in the first responders organizational routines. And while there is a lot of knowledge on both the benefits and the challenges of SMCS in crisis context, both academics and practitioners struggle to integrate the knowledge coherently and consistently. By providing a framework based on co-creation activities, we believe the use of SMCS can be more successful. Next, we introduced the Framework developed in the European project LINKS and its implementation in a case study on industrial, chemical hazards.

The case study illustrates how the Framework helped to identify key components for effective SMCS integration in crisis management. However, continuous iteration is necessary for a successful use and integration of SMCS in crisis management and communication practices. The iterative process and the participatory and action-oriented case study approach allowed refinement to address emerging challenges and specific needs. The community-based workshops served as a means to apply and refine SMCS integration. Local community ambassadors networks were vital to developing effective tools and resources for enhancing preparedness and response capabilities in specific contexts.

The case has also shown how the Framework can contribute to organizational change by enhancing preparedness and response capabilities for chemical incidents in healthcare and educational institutions. By integrating the feedback from community-based workshops professional first response organizations made a start with the development of effective practices for the integration of SMCS. Perhaps the most important lesson when it come sot the successful use of social media for crisis and risk communication is that it should be combined with or contain concrete ' action perspectives' and that face-to-face meetings with those who are supposed to follow up the messages are crucial.

Finally, the ambassador program is an example of how crisis management organizations can be actively engaged with a diverse range of community organizations, including educational institutions, healthcare institutions, and neighborhood support groups to enhance preparedness and response capabilities for chemical incidents in municipality neighboring a chemical hazardous site.

A Promising Outlook

The Framework's focus on local implementation has allowed for a tailored approach that considers local diversity, vulnerability, accessibility, and institutional learning processes, enhancing disaster resilience and coordination between authorities and citizens. The co-created nature of the Framework proposed in the paper has contributed to its legitimacy. Looking to the future, the Framework can contribute to development of organizational and institutional routines based on the experiences of both professional first responders and citizens. By sharing practical perspectives, it will continue to help shape the development of more comprehensive and effective

resources for engaging citizens and improving the use of SMCS, beyond the case of Chemelot.

We believe that using such integrative frameworks for SMCS based on co—creation approaches will result in better communication practices in disaster management and ultimately contributing to a safer and more resilient society.

ACKNOWLEDGMENTS

This work was supported by the LINKS Project that has received funding from the EU Horizon 2020 Research and Innovation Programme under Grant Agreement No. 883490. We would like to thank the project's partners Safety Region of South Limburg, Sitech Services and Chemelot for providing access and for co-organizing the workshops.

ABSTRACT

Typhoons significantly impact socio-economics, varying in impact due to unique characteristics. However, limited studies explore why similar intensity typhoons affect regions differently. This study compares the emergency response measures of Zhuhai, Guangdong Province, China, in response to typhoon Hato (2017), Mangkhut (2018), and Higos (2020). These three similar typhoons offer an empirical opportunity to assess the effectiveness of emergency management. This research builds a timeline of Zhuhai's emergency response measures to the typhoons, collects Weibo data 72 hours before and after the typhoon landfall, performs keyword frequency analysis on contents and analyzes in detail the content of weibo postings, and changes in sentiment. Results show that timely and systematic emergency response measures may reduce disaster losses, which means emergency management is crucial in mitigating typhoon impacts, offering valuable lessons for other coastal cities.

Keywords

Typhoon disaster, emergency management, comparative analysis, data mining.

INTRODUCTION

Typhoon is an extremely destructive natural disaster whose impact spans the corners of globe (Gettelman et al., 2018). Worldwide, about 150 million people are affected by typhoons each year (Geiger et al., 2021). The Typhoon can trigger strong winds, heavy rainfall, storm surges and other disasters, posing a significant threat to human life safety and social property, and causing severe impact on industries such as agriculture, fisheries, and transportation. For example, Hurricane Katrina in 2005 caused severe flooding in areas such as New Orleans, which dislocated a large number of residents and resulted in more than 1,800 deaths and an estimated $125 billion in economic damages, also exposing the humanitarian crises (Guidotti, 2006). Similarly, Hurricane Haiyan in the Philippines in 2013 affected about 12.2 million people, causing almost 490,000 homes completely destroyed and

WiP Paper – Social Media for Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024

more than 590,000 homes partially destroyed, resulting in economic losses estimated at PhP 424 billion , representing 3.7 percent of GDP that year in Philippines (Santos et al., 2016). In addition, Typhoon Haima in 2016 (Zhang et al., 2019) and Super Typhoon Mangosteen in 2018 (Choy et al., 2020) wreaked havoc in the Philippines and Southeast Asia, causing thousands of loss lives and devastating the local economy and social stability. These cases highlight the threat and danger of typhoons as an extreme weather phenomenon. Studies have shown that under global warming and climate change, the intensity and uncertainty of typhoons are continuing to increase, and the number and proportion of typhoons with high intensity will rise (Xu et al., 2020). Hence, there is an urgent need to attach greater importance to typhoon disasters and the corresponding emergency management measures.

Typhoon disaster emergency management encompasses organized, planned, and coordinated activities to mitigate the impact of typhoons on lives, property, and the socio-economy. Worldwide research focuses on risk assessment, early warning, emergency response, and post-disaster recovery. Risk assessment is crucial for comprehensive disaster mitigation and emergency management, helping prevent and reduce losses (Shiyuan et al., 2006). Early warning systems are essential, and researchers aim to improve prediction accuracy using modern meteorological and information technology (Huo et al., 2019; Jiang et al., 2018). Innovations like drone technology enhance monitoring, visualization, and analysis, strengthening meteorological and disaster forecasting collaboration (Chen et al., 2020). Multi-departmental and multi-level warning systems are established and improved, with various release channels to ensure timely warnings to the public. Post-typhoon reconstruction aims to restore normalcy, emphasizing environmental protection and sustainable resource use. It also promotes social psychological recovery and economic revitalization. Comprehensive measures, including enhanced early warning sy stems and improved policies, aim to address the profound impact of typhoons, ensuring a sustainable an d steady future for society (Sylwanowicz et al., 2018).

Typhoon disaster emergency management hinges on swift and effective emergency response. Scientific typhoon emergency plans delineate departmental responsibilities, coordinate resources, and ensure rapid, effective responses. A study retrieve the most similar historical cases, providing a reference for generating emergency plans for target typhoon trajectories (Li, 2022). Scientific evacuation plans (Sun et al., 2020) and the selection of emergency shelter locations (Anping, 2010) are directly related to personnel safety. A model based on typhoon track changes aids in emergency shelter allocation (Qin et al., 2019). Meanwhile, the reserve and demand forecasting of relief supplies are crucial aspects of emergency response (Pan et al., 2017; Uichanco, 2022). By predicting the real-time and future needs of affected areas, various types of relief supplies can be reasonably stocked to ensure timely and effective rescue operations after disasters occur. Additionally, the adequacy of household emergency preparedness has garnered attention. Through investigative research, scholars have found that enhancing household awareness and preparatory measures for typhoon events can effectively reduce disaster-related losses (Chan et al., 2019). The timeliness and effectiveness of post-disaster rescue are crucial for mitigating disaster losses and safeguarding people's lives (Santiago et al., 2016). The restoration of water networks (Wei et al., 2018), power grids (Liu et al., 2023), communications (G.C et al., 2019), and transportation (Wang et al., 2018) is essential for resuming normal social functions in affected areas. Researchers are dedicated to enhancing the disaster resistance of these infrastructures and studying efficient restoration solutions to expedite the return to normal social operations after disasters. The recovery of the healthcare system is a critical aspect of typhoon disaster emergency response. Scholars focus on ensuring adequate medical resources, timely emergency services, and optimizing the organizational structure of the healthcare system to meet medical needs during disasters (Lai et al., 2003; Su, 2013). In recent years, social media has demonstrated a significant role in crisis response (Liu et al., 2020), particularly in typhoon disaster emergency management (Athanasia & Stavros, 2015; Pollack et al., 2015). Its immediacy and interactivity make it a pivotal channel for information dissemination, aiding the public in quickly accessing warnings and emergency measures. Social media content analysis offers new insights and means for risk assessment and early warning. Furthermore, social media facilitates the coordination and integration of rescue efforts, enhancing rescue efficiency. For instance, studies have employed sentiment analysis through artificial neural networks to assess the urgency of relevant social media information, thereby enhancing the efficiency and effectiveness of emergency management (Ermino et al., 2022).

China, with its extensive coastlines and unique geography, is highly susceptible to typhoons (Wang et al., 2021), particularly in the major deltas of Tianjin, Shanghai, and Guangzhou (Yin et al., 2013). The southeast coast experiences frequent typhoons and significant damage, while rapid economic development and population density have increased economic losses from typhoon disasters (Li et al., 2016). As a coastal city in Guangdong Province, Zhuhai is located on the west bank of the Pearl River and is directly affected by the typhoon season. Historical records show that Zhuhai has endured numerous severe typhoons, posing constant challenges to urban management and disaster prevention and mitigation efforts. Differences in actual damage caused by similar-intensity typhoons are observed. This study compares three recent typhoons—Pigeon (2017), Mangkhut (2018), and Higos (2020)—with similar paths and intensity, all significantly impacting production and living in Zhuhai.

Using a comprehensive big data approach, this study analyzes news and social media data on Zhuhai's typhoon disaster emergency management. Through word frequency and categorical analysis, we aim to understand the evolution of Zhuhai's emergency response to similar-intensity typhoons. Results show Zhuhai's consistent optimization of emergency measures, which improves the city system's resilience to natural disasters. This study provides theoretical insights for disaster prevention, mitigation, and sustainable urban resilience.

OVERALL STRUCTRUE

This study (Figure 1) focuses on three recent typhoons hitting Zhuhai — Hato (2017), Mangkhut (2018) and Higos (2020) — with similar tracks and intensities. Data mining is used to collect relevant news articles and Weibo data tagged with 'Zhuhai' and 'typhoon', while web crawling retrieves Weibo during a 144-hour window, encompassing 72 hours before and 72 hours after each typhoon's landfall, forming a comprehensive disaster event dataset. Analyzing Weibo content via lexical frequency, word clouds and categorization, the study uncovers prominent public concerns and tracks changes in emotional sentiment throughout the warning-to-recovery cycle. It offers a new perspective on disaster management by vividly illustrating these fluctuations in a time series graph.

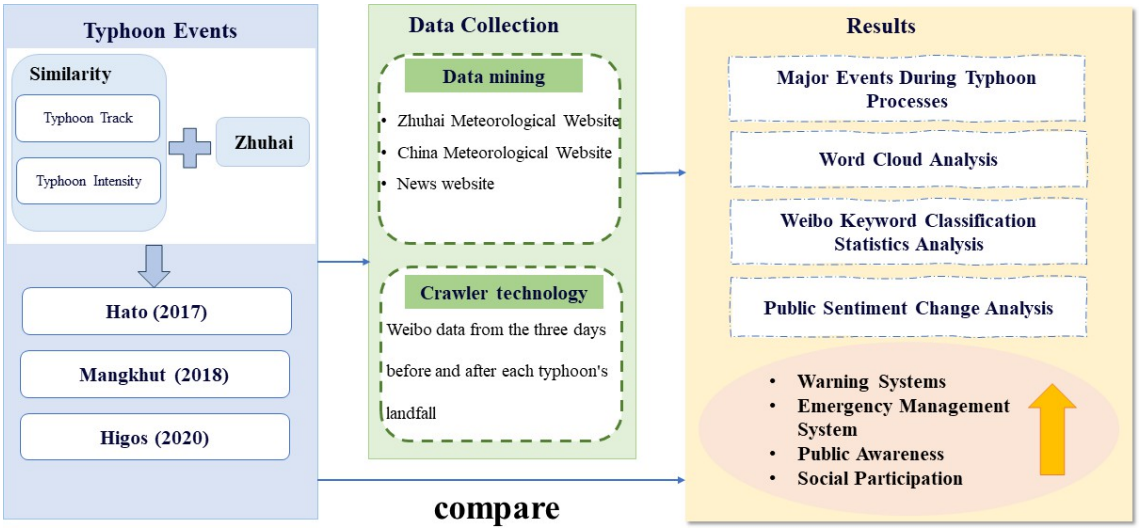

Figure 1. The overall structure of this paper

STUDY AREA AND TYPHOON EVENTS

Study Area

Zhuhai, situated in Guangdong Province's southwestern Pearl River Delta, is a central Pearl River Delta city and boasts the region's largest ocean area, most islands, and longest coastline. It uniquely connects to both Hong Kong and Macao via road. Covering 1,725 km² of land and 9,348 km² of sea within its territorial baseline, Zhuhai had 2.477 million residents by late 2022, with a 90.76% urbanization rate. Administered through Xiangzhou, Doumen, and Jinwan districts, it includes 15 counties, 10 streets, a nd 329 villages/communities (Figure 2). Zhuhai experiences a subtropical monsoon climate, prone to various catastrophic weather influences and emergencies, particularly typhoons in summer and autumn. Typhoons bring substantial unpredictability and complexity, inflicting wind, rain-induced flooding, and coastal storm surge disasters on Zhuhai. The city averages around 4 typhoons annually, with 1 severe impact and 5 instances of heavy rainfall, according to the Zhuhai Meteorological Bureau's "White Paper on Meteorological Public Services". (Su et al., 2022)"

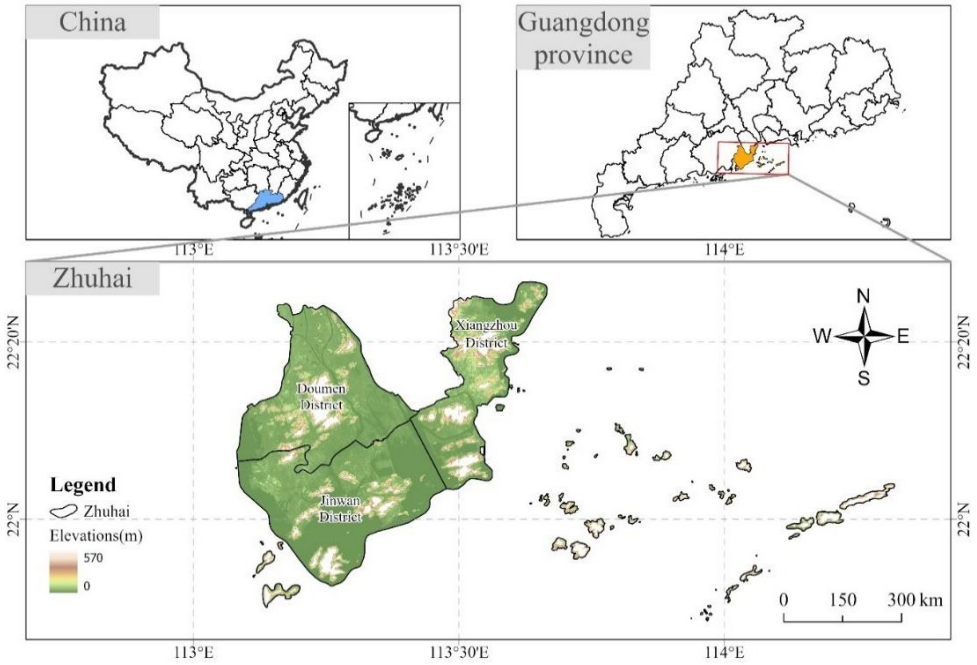

Figure 2. Geographic location of zhuhai

Typhoon Events

Using the 1949-2022 tropical cyclone dataset from the China Meteorological Administration (Lu et al., 2021; Ying et al., 2014), a 300 km radius around Zhuhai was analyzed for typhoon impact. Excluding the unnumbered typhoons, a total of 1540 typhoons are collected in the dataset, and finally 228 typhoons affecting Zhuhai are extracted, averaging 3.08 typhoons per year. Typhoons Hato (2017), Mangkhut (2018), and Higos (2020) are selected as the study objects (Table 1) based on their intensity, wind speeds, trajectories (Figure 3), and impact on Zhuhai.

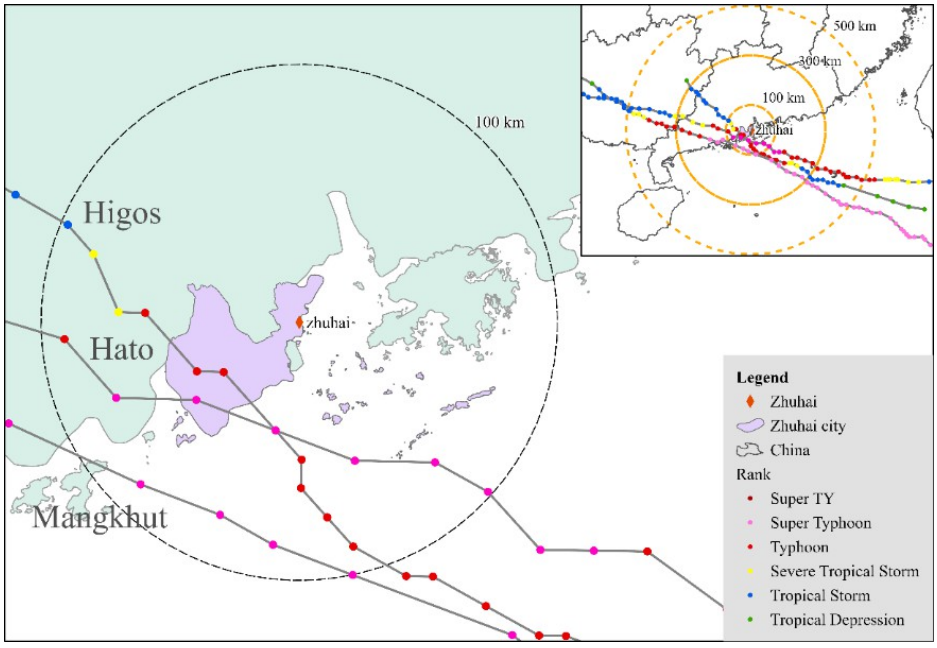

Figure 3. Trajectories of typhoon Hato, Mangkhut, Higos

Table 1. Disaster Information of Typhoons and its Impact on Guangdong Province

Typhoon	Hato	Mangkhut	Higos
Year	2017	2018	2020
Generation time(month/day)	8/20	9/7	8/16
Landing time(month/day)	8/23	9/16	8/19
Landing site	Zhuhai, Guangdong	Taishan, Guangdong	Zhuhai, Guangdong
Landing intensity	Super Typhoon	Super Typhoon	Typhoon
Maximum wind power (level) (wind speed, m/s)	14(48)	14(42)	12(33)
Affected areas (mainland China)	Guangdong, Guangxi, Yunnan, Hunan, Guizhou, Fujian	Guangdong, Guangxi, Hainan, Hunan, Yunnan, Guizhou	Guangdong, Guangxi
Impact on Guangdong Province			
Affected population(10,000 people)	142.4	306.6	6.3
Deaths (people)	13	5	0
Missing (people)	0	0	0
Transfers (10,000 people)	21.3	126.4	4.7
Collapsed houses (10,000)	0.1	0.2	0
Affected area (10,000 hectares)	6.4	23.2	1.23
Direct Economic Losses (Billions of CNY)	27.36	13.29	0.42

The typhoons Hato, Mangkhut, and Higos share similarities: they occurred consecutively, hit Guangdong Province with typhoon-level intensity, and exhibited distinct seasonal patterns. Their similar tracks suggest Guangdong, particularly Zhuhai, is a key impact zone. Despite these similarities, they differed in their impact on Guangdong. Based on statistical data regarding the affected population and areas, typhoon Hato demonstrates an exceptiona **l**y high level of destructiveness and ferocity. Nevertheless, it is noteworthy that the direct economic losses attributed to Hato are merely half of those incurred by Mangkhut, along with a relatively lower count of fatalities. Similarly, despite its slightly reduced intensity, Higos has incurred lesser losses, leading us to inquire about the presence of other influencing factors. These unusual phenomena have piqued our curiosity, necessitating a further exploration of the underlying reasons for such outcomes.

METHODOLOGY

The data collection process involves systematically scraping web content using the Octopus Crawler. Octopus Crawler analyzes web pages and, leveraging regular expressions and XPath techniques, accurately locates and extracts HTML elements containing target data from the web pages. Data pre-processing includes manual deduplication and filtering of invalid content. In the deduplication process, user IDs, posting times, and text contents are compared to effectively remove duplicate Weibo entries. Invalid content filtering removes irrelevant items such as advertisements, entertainment news, and posts containing only emoticons, symbols, and web links with minimal text information, thereby improving the purity and accuracy of the data. Next, the preprocessed dataset is utilized for keyword extraction using the "jieba" package and TF-IDF (Term Frequency-Inverse Document Frequency) algorithm in Python 3.11. The "jieba" package performs Chinese word segmentation, laying the foundation for TF-IDF calculation. TF-IDF takes into account both term frequency (TF) and inverse document frequency (IDF), where TF reflects the importance of a word in the current document (Equation (1)), while IDF reflects its generality in the corpus (Equation (2)). The TF-IDF value is obtained by multiplying TF and IDF (Equation (3)), with a higher value indicating greater importance of the word. Where n represents the frequency of word t in document d, N stands for the total number of words in document d, p denotes the total count of documents in corpus D, and q indicates the number of documents that contain word t.

$$\mathrm{TF}(t, d) = \frac{\mathrm{n}}{\mathrm{N}} \quad (1)$$

$$\mathrm{IDF}(t, D) = log\ \frac{p}{\mathrm{q} + 1} \quad (2)$$

$$\mathrm{TF} - \mathrm{IDF}(\mathrm{t}, \mathrm{d}, \mathrm{D}) = \mathrm{TF}(t, d) \times \mathrm{IDF}(\mathrm{t}, \mathrm{D}) \quad (3)$$

SnowNLP is a package in Python 3.11 for Chinese text sentiment analysis. It assigns a sentiment score between 0 and 1, with values closer to 1 indicating a more positive sentiment, closer to 0 denoting a more negative sentiment, and around 0.5 suggesting neutrality or ambiguity. The score is often discretized into positive, neutral, and negative categories for easier interpretation in practical applications.

RESULTS

Major Events During Typhoon Processes

Utilizing big data technology, a systematic collection and chronological arrangement of key event news is conducted for the 72 hours surrounding typhoon landings, encompassing sources such as Zhuhai meteorological websites. This encompasses timely warnings, government emergency responses, societal participation, mutual assistance, and post-disaster recovery. Through in-depth analysis, a comprehensive understanding of typhoon emergency management is achieved. Specifically, by comparing response effectiveness, practical strategies are identified, and areas for improvement are pinpointed. In responding to the typhoon, Zhuhai has adopted a series of effective and strategic emergency response initiatives (Table 2). Typhoons Hato, Mangkhut and Higos have some similarities in Zhuhai's emergency management initiatives, including the following:

1. Early warning system activation: Before typhoon strikes, Zhuhai city has activated the early warning system, releasing early warning information to the public through radio, television, cell phone text messages and other means to remind the public to take precautionary measures.
2. Emergency plan initiation: Before the typhoon struck, Zhuhai all activated their emergency plans, taking measures such as stopping work, production, market and classes, opening a number of shelters, relocating people from areas likely to be affected, carrying out hidden dangers, and taking precautionary and coping measures to minimize the impact of the typhoon on production and life.
3. Organization of rescue forces: In the wake of typhoons, Zhuhai has promptly organized rescue forces, including firefighting, medical and public security departments, to be ready to respond to emergencies and to actively carry out rescue work to ensure that the affected citizens receive timely relief.
4. Post-disaster recovery work: In the aftermath of typhoon, Zhuhai acted swiftly and actively carried out post-disaster recovery work. Government staff, the public, party members and volunteers from all sectors of society made concerted efforts to work together on infrastructure repair, road clearing, food safety inspections, etc., to ensure that citizens' living and working order returned to normal as soon as possible.

Comparative analysis of typhoons Mangkhut and Higos shows earlier warnings, leading to better Zhuhai preparation. Government, organizations, and public responded swiftly and effectively during critical 24 hours, with district governments actively identifying risks. This improved typhoon response in Zhuhai is not coincidental, but a result of past reflections and improvements. Before super typhoon Hato, Zhuhai lacked similar-sized typhoon references, potentially leading to underestimation of the typhoon's hazards by the public. Challenges prompt Zhuhai to improve its response, significantly enhancing warning accuracy and timeliness. The emergency response becomes more efficient, with departments quickly coordinating resources and protecting infrastructure. For instance, during Higos, a comprehensive emergency command center ensures timely and accurate warning dissemination.

Table 2. Timeline of emergency management measures for typhoon Hato, Mangkhut, Higos

	Hato	Mangkhut	Higos

Word Cloud Analysis

Public attention and participation in typhoon disasters play a vital role in emergency management. Employing data scraping techniques on the Weibo platform, we captured and analyzed public Weibo postings spanning the entire three days before and after each typhoon landfall, inclusive of details such as post timestamps, authors, and content. This yielded a rich trove of raw data for subsequent analysis, enabling an in-depth exploration of public focus points, emotional attitudes, and shifts in social discourse during typhoon events. After meticulous screening and organization, 11,221 Weibo posts were retained from an initial pool of 12,924. Of these, 4,693 pertained to typhoon Hato (2017), 4,862 to typhoon Mangkhut (2018), and 1,666 to typhoon Higos (2020).

Employing the "jieba" package and TF-IDF calculations for keyword extraction, we observed that keywords with higher term frequencies typically exhibit correspondingly elevated TF-IDF values, substantiating the efficacy of our keyword extraction approach. A threshold of 0.1 is chosen, selecting keywords as those with TF-IDF values exceeding this threshold. The Chinese keywords are then manually translated into English and used to generate a word cloud via Python programming. This allowed us to gain a visual, intuitive understanding of the focal points of public attention and emotional responses during the typhoon period. Statistical analysis of Weibo posts on the three typhoons identified high-frequency words (Figure 4a) like "typhoon," "Zhuhai," "landfall," "news," and "warning," reflecting the substantial societal impact and concern for the affected region. Meanwhile, each typhoon showed distinct focal points: typhoon Hato in 2017 (Figure 4b) emphasized intensity, urgency, and severe damages; Mangkhut in 2018 (Figure 4c) highlighted the importance of preparedness, safety measures, and post-disaster rescue; Higos in 2020 (Figure 4d) underscored the role of early warning systems in risk mitigation and loss reduction. These findings demonstrate continuous improvements in typhoon emergency management in terms of technology, response maturity, risk management strategies, social engagement, and public awareness.

(a) All three Typhoons (b) Typhoon Hato

(c) Typhoon Mangkhut (d) Typhoon Higos

Figure 4. Weibo content keywords about typhoons

Weibo Keyword Classification Statistics Analysis

Weibo user content is categorized as Warning (disaster alerts and prevention), Damage (post -landfall situations), and Response (immediate rescue and aid). Figure 5 highlights the stage characteristics in the 144 hours surrounding typhoon landfall. As typhoons approach, content shifts from warnings to damage reports and response efforts. The number of posts peaks post-landfall, reflecting societal concern and urgent response. Before landfall, Weibo disseminates warnings to prepare the public. Afterwards, damage reports and rescue actions dominate, with posts peaking, reflecting societal urgency. As recovery begins, content transitions to reflecting progress, unity, and hope for the future. The process of discussions, ranging from early warnings to disasters and then to rescue efforts, reflects the evolution of typhoon characteristics and the shift of public attention. Furthermore, comparing the three typhoons, Typhoon Mangkhut had the highest information volume, with a significant focus on warnings around landfall. In contrast, Typhoon Hato mainly comprised damage messages, possibly due to lessons learned from the previous year, leading to increased emphasis on pre-disaster warnings and mitigation, which may have contributed to reduced losses during Typhoon Mangkhut. The lower volume and attention for Typhoon Higos may be attributed to its milder impact, swift movement, and the accumulation of typhoon experience, enabling improved early warning and response. Social media is vital in typhoon management, providing real-time information and mobilizing the public.

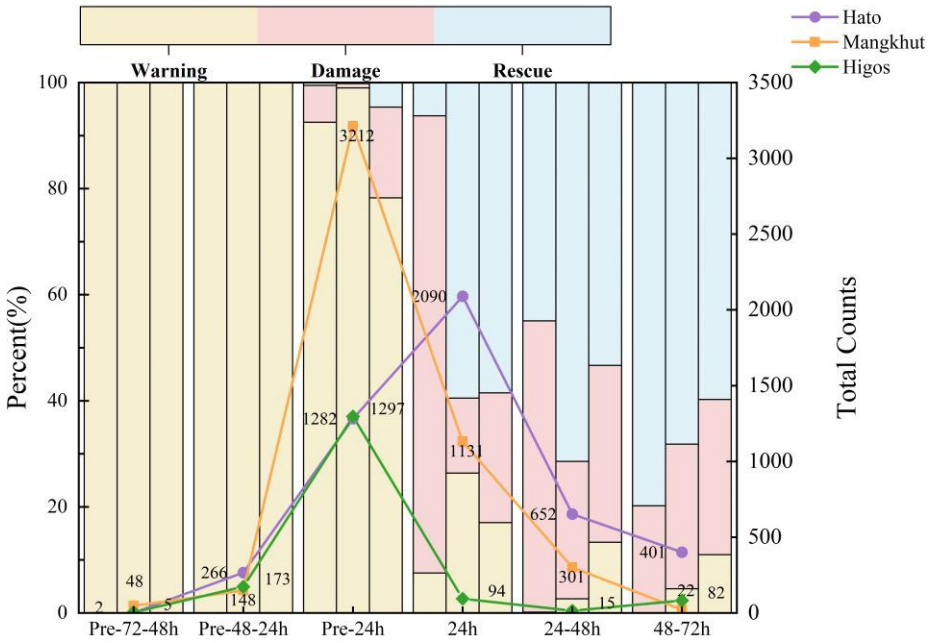

Figure 5. Weibo messages classification and counts

(Left to right: typhoon Hato, Mangkhut, Higos. Bar show percentages, Line are number of Weibo posts)

Public Sentiment Change Analysis

SnowNLP package is used for sentiment analysis, classifying Weibo content as positive, negative, or neutral based on sentiment scores (scores > 0.6 = positive, < 0.4 = negative, 0.4 -0.6 = neutral). Figure 6 reveals how Weibo reflect public emotional responses to approaching typhoons. Prior to a typhoon, positive emotions tend to gradually decrease or remain stagnant, while negative emotions escalate, indicative of rising anxiety and concern. During the typhoon, negative sentiments peak due to fear and distress caused by the storm's impact and hazards. Post-typhoon, positive emotions rebound and negative ones subside as individuals recover and appreciate relief efforts. By comparative analysis, typhoon Higos exhibits a comparatively high level of positive sentiment, paralleling its relatively low disaster intensity and damage, along with more structured and efficient emergency management strategies. Furthermore, there has been a decline in the proportion of negative sentiment and a concurrent increase in positive sentiment from 2017 to 2020, suggesting that the public has become more proficient in typhoon emergency response. This accumulated experience not only assists individuals in overcoming their fears but also testifies the continuous improvement in emergency mana gement practices.

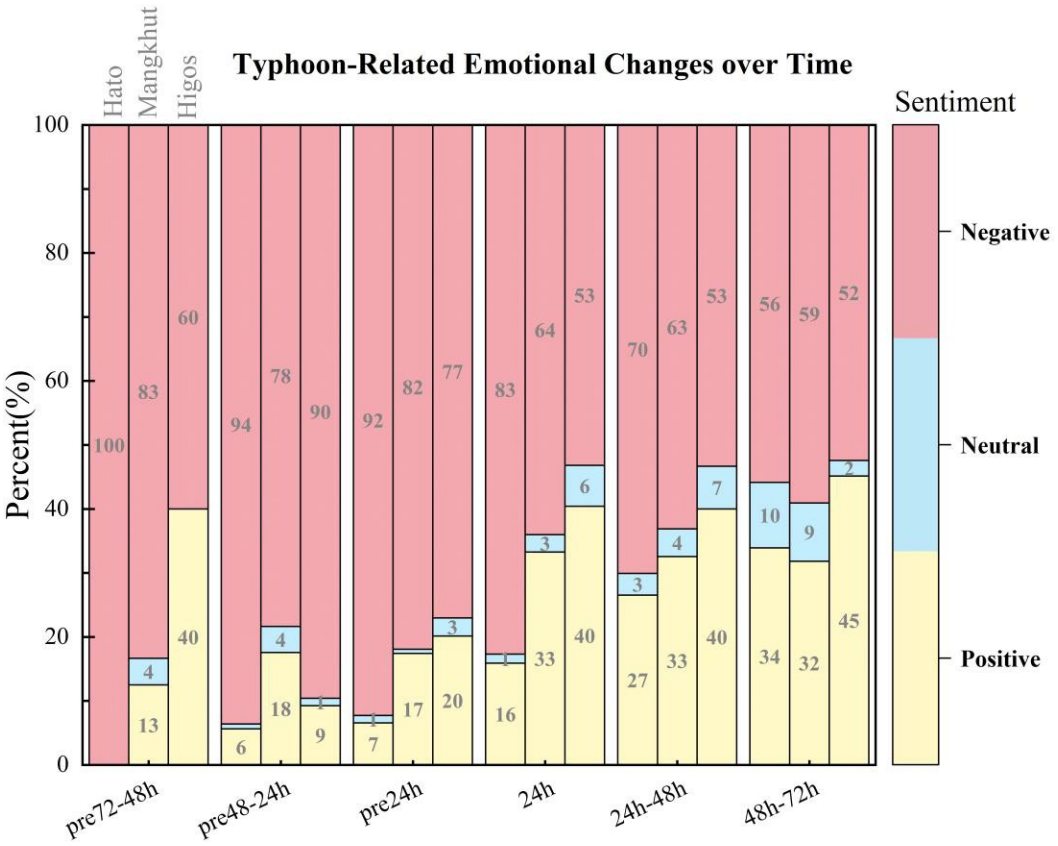

Figure 6. Sentiment evolution in public Weibo activity during typhoons

(Left to right: typhoon Hato, Mangkhut, Higos)

DISCUSSION

This study presents a comprehensive examination of the impacts of typhoons Hato (2017), Mangkhut (2018), and Higos (2020) on Zhuhai, incorporating an analysis of typhoon characteristics, response strategies, and public sentiment. Initially, comparative analysis of typhoon paths and collation of key disaster data facilitated a holistic understanding of the typhoons and their effects on Zhuhai. Subsequent scrutiny of implemented response measures post-landfall revealed a decreasing trend in economic losses and casualties, indicating enhanced emergency management capabilities and accumulated experience. Weibo data analysis was employed to gauge public sentiment and concerns. The keyword clouds generated from this analysis reveal distinct foci of public attention, ranging from the intensity of Hato, to the rescue efforts during Mangkhut, and the warning sy stems associated with Higos. Statistical analysis of content categories elucidated the shifting public attention, encompassing warnings, disaster impacts, and rescue operations. Sentiment analysis of Weibo showed negative emotions prevailing during typhoons, gradually giving way to positive sentiments as focus shifted towards recovery. A declining trend in negative emotions from 2017 to 2020 suggests improving emergency management practices.

All typhoons have provided valuable experiences and lessons to Zhuhai, leading to enhancements in typhoon prevention mechanism. The Hato specifically highlighted the seriousness and complexity of typhoon disasters, resulting in significant improvements. Zhuhai has upgraded its early warning system, forecast accuracy, and emergency response, reflected in the "Zhuhai Typhoon Prevention Regulations" since February 2020. Technological advancements have strengthened Zhuhai's emergency management. Media and edu cation have raised public awareness, fostering community-wide disaster prevention and government cooperation. Despite challenges from climate change and urbanization, Zhuhai's progress highlights the need for enhanced early warning systems, cross-sectoral coordination, infrastructure, and social participation in disaster response. Zhuhai's achievements in typhoon prevention underscore the significance of experience summarization, mechanism building, and public awareness in tackling natural disasters. Sharing effective emergency management practices globally is crucial to reducing typhoon threats.

LIMITATIONS

When conducting a thorough examination of the study, several limitations must be acknowledged, which may potentially impact the accuracy and comprehensiveness of our findings. Firstly, technological and platform constraints limit data collection to hourly intervals and a maximum of 50 pages, possibly omitting crucial content and affecting the comprehensiveness and depth of the data. Secondly, the classification of Weibo content involves subjective judgments, such as simplifying complex content related to disasters and rescue into a single category, which may affect the accuracy of the results. Moreover, In employing SnowNLP for sentiment analysis, its limitations primarily stem from inadequate handling of emotional complexity. Social media texts often exhibit user sentiments that are not simply dichotomized as positive, neutral, or negative, but rather may encompass various compounded emotions interwoven within a single post. General-purpose sentiment models like SnowNLP may struggle to discern subtle emotional variations in public responses to typhoon events. Categorical sentiment classification (positive, neutral, negative) as opposed to fine-grained scoring, sacrifices analytical precision. Despite these limitations, this study still provides meaningful analysis and conclusions based on the available data.

CONCLUSIONS

Typhoons, characterized by immense destructiveness and unpredictability, pose substantial threats to human life, infrastructure, and societal stability. While the extent of damage varies for typhoons of comparable intensity and trajectory, efficacious emergency management is vital. Essential components include early warnings, evacuations, preparedness training, and swift post-event recovery, which collectively mitigate impacts, minimize casualties, and enhance community resilience.

This study examines the coastal city of Zhuhai, China, frequently battered by typhoons, comparing its emergency management during Hato (2017), Mangkhut (2018), and Higos (2020). Employing a big data approach, it collates news, Weibo posts, and ancillary data preceding and following each typhoon's landfall. Key event sequences for 72 hours around landfall and word frequency analysis, categorical statistics, and sentiment analysis on Weibo contents are conducted to trace the emergency management process, analyze Zhuhai's measures, characteristics, and effectiveness. Zhuhai demonstrates continuous adaptation and optimization of its response to similarly intense typhoons. The study draws the following main conclusions: Enhanced warning systems significantly boost public responsiveness, curbing disaster losses. Systematic coordination in emergency management is pivotal for seamless rescue and recovery. Heightened public awareness and social engagement are instrumental in loss mitigation.

The study illuminates Zhuhai's strategic adaptations in typhoon response, offering a critical lens on its coping mechanisms. These experiences and strategies provide instructive references for Zhuhai and other coastal cities to better prepare for and mitigate typhoon impacts. The derived lessons hold global significance in strengthening coastal cities' disaster response capabilities, reducing typhoon-related losses, protecting lives and assets, and fostering sustainable urban development.

ABSTRACT

We evaluated the utility of the large language model (LLM) ChatGPT to develop situation awareness related to the forced displacement of Ukrainian refugees into Poland. Utilizing text messages derived from the Help for Ukrainians in Poland Telegram message group, we used ChatGPT to translate messages in multiple languages into English and identify message topics and themes. Topics and themes from beginning of the war in Ukraine in 2022 were analyzed and visualized using K-means clustering and word clouds. The language identification and translation capabilities of the LLM were evaluated by two human evaluators and measured using Kappa (0.86) and BLUE scores (0.46) with the LLM performing effectively. We conclude that the ability of LLM using carefully developed language prompts for large data volume analysis with no need for manual human analysis shows promise for humanitarian analytics focused on rapidly identifying potential key trends, needs, and locations of displaced people.

Keywords

Ukrainian refugees, Poland, Large Language Model, ChatGPT.

INTRODUCTION

The unprovoked Russian invasion of Ukraine in 2022 has created one of the largest humanitarian crises in modern times. According to the UN, as of August 2022, 1,388,339 Ukrainian refugees have registered for temporary protection in Poland (United Nations High Commissioner for Refugees (UNHCR), 2022b) (Figure 1).

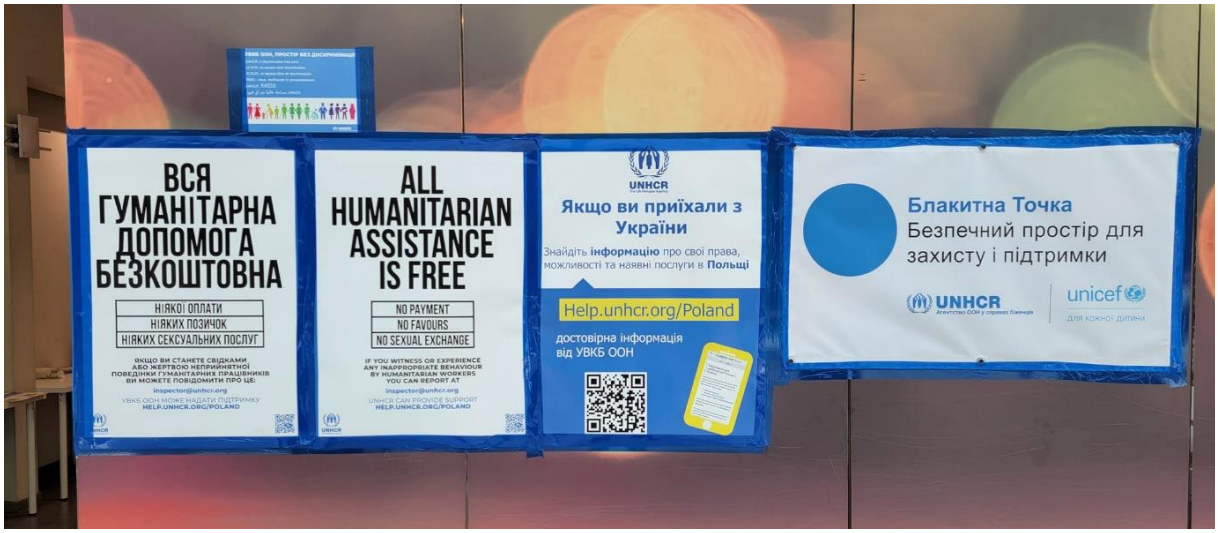

Figure 1. An example of 'Blue Point' refugee assistance center in Poznań, Poland (picture by author, 2022).

Although many Ukrainian refugees are returning home, with the war in Ukraine showing no end in sight, it is likely that many will remain in Poland for many years to come, as is typical in protracted forced displacement situations (UNHCR Regional Bureau for Europe Data Identity Management and Analysis Unit (DIMA), 2022).

International organizations that track forced displacement situations like the International Organization for Migration (IOM, UN Migration) monitor the situation of refugees once they arrive in a host country (c.f (International Organization for Migration, 2023b). In the case of the Ukrainian situation in Poland, it is important to know where and why refugees are settling in particular places in Poland and issues they are facing as there are several issues that may drive these decisions. For example, International Organization for Migration (2023a) outlines how in Warsaw, the main factors for why refugee population chose to settle in Warsaw include employment opportunities, accommodation availability and cost, and availability of health, educational, and other services.

Additionally, the general relationship between Polish society and Ukrainian refugees in Poland overtime is important to monitor. Poland received great praise from the international community for its support of Ukrainians in the first few months of conflict in 2022 in terms of social support, legal status, education and other factors (United Nations High Commissioner for Refugees (UNHCR), 2022a). However, as the war in Ukraine continues into the foreseeable future, some sources are signaling that Polish support systems have already, and will continue, to come under strain (Reidy, 2022).

A significant challenge exists for keeping track of the situations that individual displaced people may be experiencing once inside a host country. For example, official Polish government data sources on PESEL registrations (a system to track foreigners in Poland, see: (gov.pl, n.d.)) can give an indication of where refugees may be settling at the administrative level 2 in Poland (also known as a Powiat, similar to a county or district). Although this is a very useful starting point, refugees do not always reside in the location where they register for PESEL, making this data source not necessarily an accurate representation of what displaced people may be experiencing (Figure 2).

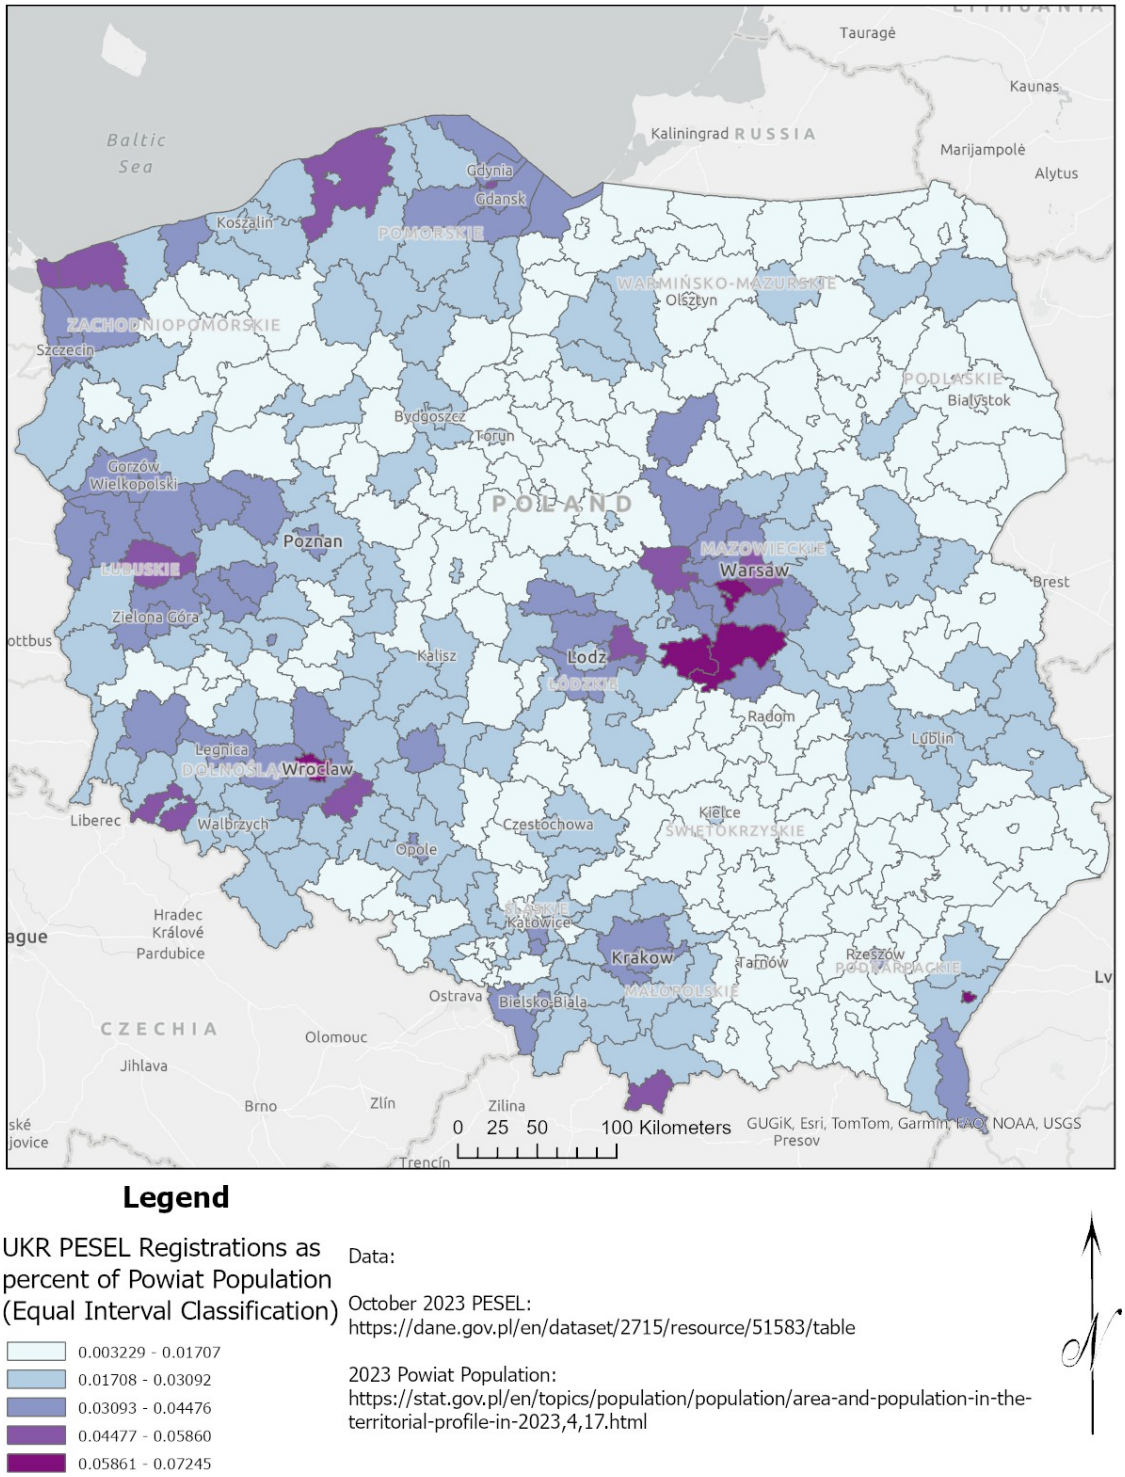

Figure 2. Ukrainian PESEL registrations in Poland as of October 2022. Understanding of where Ukrainian Refugee populations in Poland are is a challenging problem due to data granularity and temporality issues. A map like this is often the best representation of refugee locations but often inaccurate as refugees frequently move after receiving a PESEL.

Besides knowing *where* placed people may be located, are the additional challenges of understanding *what* the issues are that displaced people may be experiencing. Social media has a long established precedent in ISCRAM-related research as one potential source of data that can be used for developing situation awareness about a given crisis (c.f. (Hughes & Palen, 2009; Power, Robinson, & Cameron, 2022).

Generative AI is offering new promise for conducting social media analysis due to the lower entry barriers of accessing Large Language AI models (LLM) using human dialogue prompts. We argue that this approach presents a significant opportunity for non-technical specialists, such as humanitarian professionals, to utilize the power of LLM for social media analytics to ideally fill gaps in situation awareness knowledge about displaced people. A comparative study has been made among Pa LM, BERT and GPT language models for topic categorization using AG News Dataset (Yerramreddy, Marasani, Gowtham, & Abhishek, 2023). However, the investigation for social analysis in Ukrainian language is not given. Thus, in this pilot work we investigated the question: What can LLM reveal about the Ukrainian forced displacement situation in Poland? To investigate this question, we conducted a pilot investigation to specifically investigate and evaluate the use of LLM tools to (1) translate social media messages to English and (2) classify translated social media messages by topic and theme to understand the Ukrainian forced displacement situation in Poland.

BACKGROUND

LLM like ChatGPT are perhaps one of the most significant technology paradigm shifts in in recent years. The ability of the LLM to receive input via human dialogue and provide natural language responses is quickly demonstrating its ability in application domains ranging from business to education. In the humanitarian domain, AI language models can help address several challenges related to natural language processing (NLP)-centered analytics such as language translation and thematic analysis. NLP is generally unknown to humanita rians (Rocca, Tamagnone, Fekih, Contla, & Rekabsaz, 2023). Limited academic research has been conducted to date on the efficacy of LLM models for humanitarian applications. The literature that can be found on the use of AI models like ChatGPT for humanitarian applications has highlighted operational issues such as content creation for advocacy, supporting funding applications, legal document generation, and identifying support organizations (Crew et al., 2023; Roane, 2023). Tanner (2023) identified several issues identified from several humanitarian AI projects related to the broader application of artificial intelligence in humanitarian applications such as effective data strategies, the need for skilled data science professionals and ensuring proper data custody. However, the report explicitly stated that all the projects were conducted before the advent of LLM like ChatGPT.

METHODOLOGY

Figure 3 graphically outlines the workflow used to investigate what LLM can reveal about the Ukrainian forced displacement situation in Poland using social media.

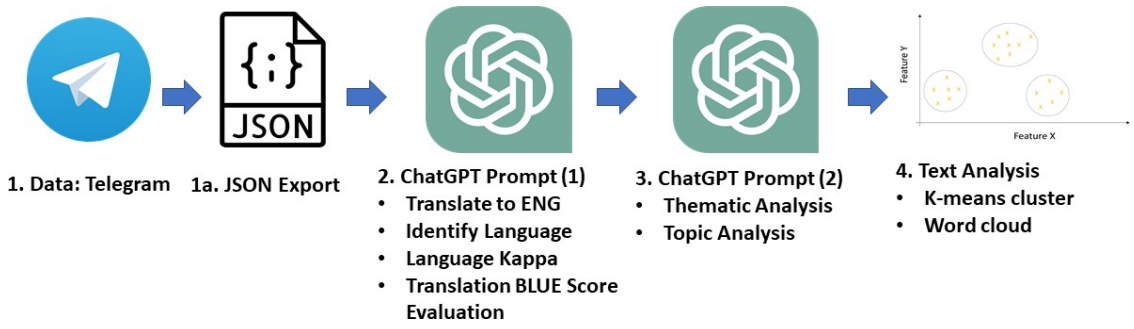

Figure 3. Ukrainian Refugee Social Media Analysis with ChatGPT work flow steps.

Step 1: Data Source

Telegram is a social media platform that is popular in Ukraine. In particular, the service has been extensively utilized by Ukrainians to discuss the ongoing war with Russia and as a tool for information-sharing among Ukrainian refugees in Poland. In the research presented here, we utilized the Telegram message community called Help for Ukrainians in Poland (UKR: Помощь украинцам в Польше) (Telegram, 2024). At the time when this research was conducted, this group had over 17,000 members with frequent daily posting (Figure 4).

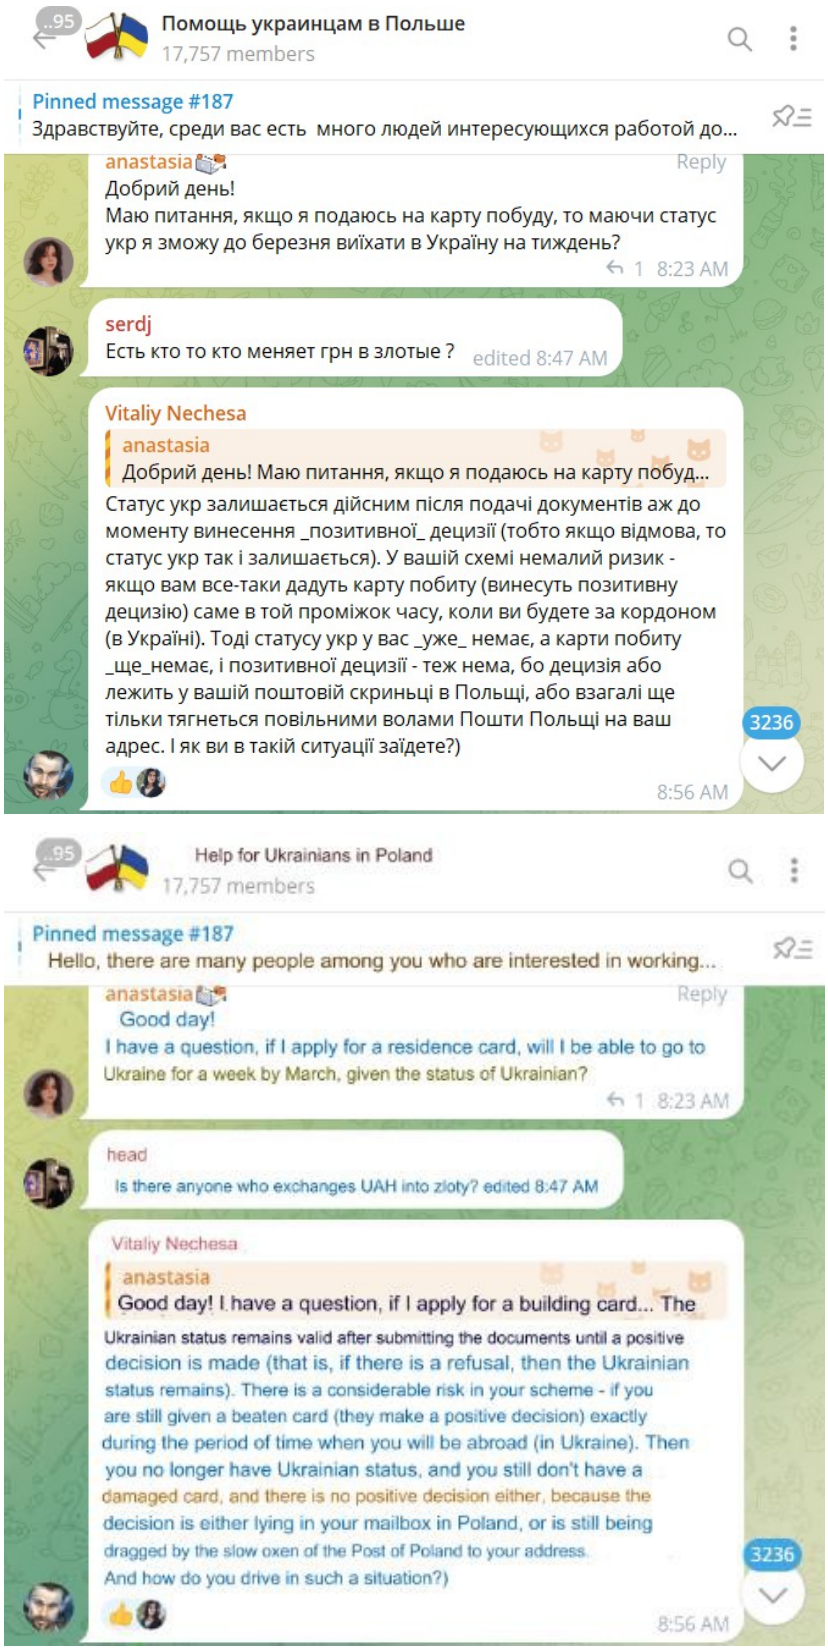

Figure 4. Screen shot of the Help for Ukrainians in Poland Telegram group. The image on the top is in the original source language, the image on the bottom is a Google image translation to illustrate the types of conversions conducted in the group.

Data from Telegram groups can be easily downloaded without requiring any special API programming like other social media platforms Thus, we downloaded the entire collection data from this group dating back to 2022 at the beginning of the war up until January 2024 . This yielded over 2.39 gb of data ranging from images to audio clips to text messages. In the work presented here, we focused only analysis of text messages that were provided in a JSON format as per step 1a seen in Figure 3.

Step 2: ChatGPT Prompt 1 – Message Translations and Language Identification

We utilized the gpt-3.5-turbo-0613 model via the OpenAI API in Python (OpenAPI, 2024). As this was an exploratory pilot project, this model was deemed sufficient vs other alternatives.

Perhaps the most important area of research with LLMs is prompt engineering, or how a human makes a natural language request of the AI model. Engineering plays a crucial role in designing AI systems that can understand and fulfill user queries accurately. By crafting prompts that are specific, well-structured, and tailored to the task at hand, engineers can guide the AI to produce results that meet user expectations. Beyond relevance, engineering also involves formatting the output of AI systems in ways tha t facilitate further analysis and processing. This includes organizing the information, presenting it in a structured manner, and ensuring compatibility with downstream tools and workflows. Careful prompt engineering is essential to ensure that the AI retu rns back relevant results as well as results that are formatted in ways that can be utilized for further analysis. By structuring prompts and results retuned in JSON format, they can be easily manipulated and managed programmatically, allowing for automation and integration with other workflows. This can be particularly useful in scenarios where a large number of prompts must be generated or dynamic adjustment of prompt parameters.

In step 2 of the workflow, we were interested in (1) having the Telegram messages translated to English and (2) have the LLM identify what language it thought the message was in. Our motivation was twofold. First, English is generally the language used by the international humanitarian community, even though there are numerous humanitarian staff in Poland that speak Polish and Ukrainian. Therefore, we wanted to investigate how using LLM could enable a wider group of humanitarian professionals to access information in languages other than English. Second, people from Ukraine in many cases speak both Ukrainian and Russian, or primarily Russian. The messages provided in the Help for Ukrainians in Poland Telegram group board are posted in both a mix of Russian, Ukrainian and other languages. Therefore, we are interested to assess how well the language model was at identifying a particular language in order to build trust that results from the LLM were accurate.

The following prompts were used to receive both the English translation of an input text and the language that ChatGPT identified from its analysis:

PROMPT_PART_1 = "Translate this text to English <start> "

PROMPT_PART_2 = " <end>. Return back two things. The first is your translation to English of text that was between the <start> and <end> tags. The second is a one-word description of the language of text that was between the <start> and <end> tags. "

PROMPT_PART_3 = "Put the two items you return into a JSON structure. Your translation to English of text that was between the <start> and <end> tags placed inside a JSON tag named translation. Your one-word description of the language of text that was between the <start> and <end> tags inside a JSON tag named language. Do not return any additional text, descriptions of your process or information beyond two items and output format of the tags specified."

Telegram message texts was processed from the JSON file downloaded in Step 1A and placed inside of the start and end tags as per the aforementioned prompts. The use of <start> and <end> tags was used after several iterations of developing prompts as they were found to be effective for clearly defining what text chat GTP should be focused on for translations as opposed to output formatting instructions.

LLM models can also benefit from being given a motivation to help establish the task being asked to do. Therefore, the following motivation message was sent in along with the prompts.

MOTIVATION_MESSAGE = "You are a skilled linguist who is an expert in identifying what language a given text is and doing translations of that text to English."

Using these prompts, we processed over 20,000 messages into English dating from 2022 to 2023. All of the English translations along with the original Source message, date of the message ID of the message and identified language of the message were stored in a CSV file. This allowed for the next step in the workflow to conduct thematic and topic analysis on the English translations that we discuss in the next section.

Step 3: ChatGPT Prompt 2 – Thematic and Topic Analysis

Identifying themes and topic from text is a common natural language processing goal particularly in the application of developing situation awareness in an ongoing protracted crisis situation like Ukrainian refugees in Poland (Rocca et al., 2023). Therefore, in step 3 of our process, we investigated the ability of ChatGPT to identify topics and themes from the English language translations that were derived in step 2 and discussed previously. Our motivation here was to investigate how high level thematic and topic summaries of what was being discussed in social media could be derived for developing an initial situation assessment that could then be followed up upon for further deeper investigation and situation awareness at local levels as per the well-established ideas of the process of achieving situation awareness (Endsley, 1995).

The following prompts were used to receive to receive topic and thematic summaries of individual messages:

PROMPT_PART_1 = "Conduct a thematic analysis of this text <start> "

PROMPT_PART_2 = " <end>. Return back two things."

PROMPT_PART_3 = "The first is your general thematic assessment of text that was between the <start> and <end> tags. The second are any topics you found in the text that was between the <start> and <end> tags. "

PROMPT_PART_4 = "Put the two items you return into a JSON structure. Your general thematic assessment of text that was between the <start> and <end> tags placed inside a JSON tag named theme. Any topics you found in the text that was between the <start> and <end> tags inside a JSON tag named topic."

PROMPT_PART_5 = "Do not return any additional text, descriptions of your process or information beyond two items and output format of the tags specified."

Like step 2, English language message texts processed in Step 2 were placed inside of the start and end tags of the aforementioned prompts.

The following motivation was used to help establish the task that ChatGPT was being asked to do.

MOTIVATION_MESSAGE = "You are a skilled humanitarian analyst who is an expert in conducting thematic analysis of English language texts."

Topics and themes returned back from chatGPT as text were stored in a .csv file as an input to topics and theme text analysis in step 4 in the process that we discussed next

Step 4: Topics and Themes Text Analysis

Given the very large volume of unstructured text derived from step 3 thematic and topic analysis, we use the well-established methodology of K-means clustering to group similar topics and themes based on words in those messages to derive a summary representation of topics and themes (Kumbhar, Mhamane, Patil, Patil, & Kale, 2020). Specifically, topic and theme texts were first processed to remove stop words, or words with no significance like ‘the’ ‘and’ ‘is’, and converted into a TD-IDF vector, or the importance of a given word in a single Telegram message relative to the overall collection of messages. The optimal number of clusters were calculated using a silhouette score that determines how well the messages might cluster in general and the optimal number of clusters. K-means clustering, which will partition text found in the messages into similar and dissimilar clusters, was then performed using the optimal number of clusters derived from the silhouette score. The dimensionality of the clusters was then reduced using principal component analysis (PCA). PCA was performed to reduce the dimensionality of the data space (or reducing the number of words in a given cluster while preserving the most important words) to allow for graphical representation of clusters derived from K means processing. A graphical representation of the clusters derived by calculating the centroid of a given cluster based on the term with the highest TF-IDF score in that cluster. This term was then plotted to create a graphical representation of the cluster. Additionally, word cloud generations were generated as an additional source of graphical representation of the text analysis.

RESULTS

As discussed previously, a particular motivation of this work was to utilize LLM to conduct language translations so that content derived from social media could be more widely accessible to a wider range of humanitarian professionals who may not in fact speak Polish, Ukrainian, or Russian. Therefore, we were interested in the effectiveness of the LLM to (1) specifically identify what language a given message was in and (2) the accuracy of the translation from a given language into English. Understanding the accuracy and effectiveness of such language tasks is important so that the AI can be considered trustworthy.

To facilitate these evaluations, two native speakers of Ukrainian and Russian with fluency of English were

recruited to perform the same tasks that the LLM conducted in terms of (1) identifying what language a given message was in and (2) do a translation of the message into English. These two evaluators worked on a sample of 108 messages. This sample size was deemed sufficient given the high expense of conducting human translations. Messages were selected for human evaluation with the criteria that the message contained no emojis or other non-text characters that could not be directly translated into English. Comparison of the human vs LLM of langua ge identification identified using Cohen's Kappa and accuracy of the LLM translation to English evaluated using BLEU (Bilingual Evaluation Understudy) score are discussed next.

Language Identification Kappa

Cohen Kappa is a well-established statistic to measure to assess the level of agreement between two evaluators (Viera & Garrett, 2005). In the work presented here, we were interested in comparing what language a given Telegram message was as rated by both a human evaluator and the LLM. The percentage of agreement between the human annotator and the LLM was 96.2% with a Kappa score of 0.86. These results indicate that the LLM was very effective at identifying what language a given Telegram message was across Russian, Ukrainian, Polish and other languages when compared to the same assessment done by a human.

Translation BLUE Score

BLEU is a very well established metric for automated evaluation of machine translations (Papineni, Roukos, Ward, & Zhu, 2002). English translations of a given Telegram message provided by the LLM were evaluated against two human translations of the same message using a Corpus BLUE score. A 4-gram precision was calculated with the weights 0.1, 0.1, 0.4, 0.4 to place higher emphasis on 3-gram and 4-gram precision (40% each) as these would be considered more useful for thematic and topic analysis and lower on 1-gram and 2-gram precision (10% each). The Corpus BLUE score result was: 0.46. Thus, it can be considered the LLM translations provided "High quality translations" (Google Cloud, n.d.).

K-MEANS TERM CLUSTERING AND WORD CLOUDS

Given the overall time frame of the data set that was processed, it was deemed more feasible to examine thematic and topic analysis based on particular time periods during the forced displacement of Ukrainians into Poland. Specifically, we performed K-means clustering on messages from the date range of 26 – 28 February 2022 within the overall data set processed by the LLM. This date range covers the very beginning of the Help for Ukrainians in Poland telegram group. It also coincides with the opening of the war in Ukraine including the first significant military attacks on large Ukrainian cities such as Kiev and Kharkiv causing thousands of people to begin fleeing to Poland (BBC News, 2022). Our goal was to do an initial assessment of themes that would be found in the data set. Figure 5a and 5b graphically show the results of K-means clustering around thematic analysis conducted by the LLM. Figure 6 shows a word cloud representation of thematic analysis conducted by the LLM. Figure 7 shows the results of a K-means clustering of the topic analysis conducted by the LLM. Figure 8 shows the results of a word cloud representation of the topic analysis conducted by the LLM. These figures are followed by a discussion of these results.

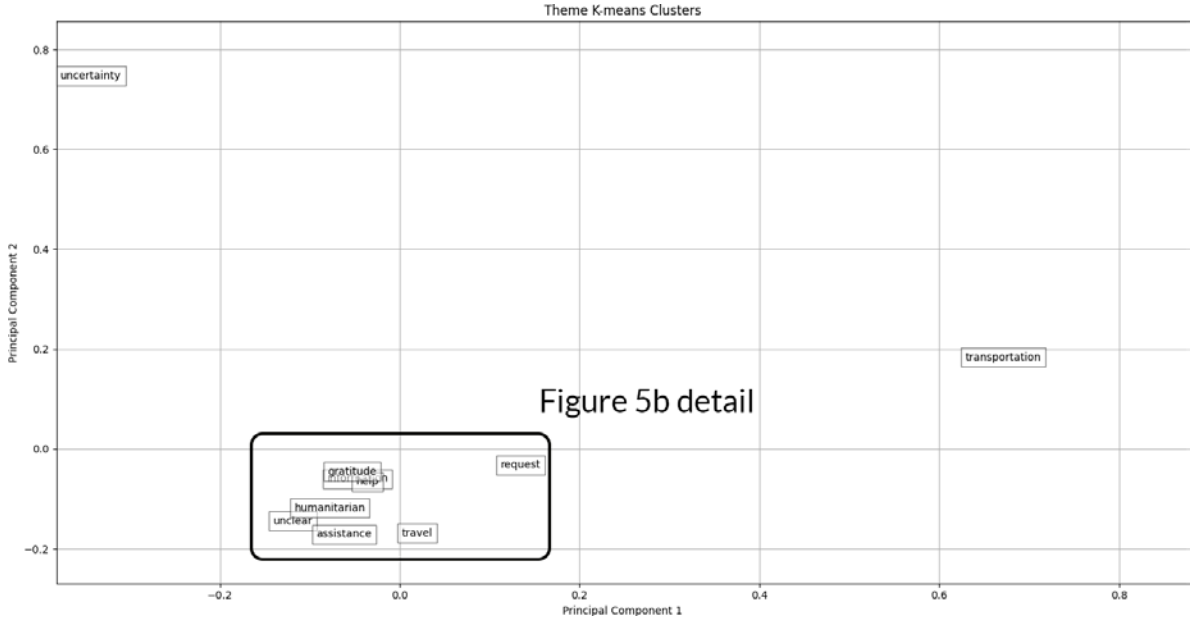

Figure 5a. Theme clusters – overview

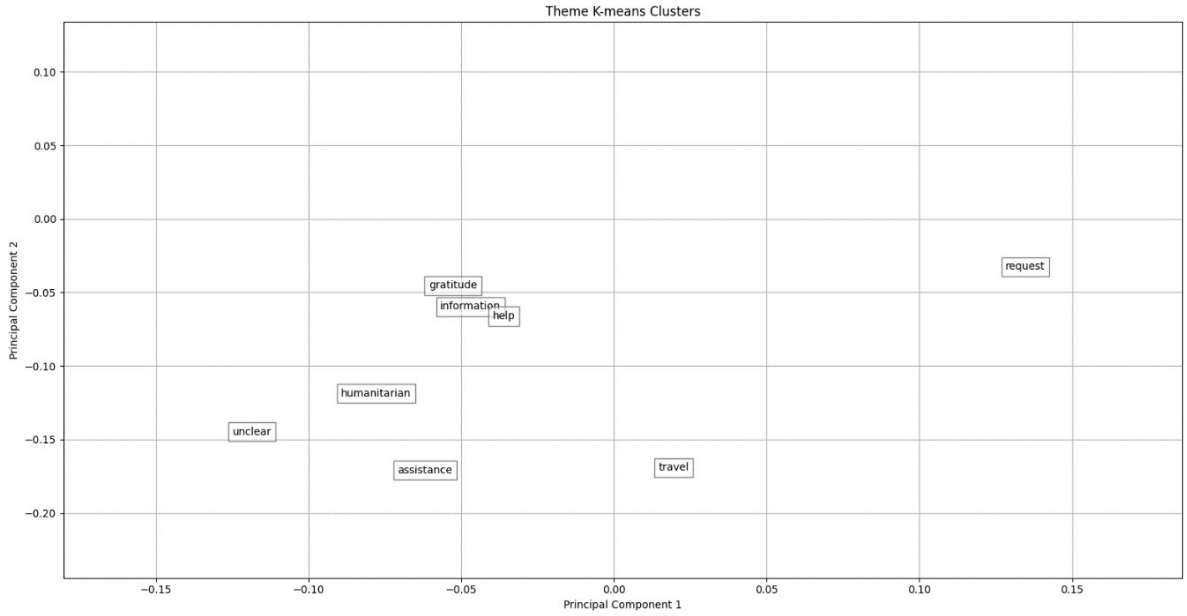

Figure 5b. Theme clusters - detail

Figures 5a and 5b. K-means Theme Clusters

Figure 6. Theme word cloud

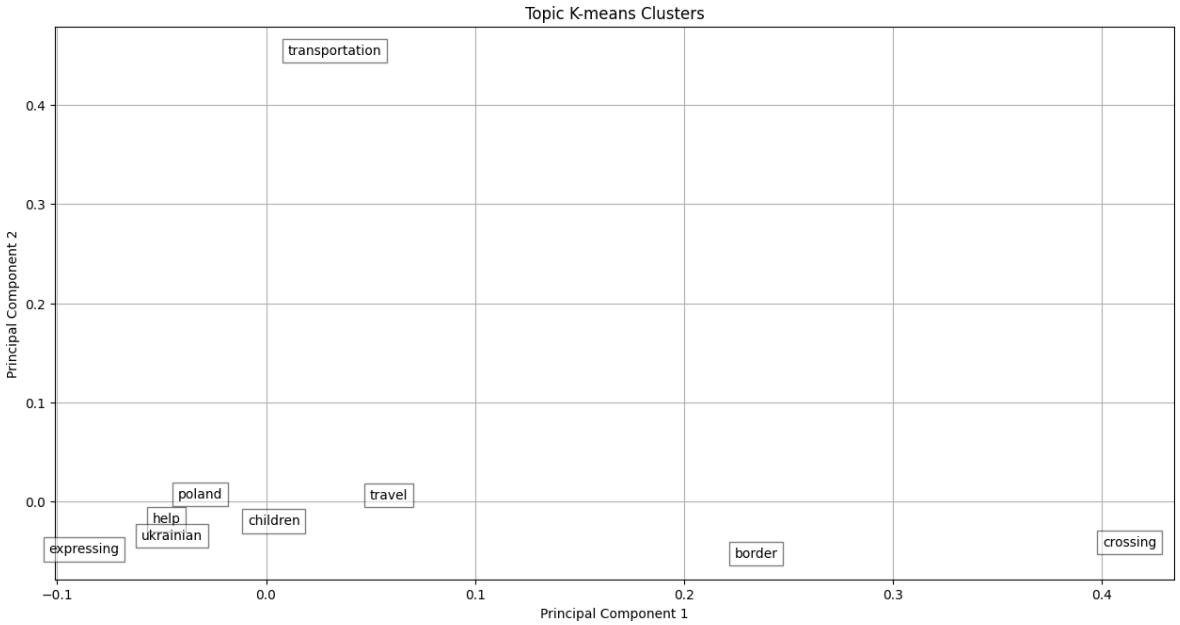

Figure 7. K-means topic clusters

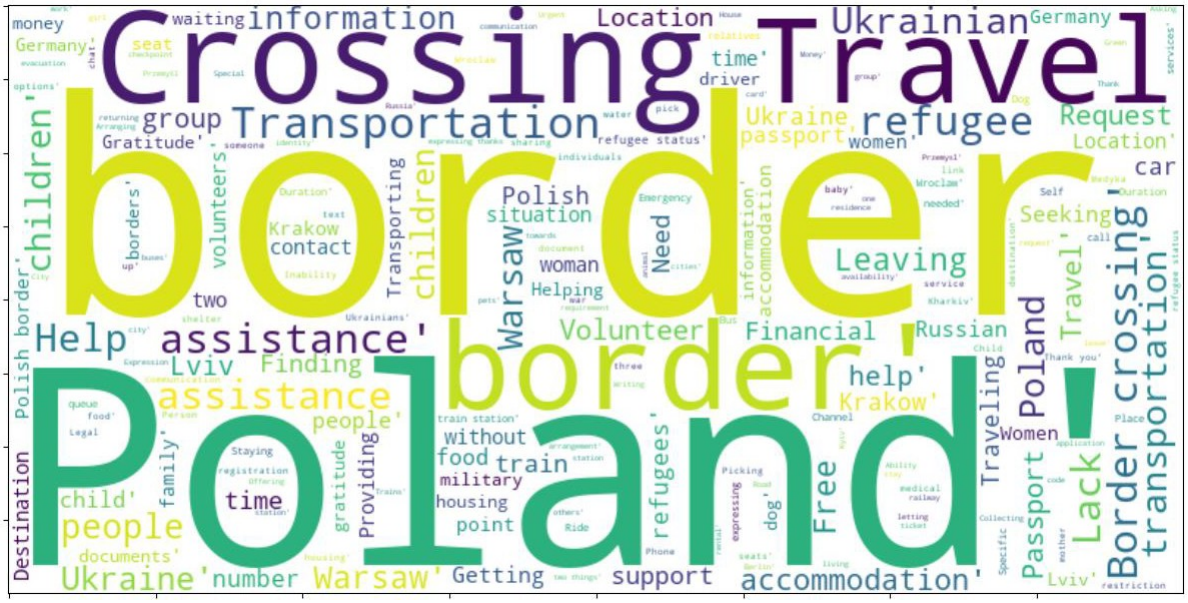

Figure 8. Topic word clouds

Discussion

The LLM generally recognized themes and topics that would be expected when large volumes of people were being forcibly displaced out of Ukraine into Poland. It is interesting to note in the *theme* clustering (Figure 5a), the expected clusters related to supporting people who are looking for transportation and movement in general were found but *uncertainty* also emerged as a cluster. The detail of the theme clusters shown in Figure 5b also shows an interesting pattern of clusters of people who are showing gratitude for information and help. Crossing the border into Poland is clearly the main *topic* of messages that were from the date range analyzed. Again, this is what one would expect. However, it is interesting to note that the topic of *children* emerged as its own cluster as seen in Figure 7. Geography can also be seen within the topic word cloud of Figure 8 such as several specific locations within Poland such as Warsaw, Krakow, Poland/Ukraine border locations such as Lviv and countries such as Germany. These results can reveal potential movement trajectories of the forcibly displaced.

LIMITATIONS AND FUTURE WORK

In the following section we outline several limitations we acknowledge in this work but subsequently provide opportunities for future work. We also identify other general areas for future work.

In this work, we only worked with one version of the chat GPT model (gpt-3.5-turbo-0613). ChatGPT and other LLM are constantly evolving. Therefore, follow-up work could include running the same analysis with a different version of ChatGPT. We also did not compare the NLP functions of ChatGPT against other LLM models such as Google Pa LM and Gemini, Microsoft Copilot, Meta's LLa MA or others. In particular it would be worth investigating how different LLM respond to different types of natural language prompts and the types of results that would be returned.

As per the motivation to investigate the use of LLM specifically to utilize the ability of human natural dialogue to interact with AI, we specifically did not look into using traditional AI natural language processing methods that often require extensive computer science experience to operate that would be beyond the practical scope of operation by most humanitarian professionals.

We only conducted an initial analysis of the text to identify general topics and themes within messages that had been translated to English. This is an area of significant follow-up research. In particular, conducting a sentiment analysis on messages and also identifying erroneous and false information inside of social media messages as per the well-established and recognized phenomena of false information being provided by trolls and malicious actors during a crisis (Federal Emergency Management Agency (FEMA), 2017).

For example, it was pointed out by one of the human evaluators that Russian bots are often active in attempting to spread false information into Telegram social media groups as per statements we found like this *"Stop senseless*

bloodshed! The Russian people are not your enemies, surrender! And you will be treated well: you will receive tasty hot food and warm clothing, and if you are wounded - medical assistance."

We only worked with one message group within one source of social media (Telegram: Help for Ukrainians in Poland). There could be extensive follow-up research on combining multiple streams of social media to develop a more comprehensive picture of situation awareness related to displaced people. Additionally, Telegram has an age bias, most users are younger, more tech-savvy people. Thus, results from this analysis would likely exclude the needs and situations of many older individuals or individuals without smart phones.

We also conducted the topic and thematic analysis based on a translation to English as we acknowledge out limitation and lack of knowledge of Ukrainian and Russian. Deeper incorporation of specialists with expertise in Ukrainian and Russian languages could enable a similar analysis to be done in the source languages and compare those results with those done via English translations. Related to all these points, it is important to acknowledge that ChatGPT itself has gender, racial, and cultural bias derived from its own training data that could impact analysis results (Ray, 2023).

The current word cloud and K-means results presented here are not inherently be useful for humanitarian practitioners. However, future research in automated sorting and filtering of topics, such as messages related to health care and medical needs, would allow for more detailed analysis of specific needs and potential barriers to services. Identifying methods for filtering out "non-relevant" text would also enhance the utility of the word cloud or word frequency analysis. Identifying repeated phrases (i.e. "...schedule a medical appointment..." or "...lon g waiting times...") could also assist in identifying more specific key themes. Thematic analysis using Latent Dirichlet Allocation (LDA) could offer an improved approach over K-means to support this research direction (Westrupp et al., 2022).

Areas of visualization follow-up research would include identification and geocoding locations within the messages to generate geospatial visualizations to understand more specifically about the location of refugees and their movements over space and time, and issues they are facing (Hübl, Cvetojevic, Hochmair, & Paulus, 2017). For example, placing geocoded messages within the context of a map like shown in Figure 1 where official government data sources could be combined with social media data sources to generate a more comprehensive overall picture of the situation of refugees in Poland (Tomaszewski, 2021). There is also extensive visualization research that could be conducted on hierarchal visualization that could be done to allow topic and thematic clusters to be investigated in terms of specific messages within those clusters for more insight and follow-up on specific messages (Elmqvist & Fekete, 2009).

Finally, the work presented here was a pilot study to evaluate the technical aspects of an LLM within the context of a humanitarian crisis situation. Metrics like Kappa and Corpus BLUE scores are easy to understand metrics that can be used to communicate with non-technical humanitarian professionals as an initial step in building trust and acceptance of LLM in the context their ability to be effective at language translations within the context of an international crisis. The ISCRAM community has long made calls for more integration between the academic research and practitioner groups within the overall community. Approaches like one presented here can help begin to cross this divide.

Longer term, it will be important that the approaches like those presented here are evaluated by working humanitarian crisis professionals engaged in situation awareness activities related to forced displacement. For example, analyzingthe accuracy of LLM analysis as compared to existing ground-truthed data sources reflecting the needs and situations of Ukrainian refugees in Poland such as the Multi-Sectoral Needs Assessment (MSNA) report which is based on extensive survey data collection with Ukrainian refugee populations (United Nations High Commissioner for Refugees (UNHCR), 2024).

CONCLUSION

In this work, we evaluated the utility of a large language model (LLM) to develop situation awareness related to the forced displacement of Ukrainian refugees into Poland. Specifically, utilizing text messages derived from the Help for Ukrainians in Poland (UKR: Помощь украинцам в Польше) Telegram message group, we translated messages in a variety of languages including Russian Ukrainian, and Polish into English using ChatGPT. The contents of the messages were then analyzed with ChatGPT to identify topics a nd themes within those messages. The text of topics and themes generated by ChatGPT were then analyzed using K-means clustering to identify the most important topics and themes from within the data that was collected. The language identification and translation capabilities of the LLM were evaluated by two human evaluators and measured using Kappa and Corpus BLUE scorers with the LLM Performing effectively (Kappa: 0.86, Corpus BLUE: 0.46).

It can therefore be concluded that within the scope and acknowledged limitations of the work presented here that the ability of LLM using carefully developed language prompts for large data volume analysis with no need for

manual human analysis shows promise for humanitarian analytics focused on rapidly identifying potential key trends, needs, and locations of displaced people.

As a final takeaway from the work presented in this paper, we asked ChatGPT itself the following for future guidance in this line of work via this prompt:

What would you say to a human academic and practitioner audience interested in information systems for crisis response and management in terms of your ability to help with understanding the situation awareness of Ukrainian refugees who have been forcibly displaced into Poland?

And received back the following reply:

As an AI language model, I can provide valuable assistance in understanding the situation awareness of Ukrainian refugees who have been forcibly displaced into Poland within the context of information systems for crisis response and management.

Here's how I can help:

Data Analysis and Interpretation: I can process and analyze large volumes of data from various sources such as news articles, social media, official reports, and humanitarian organizations' databases to extract insights about the situation of Ukrainian refugees in Poland. This includes understanding their demographics, needs, concerns, and challenges.

Trend Analysis: By analyzing patterns and trends in the data, I can help identify emerging issues, hotspots of activity, shifts in refugee movement, and changes in the humanitarian situation over time. This information is crucial for decision-making and resource allocation by crisis response teams and policymakers.

Risk Assessment: Utilizing natural language processing (NLP) techniques, I can assess the sentiment and tone of refugee communications to identify areas of distress, potential conflicts, or security risks. This aids in proactive risk management and early intervention to prevent escalation of crises.

Resource Allocation Optimization: Through optimization algorithms and predictive modeling, I can assist in determining the most efficient allocation of resources such as food, shelter, medical supplies, and transportation based on real-time needs assessments and demand forecasts.

Communication and Coordination Support: I can facilitate communication and coordination among various stakeholders involved in the crisis response, including government agencies, non-governmental organizations (NGOs), aid workers, volunteers, and affected communities. This ensures timely exchange of critical information and enhances collaboration efforts.

Decision Support Systems: By providing synthesized reports, dashboards, and visualizations, I can support decision-makers in gaining a comprehensive overview of the situation, evaluating the effectiveness of interventions, and making informed decisions to improve crisis response strategies.

Overall, my capabilities extend to assisting academic researchers and practitioners in gaining deeper insights into the situation awareness of Ukrainian refugees in Poland, enabling them to develop more effective information systems and strategies for crisis response and management.

Thus, it is notable that ChatGPT in its current form does have an awareness of how it can support humanitarian operations and it will be interesting to see how these functionalities can be further utilized in the future.

However, LLM are not a panacea. Caution should be considered in that social media and LLM contain bias, falsehoods rumors and other potential pitfalls that can interfere with true understanding of a humanitarian situation (Acerbi & Stubbersfield, 2023; Gallegos et al., 2023). Further evaluation of LLM, social media and combination of official government data sources can show a pathway forward for better understanding of what people who are forcibly displaced are experiencing and how they can be supported.

ABSTRACT

Automatic summarization of natural and human-made disaster events is an important area to increase situational awareness for human response organizations and disaster management. However, the incorporation of multiple data sources poses a challenge to current summarization systems, as the typically large document collections exceed the input limits of neural models. Additionally, Large Language Models (LLM) often omit key information present at different positions in long context inputs. Furthermore, disaster reporting requires fine-grained information content and therefore relaxes the restriction to high compression rates, resulting into rather long summaries. In this work, we study different extractive and LLM-based abstractive baselines and highlight shortcomings in present approaches. Our experimental results on the CrisisFACTS datasets show that LLM-based approaches tend to fail in generating long informative summaries. Taking these limitations into account, we propose a disaster summarization framework and introduce query-focused extensions, which demonstrate advantages and superior performance over the baseline methods.

Keywords

Crisis Informatics, Disaster Summarization, Large Language Models, Integer Linear Programming

INTRODUCTION

Disaster management is a critical process responsible for various key phases (e.g., preparedness, response, and recovery) during mass-emergency incidents, where human decisions heavily rely on a comprehensive understanding of the specific event. Situational awareness aims to provide an ideal understanding of what is happening during an event with numerous actors and sub-events (Vieweg et al., 2010). However, both the lack of information and the overload due to today's information ecosystem can paralyze disaster management and humanitarian response organizations (Imran et al., 2014; McCreadie & Buntain, 2023). It is therefore crucial to automatically localize valuable information and condense it into summary reports that can effectively contribute to situational awareness. Emerging heterogeneous information sources such as social media and microblogging platforms rapidly disseminate crucial details about ongoing events and offer new opportunities to complement traditional approaches (Imran et al., 2014). However, the high-velocity nature of content generation and the properties of different source domains and events pose challenges to current disaster reporting approaches (Kaufhold, 2021; Seeberger & Riedhammer, 2022b).

Unlike most other summarization tasks, we identify several key challenges for disaster reporting: (1) The lack of annotated datasets limits the application of supervised methods and makes it difficult to train sophisticated end-to-end models. (2) Compared with classical query-focused summarization, the information need about an event is complex and requires considering up to dozens of queries simultaneously, depending on the disaster type (McCreadie & Buntain, 2023). For example, it is necessary to capture many aspects such as the burned area, missing persons, contamination level, and evacuation orders during a wildfire event. (3) The multi-stream setting leads to large collections of noisy documents that cause issues regarding the length limitations of recent transformer-based models (Lewis et al., 2020). (4) The target summaries of most summarization tasks are rather short (e.g., up to 250 tokens) and the generation of long summaries (e.g., reports) remains challenging for abstractive methods (Chang et al., 2023; Kryscinski et al., 2022). Recent advances in pre-trained and instruction-following LLMs (Touvron

WiP Paper – Social Media for Crisis Management
Proceedings of the 21st ISCRAM Conference – Münster, Germany May 2024
Berthold Penkert, Bernd Hellingrath, Monika Rode, Adam Widera, Michael Middelhoff, Kees Boersma, Matthias Kalthöner, eds.

et al., 2023) as well as distant supervision (Y. Xu & Lapata, 2020) offer opportunities to address these issues; however, they are relatively unexplored in the disaster summarization domain.

In this work, we explore several LLM-based summarization frameworks for generating disaster reports, aiming to highlight new developments across disasters in the form of event timelines (McCreadie & Buntain, 2023). Due to the lack of appropriate training data, we rely on zero-shot and distant supervision methods while focusing on recent open-source LLM developments.

Contributions

(1) Disaster Summarization Framework To address the identified challenges, we design a disaster summarization framework that unifies and extends best practices from different related summarization domains. Automatic evaluation results show improvements over baselines but also highlight shortcomings related to summary generation lengths.

(2) Query-Focused Selection (QILP) We introduce query-focused extensions to an ILP-based extractive summarizer and report absolute improvements of up to 7.65 points for ROUGE-2 w.r.t. NIST reference summaries. In addition, we suggest to use QILP for subsequent selection of abstractive event nuggets and show improvements for the majority of evaluation metrics.

(3) Evaluation & Ablation Study We compare our method with several introduced extractive and abstractive baselines and underscore limitations regarding reference summaries. These are mainly connected to extractive and abstractive biases introduced due to the NIST reference summary creation process. Furthermore, we provide insights into the impact of document sources as well as retrieval pipelines.

RELATED WORK

Query-Focused Summarization

Query-focused summarization aims to generate a summary of given documents that satifies the information need of a specific query. This query often represents keywords, short titles, or long narratives that may cover multiple aspects. Due to the limited availability of query-specific datasets, initial work in this area focused on unsupervised extractive approaches (Litvak & Vanetik, 2017; Wan, 2008; Wan et al., 2007) and later utilize cross-task knowledge from question answering (QA) datasets (Egonmwan et al., 2019; Laskar et al., 2020; Su et al., 2020, 2021; Y. Xu & Lapata, 2020). Another line of research focuses on the utilization of generic summarization tasks by employing pseudo-queries (Vig et al., 2022; Y. Xu & Lapata, 2021) or latent query modeling (Y. Xu & Lapata, 2022). According to Vig et al., most abstractive summarization models follow an extract-then-abstract pipeline and can be categorized into two-step approaches, consisting of an extractor model that scores the source documents and an abstractor model that consumes the documents up to the input length limit (Vig et al., 2022). In contrast, end-to-end approaches aim to address shortcomings due to the performance of the extractor and achieve superior performance for several benchmarks (Vig et al., 2022). However, end-to-end models require appropriate training data and mechanisms that can handle long input texts. Moreover, most approaches focus on tasks with only one or a small number of queries, which is different from the task of summarizing disasters. Our work builds on two-stage models to cope with the lack of annotations as well as noisy and large data streams that are common in disaster events.

Long Document Summarization

The long document summarization field primarily addresses the input length limitations of neural abstractive models. Recent work can be broadly categorized into sparse attention, extract-then-abstract, divide-and-conquer, and hierarchical models (Mao et al., 2022). Sparse attention models such as Longformer (Beltagy et al., 2020), BigBird (Zaheer et al., 2020), and Reformer (Kitaev et al., 2020) utilize different attention mechanisms to reduce the quadratic memory cost of full attention. Several hierarchical models have been proposed for long input processing including models such as HAT-Bart (Rohde et al., 2021) and HMNet (Zhu et al., 2020) which take hierarchical structures into account. Extract-then-abstract methods are similar to the previously mentioned query-focused two-step approach. Most of these two components are trained separately (Bajaj et al., 2021; J. Xu & Durrett, 2019; Y. Zhang et al., 2021), but some work attempts to bridge the two stages by reinforcement learning (Bae et al., 2019; Chen & Bansal, 2018) or joint training (Mao et al., 2022). Divide-and-conquer models break long text inputs into multiple parts, which are summarized separately and then combined into a final summary (Gidiotis & Tsoumakas, 2020; Grail et al., 2021; Y. Zhang et al., 2022). Most recent work perform zero-shot LLM approaches and follow

hierarchical merging and incremental updating strategies (Chang et al., 2023). Hierarchical merging divides the input into several chunks and combines multiple levels of summaries until a desired length (Wu et al., 2021). In contrast, incremental updating aims to overcome the missing context of hierarchical merging by iteratively updating an existing summary with new input chunks (Adams et al., 2023). In our work, we explore divide-and-conquer approaches since they can be easily applied in a zero-shot setting. As previously mentioned, we also rely on the retrieve-then-abstract model. This enables the processing of large and noisy document collections.

Disaster-Related Summarization

Disaster-related methods mostly cover the summarization of social media posts or web news for mass-emergency events. Initial work proposed models for summarizing Twitter posts, which often consist of a classification and subsequent summarization step. The classification step involves the pre-filtering of noise and assignment into predefined categories, which are then summarized into specific or general summaries (P. K. Garg et al., 2023; Rudra et al., 2015, 2018, 2019). Rudra et al. introduced a pipeline consisting of a classifier followed by an extractive summarizer formulated as Integer Linear Programming (ILP) that aims to maximize content words and sub-events coverage w.r.t. specific categories (Rudra et al., 2018). Nguyen and Rudra employs a rationale-motivated classifier to extract rationales that are further used for ILP-based summarization (Nguyen & Rudra, 2022). For temporal summarization, other work focuses on saliency prediction and mechanisms that utilize similarity- or cluster-based methods for summarization (Dusart et al., 2021, 2023; Kedzie et al., 2015). Apart from temporal summarization studies such as TREC TS (Aslam et al., 2015), real-time summarization, with a focus on mobile device notifications and daily email digests from Twitter streams, has gained attention (Sequiera et al., 2018). Most recent work is centered around multi-source datasets, such as CrisisFACTS (McCreadie & Buntain, 2023), and the use of reinforcement learning (Cambrin et al., 2024) or pre-trained LLMs for query-focused disaster reporting (Pereira et al., 2023; Seeberger & Riedhammer, 2022a, 2023). Pereira et al. builds on QA-motivated methods and uses chain-of-thought (CoT) to extract relevant facts from retrieved stream items (Pereira et al., 2023) while FloodBrain (Colvert et al., 2023) aims to generate flood-related reports from web-based content using retrieval-augmented generation. However, classification-based pipelines are limited to predefined categories while summary aspects differ across events. Therefore, we focus on distant supervision for the extractive component. Since summarization on concept level has shown promising results in different domains (Ernst et al., 2022; Riedhammer et al., 2010), we use QA-motivated CoT for fact extraction.

METHOD

In the following, we define our framework for disaster summarization and propose components to overcome the challenges of noisy and large document collections. We give an overview of our approach in Figure 1. In the next section, we formulate our task and present the two-stage pipeline. Then, we detail the Extractor and Abstractor components. Lastly, we introduce extensions to an ILP-based selection model adapted to the query-focused case.

Retrieve-then-Summarize

In disaster summarization, the input consists of $\mathrm{D} = \{d_1, \ldots, d_N\}$ as a set of event-related documents and $\mathrm{Q} = \{q_1, \ldots, q_M\}$ as a set of queries with N and M as the number of documents and queries, respectively. Each query $q \in \mathrm{Q}$ typically consists of a short natural text or a list of keywords and covers a topic or aspect (e.g., wildfire containment). The set of queries Q aims to fulfill the user's information need that is composed of various of these event aspects. Since the initial corpus is often large and still contains irrelevant documents, we employ an Extractor to retrieve and reduce the set of documents to query-related clusters $\mathrm{C} = \{\mathrm{C}^{(q_1)}, \ldots, \mathrm{C}^{(q_M)}\}$ with $\mathrm{C}^{(q_i)} = \{d^{(q_i)}_1, \ldots, d^{(q_i)}_k\}$ consisting of the top-k candidate documents ranked by relevance score. Then, optionally, each cluster $\mathrm{C}^{(q_i)}$ is further refined by a reranking model which operates over all retrieved document-query pairs to estimate semantic matching scores. The Abstractor generates an output summary S (e.g., list of event nuggets) from the cluster pool $\bigcup_{i=1}^{M} \mathrm{C}^{(q_i)}$. Following the view of event timeline summarization, each summary S_t is created w.r.t. a time period $p_t \in \{p_1, \ldots, p_T\}$ with T as the number of time periods and $\mathrm{D}_t \subseteq \mathrm{D}$ as the subset of documents created within the time period p_t. For the sake of clarity, however, we omit the time index t, consider each time period as an independent summarization task and leave redundancy issues for future work.

Extractor

How to model long texts and large document collections is an ongoing research area and various techniques have been proposed to overcome length and GPU memory limitations of neural models by independently processing

chunks. It is common practice to use preprocessing functions such as truncation, chunking, and content selection

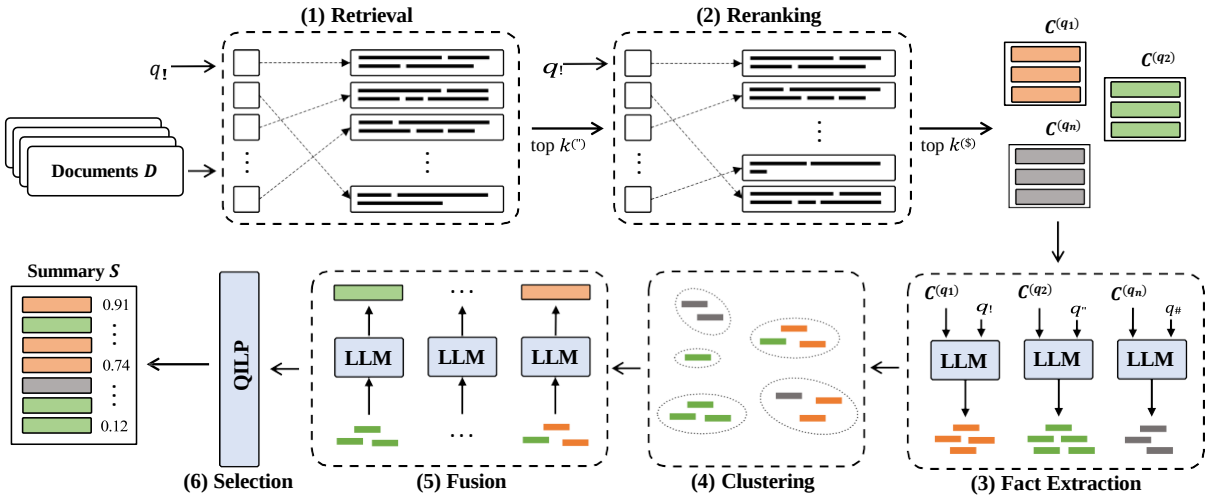

Figure 1. Overview of our framework for disaster summarization. The Extractor consists of stages (1) and (2) while the Abstractor is composed of stages (3), (4), and (5). Stages (1) and (2) retrieve and rerank all documents and extract query-related clusters. (3) generates the query-related facts and (4) clusters the facts into topic groups. Subsequently, (5) fuses the topic clusters to event nuggets. Optionally, (6) selects the event nuggets to create the final summary.

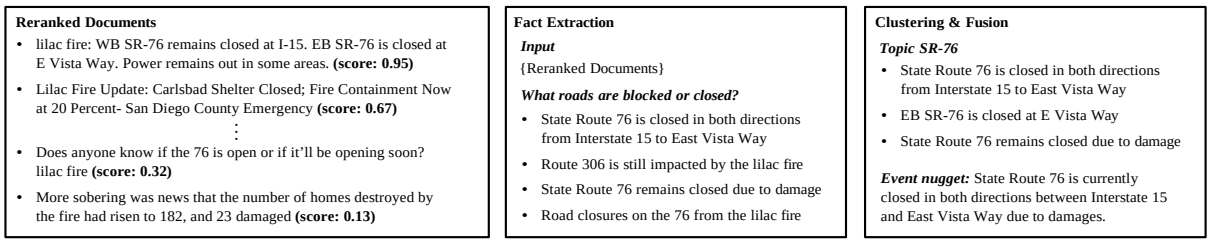

Figure 2. Example for the event nugget creation process w.r.t. the query *What roads are blocked or closed?* and Lilac Wildfire event.

(Dong et al., 2023) while salient content selection can be achieved with retrieval-based models. In our work, we employ content selection methods since text documents from web news, social media, or microblogging platforms are typically short, often irrelevant, and occur in large volumes.

Based on the assumption that salient information occupies only a small portion of long documents (Ding et al., 2020), we employ a two-stage retrieval pipeline as our Extractor in order to reduce the set of documents D to the salient sets of query-related clusters C. As initial step, we retrieve the top-$k^{(1)}$ candidates for each query $q \in Q$ using an efficient sparse retrieval model. Then, we process the concatenation of each query-document pair and obtain a scalar score $s_{ij} = E(q_i, d_j)$, where $E(\cdot)$ represents a neural reranker model and s_{ij} the document relevance
w.r.t. a query q_i. Then, the top-$k^{(2)}$ candidates are selected by descending order of the scores, resulting into a reranked set C'. In Figure 2, we can see that relevant documents achieve higher relevance scores for the query *What roads are blocked or closed?*.

However, the event-related documents may cover different aspects of the event and therefore can obtain multiple high relevance scores for different queries. If we require a single saliency score (e.g., for extractive summarization), we address this issue by a fusion function $f(\cdot)$ to obtain a final saliency score s_j for a document d_j. There exist several rank- and score-based fusion techniques, but in preliminary experiments, we found CombSUM (Fox & Shaw, 1994) to be an effective fusion method. CombSUM calculates the final saliency score for a document as $s_j = \sum_i s_{ij}$ by summing up the relevance scores for each query. As depicted in Figure 1, the Extractor consists

of the main stages (1) Retrieval and (2) Reranking.

Abstractor

In contrast to recent long document processing approaches, we follow a QA-motivated[1] method to enable *event nugget*-based summarization. We first extract all query-relevant facts for the documents and then generate event nuggets employing a clustering-based summarization approach (Ernst et al., 2022). Inspired by (Pereira et al., 2023), we use an instruction-following LLM to generate our facts. Therefore, we utilize the CoT technique and prompt the model to provide a list of facts which serve as evidence for answering the query q based on the provided documents $\{d_1, \ldots, d_j\}$ with $d_i \in C^{(q)}$. The exact prompt is shown in Table 10. For example, we prompt the LLM with the query *What roads are blocked or closed?* and obtain the facts only relevant to this query (Figure 2).

In the next step, all extracted facts are clustered into semantically similar groups. This further prevents redundancy by avoiding multiple facts covering the same piece of information (e.g., *State Route 76 closed*). For clustering, we compute the cosine similarity for each pair of facts using sentence embeddings from a transformer model and then apply affinity propagation. We opt for affinity propagation since the approach does not require specifying the number of clusters and has demonstrated state-of-the-art performance in the disaster summarization domain (Kedzie et al., 2015). Lastly, the resulting documents of the topic clusters are merged with an additional summarization step using the identical LLM (Table 5). Simply selecting the cluster exemplars has shown insufficient results as this approach would discard similar sub-events with different entities such as locations.

For event nugget importance, we recompute the relevance scores for each event nugget and utilize the saliency scores for ranking. That is, each generated event nugget is fed into the neural reranker model, and the resulting scores are used for saliency. The final summary is produced by appending the ranked event nuggets until the desired summary length or by using an optional extractive selection model that we detail in the next section.

Query-Focused Selection

As extractive selection model, we extend previous concept-based methods and model the extractive summarization as an ILP problem (Gillick & Favre, 2009; Riedhammer et al., 2010; Rudra et al., 2018; Seeberger & Riedhammer, 2022a). Concepts typically represent units such as bi-grams, entities, and key-phrases. Our objective is to maximize the coverage of these units while keeping redundancy low. In the rest of this paper, we refer to our extensions as Query-Focused Integer Linear Programming (QILP). The introduced extensions aim to incorporate document saliency and query coverage on the summary level. Note that the extractive summarization can be applied on both the documents directly and generated event nuggets. In particular, we maximize the following objective:

$$\underset{d}{\text{argmax}} \quad \alpha \sum_i w_i c_i + \beta \sum_j s_j d_j - \gamma \sum_p \rho_p (1 - z_p) \tag{1}$$

$$\text{subject to} \quad \forall j \quad \sum_j d_j \leq L \tag{2}$$

$$\forall i \quad \sum_j d_j o_{ij} \geq c_i \tag{3}$$

$$\forall i, j \quad d_j o_{ij} \leq c_i \tag{4}$$

$$\forall_i \, c_i \in \{0,1\} \quad \forall_j \, d_j \in \{0,1\} \quad \forall_k \, z_k \in \{0,1\} \tag{5}$$

Concept Coverage and Document Saliency The first and second term in Equation (1) correspond to the concepts coverage and documents saliency, respectively. Formally, let c_i denote the presence of concept i in the summary, d_j denote the presence of document j in the summary, w_i denote the weight of concept i, and s_j denote the saliency of document j. The final score of the concepts coverage and documents saliency is expressed as the sum of positive weights w_i of concepts and scores s_j of documents covered in the summary. If not otherwise mentioned, we use bi-grams as concepts and frequency as weights.

Consistency Constraints Constraints ensure that if a document is selected, all concepts are also selected and if a concept is selected, at least one document that contains it is selected. Additionally, we ensure that the expected summary length do not exceed the defined length L. Here, the variable o_{ij} denotes the occurrence of concept i in document j. In detail, Equation (2) ensures the length constraint and Equation (3) ensures that if a concept i is selected, then there is at least one summary document covering it. Equation (4) ensures that if a document j is selected to be included in the summary, then all concepts in that document are also included in the objective function.

[1]We follow a typical Question-Answering task and extract the answer (facts) for a question (query).

Query Coverage We assume that only a subset of queries are salient depending on the event and day. Thus, we aim to select a characteristic set of documents which covers the salient queries. We already know that each document j is associated with a relevance score $s_{i\ j}$ w.r.t. to a query q_i. Based upon this, we create a m-dimensional target vector $\tau(\mathrm{D}')$ and summary vector $\pi(S)$ that represents the fraction of documents in D' and S that cover the queries Q. Here, the set D' denotes the generated event nuggets for the abstractive and documents for the extractive case. Specifically, $\tau(\cdot, i)$ and $\pi(\cdot, i)$ denote the fraction of documents that cover query q_i. We compute the target and summary vectors as the normalized mean of relevance scores (Lappas et al., 2012). The third term in Equation
(1) aims to match the target vector τ by imposing penalities on certain assignments with soft constraints. The variable z_p serves as an indicator if the constraint p is satisfied and ρ_p acts as penality score for constraint violation:

$$\forall p \in \mathrm{Q}, \quad z_p = \begin{matrix} 1 & \text{if the query contribution } \pi(S,p) \geq \tau(\mathrm{D}',p) \text{ or} \\ 0 & \text{otherwise.} \end{matrix} \tag{6}$$

In this way, we reward the model for selecting documents which cover salient queries. However, we want to avoid penalization for ignoring queries with low saliency. Therefore, we apply an adaptive truncation threshold θ and only consider the $k^{tr} = \max_{k\ i} \tau(\mathrm{D}', i) \leq \theta$ queries. For instance, the queries q_1 with *What area has the wildfire burned?* and q_2 with *Where are firefighters needed?* are more salient topics w.r.t. a wildfire event than the query
q_3 with *What curfews are in place?*. In this case, we assume the target vector with the corresponding queries q_1, q_2, q_3 is $\tau(\mathrm{D}') = (0.8, 0.6, 0.05)$ and the summary vector should match this target vector. We balance the linear combination of terms in Equation (1) with the hyper-parameters α, β, and γ, which can be any scalar values.

EXPERIMENTAL SETUP

Dataset

For our experiments, we use the CrisisFACTS datasets from 2022 and 2023 (McCreadie & Buntain, 2023). Both datasets include overall 18 disaster events and additional metadata (e.g., search keywords, queries, event types, and source types). Each event-day pair consists of multi-stream data and is extracted from the online sources Twitter, Facebook, Reddit, and Webnews. All documents are provided as stream items. That is, the documents are already segmented into short chunks which we use for our experiments. Along with the muli-stream data, the authors provide ground truth summaries extracted from Wikipedia, ICS-209 forms (Denis et al., 2020), and NIST annotated event nuggets. In Table 4, we provide further details about the number of stream items, days, and event types. More details on the dataset and summary construction process can be found in (McCreadie & Buntain, 2023).

Evaluation

In compliance with (McCreadie & Buntain, 2023), we evaluate the system summaries with ROUGE-1/2/L2 and BERTScore F1-scores (T. Zhang et al., 2020). System summaries for each event-day pair are constructed by the concatenation of all event nuggets (ordered by importance score) up to a threshold of 32 items. For fair comparison, all event nuggets must not exceed 200 characters and each final summary is bounded to $32 * 200 = 6400$ characters. However, we found that 83% (1691 tokens on average) of the NIST reference summaries exceed the token limit 512 of the authors choosen BERTScore model DeBERTa3. In other words, only a fraction of the most important event nuggets is evaluated from a semantic perspective. For completeness, we evaluate and report with BART4 instead but emphasize that the metrics are still flawed by truncation. This model has a context size of 1024 and doubles the event nugget coverage. Other models with larger context size have been reported with no distinguishing power (Bertsch et al., 2023).

Model Details

For the Extractor component, we use BM25 (Robertson & Zaragoza, 2009) with default settings of the *PyTerrier* (Macdonald & Tonellotto, 2020) library and extend it with Bo1 (Amati & Van Rijsbergen, 2002) query expansion to increase the recall. We set the number of feedback terms and documents as 3 and 20, respectively. As reranker, we employ MonoT55 (Nogueira et al., 2020) trained on MS MARCO and select the top-$k^{(1)}$=250 and $k^{(2)}$=50

2We compute all ROUGE scores with the *TorchMetrics* library and use the *PorterStemmer* as preprocessing step.

4https://huggingface.co/facebook/bart-large-mnli
5https://huggingface.co/castorini/monot5-large-msmarco-10k

candidates for each event-day-query triple. If not otherwise specified, all models and baselines use the same candidate documents as well as relevance and saliency scores.

Regarding the Abstractor component, we choose the *Transformers* (Wolf et al., 2020) library and use MISTRAL-7b[6] (Jiang et al., 2023) with greedy decoding as our instruction-following LLM. To increase the context, we select the left and right documents of each candidate document up to a limit of 500 characters. Due to computational constraints, we limit the number of input tokens for all considered methods to 4096. In terms of clustering, we utilize a *Sentence Transformers* model[7] to compute the sentence embeddings and cosine similarity between fact-pairs. We provide further prompt details in the Appendix Prompt Details.

For QILP, we use bi-grams and frequency as concepts and weights, respectively (Gillick & Favre, 2009; Riedhammer et al., 2010). All scores are normalized and the hyper-parameters are set to $\alpha = 1$, $\beta = 1$, $\gamma = 5$, $\rho = 1$, and $\theta = 0.7$ which we selected based on the TREC TS dataset (Aslam et al., 2015). We refer to our final models as follows: QILP[8] denotes the extractive approach that consists of the Extractor and QILP summarizer. LLMNug-Concat consists of the Extractor and Abstractor based on simple fact concatenation up to the event nugget character limit. That is, we skip the clustering and fusion steps in Figure 1 and use multiple facts to present one event nugget. LLMNug-Concat w/ QILP extends the previous model with QILP for final selection. LLMNug-ClusterFuse employs the proposed fact extraction and cluster fusion while LLMNug-ClusterFuse w/ QILP represents the extension with QILP selection.

Baseline Systems

We aim to establish an upper bound for the comparison of our models as well as extractive and abstractive baselines. Here, we only focus on NIST-based reference summaries since ICS forms are rather long and do not provide any splits for event-day pairs. We generate extractive oracles with a greedy search and denote them as Oracle. Specifically, we start with an empty set and iteratively select documents such that the concatenation maximizes the average of ROUGE-1/2 scores given the reference summary. For feasiblity reasons, we limit the search space to the documents retrieved by our Extractor component. Furthermore, we include a LLaMA-based[9] (Touvron et al., 2023) submission that achieved strong results in the CrisisFACTS 2023 challenge and denote it as LLaMA$_{\text{TREC}}$. LLaMA$_{\text{TREC}}$ similarly prompts query-relevant facts with a QA-motivated approach and concatenates the resulting facts to event nuggets (Seeberger & Riedhammer, 2023). In the following, we introduce the extractive and abstractive baselines.

Extractive We compare with several heuristics and extractive baselines from previous query-focused summarization work. More specifically: Random uses random selection, Lead selects the top document from each query-related cluster, and Greedy selects the overall top ranked documents (McCreadie & Buntain, 2023). As extractive models, we include the query-focused LexRank (Y. Xu & Lapata, 2020), a variant of SubMod (Dasgupta et al., 2013) composed of a linear combination of facility-location, document relevance, dispersion, and cluster contribution and lastly SCC (Rudra et al., 2018) as an ILP-based summarization framework with content word and sub-event coverage maximization. Furthermore, we conduct an ablation study for the different components of our introduced extractive model QILP.

Abstractive We perform experiments with different truncation-based and long document summarization versions while using the identical LLM with zero-shot prompting. For truncated baselines, we include Sum as vanilla summarization, SumCoT with the two-step CoT summarization approach (Wang et al., 2023), and Select+Sum as combination of QILP (L=100) with Sum (Dong et al., 2023). We truncate all inputs w.r.t. the maximal input size of 4096 and ensure that the truncation considers document boundaries. For long document summarization, we include incremental updating and hierarchical merging (Chang et al., 2023). For Incremental updating, we iterate through each chunk of documents while continuously updating a global summary with only new salient information. For Hierarchical merging, we generate summaries for each input chunk and recursively merge the summaries until we have reached one final summary. We restrict these models to the top 500 documents emitted by the Extractor component.

MAIN RESULTS

In Table 1, we report the results for NIST reference summaries including the average word count for each generated summary. A general trend is that all proposed methods outperform the extractive and abstractive baseline counterparts. Interestingly, the Greedy heuristic is competitive to our approaches and even surpasses most of the extractive and abstractive baselines. This finding is in line with the results of (McCreadie & Buntain, 2023). The Lead model also shows decent results but the Random selection achieved relatively low performance across all metrics which demonstrates the importance of document saliency (i.e., query-relevance) obtained by the Extractor.

Proposed Models The extractive summaries of our proposed approach QILP achieve better results in comparison to all extractive and abstractive baselines, especially for ROUGE-2 (26.07 and 17.49). Surprisingly, the simple concatenation of generated facts outperforms the computational more expensive clustering-based summarization approach. This highlights that disaster reports are rather focused on informativeness than coherence and fluency. The application of extractive selection also improves the LLM-based models for the majority of reported metrics. Critically, we find that most of the best performing models are extractive for NIST-22 and abstractive for NIST-23. This suggests that the reference summaries are potentially biased towards extractive and abstractive systems which could be caused by the pooling-based annotation process. For example, LLaMA$_{\text{TREC}}$ was part of the pooling-based evaluation of CrisisFACTS 2023 and therefore shows the best results for NIST-23. This finding also supports the assumption of biased reference summaries. Regarding the extractive Oracle, we still can see large gaps in terms of ROUGE-1/2/L and BERTScore. These results depict the necessity for further developments in the disaster summarization domain.

ICS-209 and Wikipedia We present the evaluation results for ICS-209 and Wikipedia summaries in Table 2. Overall, we find that the system ranks differ from the NIST reference summaries. Shorter and more general summaries achieve the best results for Wikipedia while longer and more detailed summaries have the best coverage for ICS-209 forms. This is reasonable for this kind of summary formats, where Wikipedia articles provide high-level summaries for a public audience and ICS-209 forms represent informative reports written by emergency-response personnel (McCreadie & Buntain, 2023). This suggests the selection of summarization systems tailored to the

Table 2. Rouge-1/2/L and BERTScore F_1-score (x100) results on ICS-209 forms (ICS-22) and Wikipedia (WIKI) reference summaries. ICS summaries are only available for CrisisFACTS 2022. Bold numbers indicate the best performance. Due to context size limitations, we discard the BERTScore for ICS-22.

end-user and information need. However, we emphasize that all evaluated summarization models are used in the unsupervised and zero-shot setting. Appropriate datasets and model fine-tuning can further improve the results but data collections are costly to obtain in the disaster summarization domain.

Are we gaming the benchmark? If we consider summary lengths, one can easily spot the correlating ROUGE-1/2/L and BERTScore scores. Here, the question arises if simply producing long summaries can be seen as *gaming the benchmark*. In fact, we measure a moderate Spearman's rank correlation of 0.43 (0.48) for ROUGE-2 (BERTScore) and note that length bias in neural summarization (Guo & Vosoughi, 2023; Sun et al., 2019) as well as long document summarization (Chang et al., 2023) evaluation is an active research area. However, we argue that producing long and detailed summaries is a desirable feature in the field of disaster reporting. Therefore, we see our event nugget-based summarization as an extension to obtain more informative summaries, but would also like to emphasize the length limitations of our abstractive baselines. In Appendix Examples, we show excerpts for summaries about the *Kincade Wildfire 2019* event.

FURTHER ANALYSIS

In addition to the main experiments, we further assess the impact of different setups and components. Therefore, we analyse the influence of retrieval pipelines, document sources, and provide an ablation study for the QILP model components.

Influence of Retrieval Figure 3 presents the ROUGE-2 scores for different retrieval pipelines. We conducted experiments for the sparse retrieval models DFReeKLIM (Amati et al., 2011) and BM25, sparse neural search model SPLADE10 (Formal et al., 2022), and rerankers ASNQ11 (S. Garg et al., 2020) and MonoT5 with BM25 as the first-stage retriever. The retrieval experiments highlight two important points. First, the usage of reranking

11TANDA RoBERTa-Large ASNQ-Wiki-QA

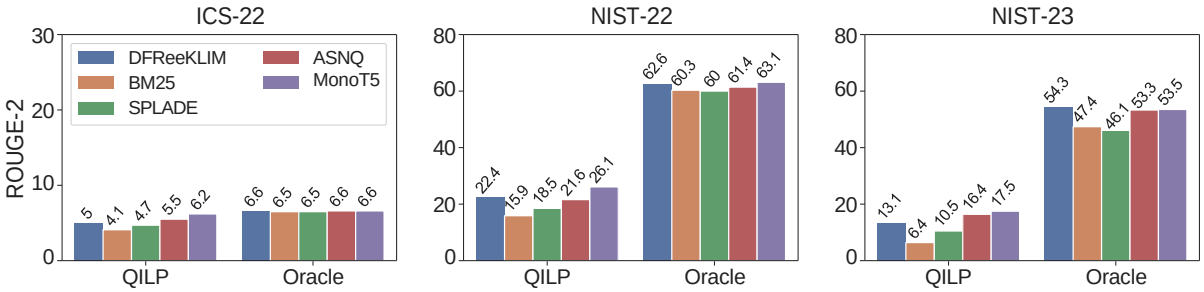

Figure 3. Rouge-2 F_1-score (x100) results for the different retrieval pipelines. We report the performance for QILP and the extractive Oracle. The rerankers ASNQ and MonoT5 use BM25 for first-stage retrieval.

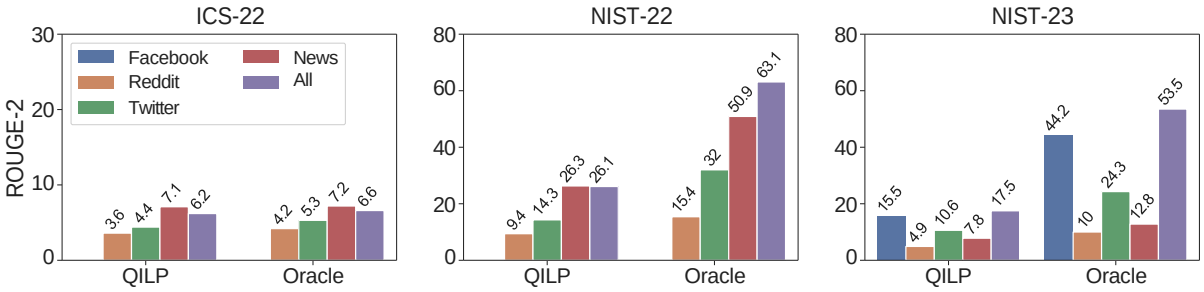

Figure 4. Rouge-2 F_1-score (x100) results for the different available document sources. We report the performance for QILP and the extractive Oracle. The label *All* denotes the mixture of all document sources.

significantly improves the results over the first-stage retrieval and highlights the importance of appropriate document scoring w.r.t. the downstream task. Second, dedicated efficient sparse retrieval models like DFReeKLIM can outperform off-the-shelf models such as BM25 by large margins but still lack behind the two-stage approaches. However, the DFReeKLIM results can be strongly biased due to the pooling-based process as the organizers use two basic DFReeKLIM variants as baseline systems.

Influence of Source Figure 4 presents the ROUGE-2 scores by restricting the input documents to the source types. Note that we only had access to Facebook posts for CrisisFACTS 2023 which explains the missing scores for ICS-22 and NIST-22 summaries. First, we can see that posts from Reddit and Twitter are mostly outperformed by the sources Facebook, News, and All for both QILP and Oracle. We assume that News already summarizes important facts about an event and Facebook often refers to published news articles or include posts written by news accounts (McCreadie & Buntain, 2023). In contrast, Twitter posts contain much noise and Reddit posts are only available in smaller scale. The drop of News for NIST-23 can be explained by both the low number of available stream items and the possible bias towards Facebook posts. This highlights the benefit of multiple document sources as long as the availability of traditional sources is limited.

Influence of Components Table 3 presents the results of our component ablation for the best performing QILP model. As already mentioned in previous sections, removing the reranking component yields the largest drop for all metrics. Exchanging the Bi-gram concepts with Entity concepts leads to an further decrease in performance that mirrors the effectiveness of simple Bi-grams for content coverage. For our saliency (Sal) and query coverage (Q-Cov) extensions, we found that removing saliency leads to a higher performance drop while the largest decrease occurs if we remove both components. In other words, the saliency and query coverage terms can be seen as complementary and not just as substitute. However, we only consider retrieval relevance scores as document saliency and would expect a performance increase by incorporating more sophisticated saliency predictors (Kedzie et al., 2015).

Efficiency Practical utilization of information systems in emergency and disaster response necessitates the deployment of efficient real-time systems. Therefore, we analyze the computation time of the proposed components concerning the event *Lilac Wildfire 2017*. All experiments are conducted with AMD EPYC 7662 CPUs and one Nvidia A100 GPU. On average, the stages of Retrieval and Reranking require 1.2 and 67.4 seconds for each

event-day pair and provide the input for the subsequent summarization components. While the extractive approach QILP only takes 0.8 seconds, the abstractive LLMNug-Concat and LLMNug-ClusterFuse approaches require 673.2 and 839.7 seconds, respectively. This highlights the computational overhead of the incorporated LLMs, which may be insufficient for summarization updates in shorter intervals. Using proprietary LLMs via API access can enhance performance and avoid the need for dedicated infrastructure. However, this also introduces latency issues and may raise data privacy concerns.

CONCLUSION

In this work, we studied the task of disaster summarization from multiple streams. We establish several unsupervised and zero-shot baselines and assess the performance with CrisisFACTS, a state-of-the-art dataset for disaster summarization. Current summarization systems reveal shortcomings related to large document collections and face challenges in generating long disaster reports. To address these issues, we introduce a retrieve-then-summarize approach and extend previous research from the query-focused and long document summarization domain. Experimental results show that our approach outperforms baselines, but we also conclude that simple extractive methods achieve competitive or better results. In addition, we examine the influence of different components and point out shortcomings related to summary length that make fair evaluation difficult. Depending on the dataset, we find that current reference summaries favor either extractive or abstractive techniques. This suggests that further efforts are needed to develop datasets and automatic evaluation metrics which take bias issues into account. Interesting future directions include the automatic evaluation of disaster reports, comprehensive human evaluation, and benchmarking of larger (proprietary) LLMs.

PROMPT DETAILS

We provide an overview of the prompts used in our work. For the LLMNug-based methods, we rely on one demonstration example as we otherwise noticed format errors that made it difficult to parse the facts. All other methods use zero-shot prompting without the use of any demonstration examples. We list all LLM-based methods and show the prompt dependencies in the corresponding brackets: Sum (Table 5), Select+Sum (Table 5), SumCoT (Table 6, Table 7), Incremental (Table 5, Table 8), Hierarchical (Table 5, Table 9), LLMNug-Concat (Table 10), and LLMNug-ClusterFuse (Table 10, Table 5).

Table 5. Generate initial summary

We are creating one detailed summary for disaster response officers. Summarize and rewrite the following documents into coherent and readable paragraphs. Do not deviate from the facts of these documents or add any new information. Include as many details as possible. The summary could include multiple paragraphs.

Documents: {documents}

Summary:

Table 6. Element extraction

Documents: {documents}

What are the important entities in this documents?
What events are happening in this documents?
What is the result of these events?

Please answer the above questions:

Table 7. Generate element aware summary

We are creating one detailed summary for disaster response officers. Summarize and rewrite the following documents into coherent and readable paragraphs. Do not deviate from the facts of these documents or add any new information. Include as many details as possible. The summary could include multiple paragraphs. Documents: {documents} {elements} Let's integrate the above information and summarize the documents:

Table 8. Iterative refinement

We are creating one detailed summary for disaster response officers and provide an existing summary up to a certain point: {previous summary} New documents: {documents} Given the new documents, incorporate any new vital information into a new coherent and readable summary. Do not deviate from the facts of these documents or add any new information. Include as many details as possible. The summary could include multiple paragraphs. Summary:

Table 9. Hierarchical merging

We are creating one detailed summary for disaster response officers. Distill and rewrite the following previous summaries into consolidated paragraphs. Do not deviate from the facts of these summaries or add any new information. Include as many details as possible. The final summary could include multiple paragraphs. Previous summaries: {summaries} Summary:

Table 10. Fact extraction

You are a fact extractor for disaster response organizations. Use the documents to answer the question based on a list of extracted facts as evidence. Please follow the instructions for the facts: 1. The facts must be short. 2. The format of one fact is text-snippet (source document). 3. Provide the source documents for each fact with the format: (Doc-1, Doc-2, ..) 4. Include fact-relevant entities such as locations, numbers, dates, etc. 5. Only include facts which are focused on the question. 6. The list items must start with * bullet points. Do not use numberings. We provide you one example within " marks: '{demonstration}' Your task: Documents: {documents} Question: {query} Facts list:

EXAMPLES

- Pharmacies, supermarkets, and restaurants are closed during blackouts in bedroom communities of San Francisco and Silicon Valley; Town Hall is closed except for essential services - - The main evacuation order encompasses a huge area of Sonoma County, including Santa Rosa - - Strong winds are forecasted to impact the Kincade Fire, Santa Rosa and much of the North Bay .; WILDFIRE SMOKE is impacting the San Francisco Bay Area and Los Angeles Area . - - The Kincade Fire has burned through 50,000 acres (20,200 hectares) of land; The Kincade fire spread across more than 75,000 acres (303 square kilometers) - - 4,548 firefighters are assigned to the fires; 4,500 firefighters have been working on containment lines and structure protection - - The Kincade Fire has burned 75,415 acres and is 15% contained - - The Wine & Food Affair event in Sonoma County may have been canceled; Classes at Chalon and Doheny have been canceled - - La Tortilla Factory's main office and production center is closed due to power outages and evacuations; Think Tank Photo offices are closed due to wildfires and evacuations - - At least eight homes were destroyed and six damaged in the LA-area blaze; Three people were killed and over 1,600 homes and other buildings were destroyed from north of Los Angeles to Malibu - - Four shelters for Kincade Fire evacuees are at capacity, while five are still accepting evacuees; Jaxon Keys' Winery & Distillery is an open shelter for large animals affected by the Kincade Fire - - A High Wind Warning is also in effect during the same period, with northeast winds 30 to 50 mph and gusts up to 60 to 70 mph, and isolated gusts up to 80 mph at higher elevations - - Volunteers are needed for Petaluma evacuation centers; Volunteers are needed for food service and general labor; Farm animals need volunteers to take them in - - Nearly 200,000 people have been evacuated from their homes throughout California; Over 100,000 structures are threatened - - Several state parks have closed due to the Kincade Fire and Public Safety Power Shutoffs; The registrar's office in Santa Rosa is closed because of Kincade Fire evacuations - - Red Flag No Parking restrictions are in effect citywide in Los Angeles due to the extreme fire danger - - An evacuation warning was announced for parts of Lake County; The entire town of Geyserville and the entire city of [redacted] are under mandatory evacuation orders -

Table 12. Summary of LLMNug-ClusterFuse w/ QILP with L=16 for request CrisisFACTS-015-r4

- The affected areas are located south of Mulholland, west of the 405 freeway, north of Sunset Boulevard, and west of Temescal Canyon. Entrance to Brentwood above Sunset Boulevard has been closed. - - Evacuation orders and warnings continue to apply to various cities and communities within the affected region. - - The towns of Geyserville and a redacted city, as well as certain communities and cities in the affected areas, are under mandatory evacuation orders due to ongoing wind events. - - Among them, around 4,500 firefighters have been actively engaged in setting up containment lines and safeguarding structures to prevent further damage. - - These evacuations have led to road closures on the 405 freeway, which is the nation's busiest highway. - - Nearly 1 million people are without power, and over 200,000 have been displaced from their homes. The Memorial bridge near Kennedy Ln was not impacted by the fires. - - Evacuations can pose challenges, especially for vulnerable communities that depend on childcare. Emergency response teams are encountering difficulties accessing some regions due to road closures. - - An evacuation warning has been announced for various areas in Lake County, including the northern part of Dry Creek Valley and Middletown, as well as the Twin Pines Casino area (Zone 4). - - Zone 4B, which includes areas south of Westside Road to Millcreek Road, has specific evacuation orders in effect. Some individuals have been unable to take their animals with them during evacuations. - - The registrar's office in Santa Rosa has closed due to evacuations. Recovery efforts are underway, with at least 124 structures confirmed destroyed in Sonoma County. - - Over 185,000 people have been evacuated from their homes in Sonoma County alone due to the Kincade Fire. Nearly 200,000 people have been displaced by the wildfires across California. - - Overflowing conditions have been reported in both emergency shelters and hotels, creating a critical need for additional assistance. - - Some evacuation orders have been lifted in other areas. Individuals in high-risk zones should be prepared to evacuate with short notice. - - Four of these shelters have reached full capacity, but fifteen continue to accept evacuees. Additionally, the Westwood Recreation Center serves as a shelter for those displaced by the Getty Fire. - - Sonoma County Fairgrounds and Napa Valley Expo are accommodating evacuees and small animals. Animal shelters are working diligently to provide care for pets displaced by the fires. - - Specifically mentioned are the need for volunteers at Petaluma evacuation centers, Sonoma County Animal Response Team (CART), Integrative Healers Action Network, and Kincade Fire Clinics. -

Table 13. Summary of QILP with L=16 for request CrisisFACTS-015-r4

- Some 180,000 people have been ordered to leave homes, with roads around Santa Rosa north of San Francisco packed with cars as people tried to flee. - - Evacuations have been lifted in a number of communities, and the Napa County emergency evacuation shelter at Napa Valley College closed today at noon. - - Over 200,000 people have been ordered to evacuate and more than 100,000 structures are threatened. . - - About 156,000 people were under mandatory evacuation orders. - - The following DOR offices remain closed due to the PSPS event: Novato, Ukiah and Lakeport. - - Nearly 200,000 people evacuated their homes in California this weekend. - - About 156,000 people were still under evacuation orders. - - Another million people have been told they could lose supplies. - - Evacuation Orders effecting 189,980 people. - - CWS Kits will be made available if requested, and we are checking in with our long-term recovery group partners in Los Angeles as to other ways that we can support them. - - The following road closures are in effect: Westside Road at Highway 101 offramp – no eastbound traffic on Mill Street Dry Creek Road at Highway 101 – no eastbound traffic on Dry Creek Road Chiquita Ro - - At least 10,000 people have been evacuated, gardeners and cleaners could be seen on their way to work. - - "There now are 4,548 people, mainly firefighters, assigned to the fire and more were expected later in the day." - - Areas North of Westside Road to Millcreek Road within Zone 4 have been reduced to an EVACUATION WARNING and are open for repopulation. - - Mandatory evacuations are in place for parts of the area. - - #KincadeFire VOLUNTEERS NEEDED #Petaluma People Services is coordinating volunteers for the Petaluma evacuation centers. -

Can User Characteristics Predict Norm Adherence on Social Media? Exploring User-Centric Misinformation Interventions

ABSTRACT

The work-in-progress explores user-centric misinformation interventions on social media as such tools are limited. Knowledge of relationships between online user characteristics and their expressed adherence to a desired norm (i.e., rejecting misinformation or supporting factual information) is understudied with limited integrated multi-modal machine-learning models to infer demographic and sociopsychological characteristics. Thus, we piloted 9,331 Twitter users tweeting COVID-19 vaccines between May 1, 2020, and April 30, 2021. Employing a CNN-LSTM framework, our model analyzes user biographies, profile images, and pre-COVID historical tweets to infer user traits over 90% accuracy for individual characteristics and an overall accuracy of 85.61%, which outperforms existing tools and other designs. Further, using multi-logistic regression, we identified significant predictors of users' adherence to desired norms, such as gender and pre-pandemic prosocial content engagement, while finding no significant age correlation. Our findings illuminate pathways for targeted misinformation mitigation strategies during critical public health crises.

Keywords

Misinformation, deep learning, social media, social norm, user-centric

INTRODUCTION

Human life has become increasingly digitized, and a massive amount of information is disseminated in an online environment. At the same time, with inaccurate and misleading content, misinformation spreads widely in the physical and digital realm and becomes a threat to society (Del Vicario et al., 2016). Misinformation can mislead individuals' perceptions and behaviors widely (Swire-Thompson & Lazer, 2020). To tackle the threat of misinformation, prebunking strategies have been proposed to achieve pre-exposure implementation and long-lasting effects on preventing the adoption of misinformation (Lewandowsky & van der Linden, 2021). Grounded in "inoculation", i.e., pre-warnings can make individuals immune from misinformation, prebunking strategies can be promising for protecting individuals from misinformation with broad and diverse topics (Cook et al., 2017; Ecker et al., 2022). Prebunking can be conducted by social norm interventions, which are particularly for population-level inoculation (Maertens et al., 2020). Social norm interventions are based on the social psychological phenomenon that people tend to conform to surrounding norms to avoid sanction or confer benefit (Constantino et al., 2022; Gao et al., 2022).

Existing practices of social norm interventions are usually designed for the general public, neglecting the heterogeneity of online users regarding their sociodemographic characteristics, psychological traits, perceptions of online information, and the capacity for detecting misinformation (Chadwick et al., 2023). For instance, questionaries among university students in Singapore have identified a significant gender difference in the

prevalence of misinformation sharing (Chen et al., 2015). A survey with 113 randomly selected social media users indicates that users between 18 and 34 years old are more likely to share misinformation (Adaji, 2023). Individuals with different influences in the online environment may also share misinformation with different tendencies (Legros & Cislaghi, 2020). Also, tendencies to generate prosocial content have been identified as influencing individuals' motivation to circulate only truthful, beneficial information (Zhu et al., 2023). Without being tailored for online users, social norm interventions may only be effective for users with certain characteristics instead of the whole population of online users.

Compared to interventions that are generally designed for the public, user-centric or tailored interventions are designed to align with the heterogeneous characteristics of online users and may potentially amplify the effectiveness of interventions (Kaufman et al., 2022). User-centric or tailored designs of interventions have been successfully applied in other domains of information dissemination and communications, such as tailored and targeted communications of hazard information and health-related information (Gao & Wang, 2021; Kreuter & Wray, 2003). However, existing models that estimate social media user characteristics have not reached high-level accuracy (Wang et al., 2019). They also have not been designed to estimate users' social psychological characteristics, such as tendencies to generate prosocial content. Also, existing studies have not comprehensively investigated the relationship between user characteristics and behaviors of sharing or rejecting misinformation, providing insufficient knowledge about selecting targeted users who may need to be motivated to adhere to the *desired norm*, expressed in tweets of rejecting online misinformation or supporting the factual information.

We aim to answer the following two research questions:

RQ 1: How can we accurately infer online users' demographic and social psychological characteristics based on their features in profile images, biography text, and online posts?

RQ 2: What are the relationships between online user characteristics (including age, gender, tendency to generate prosocial content, and influence on social media) and users' adherence to the desired norms?

Focusing on the topic of COVID-19 vaccines on Twitter, we start by capturing 9,331 sample users' expressed adherence to the desired norm from May 1, 2020, to April 30, 2021. We infer online users' demographic and social psychological characteristics by developing a multi-modal deep learning model. The input data includes users' profile information and pre-COVID tweets posted between January 1, 2019, and December 31, 2019. Then, we use multi-logistic regression to examine the relationship between user characteristics and adherence to the desired norm. The preliminary study paves the way for the design of user-centric social norm interventions and contributes to the existing knowledge body in crisis informatics in two ways. First, it develops a comprehensive model designed to accurately infer a diverse set of user characteristics by analyzing their online profiles and social media posts. By integrating different data features, the model processes textual, visual, and behavioral data to predict user traits with high accuracy. Second, our analysis reveals significant correlations between user characteristics and their propensity to adhere to the desirable norm. The findings offer actionable insights for developing user-centric misinformation mitigation strategies, particularly critical in preemptive responses to future pandemics and large-scale crises.

LITERATURE REVIEW

Existing Prediction Models of Online User Characteristics

Due to the privacy policies of online platforms, the demographic characteristics of online users are usually not recorded and are not publicly accessible (Wang et al., 2019). Existing studies have proposed various methods for predicting online user characteristics, mainly focusing on demographic characteristics, especially genders and ages (or age groups). The predictions are mainly based on biographies, online posts, or profile images of online users, and the basic method of prediction is machine learning (especially deep learning) models. For example, support vector machine (SVM) has been widely used to predict the gender and age groups of users on Twitter and Facebook (Chen et al., 2021; Fink et al., 2021). Deep learning models have also been proposed to infer the gender and age of online users based on users' profile information, such as the M3 inference, which is a multi-modal deep learning model utilizing users' profile information (Wang et al., 2019).

However, existing tools may not be effective at predicting the characteristics of English-speaking users due to the biases in input features and datasets. For example, some tools rely on profile images as the primary feature for inferring users' demographics (Golder et al., 2022; Priadana et al., 2020), and they may not perform well with users with default profile images or no profile images. Also, some tools are developed based on certain platforms, such as Instagram and Facebook (Çoban et al., 2021; Priadana et al., 2020), which may affect their accuracy in inferring the characteristics of other platforms, such as Twitter. In another case, as one of the models with the

highest inference accuracy, M3 inference can still be improved to predict English Twitter users' age and gender, as its current accuracy for age prediction is around 40% and for gender is around 80%.

Meanwhile, online users' social psychological behaviors, such as tendencies to generate prosocial content, have not been predicted by previous studies. In particular, previous studies have proposed questionnaires to collect individuals' responses to some sociopsychological questions and estimated their tendencies to engage in prosocial behaviors accordingly (Lavertu et al., 2020; Perach et al., 2023). This strategy is not suitable for large populations due to the cost and may not apply to online users who are anonymous and may not participate in online surveys.

Online User Characteristics and Information Dissemination

Online users' demographic characteristics have been found to be related to their behaviors of information dissemination and the spreading of misinformation in the online environment. In some experiments with randomly sampled social media users, it was observed that female users and users between the ages of 18 and 34 have shown relatively higher tendencies to share misinformation without detecting it (Balakrishnan, 2022; Xiang et al., 2023). In addition to demographic characteristics, individuals' perceptions and dissemination of misinformation may be influenced by their social psychological traits, such as the fear of being attacked, desire to protect their self-image, lack of self-efficacy, lack of accountability, personal traits, extraversion, empathic concern, and tendencies to being prosocial (Gurgun et al., 2022; Perach et al., 2023). Among these characteristics, the tendency to be prosocial may be related to detecting misinformation, according to the experiments in China and Hungary (Orosz et al., 2023; Sun & Ma, 2023; Zhu et al., 2023). Behaviors of being prosocial include but are not limited to generating content for supporting or helping others in pursuit of developing and maintaining harmonious relationships (Van Rijsewijk et al., 2016). Online users with varying levels of influence in online environments may also have different tendencies to share or reject misinformation. Some online users, such as online news media, celebrities, journalists, and other populations with large followings, may have a greater impact on online discussions than the ones with low-level influence (Andrighetto et al., 2013; Legros & Cislaghi, 2020). Low-influence users' attitudes toward online misinformation are likely to align with the norms that are proposed and shaped by high-influence users (Constantino et al., 2022; Wu et al., 2011).

However, studies on the relationships between user characteristics and the adoption of misinformation-related beliefs may still be limited due to their reliance on self-reported data from survey participants, while individuals' responses in the surveys may deviate from their actual behaviors and beliefs (Takeuchi et al., 2023). Online users' historical posts can provide observed information about users' tendency to reject or share misinformation, but such data has not been sufficiently investigated by existing studies. Also, existing findings about the relationships between being prosocial and detecting misinformation may not be fully applied to English-speaking Twitter users, who are not covered by their experiment samples. Additionally, existing studies have mainly examined users' tendency or behaviors to detect misinformation, which does not always equal to rejecting misinformation content or expressing adherence to the norm of rejecting misinformation or supporting factual information (Moravec et al., 2018).

METHODOLOGY

Data Collection and Preprocessing

We collected Twitter data related to COVID-19 using keywords such as "covid", "coronavirus", and "sars-cov-2" through Twitter's publicly available Streaming API, as detailed in our previous studies (Gao et al., 2022; Gao et al., 2023; Wang et al., 2017; Wang et al., 2021). To ensure privacy, results were reported only at the population level, addressing potential data privacy concerns. From the large dataset, we randomly sampled 10,000 users who tweeted about COVID-19 vaccines between May 1, 2020, and April 30, 2021. After removing suspended or protected user accounts, 9,331 users remained in our study sample. The data set includes user profiles, especially profile images and biographies. Additionally, we retrieved the sample users' historic tweets from the pre-COVID period between January 1, 2019, and December 31, 2019, using a web-scraping tool named Nitter Scraper (DGNSREKT, 2023). Both the user profile and historical tweets were employed to infer demographic characteristics and tendencies of generating prosocial content using a CNN-LSTM-based multi-modal model. Notably, we leveraged a different dataset – Wikidata – to train the model because the dataset includes self-reported year-of-birth and genders of 6,739 users (Liu & Singh, 2021). Details can be found in the Model training section. Though some users may have deleted their posts, this retrospective data collection approach relies on the assumption that tendencies of being prosocial are consistent over time (Eisenberg, 2023), minimizing the impact of deleted posts on the overall analysis.

Developing an Integrated Model to Uncover Users' Demographic and Social-Psychological Characteristics

We developed an integrated multi-modal model (Figure. 1) to infer online users' gender (male or female), age groups (under 18, 18 to 44, 45 to 64, 65 or older), and tendency to generate prosocial content ("yes" or "no").

Model Input

The input of our integrated model includes the profile images and users' biographies and pre-COVID tweets, i.e., the text, topics, and sentiment, which can be distinguished among users with different ages and genders (Holmberg & Hellsten, 2015; Nguyen et al., 2021). The user images were directly input to the image-related module. The text of users' biographies and pre-COVID tweets were preprocessed before inputting into the text-related module by tokenizing words, lowering each word, and removing English stopwords, punctuations, URLs, and @usernames (Yao & Wang, 2020). After preprocessing, the text of biographies and pre-COVID tweets were embedded into two vectors based on the corpus of biographies and pre-COVID tweets of all users, then input into the text-related module. Specifically, the embedded process converted each piece of input text into a dense vector, in which each element represented the index of a word in the corpus with a 1×60 fixed-size embedding. The topics of users' biographies and the topics of their pre-COVID tweets were determined by Latent Dirichlet Allocation (LDA) topic modeling for each user (Yao & Wang, 2020). We set the possible count of topics as eight to obtain the lowest perplexity score of topic modeling. The LDA algorithm started by calculating the probability of each word in the corpus belonging to a certain topic and assigning the words to the topics with the highest probability. Each user's biography and generated tweets were then assigned the topics with the highest frequency in their respective texts. The sentiments of users' biographies and pre-COVID tweets were detected with VADER, a keyword-based and rule-based model (Hutto & Gilbert, 2014). The topics and sentiments of users' biographies and pre-COVID tweets were also input into the text-related module of our model.

Model Structure

The multi-modal model comprises two pipelines, which process the image input and the text-based inputs separately. The first pipeline includes a Lenet-based convolutional neural network (CNN) module, which is widely used for processing imagery inputs (Lecun et al., 1998). The CNN module consists of three sets of "convolution + max pooling" layers for processing the raw profile images, of which the size is 400×400. These layers are followed by a flatting layer that turns the 2D data into a 1D vector, which is the output of the first pipeline.

The second pipeline contains two parallel processes for biography-related inputs and pre-COVID tweet-related inputs. For the biography-related inputs, the word vector is processed by a Long-Short Term Memory (LSTM) layer, which is typically utilized for capturing information from text data (Sundermeyer et al., 2012). The topic and sentiment of user biographies are transformed into two dummy vectors. The output vector of the LSTM layer and the dummy vectors of topics and sentiments are then aggregated with a dense layer, which reduces the total dimension of these three vectors and avoids co-linearity. The processing of pre-COVID tweet-related inputs is the same as the processing of biography-related inputs. The outputs of the second pipeline include one vector representing users' biographies and one vector representing users' pre-COVID tweets.

The output vectors of the two pipelines are concatenated into one vector and input into a three-layer feedforward neural network, which generates a dummy variable indicating the user's characteristics. By considering users' gender (two types), age groups (four types), and tendency to generate prosocial content (two types), an online user can belong to one of 16 classes ($2 \times 4 \times 2$). For example, one class of users can be male, under 18, and tend to generate prosocial content.

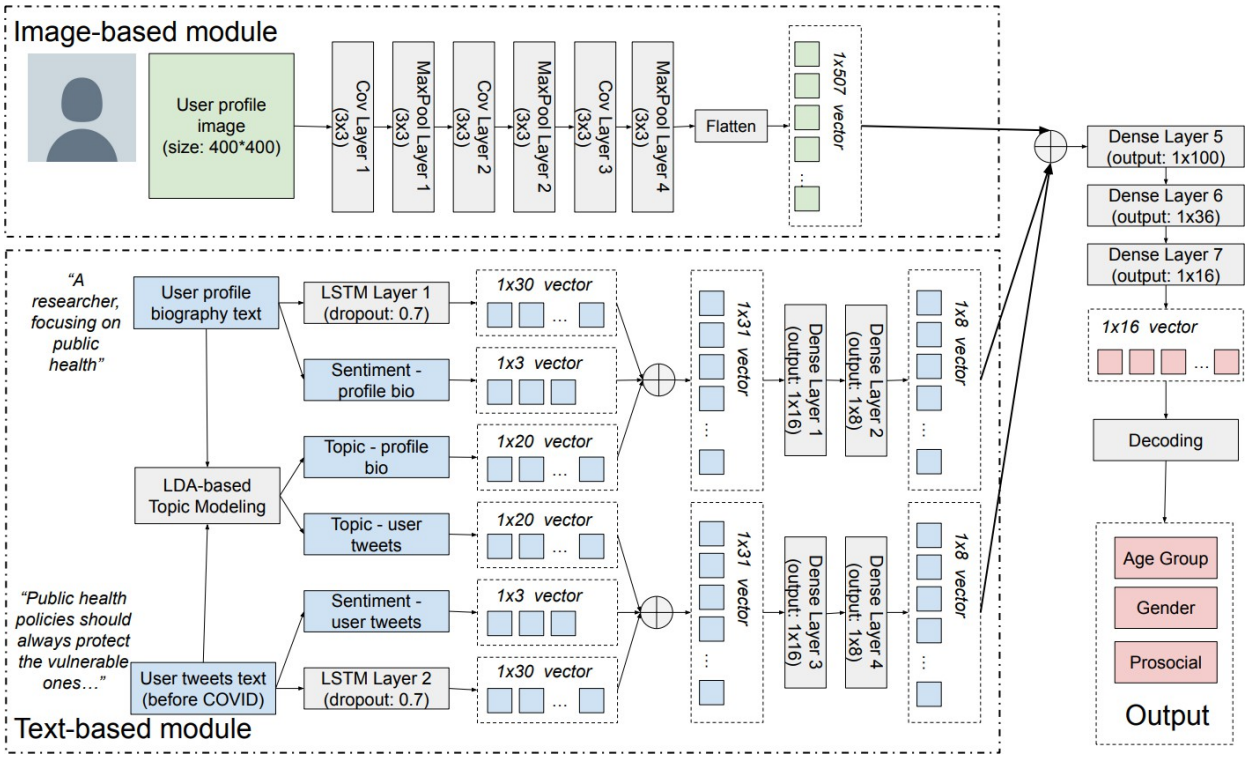

Figure 1. Architecture of the multi-modal model

Model Training

To train the model shown in Figure. 1, we used Wikidata as the training dataset containing users with self-reported year-of-birth and gender (Liu & Singh, 2021). We utilized the Nitter scraper to retrieve profile images, biographies, and pre-COVID tweets generated by the users in Wikidata between January 1, 2019, and December 1, 2019. We can retrieve the complete information from 6,739 users from Wikidata. To determine whether the combined corpora of the tweets and biographies of users in training data were prosocial or not, we labeled each user's tweet corpora based on manual reviewing and the judgment of GPT-4 (OpenAI, 2023), following existing studies (Li et al., 2024; Mujahid et al., 2023). A text was labeled as prosocial content if it contained positive, friendly, supporting, and gratitude expressions (Lysenstøen et al., 2021). An example is "How great would it be if we took the time to sit down with our veterans, visit and thank them for their service." The distribution of users in each class in the training data is shown in Figure. 2.

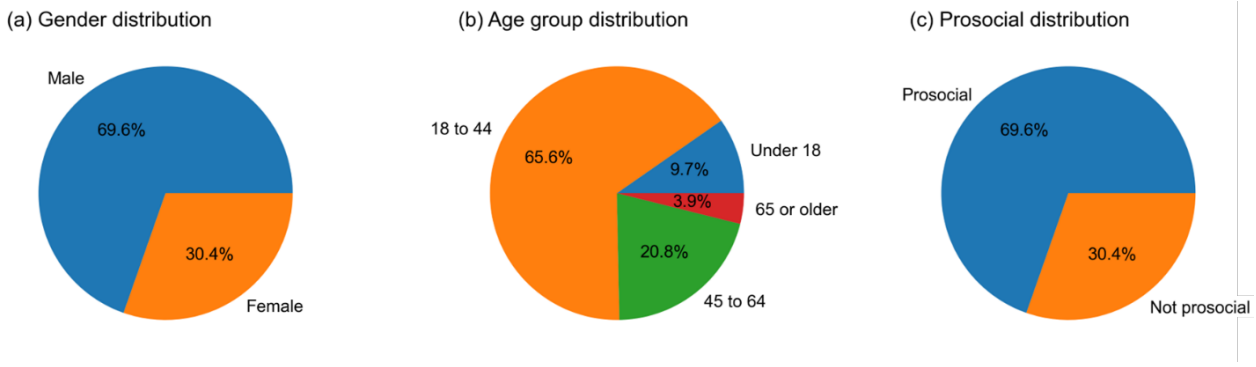

Figure 2. Distribution of genders, age groups, and users generating prosocial content in the training data

To train the multi-modal model, we split the training data into two sets, which separately took 70% (for modeling training) and 30% (for model validation) of the training dataset. The training process consisted of 20 epochs to avoid overfitting. The batch size was set to 100 to reach the balance between the times of updating model parameters and model accuracy (Smith et al., 2017). We selected Adam as the optimizer and calculated the model loss with categorical cross-entropy.

Tracking Online Users' Expressed Adherence to the Desired Norm

Leveraging the trained multi-modal model in the prior session, we can predict the user characteristics of 9,331 users. Then, we determined each user's expressed adherence to the desired norm. We started by determining if each tweet of each user expressed adherence to the desired norm. A tweet was considered as not adhering to the desired norm if its content delivered manipulated information about the side effects of COVID-19 vaccines, such as "do not take COVID-19 vaccines, they made children killed." In contrast, we considered a tweet as adhering to the desired norm if it supported COVID-19 vaccination or rejected related misinformation, such as "take COVID-19 vaccines to protect you and your family." We trained an LSTM classifier for the text classification based on 2,000 manually labeled tweets (Table 1) (Gao et al., 2023). The tweets were randomly sampled from all the real-time tweets we previously collected, which were not generated by our studied 9,331 users. LSTM was used because of its high capacity to capture phrase-level and sentence-level feature patterns (Sundermeyer et al., 2012). The validated accuracy and loss of the LSTM classifier during training are shown in Figure. 3, reaching 0.8892 and 0.2292 separately after training. Also, the RMSE of the classification outcomes is 0.3719, and the F1 score is 0.8706. These metrics indicate that our LSTM classifier has a satisfactory performance.

Table 1. Proportions of tweets expressing or not expressing adherence to the desired norm in training and testing data of the LSTM classifier

Dataset	Size	Count/Proportion of Tweets Expressing Adherence to the Desired Norm	Count/Proportion of Tweets Not Expressing Adherence to the Desired Norm
Training data	1,600 tweets	209 tweets (13.06%)	1,391 tweets (86.94%)
Testing data	400 tweets	57 tweets (14.25%)	343 tweets (85.75%)

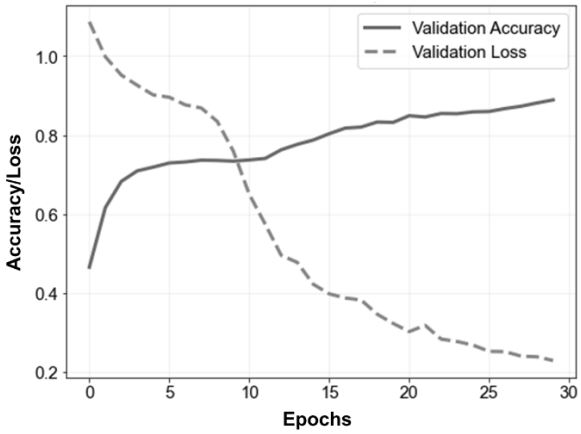

Figure 3. The accuracy and loss of the LSTM classifier during training

After determining users' expressed beliefs delivered in each tweet, we specified each user's expressed adherence to the desired norm in the twelve-month studied period (represented by $AAAAheeeeeeeeeeee$). We first specified their vaccination-relevant tweets each month. We labeled users' tweets corpora in one month as expressing adherence to the desired norm if all of their tweets about COVID-19 vaccines in that month expressed adherence to the desired norm. Based on the monthly adherence to the desired norm, we categorized users into two groups: users consistently expressing adherence to the desired norm ($AAAAheeeeeeeeeeee = 1$), and users not consistently expressing adherence to the desired norm ($AAAAheeeeeeeeeeee = 0$).

Multi-Logistic Regression for Examining the Relationship between Online User Characteristics and Expressed Adherence to the Desired Norm

We examined the relationship between the user characteristics (age, gender, tendency to generate prosocial content, and count of followers) and $AAAAheeeeeeeeeeee$ with multi-logistic regression based on 9,331 Twitter users (**Eq. 1**). One characteristic of online users is considered as significantly correlated with $AAAAheeeeeeeeeeee$ if the $pp - vvvvvvvvee$ of its coefficient is lower than 0.01 or 0.001, representing low to high levels of significance separately.

$$AAAAheeeeeeeeeeee \sim AAAAee + GGeeeeAAeeee + PPeePPPPPPeePPvvvv + IIeeIIvvvveeeeeeee \quad (1)$$

RESULTS

Prediction Outcomes of User Characteristics and Monthly Patterns of Expressed Adherence to the Desired Norm

With the multi-modal model, we inferred users' genders, age groups, and tendencies to generate prosocial content. The statistical distribution of user characteristics is shown in Figure. 4, which is similar to the distribution among the users in the training data. 65.0% of the analyzed users are male. Most of the analyzed users belong to the age group of 18-44 (77.0%) or 45-64 (17.2%). 77.5% of the analyzed users tend to generate prosocial content.

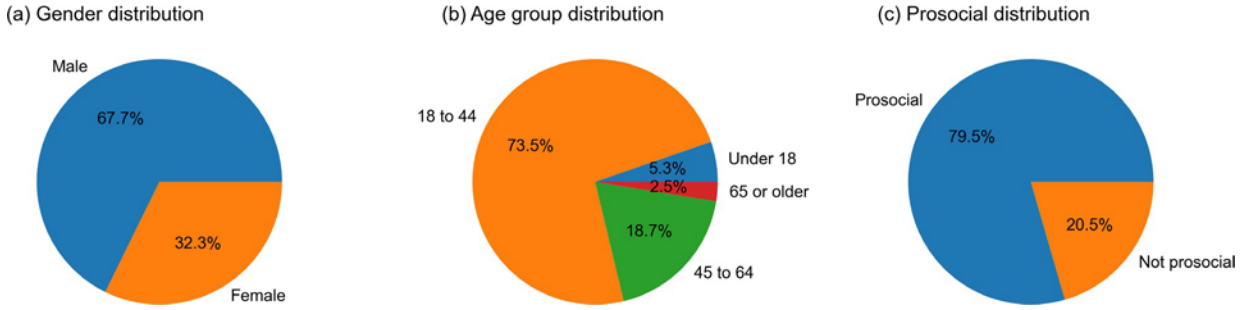

Figure 4. Distribution of genders, age groups, and users generating prosocial content among the analyzed users

After estimating the analyzed users' expressed adherence to the desired norm, we categorized users into two groups (Figure. 5a). While most of our analyzed users posted less than 200 tweets in the studied period (Figure. 5b), 44.3% of the analyzed users consistently expressed adherence to the desired norm.

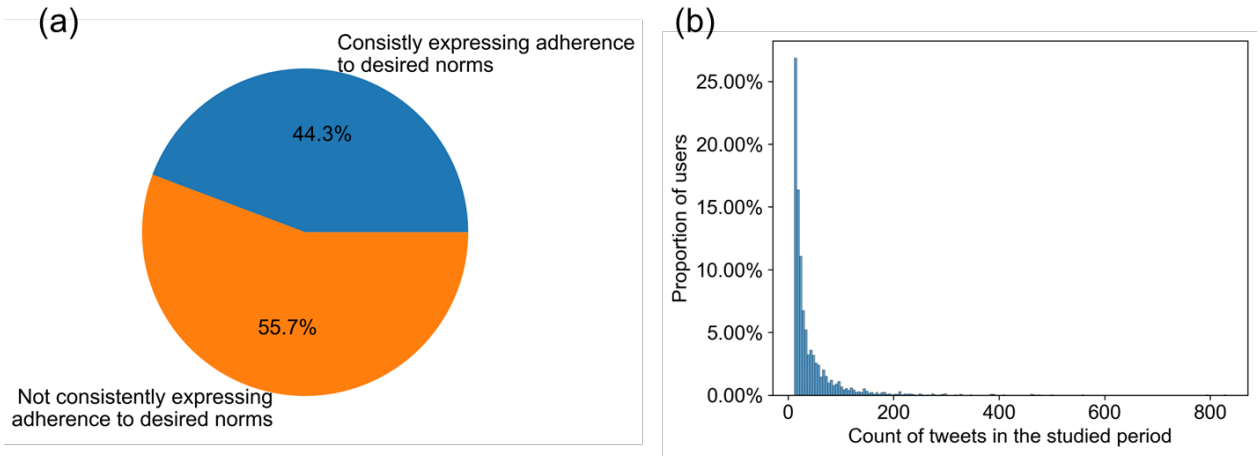

Figure 5. Proportions of users who consistently expressed adherence to the desired norm (a) and proportion of users with different counts of tweets

Evaluation of Multi-Modal CNN-LSTM Model Performance

We evaluated the multi-modal model that infers online user characteristics based on its accuracy and loss and ablation studies. In terms of accuracy and loss, our model achieved an accuracy of 85.61% when predicting online users' gender, age group, and tendency to generate prosocial content simultaneously, and its accuracy exceeds 90% for predicting each characteristic separately (Figure. 6 and Table 2). We also conducted ablation studies (Table 2), i.e., examining the prediction performance of each component of the multi-modal model and their combinations, to investigate their contributions to the prediction process. The multi-modal model has a much higher accuracy than each component classifier and each of their combinations. Among the model components, the image-based module (CNN classifier) has the major contribution and can solely achieve an overall accuracy of 60.83%, which is much higher than the text-based module.

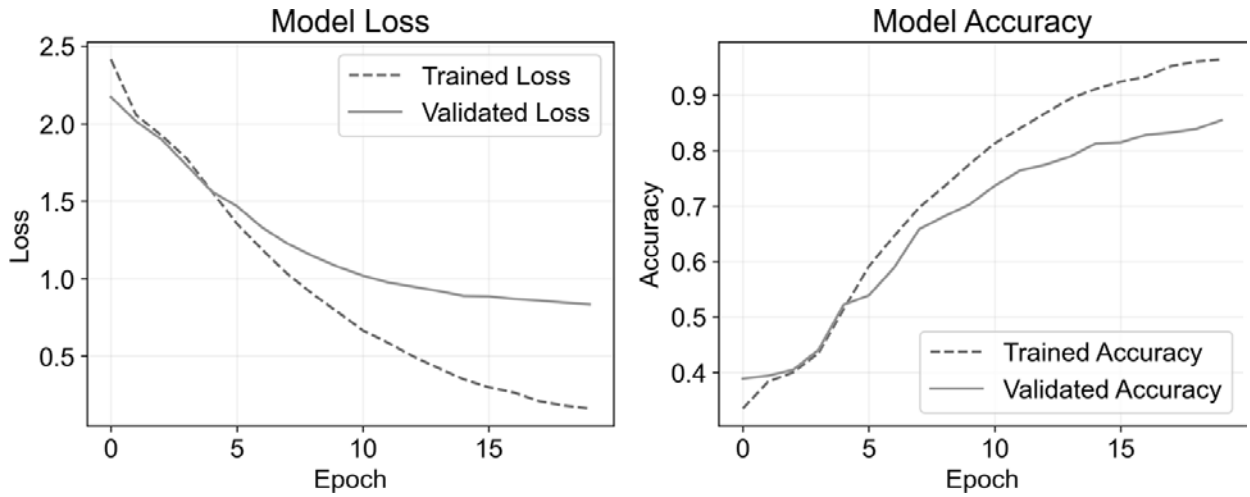

Figure 6. Loss and accuracy of the multi-modal model

Table 2. Ablation studies of the multi-modal model

Model	Inferring gender	Inferring age groups	Inferring prosocial	Overall
CNN (profile image)	0.7597	0.7538	0.8426	0.6083
LSTM (profile bio)	0.7284	0.6683	0.8029	0.5194
LSTM (tweet text)	0.6889	0.6577	0.8012	0.4486
CNN (profile image) + LSTM (profile bio)	0.7717	0.7200	0.8139	0.5710
CNN (profile image) + LSTM (tweet text)	0.7581	0.7084	0.7993	0.5480
LSTM (profile bio) + LSTM (tweet text)	0.7421	0.6889	0.8059	0.4753
Proposed model	**0.9069**	**0.9162**	**0.9467**	**0.8561**

Correlation between Online User Characteristics and Expressed Adherence to the Desired Norm

Before conducting correlation analysis, we examined the inter-correlation between online user characteristics and indicators of influence in online environments (Figure. 7). Notably, the user characteristics and influence in online environments are not significantly correlated and can be input into the regression analysis.

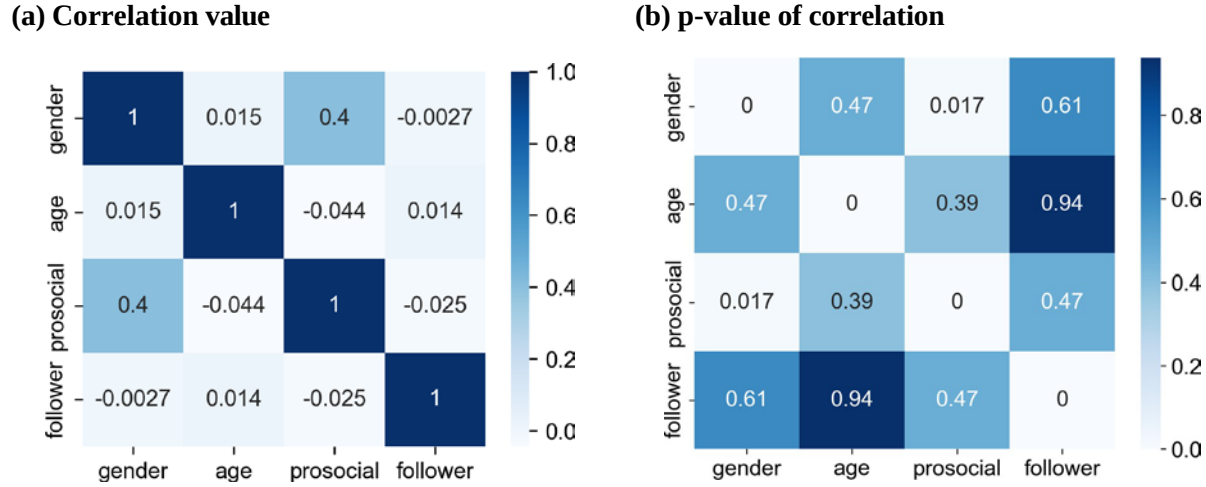

Figure 7. Correlation values and $pp - vvvvvvvvv$ between user characteristics

We then conducted multi-logistic regression to examine the relationship between user characteristics and users' adherence to the desired norm ($AAAAheeeeeeeeeeee$) (Table 3). The regression outcomes indicate that gender ($pp -$

$vvvvvvvvee = 0.008$) and the tendency to generate prosocial content ($pp - vvvvvvvvee = 0.003$) are significantly correlated with consistently expressed adherence to the desired norm. A user is more likely to consistently express adherence to the desired norm if the user is male or tends to generate prosocial content before the pandemic. In contrast, female users and users who do not generate prosocial content are less likely to express adherence to the desired norm.

Table 3. Multi-logistic regression outcomes

	Coefficient	**Confident Interval (lower 2.5% boundary)**	**Confident Interval (upper 97.5% boundary)**	$pp - vvvvvvvvv$
Intercept	-0.6695	-1.2020	-0.1370	0.0140

DISCUSSION AND FUTURE WORK

The research is among the first to explore the idea of user-centric normative misinformation intervention. The preliminary study contributes to the knowledge body of crisis informatics in online environments through two major outcomes. First, we address the need for an integrated online user characteristics inference model and propose a new multi-modal deep-learning model for predicting demographic and social psychological characteristics. With an overall accuracy of 85.61% and an accuracy exceeding 90% for each user characteristic, our model outperforms existing tools for inferring online users' demographic and social psychological characteristics based on publicly accessible data. Second, our statistical analysis has identified a significant and positive relationship between users' gender and their tendency to generate prosocial content and expressed adherence to the desired norm. The correlation highlights the necessity of paying attention to the users who are female and do not tend to generate pro-social content for social norm interventions. We expect that more customized and user-centric prebunking social norm interventions will alleviate the adverse social consequences of misinformation more effectively in the digital environment.

Our further research will continue to explore and test user-centric misinformation mitigations to advance the knowledge body of crisis informatics following the work-in-progress paper. First, we will expand the scope of online user characteristics for predicting online users' expressed adherence to the desired norm and misinformation content, such as self-esteem, optimism, and expressed satisfaction with daily life. Second, we will integrate the impact of individuals' exposure to their information environments to understand the motivation for changing expressed belief in vaccination. Particularly, online users' adoption of the desired norm is potentially related to the expressed beliefs of their social network members. Third, we will investigate other topics of online misinformation, such as healthy eating, threats and protective measures against communicable diseases, and risky behaviors (such as the use of drugs and smoking). Lastly, our future work will focus on designing user-centric interventions to mitigate online misinformation before the next pandemic or crisis. For example, we will explore the strategies to break the "echo chamber" among users who do not tend to generate prosocial content. We will also examine the effectiveness of spreading messages that deliver the desired norm or prosocial content to encourage users to reject misinformation.
